Sentiment Analysis: In multiple domains such as marketing and social media monitoring, NLP is used to determine the sentiment expressed in text data. This approach attempts to determine the opinions, feelings, or attitudes expressed in textual reviews, social media, or feedback forms. Sentiment analysis tools, such as those employed by Brandwatch, detect consumer sentiment in their feedback in order to gain an understanding of public perception, sentiment, feelings, etc. associated with their products or services. For example, by analyzing social media sentiment related to a product at the point of launch, organizations may gain invaluable insight into consumer sentiment, reactions, and overall preferences.

Speech Recognition and Generation: NLP is responsible for programs that identify spoken words and transcribe (convert spoken words to written text) them into text (speech-to-text), as well as generating speech through text (text-to-speech) and converting written text to spoken audio. Software such as Dragon Naturally Speaking allows a person to dictate text directly into their computer with the use of speech recognition. Voice recognition in applications has a wide range of uses, one being Google's Text to Speech technology that converts written text to auditory natural-sounding spoken words (text-to-speech), which is popular in applications around audiobooks and voice responses in customer service systems. These technologies form the backbone for voice activated applications, as well as transcription services, and many accessibility tools.

Information Retrieval and Search Engines: NLP contributes to the capabilities of search engines by improving understanding of the user's queries, thereby providing better search answers. Google Search utilizes NLP techniques for interpreting and indexing large amounts of content on the web, which assists in providing accurate and relevant search responses, this means monitoring, analyzing and indexing a lot of text to give efficient information retrieval.

Text Summarization: NLP is capable of automatically summarizing large amounts of documents or articles into shorter summaries. Summarization tools, like the ones provided in news aggregators or in research paper databases, provide summaries for long articles that condense the materials into overviews that allow users to gather info quickly without reviewing the entire document. This is especially valuable for organizing content, digesting information, and providing short overviews of longer documents.

Content Generation: NLP is used in content generation that includes written content including reports, news articles, and marketing language. Automated content generation software makes extensive use of NLP to generate written content that includes not only news articles but also marketing copy. OpenAI's GPT-3 is an NLP model that can

generate coherently written text that is contextually accurate in relation to a draft article, marketing content, or simply generating text as part of an application.

Healthcare and medical records: Another sector where NLP is applied is in healthcare to process and analyze medical records and academic literature. For example, IBM Watson Health leverages NLP to identify and process relevant information from patient records and academic literature to assist healthcare professionals with clinical decision making and to help healthcare professionals identify trends in patient data.

Financial Analysis: The financial and trading sectors have begun to utilize NLP to assess summary reports, news articles, and social media to identify market and sector trends and sentiments of other investors. An example of this application is Bloomberg Terminal, which uses NLP to scan news articles and social media outlets to provide actionable insights to inform investment decisions and market forecasts, which is invaluable for decision-making and forecasting in finance/financials.

Educational Tools: NLP has opened up the floodgates in educational technology in the education field by allowing systems to provide intelligent tutoring systems (ITS), language learning applications, and tools for supporting complex tasks. An example of this is Duolingo which uses NLP as the underpinning foundation to help students learn a new language through gamified motives, providing contextually relevant and adaptive exercises and feedback to assist the user in learning a new language. These types of systems primarily rely on NLP for personalizing student, feedback, prompts, and academic support.

NLP TECHNIQUES AND IMPLEMENTATION

Integrating Natural Language Processing (NLP) solutions utilizes a blend of traditional linguistic approaches and modern computational methods. These approaches are likewise designed to capture the complexity of human language and optimize performance in multiple NLP tasks. NLP implementation Approaches (Figure 2)

Rule-based approaches: Rule-based approaches in nlp leverage explicit rules about language to analyze and process textual elements. The rules are coded into the system by domain experts that encode specific syntactic and semantic rules in the system. Rule-based methods are generally effective in applications that need exact parsing of language, such as grammar checking and named-entity recognition. However, one of the drawbacks of these systems is incapacity for new or ambiguous language input, and scale of use. For example, this could include a grammar checking tool with predefined rules to delineate and correct syntactical errors present in written text.

Statistical Approaches: Statistical models utilize a probability model to analyze language patterns, typically implicating usage of a language on a large corpus of text, assuming use of a model built on tokens, hence identifying the probability of particular structures of language and of words. Particularly, Hidden Markov Models (HMMs) and n-gram models are prevalent approaches. Also, statistical methods have been used prominently in machine translation where they predict the most probable translations of words and phrases in conjunction with the relevant context. A language model predicting the next word in a sentence based on the probability of sequence of words is an example of a statistical approach.

Machine learning Approaches: Natural Language Processing (NLP) that makes use of machine learning involves developing algorithms that learn from a large collection of labeled examples to perform a certain task. Some possible tasks include classifying text, conducting sentiment analysis, or named entity recognition, which involves determining names or dates from within a sentence. For these machine learning algorithms, the training step involves providing the algorithm with a large number of examples. Each example is labeled, which helps the algorithm learn the relationships between the labels and the input. Once the algorithm has been effectively trained to learn relationships in the data set, it can apply that knowledge to perform a prediction or some decisions about the new data, data that has been previously unseen. As an example, consider having a sentiment analysis tool that was made to label a customer review as positive, negative or neutral. In developing that tool, a machine learning

algorithm would be trained on a large number of customer reviews that had already been labeled with sentiment. The machine learning algorithm would learn from those labelled examples, and for example learn that words like "great" or "excellent" indicate a positive sentiment and words like "bad" or "terrible" indicate a negative sentiment. Once trained, the model could now take a new customer review as input, even without having seen the review before, and predict the sentiment.

Deep Learning Strategies: Deep learning has now brought a significant new approach to Natural Language Processing (NLP) with neural networks and the advanced ways they understand language. Picture the neural network as intricate patterns of connections designed to recognize and interpret language structure. Neural Networks- "Think of these as digital brains, capable of learning and interpreting decisions based on input data. They facilitate our understanding of language in terms of patterns and relationships." Consider BERT (Bidirectional Encoder Representations from Transformers): Imagine you, as the reader, are trying to interpret a word's meaning based on the other words surrounding it. BERT finds a word's meaning by interpreting the entire sentence two different ways (from beginning to end and end to beginning). For example, when reading, "The bank was full of fish," BERT determines that "bank" refers to the place you find fish, not the financial institution. Primary Models are:-

Recurrent Neural Networks (RNNs): These are good at dealing with sequences after all, a sentence is a sequence, and an RNN will remember everything that it has read before.

Long Short-Term Memory (LSTM) Networks: A specific variation of RNN capable of remembering longer sequences and keeping track of relevant information.

Transformer-based Models (like BERT and GPT): A very powerful and deep model that looks at all parts of a sentence in the same way at once, rather than just at the beginning or end of the sentence; this gives it a much better understanding of context.

Hybrid Approaches: Hybrid approaches consist of combining rule-based paradigms with machine-learning approaches in order to better handle non-trivial work in Natural Language Processing (NLP). Rule-based approaches look at the language through predefined rules and/or constructs for the purpose of interpretation and processing. The rules are assembled from linguistic and psycho-linguistic knowledge, and they work best for simple and unambiguous tasks. Machine-learning approaches rely on using various datasets that allow the model to learn and recognize patterns on its own and allow the model to make some predictions based on the data. When a hybrid system applies both techniques, it can handle trivial (simple) language tasks with any dimensions of the matter in question. For example, imagine a customer service chatbot. That chatbot could use rule-based approaches to respond to the constant customer-service-who-questioning like, "What time do you open?"- with one possible answer. Then the chatbot could use machine learning, for a question that has potentiality in context that could also include customer-service-complications, would be "I have a problem with my order-man. Can you help?" - which could be a longer or shorter answer. In that sense, the hybrid system could be precise for the brief and simple, yet also be more adaptable for the complicated.

Transfer learning: Transfer learning takes a pre-learned model and adapts it to a more specific task. As a method, it works well because it uses the immense information derived from very large and varied datasets to perform better on a smaller, domain-specific task. The two components of transfer learning are: -

Pre-training: extending out on a large and diverse dataset, as a certain number of books, articles, and webpages. For example, models like BERT and GPT are pre-trained on a lot of text from the internet to learn general language patterns.

Fine-tuning: Then extending out on a smaller dataset specific to the new task. For example, if you want the task to classify legal documents, you would fine-tune the model on a dataset of legal texts. This would allow the model to

adapt its general knowledge of language, in this case, to also comprehend legal language and its terminologies. This would increase accuracy for things like legal document classification. With this transfer learning approach the model could perform even if it had not had an extensive amount of data for the specific task on which it is being trained.

Reinforcement learning: In reinforcement learning, a model improves its decisions by learning from the feedback responses it receives. In essence, the model provides decisions or actions and then receives feedback about how good or bad the response was. In this situation, it produces rewards for nice actions and punishment for mistakes. The feedback guides whether the model should continue using that action in a different context. So, in reinforcement learning, the model has an idea of what works and what doesn't. In repetition, the model uses the feedback to refine its choices and learn from the mistakes. This is similar to how we learn from trial and error based on previous experiences, with the outcome being a more focused and refined resolution to fit the choice. For example, let's assume a virtual assistant is learning to provide conversation with users. At first, the model may provide some wrong or irrelevant answers. Over time, the virtual assistant begins to interact with more users. Each reply receives feedback, such as an immediate rating or correction. The one-to-many feedback responses allows the assistant to change the wrong or irrelevant answers to improve each one of their responses. The result is a growing baseline of which types of answers were more helpful. A useful model would seem to learn how to provide a better experience for the users along the memo of they questions they provided and the feedback received.

Phases of NLP (Figure 3)

Natural Language Processing, also referred to as NLP, is a subfield of artificial intelligence that allows computers to understand, analyze, and interact with human language in order to derive meaning. NLP can typically be decomposed into five areas of processing: Lexical Analysis, Syntactic Analysis, Semantic Analysis, Discourse Integration, and Pragmatics Analysis. Each of these areas contributes to the overall decomposition of natural language understanding and processing.

Lexical and Morphological Analysis

Tokenization: The lexical phase in Natural Language Processing (NLP) is where the initial parsing of text into smaller chunks (such as paragraphs, sentences, and words) occurs. If we break text down into small enough parts, a word maybe a token, a token or lexeme is a small amount of meaning to analyze further. Tokenization is probably one of the most important steps of NLP as it allows for word-level paper processing by understanding the text more easily. In addition to tokenization, the following are more techniques related to data cleaning and feature extraction for processing text quality, in general:

Lemmatization Lemmatization refers to the action of reducing a word to its root or base form. Lemmatization allows variations of the same word to be analyzed together.

Stopword Removal Stopwords are common words with no significant meaning, for example; "and", "the", "is", etc., removing them, allows us to think about the content with purpose and not the words.

Spelling Correction Correct spelling text is a step all to itself because in tasks during NLP it is important to follow a sequence that makes sense, thus correcting any spelling errors maintains accuracy and reliability.

Preprocessing techniques such as these are important for bettering the readability of the text and that text is clear for effective analysis and processing in the following phases of your NLP.

Morphological Analysis: Morphological Analysis:- Morphological analysis is another important step in NLP that focuses on identifying and analyzing morphemes. Morphemes are the smallest meaningful units in words, which cannot be broken down further. Understanding morphemes' structure and function is key to understanding words and their parts.

Syntactic Analysis

Syntactic analysis or parsing is a component of Natural Language Processing (NLP) that involves examining the structure of the syntax of a sentence. The objective of this phase is to analyze the formulation and relationship of words in the sentence. Using more plain language, it's more about understanding the grammar in order to see how the words all work together to form meaning. It is also known as the Second Phase of Natural Language Processing (NLP). During this phase, the sentence is deconstructed into its grammatical elements (nouns, verbs, adjectives, etc.) and then the relationships between the elements are analyzed. For example, in "The cat sits on the mat" syntactic analysis determines "the cat" is the subject, "sits" is the verb, and on the mat is the prepositional phrase which shows where the action occurs.

Examples of Syntax

Correct Syntax: "She enjoys reading books."

Explanation: This sentence follows the correct structure of the standard Sentence syntax: Subject (she) + Verb (enjoys) + Object (reading books). It is included in the proper sentence structure and is grammatically correct.

Incorrect Syntax: "Reading she enjoys books."

Explanation: The word order is incorrect, rendering the sentence confusing and incorrect grammar. The meaning is unclear because the sentence does not follow the standard Subject-Verb-Object structure.

These examples help show how important correct syntax is for clear communication.

Example: Consider the sentence "She loves ice cream." Syntactic analysis will break it down as follows:

- "She" (subject)
- "loves" (verb)
- "ice cream" (object)

This breakdown helps the NLP system understand who is performing the action and what the action is, which is critical for accurately processing language. This analysis aids in analyzing the structure of the sentence which is a critical part of more complex nature language processing (NLP) tasks including machine translation, where a sentence's meaning must be preserved in another language. By understanding the syntax, the NLP system can better understand and process how words relate to each other, allowing the nature of the text to be comprehended in a more efficient way.

Semantic Analysis

Semantic analysis is the third stage in Natural Language Processing (NLP) that seeks to uncover the meaning behind the words contained in a sentence. Whereas syntactic analysis incorporates the structure of a sentence, semantic analysis considers a broader approach that tries to determine the actual intention or meaning of text. In this stage, NLP systems are considering the relationships between words as well as their combination to create meaningful phrases or sentences. The system must identify concepts, like entities (people, places, things) and their relationships, to understand the context of how each word is used. Semantic analysis doesn't attempt to analyze the grammatical structure of the sentence like syntactic analysis, but rather attempts to determine what the sentence is saying. For instance, "John bought a new car." Semantic analysis allows the NLP system to identify that "John" is a person, "bought" implies a purchase action, and "car" is the object of the purchase. The system recognizes that "new" modifies the car and provides much more meaning. So, semantic analysis allows the NLP system to know that the sentence is about a person named John, who purchased an object--a brand-new car. This understanding is vital for the NLP system to analyze the text and know how to respond.

Example of Semantic Analysis: "The car drank the coffee."

Syntactically Correct: The sentence follows proper grammatical rules, with a subject ("The car"), a verb ("drank"), and an object ("the coffee").

Semantically Incorrect: The sentence is nonsensical because a car cannot drink coffee. Although the structure is correct, the meaning fails to convey a logical understanding. Through semantic analysis, the mismatch in the subjects and actions would be highlighted and the sentence would be labeled nonsensical, even though the structure is grammatically correct. Semantic analysis is a vital part of Natural Language Processing (NLP) because it helps machines and systems understand the meaning and context of the text. Semantic analysis goes deeper than grammar--it resolves ambiguities and captures word relationships to ensure sentences are interpreted properly. Knowing what different words mean ensures high levels of performance in machine translation, sentiment analysis, chatbots, and many other applications with heavy reliance on language. The result of effective semantic analysis is strong reliability and intelligence in NLP systems, foreshadowing simplicity in more complicated tasks that demand well informed and meaningful responses.

Discourse Integration

Discourse integration is a Fourth phase of Natural Language Processing (NLP) that considers the whole point of a conversation or text beyond single sentences. The branches of NLP work with sentence-level understanding of language, such as syntactic analysis and semantic analysis, but discourse integration works to connect phrases and sentences into an understanding of the overall meaning, or flow, of a text.

Contextual Understanding: Discourse integration allows the system to understand the interrelationship of sentences. For example, if a text says, “John went into the store. He bought some milk”, discourse integration helps with linking “He” to the previously mentioned “John” and understanding that to buy the milk, it logically follows that John went into the store first.

Maintaining Coherence: It allows the text to stay coherent and logical. For example, if a narrative moved from discussing a cat to talking about a dog, discourse integration would allow the discourse tracking system to recognize the movement and maintain discourse without shifting the content unnecessarily.

Managing Pronouns and References: This step involves recognizing what pronouns (such as "he," "she," or "it") are referring to across sentences. This can help resolve ambiguity and tell what is being talked about and who is being referenced. In conclusion, integrating discourse is critical for ensuring that NLP systems read longer texts correctly, by connecting sentences and maintaining a clear meaning through the conversation or text. Discourse integration is crucial for Natural Language Processing (NLP) as it helps computers understand sentence structure, connections, and work together. It helps provide cohesive interpretation, recognizing relationships between sentences and responding appropriately. This helps in summarizing content, providing relevant responses, and enabling precise, cohesive responses and better pragmatic interpretations.

Pragmatic Analysis

Pragmatic Analysis is the fifth and final phase of Natural Language Processing (NLP), and it focuses on finding out what a word means in relation to the context it is placed within and the background knowledge about the world. The stages of NLP that precede this dealt with grammar, structure, etc., and pragmatic analysis looks at how language is used in a specific context to convey rules, meaning, or comprehension in situations rather than simply searching for meaning based on semantics. Pragmatic analysis will go beyond the literal meaning considered in semantic analysis, as we are attempting to understand latent meaning or what the writer or speaker intends to convey. In natural language, it should not be surprising that we have all encountered language where a word or phrase will have no one meaning, and the expressed meaning can rely on context, tone, and many other situational-based references. Here’s a detailed explanation with examples:

Contextual Understanding: Pragmatic analysis allows a reader to understand author's intention of a sentence by considering context and other factors. For example, if someone uttered the phrase, "It’s getting late," the literary meaning would simply be correctly interpreted as time is elapsing. However, in pragmatic analysis, the speaker may be implying that it is time to leave or finish an activity.

Interpreting Implicit Information: This step involves interpreting what is meant as opposed to what is said. For example, in a conversation regarding grocery shopping, if someone says "I forgot to buy milk," while they could simply be reminding the other listener of their need to make the purchase, they may actually be hinting and requiring a light nudge or reminder to do so. A pragmatic analysis helps the system catch these implied hints.

Recognizing Social and Cultural Contexts: Pragmatic analysis considers social norms and cultural expectations. For example, if a person were to say, "Good job!" after someone made a mistake, pragmatic analysis would take this as sarcasm rather than sincere praise. To understand sarcasm, one must understand the social context and tone.

Understanding Speaker's Intent: This phase also determines what the speaker intends to achieve with their language. For example, if I said, "Could you pass the salt, please?" A pragmatic analysis would interpret that using language to make a polite request rather than a question about the listener's ability to pass the salt.
In conclusion, pragmatic analysis is important for NLP systems to process language in a way that represents how people use language in life. Pragmatic analysis allows interpreters to pay attention to context, implied meanings, socio-cultural factors, and intentions of speakers to inform how they use language. Pragmatic analysis leads to better communication in NLP systems across a number of applications.

LITERATURE SURVEY

There have been several paradigm changes in the field of Natural Language Processing (NLP) throughout its lengthy history. Natural language processing (NLP) originally depended on systems that followed predetermined norms of language. One such early natural language processing system was SHRDLU, developed by Winograd in 1972. It was able to carry out commands given in natural language within a simple, limited setting (Winograd, 1972). However, due to their reliance on rigid syntactic restrictions and difficulty in being modified, these systems had limited usage. The statistical tools that emerged in the late 80s and early 90s revolutionized the industry. Machine translation performance was enhanced when researchers, such as Brown *et al*. (1990), utilized big bilingual corpora to develop probabilistic models. Processing could be more probabilistic and flexible with a data-driven approach than with older systems. The deep learning revolution also made another jump in the capabilities of NLP. Mikolov *et al*. (2013) made Word2Vec possible by representing words in dense vector spaces and bringing relationships of meaning into play (Mikolov, Chen, Corrado, and Dean, 2013). Other models followed Word2Vec, like Recurrent Neural Networks (RNNs), as well as Long Short Term Memory (LSTM) networks (Hochreiter and Schmidhuber, 1997), which had established methods of modeling sequential data. Indeed, deep learning systems that emulate human cognition find artificial neural networks in their bag of tricks. Later models built on Word2Vec included those based on the Transformer architecture, which changed the landscape of language processing with their introduction (Vaswani *et al*. 2017). Since then, BERT (Bidirectional Encoder Representations from Transformers) and GPT (Generative Pre-trained Transformer) have established new performance benchmarks for many different NLP tasks (Radford, Wu, Child, *et al*. 2019). The real-world implications of NLP are enormous and consequential. The most salient applications include virtual assistants like Siri and Alexa, which rely on NLP to enable voice-based interactions. Bilingual communication is also made possible, in part, by NLP tools like Google Translate, which help humans to communicate despite language differences. Firms may also use sentiment analysis to heuristically define public opinion based on consumer reviews and social media remarks (Pang and Lee, 2008). NLP techniques also enhance the user interaction of speech recognition systems and search engines to retrieve information for users. Contemporary NLP is engaged with key challenges such as ethical multiplicities including bias in language models, how to explain model outputs, and how to scale to large amounts of data. Researchers in the field are narrowly and widely interested into developing multilingual systems as well as developing systems that can reason with multimodal data (Kiela *et al*., 2019), for example, learning to understand and produce language while also being able to reason about and respond to visual and auditory data. As NLP increasingly becomes a normalized area of inquiry for natural language researchers, future work will need to focus on ethical AI directives, low resource languages and developing systems that are contextually aware and intelligent. Recent developments in Natural Language

Processing (NLP) technologies have focused mainly on hybrid architectures, emotion analysis, and reasoning frameworks. In their review of hybrid and swarm-deep learning models that incorporate RNN, Transformer and ensemble approaches, Jia *et al*. (2023) demonstrated significant performance enhancement in natural language tasks (i.e. sentiment analysis, named entity recognition, summarization), but they also noted the increased resource use for these models. Emotion Analysis is still an evolving junior field. Plaza-del-Arco *et al*. (2024) reviewed the last 154 publications of the field to identify enduring saliences within it--demographic and cultural bias, ambiguously defined emotional categories, inconsistent use of terminology, and the lack of interdisciplinary presence. Moreover, Yu *et al*. (2023) reviewed common natural language reasoning studies including those related to logical inference, multi-hop question answering, commonsense reasoning, backward and defeasible reasoning, and encouraged the growth of multi-step reasoning frameworks in the field. Alongside these academic reviews, industry reviews have noted transformational approaches in the field, including multimodal learning, low-resource utilization efficient LLMs (i.e., QLoRA, adapter), retrieval-augmented generation (RAG), methods for hallucination detection, instruction tuning, and knowledge-grounded dialogue as important dimensions to operationalize across industries in 2024–2025, including with clinical decision support, risk assessment in finance, law applications, and within scientific literature processing.

Early Development: The historical context of Natural Language Processing (NLP) describes the evolution of the field from its initial beginnings. Initially, NLP relied on rule-based systems, where researchers created rules for computers to understand language. As an example, the SHRDLU system made by Winograd in 1972 could work with commands, but only in the simulated environment created for it. These systems had their limits as they came to be heavily reliant on previously established rules which limited the complexity of language they could work with.

Shift to Statistical Methods: In the late 1980s and early 1990s, NLP also experienced a tremendous shift to statistical techniques. Brown and others began to use large amounts of bilingual text data to develop models for machine translation. Rather than modeling the rules of language as prior researchers had done, this new data-driven approach leveraged the abundance of patterns available in large datasets especially taken in context with the increased processing capabilities of computers.

The Deep Learning Revolution: The Deep Learning Revolution was defined by advances in deep learning. In 2013, Mikolov gave us word embedding (Word2Vec), which took words and represented them as continuous vectors in a way that captured their meaning better, naturally. The development of advanced neural networks, in particular, neural networks that process sequences of data (sentences) in advanced contexts (Recurrent Neural Networks and Long Short-Term Memory), was also an evolution. The branches of natural language processed by transformer networks, such as BERT and GPT, effectively transformed NLP with high performance levels evaluated and via a broader set of tasks augmenting the language revolution implications.

Current Trends and Challenges in NLP

Natural Language Processing (NLP) has made great strides in the past few decades, and it has become a key piece of many modern AI applications. With these advancements bring new challenges and emerging trends that are influencing how we will do NLP in the future. In the next section we will take a look at some of the most up-to-date trends and challenges in NLP.

Ethical and social issues: As NLP technologies continue to evolve, they continue to come with ethical issues, particularly around biases in language models. Models can and do unintentionally mimic and perpetuate gender, racial, and cultural biases, which can lead to fairly non-non-disciminatory outcomes. It is a challenge to combat and alleviate biases in general, especially for fairness in NLP systems.

Explainability in NLP: The complexity of NLP models and systems continues to grow, especially with the introduction of deep learning for many tasks. For many domains and applications, an explainable model is important if not crucial, when a model is able to provide a result but also an account and explanation of the underlying reasons.

While a machine-generated result may be correct, without explanation, users may lack trust. This is especially important for certain domains and/or applications (e.g., healthcare, finance, etc.).

Scalability and Real-time Processing: Natural language processing (NLP) models have seen increasing use cases with the growth of sophisticated techniques for processing big data on the fly, including applications such as customer service chatbots and social media monitoring. While increasing the scale of NLP models to accommodate large data sets has become more possible, it is still a major challenge to scale these models responsibly and efficiently. Although some models can use negligible resources, the computational resources needed when training or deploying NLP models can be great, which raises questions about their sustainability with regard to potential coal-based power use in resource extraction practices to sustain our energy demands, and the environmental impact in general.

Multilingual NLP: We are also seeing a growing popularity and trend towards making NLP systems language-agnostic, meaning able to interpret multiple languages, particularly low-resource languages. While the general language processing has progressed with very popular languages/domains like English, there is still a need for more models that can be more inclusive of the full linguistic diversity of the world's population.

Integration of Multimodal Data: In the future, NLP will likely involve an interaction of text with other data types, such as including audio, images, and video file types. The multimodal approach presents much higher order and more robust applications of NLP models, however, it also presents new challenges regarding the incorporation and processing these data as components of their respective model designs and training.

Current Gaps and Future Directions in NLP

Natural Language Processing (NLP) has made substantial progress and continues to exhibit gaps that can be exciting areas for future research. For instance, one major gap relates to developing NLP models for low resource language contexts. While NLP has developed astounding models like BERT and GPT for specific languages that have substantial amounts of datasets available, it is important to highlight that there are over 3,500 languages in the world, many of which lack the corpus required to train robust NLP models. To emphasize this point, only around 20 languages have large-scale and well-annotated datasets available, which leaves thousands of languages underrepresented in NLP exploration. Another area for future exploration relates to the need to include multimodal data, or integrating text with other forms of data, such as images, audio, or video data. NLP models developed today generally process text alone, but as we know human communication occurs on multiple levels. Research by Kiela *et al*. (2019) suggests that models can significantly improve upon their performance when visual data are included, such as in tasks like image captioning and visual question answering, in turn, inviting more complex and robust multimodal NLP models that will aid in understanding the underlying processes to human language and in generating human language. In addition, it is worth noting ethical AI and human-AI collaboration as relevant directions for the future of NLP as well. As NLP models become more capable, it is increasingly important to ensure they are fair, transparent, trustworthy, and aligned with human values. Research has long documented the prevalence of gender and racial bias in NLP models and demonstrated that unfair or harmful outcomes can result from biased models. Efforts aimed at removing biases and creating ethical guidelines for NLP systems will be instrumental as the field continues to emerge. In summary, while the advances in NLP are certainly impressive, focusing on multilingual NLP, multimodal data, and ethical AI will be instrumental to filling gaps and summoning the future of this ever-changing field.

Application of Natural Language Processing

NLP has a wide variety of interesting and useful applications that are relevant to different parts of our everyday experiences. Through the application of our language technologies, NLP supports task automation, improvements in communication, and extraction of insights through large amounts of data in text form. Below are some areas where NLP is producing significant outcomes:

Automated Text Summarization with NLP

Automated text summarization is an attractive NLP application that offers the potential to speed up the identification of core/main points in large quantities of text, thereby saving time and needless effort in the reading through this weight of text. This area finds practical applicability in and across many areas including news aggregator applications or legal research efforts.

News Aggregation: News aggregators simply aggregate news articles from various sources and repurpose them into a single stream. NLP here will summarize the articles so readers know what is contained without having to traverse many sources. Example: think of something like a news aggregator-think of Flipboard. It is identifying and extracting important sentences in different articles from distinct news sites. This is based on term frequency, overall positioning of sentences, named entities, characters, organizations, locations, and results in a short summary. For example; there is a 1,500 word article on a recent economic summit, a summarization function may provide us with a 100 word summary that reads

- Participating countries
- General categories discussed
- Top outputs or decisions agreed upon during the economic summit.

Legal Briefs and Research Papers: When we consider legal and academic work, documents can pile up to hundreds of pages when printed, which is an overwhelming amount of information to assess and internalize. legal professionals can use NLP-based summarization technology to relieve that burden by allowing them to read shortened summaries, whilst still having the most important information captured. For example, consider a lawyer having to quickly read a 60-page hello saying on a court judgment about a case involving several legal precedents. The lawyer can use an NLP summarizing tool, putting that 60 pages into the tool which will synthesize it into a summary with key, thematically, reportable areas including

- Legal focus areas and issues
- Major points argument made by either side
- The final conclusions reached and the supporting reasons for them

NLP Techniques Used to Summarize

Extractive Summarization: The extractor considers the text and takes sentences from it, which the extractor has determined are important. Methods: The extractor relies on algorithmic ways to choose important sentences. For example, TextRank which is similar to Google's PageRank algorithm ranks sentences from the important list in order of importance.

Abstractive Summarization: It creates new sentences that describe the main ideas in place of copying sentences from the text. Methods: The extractor uses a deep learning model - specifically Transformer architecture, like BERT and GPT - to understand context with the given text and summarize accordingly.

Hybrid methods: It is a combination of extractive and abstractive to ensure better quality and coherency in the summaries.

Sentiment Analysis

Sentiment analysis applies NLP to process the sentiments behind written text. In fact, sentiment analysis uses text data to help organizations to comprehend the public's perceptions of experience, much like surveys that measure sentiments, along with identifying certain characteristics of comments/words used. This use of NLP in sentiment analysis is applicable for research and businesses that will aim to measure and respond to the sentiments created by their audience.

Sentiment Analysis and Market Research

A global electronics provider has released its new model smartphone. The organization is attempting to assess customer sentiment and use a sentiment analysis tool that collects and assesses thousands of reviews across multiple e-commerce platforms, social media comments, and online forums.

NLP Process

Data Collection: An NLP system collects data from various external platforms like Twitter, Facebook, and Reddit as well as customer reviews on Amazon or their own website.

Preprocessing: The collected data is cleaned and preprocessed by removing noise, HTML tags, special characters, and stopwords, followed by tokenization into words and/or phrases.

Sentiment Identification: Each piece of text has sentiment classification, either positive, negative or neutral, using pre-trained models or custom built using supervised learning.

Aggregation and Analysis: The outputs are aggregated to give an overall sentiment score for the new smartphone model. The NLP tools can also capture key features or aspects, like battery life or camera quality, elucidating more precisely what customers specifically like or do not like about a product.

Strategic Adjustment: The marketing team could adjust their campaigns based on the sentiment analysis. If many consumers are dissatisfied with the battery life, they might highlight improvements in future models in their advertisements. The advantage is the company can quickly assess public opinion without having to read through thousands of reviews manually while saving on costs and time.

Sentiment Analysis in Political Campaigns

For a political party, assessing the public's perception of both their candidate and the candidate's key issues is a critical part of the election campaign process. Sentiment surveillance and analysis helps to track the public's attitude towards the political party's candidate by monitoring social media activity, blog activity, and comments on the news.

NLP Process

Data Collection: The NLP system will gather data from Twitter feeds, Facebook posts, Instagram comments, and from political blogs.

Preprocessing: The NLP will preprocess the text for different styles, languages, and dialects that is prevalent on social media.

Sentiment and Topic Analysis: The system will determine the sentiment, whether it is positive, negative or neutral, and identify the topic, which may include health care, economy, education, etc., using topic modeling.

Geographical and Demographic Insights: Sentiment analysis will show how the geography or demographics of the sample feels about the candidate, or about policy issues, which will inform targeted campaigning.

Real-time Monitoring: The campaign will receive real-time sentiment analysis, which allows them to keep up with changing feelings from the public and address misinformation.

Message Optimization: Sentiment analysis can inform the campaign to optimize messaging to potentially highlight popular policies or address misconceptions.

Sentiment analysis enables the political party to stay attuned to voter sentiments, allowing for strategic adjustments that may enhance their chances of success in the election process.

Information Extraction in Biomedical Literature and Financial Reports

Information Extraction from Biomedical Literature: Because of the volume of literature being published every day, NLP has now evolved to be an essential component to the field of biomedical research. Here is how it works:

Data Handling: There are millions of articles published everyday in the biomedical databases like PubMed. The design of NLP systems allows them to parse these articles and, ultimately, information and data from it.

Named Entity Recognition (NER): NLP models can recognize and classify text entities - genes, proteins, diseases, drug names. In a research article examining Alzheimer's, for example, NLP tools can identify mentions of proteins such as "amyloid-beta" and genes, such as "APOE."

Relation Extraction: Additionally, NLP systems can extract relationships between identified entities. In this component, the NLP system may extract "a particular drug reduced levels of a particular protein." This type of relationship extraction helps "provide" prospects about the mechanism of action regarding the drug.

Use Case in Drug Discovery: Consider scientists at a pharmaceutical company that needs to identify all articles reporting on the efficacy of a new compound by citing studies. The researchers could use automatic extraction and run NLP to identify all studies upon multiple efficacy outcomes and determine whether or not to pursue additional research and/or clinical trial of the drug in a very timely, efficient manner.
Imagine a pharmaceutical company that is looking to investigate treatment options for a rare genetic disorder. They would use NLP to review all literature on that disorder, pulling out genes, mutations, and compounds that have been previously tested, which would speed up their R and D process.

Information Extraction from Financial Reports: Financial reporting is another area where NLP tools improve data extraction and analysis.

Parsing Financial Documents: Organizations issue quarterly and annual reports that include massive amounts of data. NLP tools can be used to parse financial documents and extract selected financial metrics including revenue, profit, expense categories, as well as key metrics like ratios.

Sentiment and Tone Analysis: NLP can also be used to analyze the tone of the management discussion and analysis (MD and A) portion of financial documents as a means of deducing management's attitude and finding red flags.

Automating Compliance and Auditing: NLP systems can automate the process of identifying and classifying transactions or financial activities will help Auditors review transactions for compliance and adherence to financial guidelines.

Use case in Investment Assessments: Investment companies use NLP to track news from various sources and categorize relevant financial information about companies they are tracking. This allows investment professionals to make timely and informed decisions quickly about shifts in their strategy.

Applications of NLP (Figure 4)

For example, an investment analyst in a hedge fund might use NLP techniques to analyze earnings call transcripts of a company to assess the sentiment of the CEO and extract specific financial metrics that may signal upcoming trends to show future performance. By automating the extractions of relevant information from large data sets, NLP technologies provide considerable efficiency and accuracy gains in both biomedical and financial research. When applied to analysis, NLP technologies provide a competitive advantage and allow for much richer insights.

Summary of NLP Techniques, use Cases, and Tools (Table 1)

Natural Language Processing (NLP) uses many different methods to solve particular language problems. Rule-based systems run on established grammatical and syntactical rules. The approach is useful in tasks like grammar checking, language recognition, and pattern matching. Statistical approaches use very large linguistic corpora and help assign probabilities to word usage and structure, allowing for enhanced tasks like machine translation, auto-correct, and spell check. Machine learning employs labeled data to construct a predictable model for text classification, sentiment analysis, and named entity recognition which provides an even greater flexibility to unknown language patterns. The development of deep learning, which consists of RNNs, LSTMs, and transformers, to provide systems with contextual understanding and the ability to generate coherent text, also brings the wave of hybrid systems that bridge the interpretability of rule-based systems and the learning-based perspective of machine learning or deep learning, producing solid platforms for chatbots and virtual assistants. Transfer learning and reinforcement learning are taking NLP capabilities to new levels through pre-trained models and learning on the fly to build performance in new areas. An increasing number of tools and platforms, such as NLTK, spaCy, TensorFlow, PyTorch, BERT, and GPT, will provide all of the approaches and support the capability to implement them in the real world.

CONCLUSION

Natural language processing (NLP) is one of the most promising domains of artificial intelligence and is critical for helping to bridge the gap between understanding on the machine side and communication on the human side. In this review, we characterized the journey from the early days of natural language processing (NLP), from rule-based systems to the current epoch of machine learning systems (including deep learning and transformer-based systems like BERT and GPT) and found that, as a field, natural language processing (NLP) has moved through multiple stages, from lexical/morphological analysis to pragmatic understanding, as it has allowed for the development of systems that can, and are using, natural language in analysis, generation, and interaction. As a result of our literature review, we highlighted the diversity of fields in which NLP techniques have made it feasible, including healthcare (e.g., medical record analysis), finance (e.g., sentiment-based market prediction), education (e.g., automated tutoring systems), and everyday technology (e.g., virtual assistants, chatbots). Like all emerging fields, and with the significant advancement that natural language processing (NLP) has made, there remain a variety of challenges. Models continue to struggle with linguistic ambiguity, contextual understanding, and fairness, especially in low-resource and multilingual settings. Concerns about bias, data privacy, and the societal and environmental impact of large-scale models also require urgent attention. In the years ahead, NLP will emphasize creating more accurate, effective and also ethical, accessible, sustainable systems. Significant opportunities will come from developments in multimodal natural language processing, few-shot and zero-shot learning, and real-time, on-device language processing. Moreover, in-building user trust and ensuring the ethical use of language technologies meant a larger focus would have to be placed on explainable NLP models. By incentivizing the NLP community to fill in obvious areas of vacancy and utilize language as a force for good, this review hopes to make a valuable contribution toward subsequent research and innovation.

ABSTRACT

The fractional lateral transshipment problem is crucial in logistics and supply chain management for minimizing total operational costs and enhancing service levels through an efficient distribution system. However, in real-world scenarios, the parameters in this model are often uncertain due to uncontrollable factors such as fuel prices, road conditions, weather, and traffic. This inherent uncertainty complicates the estimation of transportation costs and profits. To address these challenges, all parameters in the model are represented as trapezoidal neutrosophic fuzzy numbers. In this paper, the neutrosophic fuzzy fractional lateral transshipment problem is formulated to optimize an objective function based on the ratio of total cost to total income. The fuzzy model is then converted into a deterministic form using a ranking function. To handle the nonlinearity of the resulting model, the Charnes–Cooper variable transformation method is applied. Finally, a numerical example is provided to demonstrate the accuracy and effectiveness of the proposed approach.

Keywords: Fractional two stage transshipment problem, variable transformation method, trapezoidal neutrosophic fuzzy numbers, lateral transshipment.

INTRODUCTION

The transshipment problem is a linear programming problem in which goods are transported from sources to destinations through one are more intermediate points. Each of these points can act as either an origin or a destination. The concept of transshipment problem was first introduced by Orden (1956) [1]. The transshipment problem can also use to finding the shortest route between two network nodes. King and Logan developed a mathematical method for simultaneously determining the threads linking product processor market points, and Rhody proposed a methodology based on a reduced matrix [2,3]. A general linear model extension of the transshipment problem to a multi-plant, multi-product, and multiregional problem was proposed by Judges et al. [4]. Hurt and Tramel suggested the alternative formulation of transshipment problem based on transport model, which would provide solutions to King and Logan's common problems without the requirement to remove artificial variables [5]. Garg and Prakash investigated the time reducing transshipment problem [6]. After that, Herer and Tzur focused at the dynamic transshipment problem [7]. Transshipment problems with fractional objective functions are often used to evaluate performance in many real-world applications. When the objective function is expressed as a ratio of two objective functions in a transshipment problem, it is called a fractional transshipment problem.Jain. S proposed an algorithm to solve the fractional transshipment problem and determine the feasible solution where goods are transported directly from source to destination [8]. However, in the business world, goods are usually transported from production houses to retailers through intermediate points. This process involves two stages of transshipment and is referred to as a two-stage fractional transshipment problem. Garg, H., et.al developed a fractional two stage transshipment problem using extension principle approach [9]. On the other hand, shipments between entities at the same level, known as lateral transshipments, enhance the flexibility and robustness of a supply chain. Kumari, A. G. K. C., et.al [10] provided a comprehensive review of literature on various lateral transhipment inventory models. However, there is a need for extended studies focused on the fractional lateral transshipment problem. In many practical processes, decision experts (DEs) typically challenge to appropriately explain their concepts with precise numbers because of the uncertainty of the information and the lack of knowledge and experience of DEs. however, they can be represented as [0, 1] interval numbers.

Zadeh (1965) has introduced the concept of fuzzy sets [11]. As an extension of Zadeh's concept of a fuzzy set, Atanassov (1983) presented intuitionistic fuzzy sets [12]. In intuitionistic fuzzy sets, the degree of membership (belongingness) and the degree of non-membership (non-belongingness). Furthermore, the concept of IFSs has been extended to Pythagorean fuzzy sets (Yager, 2013[13], 2014 [14] where the sum of squares of membership and non-membership value of any object can be less than or equal to 1 which makes PFSs more flexible than IFSs. Later, to handle inconsistent and intermediate information Smarandache introduced a neutrosophic set in which truth, falsity, indeterminacy membership function belongs to [0,1] [15]. This study introduces a new version of the fractional lateral transshipment problem, where all parameters are represented as trapezoidal neutrosophic fuzzy numbers, and the objective function is a fractional term—the ratio of total shipment costs to benefits. This proposed model is called the neutrosophic fuzzy fractional lateral transshipment problem. In this model, the resulting solution will have a fuzzy cost. Compared to the standard fractional lateral transshipment problem, the fuzzy fractional version is more complex to solve. This increased complexity arises because fuzzy numbers must be compared to determine the minimal cost, and comparing fuzzy numbers is significantly more challenging than comparing exact values. A comprehensive review of generalized fractional mathematical models and their applications has been presented by Frenk and Schaible [16]. The proposed neutrosophic fuzzy lateral transshipment problem requires specific techniques for its solution. In this study, the concept ranking function isdiscussed to address the neutrosophic fuzziness of the problem. The well-known Charnes–Cooper variable transformation method is used to convert the ratios in the objective function into a linear form. The novelty of this proposed model is neutrosophic fuzzy fractional lateral transshipment problem is discussed to solve the complex problem which is not yet investigated in this literature. The rest of the paper is designed as follows. In section 2, the basic preliminaries in neutrosophic fuzzy numberare briefly summarized; Section 3 contains the mathematical model of the neutrosophic fuzzy fractional lateral transshipment

problem; In section 4, provides algorithm for proposed method; in section 5, the numerical example is solved to illustrate the algorithm; Section 6 contains the conclusion of the paper with the future studies.

PRELIMINARIES

The basic concepts of neutrosophic fuzzy set, trapezoidal neutrosophic numbers, ranking function for defuzzification are given in this section.

Definition 2.1[17] $\tilde{S}^F$ in a universal set E is called a single valued neutrosophic and it is defined by $\tilde{S}^N = \left\{\left\langle e, T_{\tilde{S}^N}(e), I_{\tilde{S}^N}(e), F_{\tilde{S}^N}(e)\right\rangle : e \in E\right\}$ where truth, Indeterminacy, and Falsity membership functions and satisfies the condition $0 \le T_{\tilde{S}^N}(e) + I_{\tilde{S}^N}(e) + F_{\tilde{S}^N}(e) \le 3 \forall e \in E$.

Definition 2.2[17]A single valued trapezoidal neutrosophic number $\tilde{S}$ (SVTrNN) on a real line set ℝ and is defined by $\tilde{S}^N = \left\{\left\langle s_1, s_2, s_3, s_4\right\rangle : w_{\tilde{S}^N}, u_{\tilde{S}}, v_{\tilde{S}}\right\} where\ w_{\tilde{S}}, u_{\tilde{S}}, v_{\tilde{S}} \in [0,1]$ with the condition $s_1 \le s_2 \le s_3 \le s_4$, whose truth, indeterminacy, falsity membership functions are follows

$$T_{\tilde{S}^F}(e) = \begin{cases} w_{\tilde{S}} \frac{e - s_1}{s_2 - s_1} & s_1 \le e \le s_2 \\ w_{\tilde{S}} & s_2 \le e \le s_3 \\ w_{\tilde{S}} \frac{s_4 - x}{s_4 - s_3} & s_3 \le e \le s_4 \\ 0 & \text{otherwise} \end{cases}$$

$$I_{\tilde{S}^F}(e) = \begin{cases} \frac{s_2 - e + u_{\tilde{S}}(e - s_1)}{s_2 - s_1} & s_1 \le e \le s_2 \\ u_{\tilde{S}} & s_2 \le e \le s_3 \\ \frac{s_3 - e + u_{\tilde{S}}(s_3 - e)}{s_4 - s_3} & s_3 \le e \le s_4 \\ 1 & \text{otherwise} \end{cases}$$

$$F_{\tilde{S}^F}(e) = \begin{cases} \frac{s_2 - e + v_{\tilde{S}}(e - s_1)}{s_2 - s_1} & s_1 \le e \le s_2 \\ v_{\tilde{S}} & s_2 \le e \le s_3 \\ \frac{e - s_3 + v_{\tilde{S}}(s_3 - e)}{s_4 - s_3} & s_3 \le e \le s_4 \\ 1 & \text{otherwise} \end{cases}$$

Definition 2.3[17]Let $\tilde{S} = \left\{\left\langle s_1, s_2, s_3, s_4\right\rangle : w_{\tilde{S}}, u_{\tilde{S}}, v_{\tilde{S}}\right\}$ be a SVTrNN, then the score function $S(\tilde{S}^N)$ is defined as

$$S(\tilde{S}) = \frac{1}{12}(s_1 + s_2 + s_3 + s_4)(2 + w_{\tilde{S}} - u_{\tilde{S}} - v_{\tilde{S}})$$

METHODOLOGY

Mathematical Model for Neutrosophic Fuzzy Fractional Lateral Transshipment Problem (NFFLTrP)

NFFLTrPis formulated to optimize the transportation of variable quantities of a single homogeneous product from sources to depots, allow lateral shipments among depots, and finally distribute to destinations, with the objective of minimizing the total fractional transshipment cost. Consider a fractional lateral transshipment problem with I

sources, K destinations and J depots. Let $\tilde{c}_{ij}^N, \tilde{e}_{ij}^N$ denote the transportation cost and income for unit product from plant to depot (stage 1), $\tilde{s}_{hj}^N, \tilde{h}_{hj}^N$ denotethe transportation cost and income for unit product from depot to depot (stage 2). $\tilde{d}_{jk}^N, \tilde{f}_{jk}^N$ denote the transportation cost and income for unit product from depot to customer (stage 3).Also, $\tilde{a}_i^N, \tilde{b}_j^N$ are the supply and demand in source and destination. $\tilde{g}_j^N$ be denoted as a capacity at depot. The total amount of product flowing into each depot must match the total amount flowing out. Products can be shipped from any plant to any depot and from any depot to any customer, but shipments cannot occur directly between other location pairs. x_{ij}, w_{hj}, y_{jk} are defined as the amount products transport from i^{th} source to j^{th} depot, j^{th} depot to h^{th} depot and h^{th} depot to k^{th} destination point. The mathematical model for neutrosophic fuzzy fractional lateral transshipment problem is defined as follows:

$$\min Z(x,y) = \frac{\sum_{i=1}^{I}\sum_{j=1}^{J}\tilde{c}_{ij}^N x_{ij} + \sum_{h=1}^{J}\sum_{j=1}^{J}\tilde{s}_{hj}^N w_{hj} + \sum_{j=1}^{J}\sum_{k=1}^{K}\tilde{d}_{jk}^N y_{jk}}{\sum_{i=1}^{I}\sum_{j=1}^{J}\tilde{e}_{ij}^N x_{ij} + \sum_{h=1}^{J}\sum_{j=1}^{J}\tilde{h}_{hj}^N w_{hj} + \sum_{j=1}^{J}\sum_{k=1}^{K}\tilde{s}_{jk}^N y_{jk}} \quad (1)$$

Subject to (2)

$$\sum_{j=1}^{J} x_{ij} \le \tilde{a}_i^N, i \in \{1,2,3,...,I\} \quad (3)$$

$$\sum_{j=1}^{J} y_{jk} \le \tilde{b}_k^N, k \in \{1,2,3,...,K\} \quad (4)$$

$$\sum_{i=1}^{I} x_{ij} + \sum_{h=1}^{J} w_{hj} \le \tilde{g}_j^N, j \in \{1,2,3,...,J\} \quad (5)$$

$$\sum_{i=1}^{I} x_{ij} + \sum_{h=1}^{J} w_{hj} = \sum_{h=1}^{J} w_{jh} + \sum_{k=1}^{I} y_{jk}, j \in \{1,2,3,...,J\} \quad (6)$$

$$x_{ij}, w_{hj}, y_{jk} \ge 0, i \in \{1,2,3,...,I\}, h \in \{1,2,3,...,J\}, j \in \{1,2,3,...,J\}, k \in \{1,2,3,...,K\} \quad (7)$$

In the objective function (1), the numerator and denominator represent the transportation cost, income from the plant to the depot, between depots, and from the depot to the customer. Equations (2) and (3) denote the supply and demand constraints, respectively. Equation (5) ensures the capacity restriction at each depot. Constraint (6) represents the flow conservation at each depot. Finally, equation (7) describes the non-negativity constraints.

Deterministic model for neutrosophic fuzzy fractional lateral transshipment problem

The mathematical formulation of the fractional lateral transshipment problem under a neutrosophic fuzzy environment is highly complex and difficult to solve directly. To address this, a ranking method is used to convert the proposed fuzzy model into a deterministic one. which is described as follows.

$$\min Z(x,w,y) = \frac{\sum_{i=1}^{I}\sum_{j=1}^{J}\tilde{c}_{ij}^N x_{ij} + \sum_{h=1}^{J}\sum_{j=1}^{J}\tilde{s}_{hj}^N w_{hj} + \sum_{j=1}^{J}\sum_{k=1}^{K}\tilde{d}_{jk}^N y_{jk}}{\sum_{i=1}^{I}\sum_{j=1}^{J}\tilde{e}_{ij}^N x_{ij} + \sum_{h=1}^{J}\sum_{j=1}^{J}\tilde{h}_{hj}^N w_{hj} + \sum_{j=1}^{J}\sum_{k=1}^{K}\tilde{s}_{jk}^N y_{jk}} \quad (8)$$

Subject to (9)

$$\sum_{j=1}^{J} x_{ij} \le \Re(\tilde{a}_i^N), i \in \{1,2,3,...,I\} \quad (10)$$

$$\sum_{j=1}^{J} y_{jk} \le \Re(\tilde{b}_k^N), k \in \{1,2,3,...,K\} \quad (11)$$

$$\sum_{i=1}^{I} x_{ij} + \sum_{h=1}^{J} w_{hj} \le \Re(\tilde{g}_j^N), j \in \{1,2,3,...,J\} \quad (12)$$

$$\sum_{i=1}^{I} x_{ij} + \sum_{h=1}^{J} w_{hj} = \sum_{h=1}^{J} w_{jh} + \sum_{k=1}^{I} y_{jk}, j \in \{1,2,3,...,J\} \quad (13)$$

$$x_{ij}, w_{hj}, y_{jk} \ge 0, i \in \{1,2,3,...,I\}, h \in \{1,2,3,...,J\}, j \in \{1,2,3,...,J\}, k \in \{1,2,3,...,K\} \quad (14)$$

SOLUTION PROCEDURE

In this section, Charnes Cooper variable transformation method has been discussed to solve the deterministic model for finding the optimal compromise solution using Lingo Software as follows

Charnes-Cooper variable transformation method

The proposed deterministic model involves the fractional objectives, the Charnes-Cooper transformation [19]is applied to convert into an equivalent linear programming model. inequality

$\sum_{i=1}^{I}\sum_{j=1}^{J} \tilde{e}_{ij}^N x_{ij} + \sum_{h=1}^{J}\sum_{j=1}^{J} \tilde{h}_{hj}^N w_{hj} + \sum_{j=1}^{J}\sum_{k=1}^{K} \tilde{s}_{jk}^N y_{jk} \ge 0$ is true for every x_{ij}, w_{hj}, y_{jk}.

Assume that $s = \dfrac{1}{\left(\sum_{i=1}^{I}\sum_{j=1}^{J} \tilde{e}_{ij}^N x_{ij} + \sum_{h=1}^{J}\sum_{j=1}^{J} \tilde{h}_{hj}^N x_{hj} + \sum_{j=1}^{J}\sum_{k=1}^{K} \tilde{s}_{jk}^N x_{jk}\right)}$, $u_{ij} = sx_{ij} \ge 0$, $z_{hj} = sw_{hj} \ge 0$, $v_{jk} = sy_{jk} \ge 0$ which are used to convert the deterministic model into the following equivalent linear model.

$$\min Z(u,z,v) = \sum_{i=1}^{I}\sum_{j=1}^{J} \Re(\tilde{c}_{ij}^N) u_{ij} + \sum_{h=1}^{J}\sum_{j=1}^{J} \Re(\tilde{s}_{hj}^N) z_{hj} + \sum_{j=1}^{J}\sum_{k=1}^{K} \Re(\tilde{d}_{jk}^N) v_{jk} \quad (15)$$

Subject to (16)

$$\sum_{j=1}^{J} u_{ij} \le \Re(\tilde{a}_i^N) s, i \in \{1,2,3,...,I\} \quad (17)$$

$$\sum_{j=1}^{J} v_{jk} \le \Re(\tilde{b}_k^N) s, k \in \{1,2,3,...,K\} \quad (18)$$

$$\sum_{i=1}^{I} u_{ij} + \sum_{h=1}^{J} z_{hj} \le \Re(\tilde{g}_j^N) s, j \in \{1,2,3,...,J\} \quad (19)$$

$$\sum_{i=1}^{I} u_{ij} + \sum_{h=1}^{J} z_{hj} = \sum_{h=1}^{J} z_{jh} + \sum_{k=1}^{I} v_{jk}, j \in \{1,2,3,...,J\} \quad (20)$$

$$u_{ij}, z_{hj}, v_{jk} \ge 0, s > 0, i \in \{1,2,3,...,I\}, h \in \{1,2,3,...,J\}, j \in \{1,2,3,...,J\}, k \in \{1,2,3,...,K\} \quad (21)$$

RESULT AND DISCUSSION

Numerical Example

Consider an automobile manufacturing company produces automobiles at two production sites (P_1, P_2), transports them to three retail stores (R_1, R_2, R_3), and subsequently distributes them to six customers $(C_1, C_2, C_3, C_4, C_5, C_6)$ [9]. To enhance supply chain flexibility, responsiveness, lateral transshipment allowed between the retail stores. The company wants to maximize the profit by minimizing the shipping cost through the strategic use of lateral transshipments. Due to market unpredictability, transportation cost, income, supply, and demand are represented

using trapezoidal neutrosophic fuzzy numbers. Then neutrosophic fuzzy parameters are converted into crisp values using ranking function which is defined in definition 2.3. defuzzied neutrosophic transportation cost income, supply, and demand are presented in table [1,8].

Transportation cost from plant to depot (Stage 1)(Table 1)
Income from plant to depot (Stage 1) (Table 2).
Transportation cost from depot to depot (Stage 2) Table 3.
Income from depot to depot (Stage 2) Table 4.
Transportation cost from depot to customer (Stage 3) Table 5.
Income from depot to customer (Stage 3) Table 6.
Supply and Demand Table 7.
Capacity of Depot Table 8.

By using method prescribed in 4.1, the obtained optimum solutions of deterministic fractional lateral transshipment problem using Lingo Global Solver (20.0) are presented in [Table 9.]. Consequently, the comparison between fractional lateral transshipment problem and fractional direct shipment problem is detailed in [Table 10].

CONCLUSION

The supply chain management plays a significant role in the modern world by managing the complete flow of goods and services from raw materials to the final consumer. Investigating lateral fractional transshipment has become a crucial aspect of strengthening logistics operations, aiming to balance inventory, minimize stockouts, and enhance customer service. To address uncertainties in real-world scenarios, the proposed model is formulated within a neutrosophic fuzzy environment. It becomes the neutrosophic fuzzy fractional lateral transshipment problem, which introduces additional challenges due to fuzziness and the non-linearity of the fractional objective function, making it difficult to solve exactly. All parameters are converted into crisp using ranking function. After that, the deterministic model solved using Charner Cooper transformation method. The case study has been discussed for both fractional lateral/direct transshipment problem. The obtained solutions for fractional lateral transshipment show reduction in the objective function than the ordinary fractional transshipment problem. For future research, the proposed problem can be extended to solve multi objective fractional transshipment problem.

ABSTRACT

Forensic odontology, the application of dental science to legal investigations, relies heavily on the comparison of dental records and remains recovered from crime scenes, mass disasters, and identification efforts. Traditionally, this process is time-consuming, subjective, and requires specialized expertise. Artificial intelligence (AI), especially machine learning, offers a promising avenue to enhance the accuracy, speed, and efficiency of various aspects of forensic odontology. This paper explores the current and potential roles of AI in this field, discussing its advantages, limitations, and ethical considerations.

Keywords: Artificial intelligence, Forensic odontology, Human Identification, Forensic Sciences

INTRODUCTION

Forensic odontology plays a critical role in identifying unknown individuals, particularly in situations where other methods like fingerprint analysis or DNA profiling are compromised[1]. The unique characteristics of dentition, including tooth morphology, restorations, and anomalies, serve as a valuable identifier[2]. Experienced forensic odontologists meticulously compare pre-mortem dental records with post-mortem findings to establish a match[2,3]. However, the inherent subjectivity in visual comparison, the scarcity of expert odontologists, and the need for rapid identification in mass disaster scenarios underscore the need for innovative approaches. Artificial intelligence (AI), with its ability to automate complex tasks, analyze large datasets, and identify patterns, is poised to revolutionize forensic odontology[4,5,6].

Current and Potential Applications of AI in Forensic Odontology

AI's potential in forensic odontology spans several key areas

Dental Image Analysis and Automation

Radiograph analysis: AI algorithms can be trained to automatically detect and measure anatomical landmarks on dental radiographs (e.g., orthopantomograms, periapical radiographs) [4]. This minimizes inter-observer variability and facilitates the accurate comparison of pre- and post-mortem radiographs[].7 Machine learning models can be used to identify specific dental features, such as root canal fillings, crowns, or other restorations, significantly reducing the time required for manual examination[5,7].

3D reconstruction: AI can assist in creating three-dimensional models of skulls and dentition from CT scans, enabling more accurate and detailed comparisons. 8 These models can be rotated and manipulated, offering a more comprehensive view than traditional two-dimensional radiographs[5,6,7,8].

Image enhancement: AI can be used to enhance poor-quality images, improving visibility and facilitating analysis of subtle features. This is particularly useful in cases where post-mortem changes or trauma have compromised the integrity of the dental remains[8].

Automated Dental Charting and Record Integration

Automated chart generation: AI can analyze dental radiographs and clinical photographs to automatically generate dental charts, which document the presence or absence of teeth, restorations, and other anatomical features. This streamlines the process of creating a comprehensive dental profile[9].

Information retrieval: AI-powered systems can efficiently search and retrieve relevant dental records from large databases, accelerating the identification process. Natural Language Processing (NLP) can be used to extract key information from unstructured text within dental records[7,9,10].

Data integration: AI can integrate data from various sources, including dental records, photographs, CT scans, and DNA profiles, providing a holistic view of the individual[10].

Bite Mark Analysis

Bite mark feature extraction: AI can be trained to automatically extract relevant features from bite mark images, such as the shape, size, and arrangement of teeth. This reduces subjectivity in bite mark analysis and facilitates objective comparison with suspect dentition[10,11].

Bite mark matching: AI algorithms can compare bite mark patterns with dental casts or impressions to assess the probability of a match. This can assist in narrowing down potential suspects and providing valuable evidence in criminal investigations[11].

Distortion correction: AI can correct for distortions in bite mark images caused by skin elasticity and other factors, improving the accuracy of comparisons[11].
A schematic picture shows the algorithm of AI to analyse bite marks (Figure 1).

Age Estimation
Dental age estimation: AI can analyze dental development patterns on radiographs to estimate the age of an individual, particularly useful in cases involving unidentified children or adolescents. Machine learning models can be trained on large datasets of dental radiographs with known ages to predict age with greater accuracy[12].

Mass Disaster Management
Rapid identification: In mass disaster scenarios, AI can accelerate the process of identifying victims by automatically comparing dental records with post-mortem findings[12,13,14]. AI-powered systems can prioritize cases based on the likelihood of a match, enabling authorities to quickly identify victims and notify their families[13].

Data management: AI can streamline the management of large volumes of data generated during mass disaster events, including dental records, photographs, and DNA profiles[13,15].

Advantages of AI in Forensic Odontology
AI may cause reduction of subjective bias and human error through automated analysis. AI enables faster processing of dental records and images, leading to quicker identification. Standardized analysis protocols ensure consistent results across different examiners. Automation can reduce the need for highly specialized personnel and expensive equipment[9,11,15,16,17].AI-driven insights can provide objective support for expert opinions[16]. Advantages of AI over conventional methods in Forensic identification (Figure 2)

Limitations and Challenges
Data Availability and Quality: AI models require large, high-quality datasets for training. The availability of standardized dental records and radiographs can be a limiting factor.
Algorithm Bias: AI models can be biased if trained on skewed or unrepresentative data. This can lead to inaccurate or discriminatory results.
Explainability and Transparency: Black-box AI models can be difficult to interpret, raising concerns about transparency and accountability.
Ethical Considerations: The use of AI in forensic odontology raises ethical questions regarding privacy, data security, and the potential for misuse.
Regulatory Framework: Clear regulatory frameworks are needed to ensure the responsible and ethical use of AI in forensic odontology.
Acceptance by the Legal System: The admissibility of AI-generated evidence in court requires careful consideration and validation[10,18].

Ethical Considerations
The implementation of AI in forensic odontology must be guided by ethical principles to ensure fairness, transparency, and accountability. Key ethical considerations include
Data Privacy: Protecting the privacy of dental records and other sensitive information.
Algorithmic Bias: Mitigating the risk of bias in AI algorithms.
Transparency and Explainability: Ensuring that AI-driven decisions are transparent and explainable.
Human Oversight: Maintaining human oversight and judgment in the interpretation of AI results.
Accountability: Establishing clear lines of accountability for the use of AI in forensic odontology[19].

CONCLUSION

Artificial intelligence holds immense potential to transform forensic odontology, enhancing the accuracy, speed, and efficiency of identification processes. While several limitations and challenges remain, ongoing research and development are addressing these issues. As AI technology continues to evolve, forensic odontologists will need to adapt and integrate these tools into their practice. Ultimately, the successful implementation of AI in forensic odontology will depend on careful consideration of ethical implications, rigorous validation of AI algorithms, and close collaboration between AI researchers and forensic experts. By embracing AI responsibly, forensic odontology can further enhance its role in identifying individuals, solving crimes, and providing closure to grieving families. Future research should focus on developing robust, explainable, and unbiased AI models that can assist forensic odontologists in making accurate and reliable identifications.

ABSTRACT

In many places of the world, obesity becomes a significant public health concern. An obese person's respiratory mechanics are altered, their lung and chest wall compliance are diminished, their respiratory muscle strength and endurance are decreased, their pulmonary gas exchange is reduced, and their ability to exercise is limited. One breath is stacked on top of another in the breath stacking technique, which is then followed by a brief hold and expiration. Breathing that is slow and rhythmic is known as diaphragmatic breathing. This study sought to examine the effects of diaphragmatic breathing and the breath stacking technique on FVC, FEV1, and FEV1/FVC in obese persons.

Keywords: Obesity, Breath stacking technique, WHR, FVC, FEV1.

INTRODUCTION

In India, obesity has emerged as a serious health concern. Obesity is described by WHO as "a disorder with excessive fat." buildup in the body to the point where it negatively impacts health and wellness[1]. Waist-hip ratio (WHR) and waist circumference (WC) are employed as indicators of abdominal obesity, whereas weight and body mass index (BMI) is utilized to gauge overall adiposity. The waist-to-hip ratio, which measures how much body fat is distributed

from the abdomen to the lower body, is calculated by dividing the waist circumference by the hip circumference at its widest point[2]. The WHO defines central obesity as having a waist-to-hip ratio (WHR) of≥0.90for males and ≥0.85 for women[3]. It is thought that abdominal obesity affects the mechanical properties of pulmonary function by altering lung compliance, a labour of breathing, and elastic recoil. The relationship between the diaphragm, chest wall, and lungs is changed as fat builds up. As a result, acquiring too much weight may have an impact on one's ability to exercise as well as their pulmonary function, small airway function, expiratory flow limitation, changes to their breathing patterns, reduced respiratory muscle strength and endurance, and pulmonary gas exchange[4]. A screening procedure for overall respiratory health is spirometry. The forced vital capacity (FVC) and forced expiratory volume are the primary outcomes of spirometry (FEV). The forced expiratory volume (FEV) is the forced volume of inspiration forced to expire in t seconds. To categorize the severity of obstructive lung disorders, forced expiratory volume in the first second (FEV_1) is used[5]. The amount of gas expelled in the residual volume at maximal inspiration is known as the vital capacity (VC). The FVC is similar, but the patient is exhaling as quickly and forcefully as possible. An FEV_1/FVC ratio of more than 0.70 with both FEV_1 and FVC above 80% of the expected value is considered normal spirometry data. Spirometric abnormalities in patients with mild to moderate obesity represent systemic restraint defects, whereas severe & morbid obesity represents true airflow obstruction. The mechanism may be related to small airway disintegration brought on by decreasing lung volumes with increasing weight problems, or it may be unrelated[6]. A quick approach that addresses both trapped secretions and oxygen intake is breath stacking. Marini and colleagues first described it in 1986, and it involves encouraging someone to take deep, spaced-out breaths while stacking each one on top of the previous one. Encouraging the patient to breathe in slowly and stacking breaths as tolerated, this approach enables the lungs to take in more air than usual inspiration. It is then followed by a brief hold before gradual expiration.[7] Yet, no research has been identified that compares diaphragmatic breathing and the breath stacking technique on pulmonary functions in obese people.So, the goal of this study is to ascertain the impact of the breath stacking technique and diaphragmatic breathing in obese adults and then to compare the impact of each.

OBJECTIVES OF THE STUDY

- To find out the effect of the Breath stacking technique on FVC, FEV_1, and FEV_1/FVC ratio in obese individuals.
- To find out the effect of Diaphragmatic breathing on FVC, FEV_1, and FEV_1/FVC ratio in obese individuals.
- To compare the effect of Breath stacking and Diaphragmatic breathing on FVC, FEV_1, and FEV_1/FVC ratio in obese individuals.

Hypothesis

Experimental hypothesis

There is a significant difference between the effect of the Breath stacking technique and Diaphragmatic breathing on pulmonary functions in obese individuals.

Null hypothesis

There is no significant difference between the effect of the Breath stacking technique and diaphragmatic breathing on pulmonary functions in obese individuals.

MATERIALS AND METHODS

Study design: An interventional study.
Study setting: Shri K. K. Sheth Physiotherapy College, Rajkot
Source of data: In and around Rajkot city
Study population: Obese individuals.
Sampling technique: Purposive sampling for selection and group allotment of a subject by simple random sampling.
Study duration: 6 days /week for 2 weeks.
Sample Size: 46 obese individuals were selected for the study.

$n = 2\frac{S^2(Z1+Z2)^2}{(M1-M2)^2}$

Where, M1= Standard deviation of Intervention1, M2= Standard deviation of intervention 2
Z1= Z value associated with alpha, Z2 = Z value associated with beta
46 obese people between the ages of 35 and 55 participated in the study after the ethical committee gave its clearance. Those who were willing to participate in the study were asked to sign a written consent form after being fully informed of its goals and methods. (ANNEXURE 10.1). Purposive sampling was used to pick the subjects. The subjects were divided into groups using just random sampling. Name, Age, Sex, Height, Weight, BMI, WHR, Personal History, History of Respiratory Illness, and PFT measurements were all noted for each individual. (ANNEXURE-10.2).

Inclusion Criteria
- Age group: 35-55 years
- Gender: both male and female
- Subjects with BMI: ≥ 25kg/m²
- Subjects with waist-hip ratio ≥ 0.80 women, men ≥ 0.95.

METHODOLOGY

46 obese individuals were selected for the study fulfilling the inclusion and exclusion criteria. Subjects were assigned into two groups by simple random sampling.

Group A: 23 subjects had received the breath stacking technique.
- Sit comfortably and loosen restricting clothing or belts.
- Take in a full breath through the nose, allowing the stomach and lower ribcage to expand outward.
- Trap this breath by closing the vocal cords.
- Take another short breath and trap it.
- Take a third breath until your lungs are full.
- Hold the breath for 2 to 3 seconds.
- Let all the air out of the lungs through the mouth making a shushing sound.
- Take rest for a minute before repeating.
- Repeat for 3-5 cycles of BS. (For 10-15 minutes 6 days/week for 2 week.

Group B: 23 subjects had received diaphragmatic breathing.
- Subjects were asked to sit in a semi-fowler position.
- They were told to place their hand below the anterior costal margin and feel the movement occurring.
- Then the subjects were told to breathe in slowly and deeply through the nose allowing the abdomen to rise slightly and then relax and exhale slowly through the mouth.
- This breathing technique was performed for 10-15 minutes such that the patient takes 6 to 8 deep breaths per minute.
- This breathing technique was given for5 days/week for 2 weeks.
- Pre and post-pulmonary function test was taken as per the standard outlined by the American Thoracic Society.
- For measurement of FEV1, FVC, and FEV1/FVC ratio, patients were asked to take the deepest breath as much as possible then place the mouthpiece in their mouth with lips sealing it, and immediately exhale hard and fast for as long as possible, preferably at least 6 seconds followed by a rapid inspiration from the mouthpiece.
- Three trials were given for each procedure and the best trial was selected. The trial was considered “unacceptable” If it showed evidence of cough, early termination of expiration, or inconsistent effort.
- After the collection of data, pre, and post-values for FEV1, FVC, and FEV1/FVC were analyzed by statistical software and results were found.

RESULTSAND DISCUSSION

- All statistical analysis was done using SPSS 26.0 software. Before applying the statistical test, data were screened for normal distribution using the Shapiro-Wilk test.
- All the outcome measure was analyzed at baseline and 2 weeks of intervention using an appropriate statistical test. The level of significance was kept at 95% changes in the outcome measure were analyzed within-group as well as between-group.

Interpretation

- In group-A, a significant difference was found in pre & post-FVC (l) ($Z = 4.198$, $P < 0.05$), FEV_1 (l/s), ($Z = 4.198$, $P < 0.05$), and FEV_1/FVC ($Z = 2.805$, $P < 0.05$).Which is shown in Graph 1 and table 1.
- In group B significant difference was found in pre & post-FVC (l) ($Z = 4.199$, $P < 0.05$), FEV_1 (l/s), ($Z = 4.198$, $P < 0.05$), and FEV_1/FVC ($Z = 3.182$, $P < 0.05$).Which is shown in Graph 2 and table 2.

Inter Group comparison of Group A and Group B suggested that there was a significant difference for FVC (l) ($U = -3.374$, $P < 0.05$) and FEV_1(l/s), ($U = -3.462$, $P < 0.05$) and not a significant difference for FEV_1/FVC ($U = 0.438$, $P > 0.05$) between the two Groups. Which is shown in Graph 3 and table 3.
Hence, the result of this study supports the experimental hypothesis.

DISCUSSION

The study intended to find out and compare the effect of the Breath stacking technique and diaphragmatic breathing on pulmonary function tests in obese individuals. The result of this study supports the experimental hypothesis. Thereasonforthereductioninpulmonaryfunctioninobeseindividualsisthetrunkfat,whichmaycompressthethoraciccavity andrestrictthediaphragmaticmovement,resultinginreducedverticaldiameterofthethoraciccavity.Itreducesthecomplian ceofthelungsand the thoracic cavity resulting in increased load on the respiratory muscles. This may end up with are duction in lung volumes and flowrates. [8]. During normal breathing after a particular degree of stretching, pulmonary stretch receptors in alveoli are stimulated and send an impulse to respiratory centers for inhibition of inhalation and to begin with exhalation. Yet, when breathing diaphragmatically, the lung expands significantly and the alveolar walls are stretched to their greatest degree. The stretch receptors are thus trained to with stand more and more stretching, so that the duration at which inhibitory neural impulse generated by stimulation of such pulmonary stretch receptors increases, thus it improves ventilation.[9]. Breath stacking allows larger mobilization of inspired air. The completion of slow, deep inspirations, followed by a post-inspiratory pause, with a pause of at least five seconds, allows the air to disperse itself uniformly. The breath-stacking increases the amplitude and duration of thoracic expansion. During airway occlusion, the central drive increases gradually and Maximum inspirations cause increases of the trans-pulmonary pressure and the post-inspiratory pause, with the maintenance of this raised pressure, contributes to the increases of the PaO2, presumably through the recruitment of the collapsed alveoli.[10]

CONCLUSION

Breath stacking technique and diaphragmatic breathing both were effective in improving pulmonary functions in obese individuals after performing breathing techniques for 6 days/week for 2 weeks and there was a significant difference between both groups and breath stacking technique was more effective than diaphragmatic breathing in improving pulmonary function in obese individuals.

ACKNOWLEDGEMENT

Authors would like to thank all the Subjects of the study without whom this task would not have been possible.

ABSTRACT

This design includes effective and accessible UV Spectrophotometric and colorimetric ways for the Estimation of Firocoxib in bulk and retailed expression, which is simple, precise, accurate and provident. originally, standard and sample stock results were prepared by using DMF. The absorbance of firocoxib medicine result is measured at 410 nm, 415 nm in system A and system B independently, in UV range absorbance maxes is measured at 290nm. The working standard results were prepared with reagents Fecl3 and k2Cr2O7. This system validated for Linearity, Accuracy, Precision, Ruggedness, Robustness, LOD, LOQ and Assay as per ICH guidelines.

Keywords: Firocoxib, UV Spectroscopy[4], Colorimetry, Method development[5], System confirmation[6,7], Ferric chloride and Potassium dichromate.

INTRODUCTION

The medicine Firocoxib is a nonsteroidal anti-inflammatory medicine (NSAIDS). It's used to treat pain and inflammation in Dogs and nags. Acts by inhibiting cyclo oxygenase-2. The UV Spectrophotometric and Colorimetric styles for estimation of Firocoxib weren't developed ahead and this study develop easy and provident styles.

Structure(Fig.10)

MATERIALS AND METHODS

Materials
Chemicals (Table: 28)

Instruments
- Weighing balance
- UV Spectrophotometer
- Colorimeter
- Micropipette
- Volumetric flask
- Measuring cylinder
- Beaker

Method development
Colorimetry
Selection of solvent
Solubility studies were conducted to the firocoxib with many solvents. It was set up that firocoxib was freely answerable in Dimethyl Formamide.

Selection of reagent
Reagent was named grounded on the chemical structure of Firocoxib. Linearity of medicine was set up with ferric chloride, Potassium permanganate in system A and system B independently.

Preparation of standard stock solution
Standard firocoxib of 10 mg was counted and transfer into a 10 ml volumetric beaker and dissolved in DMF. The beaker was shaken and volume was made up to the mark with DMF to give a result 1000µg/ml (stock result).

Method A
Determination of maximum absorbance wavelength of 10µg/ml solution
Stock result of firocoxib was further mixed with DMF to get attention of 10µg/ml and 1ml of reagent was added. Absorbance was checked at colourful wavelengths and it was set up that 410nm is the maximum absorbance wavelength[10].

Selection of attention of reagent
Colourful trails were made with 1,2, 3,4, 5, 6, and 7(mg/ ml) reagent results. More linearity was attained with 3(mg/ ml) reagent result in system A.

Effect of volume of reagent on the linearity of coloured complex
Colourful working standard results are prepared using different volumes of 3(mg/ml) reagent and absorbance is measured. Finest result was attained with volume 1 ml reagent result [11,12].

Effect of time on the linearity of the colour complex
Absorbance of the coloured complex result is observed in a series with time intervals of 15 minutes and the linearity is observed from starting up to 90 minutes.

Selection of logical concentration range

From standard stock result of Firocoxib medicine, applicable aliquots 10 to 130µg/ml independently were pipetted out into a 10 ml volumetric beaker. To each sample add 1 ml of 3(mg/ml) reagent result and made up to the mark with DMF to attained working standard results of attention from 20- 130µg/ ml. Absorbance of these samples were measured at 410nm.

Construction of calibration curve

From the attained absorbance values estimation wind was constructed. Regression equation and correlation measure (R^2) are determined.

METHOD-B

Determination of maximum absorbance wavelength of 10mg/ml result

Stock result of Firocoxib was further adulterated with DMF to get attention of 10µg/ml and 2 ml of reagent was added. Absorbance was checked out at wavelength of 415nm is the maximum absorbance wavelength in system B (Potassium dichromate).

Selection of concentration of reagent

Colourful trails were made with 1, 2, 3,4(mg/ml) reagent. More linearity was attained with 2(mg/ ml) reagent result in this system.

Effect of volume of reagent on linearity of colour complex

Linearity of coloured complex was measured with different volumes of reagent. It was set up that 2 ml of reagent gives linearity.

Effect of time on the linearity of colour complex

The colour of medicine result with reagent replied after 10 min stability of complex was set up to 125 min.

Selection of logical concentration range

From standard stock result of firocoxib medicine, applicable aliquots µg/ml independently were pipetted out into a 10 ml volumetric beaker and 1 ml of reagent was added and made up to the mark with DMF to attained working standard results of attention from 10- 100µg/ ml. Absorbance for these results were measured at 415nm.

Construction of calibration curve

From standard firocoxib stock result attention of 10- 100µg/ml in system B were prepared. Absorbance value of a result in system B were measured at 415nm. From the absorbance value, estimation wind was constructed. Retrogression equation and correlation measure(R^2) are determined[13].

Method development of UV spectrophotometry

Method development involves the following types

Determination of maximum absorbance wavelength of 10µg/ml result:

Stock result of firocoxib was further adulterated with DMF to get attention of 10- 50µg/ ml. Absorbance was checked out at colourful wavelengths and it was set up that 291nm is the maximum absorbance wavelength[14].

Selection of concentration range

From standard stock result of firocoxib, applicable aliquots, 100µg/ml independently were pipetted out in a 10 ml volumetric beaker and was made up to with DMF attained working standard results of attention from 10- 100µg/ ml. Absorbance for these results were measured at 291nm.10- 50µg/ ml attention were showing direct values.

Construction of calibration curve

From standard firocoxib stock result attention of 10-50µg/ ml. Absorbance value of each result against different attention and DMF as a blank were measured at 291nm. From the absorbance value estimation wind was constructed. Regression equation and correlation measure(R^2) were determined.

METHOD VALIDATION

Linearity

Method A

From standard-issue stock result of Firocoxib applicable aliquots of µg/ml independently where pipetted out in 10 ml volumetric steins and append 1 ml of 3(mg/ml) $FeCl_3$ reagent and were made up with DMF to gain working standard-issue results of attention from 10- 100µg/ ml. Absorbance for these results was measured at 420nm. This attention was showing off direct valuations. From that absorbance value, the regression equation and correlation measure(R^2) are determined[15].

Method B

From standard-issue stock result of firocoxib, applicable aliquots of 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120µg/ml independently where pipette out in 10 ml volumetric steins and append 2 ml of 2% w/v were made up with DMF to gain working standard-issue results of attention from 10- 120µg/ ml. Absorbance for these results was measured at 415nm. This attention was showing off direct valuations. From that absorbance value, the regression equation and correlation measure(R^2) are determined.

Precision

Precision of styles was studied as intraday and inter day was performed by analyzing the three nonidentical attention of medicine for three moments in the same day. Inter-day perfection was performed by analyzing three nonidentical attentions of medicine for three days in a week. Three nonidentical attention were LQC, MQC, and HQC[16].

Accuracy

The accuracy of proffered methods was assessed by reclamation inquiries at three nonidentical situations i.e. 80%, 100%, and 120%. The reclamation inquiries were carried out by adding known quantum of standard-issue result of the medicine to the pre analyzed phrasings, results were also analyzed by professional styles [17,18].

Ruggedness

Absorbance valuations were taken by two judges with the same instrument and with the two instruments by the same judges[19,20].

Robustness

The robustness is a parameter that has been estimated in confirmation inquiries of logical styles, which has been outlined as the capacity of procedure to produce unprejudiced effects in the presence of fragile changes in the experimental conditions[21,22]. Robustness of the eluded procedure was assessed by assessing the influence of fragile variation in experimental variables (measure of reagent, temperature, and heating time). The effects offered. The robustness of the proposed system was determined by(a) changing the pH of the media by ± 0.1 unit and(b) changing the attention of the reagent by ± 0.1 unit.

Limit of Detection and Limit of Quantification

LOD is the smallest attention of analyte in a sample that can be detected but not inescapably quantified. LOW is the smallest attention of analyte in the sample that can be quantitatively determined with perfection and delicacy [23,24].
LOD and LOQ was calculated from direct wind utilizing following formulas
LOD = 3.3 σ/ slope,
LOQ= 10 σ/ pitch,

Where σ = the standard-issue divination of the reaction and S = slope of calibration curve.

DISCUSSION

All the styles were validated and developed as per ICH companion lines. The styles for the estimation of firocoxib medicine in brunt and retailed lozenge shape were set up to be accurate, simple, precise, robust, sensitive and reproducible. These styles were validated in tours of linearity, perfection, delicacy, robustness, ruggedness, LOD, LOQ and particularity. The medicine is followed the Beer's lambert's law over the attention range from 20-130(µg/ml)10-
100(µg/ml),50(µg/ml)in A,B independently andUVSpectroscopy utilizing retrogression dissection the direct equation Y = 0.0013 x 0.0523, 0.0013 x 0.0523, 0.0096x 0.3146 with correlation measure of r2 = 0.9995 in all styles independently 23,24. The perfection effects show off RSD lower than 2 at each position in all styles, which easily shows that the system is precise enough for the dissection of Firocoxib. The delicacy of the styles was chorded by reclamation inquiries. The robustness and ruggedness inquiries make known that the styles is able robust and inured. The LOD and LOQ valuations demonstrate that perceptivity of the styles. Determination of Firocoxib medicine in brunt and retailed expression of two brands showed off, content of Firocoxib were veritably close to the labelled quantum. The RSD valuations in all the parameters were within the respectable limitations. The UV Spectrophotometric system is simple, sensitive and accurate.

ACKNOWLEDGEMENT

We express our heartful gratefulness to the Sequent scientific Ltd, Staff in the Department of pharmaceutical Analysis in Sri Krishnadevaraya University, Anantapur for whole hearted cooperation in doing this research work.

CONCLUSION

The above developed methods are simple, accurate and ecofriendly and can be used routinely in quality control labs.

ABSTRACT

The term menopause means 12 months of amenorrhea from the final menstrual date. Physical fitness defined as series of elements associated with health and its performance of activity of daily living which represents one's ability to execute operational capability to perform physical activity. In postmenopausal women hormone reduction associated with reduce muscle strength, mass, agility, flexibility which affects activities of daily living. Thus, the purpose of the study was to find out the physical fitness in postmenopausal women. It was an observational study for which 125 postmenopausal women were taken. Inclusion Criteria were postmenopausal women, aged 45-55 years, willing to participate for the study, who do not exercise regularly, able to understand English language. Exclusion Criteria were OA of any joint, women with hysrectomy, women on hormone replacement therapy, unable to understand English language. For evaluation of the physical fitness the Senior fitness test was used. The data was analyzed using SPSS 20 version. The mean age of the postmenopausal women was 50±3 years. The mean score of the chair stand test was 15.26, the biceps curl test 13.17, 6-minute walk test 500.20, the chair sit and reach test 25.00, the back scratch test 15.56, the 2.45M up and go test 8.99.There was reduce physical fitness in terms of reduce flexibility, upper limb and lower limb strength, agility, aerobic endurance.

Keywords: Menopause, Physical Fitness, Senior Fitness Test, Postmenopausal Women

INTRODUCTION

The term menopause means 12 months of amenorrhea or no menses from the final menstrual date. It is the final phase of women's reproductive life which is part of normal aging process. Its further divides into three phases: perimenopause, premenopause and postmenopause. Each phase has different characteristics and effect on women's wellbeing. The changes occur at the time of menopause is due to decline hormone level in blood mainly estrogen. During the menopause various impleasure symptoms experienced by the women such as vasomotor, hot flashes, fatigue, joint problem, psychiatric, sleep disturbances, urogenital atrophy which is also a part of normal aging process [1]. The term menopause is known as the last menstruation, generally lasts between 46 and 52 years, and marks as aging of a woman's reproductive system [1]. Hormonal changes associated with menopause starts many years prior to menopause and linked with gradual increase in follicle-stimulating hormone (FSH) and sudden decrease in systemic female sex steroids (estradiol and estrone) 6 months around the menopause. At the time of menopause different symptoms affect the quality-of-life women along with these symptoms leads to decrease in physical fitness which is also associated with increase in age. Physical fitness defined as series of elements associated with health and its performance of activity of daily living which represents one's ability to execute operational capability to perform physical activity [2]. There is gender related decrease in physical activity performance, which is markley seen in females than in males at their middle age which is mainly because of females have rapid change in hormone level in menopausal life[3]. Menopause-induced changes in sex hormones like estrogen can lead to a decline in physical activity, and this, in turn, may impact skeletal muscle function and overall performance. The decline in spontaneous physical activity (PA) that occurs with menopause could be partly due to the loss of estrogen's neuroprotective effects, which might make women feel less motivated or experience increased fatigue. The estradiol replacement can reverse this decline are quite insightful. In rodents, estradiol replacement has been shown to improve motor function and potentially increase PA, suggesting that hormone therapy could be beneficial in mitigating some of the physical activity-related changes seen during menopause. The decline in physical performance during menopause may partly be a result of reduced physical activity (PA) and hormonal changes. That makes sense—when estrogen levels drop during menopause, it can affect muscle strength, endurance, and overall energy levels. The reduced spontaneous PA, along with the loss of estrogen's positive effects on muscle mass and metabolism, could contribute to the observed decline in physical performance.

This could be a multifactorial issue, where hormonal changes not only affect muscle tissue directly but also influence factors like mood, sleep, and joint health, which in turn impact physical activity levels[3]. The symptoms which commonly seen during process of aging were reduction in muscle strength, decline in cardiovascular and logical capacity with reduce joint mobility. These symptoms were more evident in postmenopausal women because of osteoporosis and sarcopenia. The physical fitness associated with age can be evaluated by various fitness tests. The physical fitness consists of various parameters such as cardiorespiratory endurance, muscular strength, flexibility, balance, agility and body composition. These parameters can be evaluated and improved by well-structured exercise program[4]. To perform activities of daily activity the physical performance is necessary. Reduce walking speed and mobility restrictions are due to reduction in muscular strength and power associated with increase age. This can be mainly seen in later age of life but in women it can begin in her midlife because of change in hormonal level during menopausal life[5]. Hormone mainly estrogen majorly takes part in keeping skeletal muscle homeostasis and its action in postmenopausal women have reduced muscle mass, muscle power and muscle strength compare to premenopausal women[5]. In postmenopausal women reduction in physical activity mainly due to sedentary lifestyle which can be associate with increase in age also. Alternatively, further longevity, low morbidity and mortality can be visualized in physically active individuals. Postmenopausal women with inactive lifestyle have reduce resistance, strength and lower limb muscle velocity. Along with this, reduction in walking speed is due to muscular weakness and reduce cardiorespiratory capacity which results in less safety. It also causes reduce walking frequency in daily routine, and results in more time of incactivity [6]. The physical fitness known as the functional capacity to carry out day to day activities by their own in the absence of exhaustion. Increase age associated with decline in physical fitness which includes strength, agility, endurance and flexibility results in problems in routine

activities and normal activity performance [7]. There are various validated tools used to assess the physical fitness from them we used the senior fitness test developed by Rikli and Jones. The Senior Fitness Test is a functional test of muscular strength, endurance, balance and flexibility. The senior fitness test includes the chair stand test, the biceps curl test, the 6 – minute walk test, the chair seat and reach test, the back scratch test, the 2.45-m Up-and-Go test to asses various physical fitness measures in the postmenopausal women [8]. Menopause itself is period of 4-6 years in women life depending upon individual. So, most of the time of women spend in her postmenopausal phase. To live functionally independent in later years of life is most important for that one has to be physically fit. Reduction in the fitness results in institutilization, long term illness and mortality. Estrogen deficit in postmenopausal phase results in increase fat mass, reduction in bone mineral density and lean body mass [9]. This leads to reduction in motor skills, flexibility, speed, muscle strength which interferes with activities of daily living. Thus, the aim of the study was to find out the physical fitness in postmenopausal women.

MATERIALS AND METHODS

After getting the ethical clearance from the institutional ethical committee the study was conducted. It was an observational study done between 1 February 2024 to 1 April 2024 in Ahmedabad, Gujarat. CTRI registration was obtained and number of CTRI registration is CTRI/2024/01/062074.For this observational study 125 postmenopausal women between 45-55 years were taken. The physical fitness of postmenopausal women was evaluated using the senior fitness test. For the enrollment in the study, inclusion Criteria were postmenopausal women, women aged 45-55 years, willing to participate for the study, who do not exercise regularly, able to understand English language. The postmenopausal who do not meet Exclusion Criteria, OA of any joint, women with hysrectomy, women on hormone replacement therapy, unable to understand English language were excluded from the observational study. Written and informed consent obtained from each participant and their privacy about enrollment in the study was maintained. Two trained physiotherapists were always there for accuracy of the procedure. After explaining and demonstrating the test to the participant the recording of the result was done. The test was carried out in the physiotherapy department with instruments required for it. Rikli and Jones developed the Senior Fitness Test for adults aged over 60 years. It is use to evaluate physical fitness in healthy individuals. It does not require any expensive equipment to measure the physical fitness [8].

It includes total 6 functional test to evaluate physical fitness in postmenopausal women.

1. The Chair Stand Test. This requires people to repeatedly stand up from and sit down on a chair for 30 seconds. The number of stands is recorded. This reflects lower body strength.
2. The Biceps Curl Test. This requires people to repeatedly lift a 5 lb (2.27 kg) weight (for women) for 30 seconds. The number of lifts is recorded. This reflects upper body strength.
3. The 6-minute Walk Test. This is measured in distance (m) and reflects aerobic endurance.
4. The Chair Sit and Reach Test. This is measured in distance (cm) and reflects lower body flexibility.
5. The Back Scratch Test. This is measured in distance (cm) and reflects upper body flexibility.
6. The 2.45-m Up-and-Go test. This is measured in time (seconds) and reflects agility and dynamic balance.

Thus, by the above different test the physical fitness of postmenopausal women was taken. The test was carried out in the physiotherapy department of the college under the supervision of the expert. For the statistical analysis statistical package for the social sciences (SPSS) 20 version was used. The mean age of postmenopausal women was calculated. The mean value of each fitness test was calculated. From the results obtaining from above test the physical fitness of postmenopausal women was calculated.

RESULT

As per the findings of the observational study, the mean age of the postmenopausal women was 50±3. The physical fitness of postmenopausal women was calculated from obtained results of test analysis. The mean score of the chair stand test was 15.26, the biceps curl test 13.17, 6-minute walk test 500.20, the chair sit and reach test 25.00, the back scratch test 15.56, the 2.45M up and go test 8.99.(Table 1)

DISCUSSION

The physical fitness being one of the important aspects for evaluation as age advances here in our study the main reason for its evaluation is the effect of the hormones during the menopausal age. The result of the study shows the mean age of the postmenopausal women included for the observational study was 50±3. This age group is the most prevalent for the menopausal symptoms to begin. The results obtained from our study, indicates overall decline in score of all test measures which shows reduction in physical fitness in postmenopausal women. As per the study done by researcher in it shows the reduction of physical fitness in women than men. This was due to gender prevalent factors which are in inverse relation with that of age. Here the fitness in terms of physique is most commonly affected in the later phase [11]. The lower body strength was evaluated by the chair stand test in this observational study. The result of which indicates reduce lower limb strength in postmenopausal women. Lower extremity strength shows the routine physical activity level due to repeated involvement of limb muscles used in daily routine. A multifactorial affection is involved in the reduction of this strength as a female even under goes the process of parity and ligamentous laxity are most common in that phase. In post-partum period a female might not have gone through proper strengthening protocol which may lead to reduce the strength of lower body in the later life. Thus, it shows the common effect of physical activity deterioration linked between lower limb strength and menopausal status [3]. The similar results found in the study done by slawinska *et al*. (2000) which suggest 50.6% reduction in lower limb strength than the normal data obtained. The other study also shows similar results suggesting decrease in lower body strength compare to upper body strength in women more than a middle age group[3]. Bondarev *et al*. shows postitive results as we found in this study which says reduction in lower body strength is 29.74% in 50 to 80-87 years age.

Along with this, other studies suggest reduction in strength 1% every year in 45-60 years age which increases 1.5% every year after 60 years[10]. Thus, it makes it evident enough to study this particular age group for their physical fitness of lower body strength where the muscles of the entire leg work in a synchrony so as to gain the outcome. This is important for the purpose of mobility. Paterson *et al*. (2007) says reduce lower limb strength more compare to upper limb strength [1]. This could possibly be due to the postures adapted in daily living. The arm strength in postmenopausal women was tested by the biceps curl test which shows reduction in upper limb strength in our population. slawinska *et al*. (2000) says 21.3% reduction in upper limb strength in comparision with normal data obtained from the study[11]. Findings of the recent study shows there was reduction in the muscle strength which was also supported by the results of the other studies which states that there was reduction in muscle mass by 4% in the postmenopausal women compare to premenopausal women which results in reduction of muscle strength at menopause due to loss of muscle mass [5]. The 6- minute walk test was used to evaluate the aerobic endurance of postmenopausal women. Bondarev D. *et al* studied the reduction in exercise tolerance and aerobic capacity in postmenopausal women compared with premenopausal women which is in favour of our recent findings [5]. As evaluated by many researchers the focus on the reduction in physical fitness could be most commonly due to a decline in the mass of an individual muscle which is termed as sarcopenia, which leads to tightness of muscles, a lower strength as well as the endurance alterations in the mass affected. All the three aspects of the physical fitness are evaluated in the present study by various test.

This accounts to identify the lower fitness related to muscle mass alteration. The recent assessment has seen the same and thus could propose that the fitness is reduced identically due to the alteration in the muscles itself. The joint undergoes changes pertaining to the bones where osteoporosis is majorly seen in this age group and further increases linearly with age. The upper and lower body flexibility was assessed by the back scratch test and the chair sit and reach test repectively, the result of which shows decline in upper limb and lower limb flexibility. Ridhi singhavi *et al*. results indicate there was an average flexibility between 40-55 years of age [9]. To measure the agility in postmenopausal women the 2.4 meter up and go test was used. The test results show decline in agility in study population. Other supporting studies finds the similar declines in the agility which was in favour of present study(10). The research done by Bondarev *et al*. indicates there were 46% reduction in agility and balance which was

observed in the females of the same condition[5]. The falling of the outcomes of most of the parameters of physical fitness found in current study was in favour of the other researchers. As per Espeland *et al*. (2007) decrease lower limb strength, aerobic endurance, agility, dynamic balance and flexibility are associated with advancing age and results decline in mobility [12]. The study by Schultz *et al* (1997) decrease in lower limb strength results in reduce functional activities such as getting up from the chair [13]. This is a matter of concern for the population particularly in that age group. It is important to identify the problems prevalent in this cohort so as to further plan the management stratergies. There were many factors responsible for reduction of physical fitness in postmenopausal women like age, gender, associated co-morbidities, but along with them the decrease in physical fitness in postmenopausal women was mainly due to hormone reduction in the blood during the time of menopause which negatively affects their muscle power, strength, flexibility, endurance and agility.

CONCLUSION

After the result obtained from recent study it concluded that there was decline in the physical fitness in postmenopausal women. For the future recommendations further exercise regime can be developed to increase the physical fitness in postmenopausal women to have better quality of
life.

ACKNOWLEDGEMENT

I will be gratified to extend my thanks to the department of physiotherapy at Arush Physiotherapy College, Ahmedabad for providing me the space to conduct my data collection. I would further take the opportunity to thank Dr Neelam Rathod H.O.D at Arush Physiotherapy College for the constant support and Dr Kartik Patel for his guidance while data analysis and interpretation.

Funding The study has received no funding.

Conflict of Interest The authors declare that there is no conflict of interests regarding the study or this article.

Author Contributions Dr.Zarana Khamar Tvisha Patel has designed the study with even preparation of the manuscript. The review of the protocol as well as the analysis of the data and interpretation of result was done by Dr. Arvind Kumar. Dr. Tvisha Patel recruited the participants and collected the data.

Ethics approval The ethical approval was obtained post review by the Institute's ethical committee, Venus Institute of Physiotherapy: VIP/2023/EC/111. The trial is registered in Clinical Trial Registry- India: CTRI NO: CTRI/2024/01/062074

Data availability: The data will be available on request, maintaining confidentiality of the patients.

ABSTRACT

High-amylose corn starch (RS) is a novel type 5 resistant starch that can be used for the formulation of foods. RS5 was developed by using FFAs to treat high amylose corn starch. It is distinguished by the existence of amylopectin crystallites in RS5 that are long-chain double-helical. The granules of RS5, which are made of a mixture of corn oil and saline, have been subjected to gelatinization and retrogradation on progressive heating/cooling of the aqueous solution. The modified starches are used in both food and non-food industries. The modification of starches is designed to change the gelatinisation characteristics, gelling tendency, and rheological properties of the starches. SEM images revealed the disrupted structure of granulations after processing. Because of its decreased crystallization, the modified starch was shown to be extremely heat stable and to have an anti-staling action in bread and biscuits.

Keywords: Resistant Starch, Carbohydrates, Amylose, Amylopectin, Native (corn) starch

INTRODUCTION

Starch -An Outlook

The primary dietary carbohydrates are starches; sugars make up the remaining types. Potato and cereal products are the examples of plant-based sources of starchy foods.Starch consist of amylase and branched amylopectin molecules in molar ratios of (15% - 25%) and (85% - 75%). The primary components of the starch granule are a combination of two polymers and an essential. Amylase is a linear polymer, and amylopectin is a highly branched polymer (Tester *et al*., 2004).

Amylose

A linear chain of 1α4-linked α-D-glucopyranosyl units makes up amylose. Very few α-D-(1 α 6) branches are present in many amylose molecules; they may appear once every 180–320 units, or 0.3-0.5% of the connections. Amylose molecules typically weigh around 10 g/mol and have a degree of polymerization (DP) of 6000. Both single and double helices can be readily formed by the chains. While the hydrophilic hydroxyl groups are located on the outside of the coil, the majority of the hydrogen atoms are lipophilic and found inside the helix (Whistler and BeMiller, 1997).

Amylopectin

The highly branched polymer amylopectin has a DP of 2 α 10 and an average molecular weight between 10 and 5 α 10g/mol. It is therefore one of nature's biggest polymers. It is composed of thousands of small linear chains of α-(1 α 6)-linked α-D-glucopyranosy l units connected to one another. The branch point linkages constitute 4-5% of the total linkages (An amylopectin molecule consists of main chain, called the C chain, which carries the one reducing end-group and numerous branches, in termed A chains and B chains. Short chains (A chains) of DP 12-16 that can form double helices are arranged in clusters.The clusters comprised 80% to 90% of the chain and are linked by longer chains (B chains) that form the other 10% to 20% of the chains. Most B chains extend into 2 (DP) about 40) or 3 clusters (DP about 70), but some extend into more clusters (DP about110) Thompson, (2000).

Types of resistant starch

Resistant starch is defined as a portion of starch that cannot be digested by amylases in the small intestine and passes to the colon to be fermented by microbiota Resistant starch classification system are based on starch digestive rate. This system divides starches into rapidly digestible starches, slowly digestible starches, and resistant starches based on the results of in vitro digestion as proposed by (Englyst *et al.*,1982). There are currently 5 types of resistant starch as summarized below

Resistant Starch Type 1

According to Hernández, Emaldi, and Tovar (2008), RS1 is the name used to describe RS in which the starch is physically inaccessible to digestion, such as when grains, seeds, or tubers have intact cell walls. Because RS1 is heat stable for the majority of routine cooking processes, it can be used as an ingredient in a large range of traditional dishes (Sajilata, Singhal, and Kulkarni, 2006).

Resistant Starch Type 2

Natural, uncooked starch granules, like raw banana or potato starches, have a low hydrolysis susceptibility due to their crystallinity (Hernández *et al*., 2008). RS2 refers to native starch granules that are shielded from digestion by their shape or conformation. This compact structure explains the refractory nature of RS2, including ungelatinized starch, and restricts the accessibility of digesting enzymes and different amylases. Foods such as bananas include uncooked starch (Sajilata *et al*., 2006). According to Wepner, Berghofer, Miesenberger, and Tiefenbacher (1999), high-amylose maize starch is a special kind of RS2 that maintains its structure and resilience even when several items are processed and prepared.

Resistant Starch Type 3

Materials generated from non-granular starch that are resistant to digestion are referred to as RS3. According to Wepner *et al*. (1999), RS3 forms are typically created when starch granules retrograted According to Hernández *et al*. (2008), retrograted starches, or RS3, can occur in cooked foods that are stored at room temperature or at low temperatures. Accordingly, RS3 is present in most moist-heated foods (Sajilata *et al*., 2006). The thermal stability of RS3 makes it very interesting. This permits its usage as an ingredient in a broad range of traditional dishes and makes it stable in the majority of typical cooking processes (Haralampu, 2000).

Resistant Starch Type 4

RS can be created by chemically altering starch. When starch is modified using octenyl succinic anhydride (OSA), hydrophobic groups are added to the starch molecules, which prevents amylolytic enzymes from attaching to the

starch (Zhang and Hamaker 1998; Han and BeMiller 2007; He *et al*. 2008). Cross-linking of starch is another effective method to prepare RS4 (Woo and Seib 2002; Xie *et al*. 2006; Al-Tamimi *et al*. 2010).

Resistant starch type 5

The single-helical complex formation between amylose and lipids has also been used to develop RS 5 (Gelders *et al*. 2005; Hasjim *et al*. 2010). A RS5 product, containing up to 75% RS (AOAC Method 991.43), has been prepared by complexing partially-debranched high-amylose corn starch with FFAs. In vivo an investigation into human feeding has shown that the RS5 is resistant (Hasjim *et al*. 2010).

The following are the benefits of using amylose-lipid complex as Resistant Starch 5 over other varieties

- Amylose-lipid complexes exhibit greater thermal stability than most native starch granules with B- and C-type polymorphs (RS type 2), such as those found in potatoes and bananas.
- Compared to retrograded amylose (RS type 3) and chemically modified starch (RS type 4), forming amylose-lipid complexes requires less intensive physical or chemical treatment.
- These complexes can spontaneously reassemble during cooling after being heated beyond their dissociation temperature (Biliaderis and Galloway, 2000; Hasjim *et al*., 2010).

Production of resistant granular starch through starch-lipid complex

By promoting the production of amylose-lipid complexes (RS type 5) within starch granules, a novel method has been developed lately to increase the concentration of resistance starch (RS). In order to cleave the branch points in amylopectin, debranching enzymes, such as pullulanase or isoamylase, are applied to inflated starch granules. The long chains that are released from amylopectin then behave similarly to those of amylose, which allows them to efficiently form complexes with fatty acids (FAs). Because of its high amylose content and profusion of long amylopectin branches, high-amylose maize starch VII (HA7) was chosen for this technique (Jane *et al*., 1999; Li *et al*., 2008). An HA7 starch suspension is first heated to a high temperature in order to create the complex, and then it is enzymatically treated with either pullulanase (PUL) or isoamylase (ISO). Enzymatic debranching is followed by the extraction.

Application of RS Type 5

RS is present in up to 75% of the (ISO-treated HA7)-FA and (PUL-treated HA7)-FA complex products following enzyme digestion at 100 C in excess water using the AOAC Method 991.43. According to the findings, RS type 5 in the (ISO-treated HA7)-FA and (PUL-treated HA7)-FA complex products is thermally stable and, as a result, appropriate for heating-intensive food processing. Furthermore, an ISO-treated HA7-PA complex product's heat stability has been evaluated in bread-making. 72% (dry basis, db) of the wheat flour in a white bread recipe was swapped out with ISO-treated HA7)-PA complex product (60%, db) and wheat gluten (12%, db) (Hasjim *et al*., 2010).

The analytical result of the RS content of the bread containing RS type 5, determined using the AOAC Method 991.43, was 34.4% (db), which was similar to the value calculated (33.6%, db) from the RS contents of the wheat flour, (ISO-treated HA7)-PA complex product and wheat gluten used to make the bread. Although bread made with such a high content of RS type 5 was not intended for a desirable texture, the result proves that RS type 5 is more heat stable and its enzyme resistance remains in the bread after baking (Tufvesson *et al*., 2003).

Properties of RS 5

The formation of a single-helical complex between amylose and lipids makes it resistant to enzymatic hydrolysis. Starch's digestibility is further decreased by the amylose-lipid complex (ALC), which also prevents starch granules from expanding. Monoglycerides, phospholipids, long-chain alcohols, and free fatty acids (FFAs) are among the lipids that have been demonstrated to form a helical complex with amylose. According to Jane and Robyt (1984) and Gelders *et al*. (2005), amylose helical complexes with fatty acids and other substances that possess hydrophobic moiety are resistant to hydrolysis by enzymes.

MATERIALS AND METHODS

Selection of sample

Normal yellow colour high amylose corn starch (*Zea mays*) was purchased from the local market in Salem, Tamil Nadu, The starch sample was sealed in polyethylene bags for further analysis and stored at normal room temperature. Pullulanase enzymes from bacillus acidopullulytic enzyme (promozyme 400 L) was purchased from SD-Fine chemical companystearic acid was purchased from sigma chemical company, USA and it was used for analysis.

Preparation of Resistant starch

Type 5 resistant starch was made using a modified version of Hasjim *et al*. (2010)'s methodology. Following a one-hour stirring preheating period at 80°C, a starch suspension (10%, w/w, dry basis, db) was debranched using pullulanase (5 units/g starch, dry starch basis, dsb) at 60°C for twenty-four hours. After adding corn oil and 10% w/w stearic acid to the debranched-starch suspension, the mixture was vigorously stirred and kept at 80 °C for an additional hour. Centrifugation was used to recover the RS5, which was subsequently cleaned with a 50% (v/v) ethanol aqueous solution, dried at 37 °C, and crushed into a fine powder.

Chemical composition Of NCS Treated SACS, COCS starch

Starch yield

Starch yield was determined by the following method. The NCS, SACS and COCS of each starch were weighted and it was prepared by the Hasjim *et al*., (2010) method. The following formulas were followed for the starch yield of each starch respectively.

Chemical analysis

The moisture content of native corn starch (NCS), treated (Corn oil and Stearic acid) was determined by (AOAC, 2005), ash (AOAC, 2004), fat (Soxhlet method: Sadasivam and Manickam, 2005), crude fibre (Acid and Alkali digestion method: Sadasivam and Manickam, 2005), total carbohydrate content can be calculated by determining the difference between 100 and the sum of moisture, ash, crude protein, crude fat and crude fibre (Akpapunam and Sefa-Dedeh, 1995; Onyeike and Oguike, 2003; Ponka *et al*., 2005), total energy by multiplying the total carbohydrate content into the one gram (1 g) of pure energy value of Carbohydrate and protein as 4 Kcal, total fat as 9 Kcal. The detailed procedure of chemical composition of starches given in annexure -I.

Amylose Content of NCS and treated SACS, COCS

Total amylose (T-AM) and free amylose (F-AM) content were determined by iodine binding according to Chrastil (1987). Five milliliters of 85% ethanol were added to a test tube containing twenty milligrams of starch (NCS, SACS, and COCS), which was then kept at 60°C for thirty minutes while being periodically mixed to extract the lipids. The supernatant liquors were disposed of after the samples underwent centrifugation. To solubilize the starch, 4.0 ml of deionized water and 2.0 ml of 1.0 M NaOH solution were added to the lipid-free samples. The test tubes were then heated to 100°C for 30 minutes while being stirred occasionally. In a different test tube, 5 ml of 0.5% trichloroacetic acid was combined with 0.1 ml of this solution. The tubes were vortexed, then 0.05 ml of an iodine solution (1.27 g I2 and 3.0 g KI/l) was added and mixed right away. After 30 minutes at 25°C, the absorbance was measured at 620 nm in comparison to an H2O blank. Total (T-AM) values were derived from iodine binding using hot ethanol with and without lipid samples NCS, SACS, and COCS, respectively.

Functional Properties of NCS Treated SACS, COCS starch

Water Absorption Capacity

The Anderson *et al*. (1969) method was used to test the water absorption capacity of treated and native maize starch samples. In short, 0.5 g of the material was combined with 6 ml of distilled water and centrifuged. To determine the dry solids weight, the sample was centrifuged and then held in a water bath at 30 °C with constant stirring for 30

minutes. The suspension was then put in a petridish and dried at 105 °C for 4 hours, and the wet sediment was weighed. The WAC was determined as

WAC = ((Weight of wet starch − Weight of dry starch) / (Weight of dry starch)) × 100

"The water absorption capacity of native corn starch (NCS) and treated corn starch is crucial in the formulation of baby foods due to its functional role in developing ready-to-eat products."

Oil absorption capacity

Using the methodology outlined by Abbey and Ibeh (1988), the Oil Absorption Capacity (OAC) of treated and native corn kernels was measured.1 g of the starch sample was placed in a centrifuge tube of known weight, and 10 ml of oil was added. After 30 minutes of standing, the mixture was centrifuged (3500 g, 15 min), and the supernatant was disposed of. The weight gain was considered the water/oil absorption capacity after the tube and residue were weighed. A collection of information on the areas of application in food formulations is provided by the oil absorption capacity of NCS and treated corn starch.

AOAC = ((Empty weight of the centrifuge - weight of the after centrifuge) / (Weight of the sample)) × 100

Swelling Power

According to Peroni *et al*. (2006), the swelling power of treated and native maize starch samples was calculated. Glass tubes with coated screw covers were filled with 0.2 g of flour sample (dry starch base) and 18 g of distilled water. The tubes were placed in a shaking water bath at 60, 70, 80 or 90ºC for 30 min. After that, the tubes were taken from the bath, dried and weighed. The weight of the mixture was completed to exactly 20 g. The tubes were closed, inverted for homogenization and centrifuged at 1700 g for 5min. The supernatant was removed carefully and swelling power was determined as sediment weight divided by dry weight of flour (g/g), The swelling power of NCS and treated corn starch provide a data on process condition (such as nature of starch materials).

Structural Properties Of NCS Treated SACS, COCS starch

Scanning Electron Microscope (SEM)

A Scanning Electron Microscope (SEM) (JEOL-Model 6390, Japan) was used to examine the granule morphology of flour, native (corn) starch, and treated (corn) samples.On a double-sided tape that was attached to a SEM stub, the starch granules were scattered. After being covered with gold, the samples were put inside the SEM chamber. A scanning electron microscope device operating at a 15 kv accelerating voltage was used to take photomicrographs. The structural and size differences between NCS and treated corn starch are examined by morphological characteristics.

Light microscopy

The experiment was conducted using a polarization microscope (Axioskop 40 Pol/40 A Pol, ZEISS, Oberkochen, Germany) fitted with a 35 mm SLA camera. Since iodine slips inside the amylose coil and forms a rich blue color inclusion complex, it was utilized to analyze the interior structure of starch granules. Before being inspected under a light microscope, 1 ml of 5% starch suspensions were stained with 0.25 ml of an I2–KI diluted solution (2 mg/ml I2 + 20 mg/ml KI). They were then repeatedly washed with distilled water 20 minutes later and dispersed in a 1:1 (v/v) glycerol/water mixture to reduce evaporation and granule movement in the field. The unstained starch's morphology was examined using both ordinary and polarized light. Chen Pei and colleagues (2010). Information on the granule shape and structure of NCS and treated corn starch is provided by light microscopy details.

Statistical Analysis

All determinant values were the average of triplicate values except instrumentation. LSD (Least Square Difference) as post hoc comparison was done to compare the means after one way analysis of variance (ANOVA). All statistical analyses were conducted using the Statistical Package for the Social Sciences (SPSS), Version 17.0.

RESULT

Preparation of RS 5

In order to create RS, amylose and lipids have also formed a single-helical complex (Gelders *et al*., 2005; Hasjim *et al*., 2010). FFAs have been complexed with partially-debranched high-amylose corn starch to create an RS5 product that contains up to 75% RS (AOAC Method 991.43). The procedure of Hasjim *et al*. (2010) was followed in the preparation of the RS 5 of SACS and COCS.

Chemical Composition of Native and Treated Corn Starch

A straightforward and practical method of demonstrating the purity of starch extracts is by their chemical composition, where higher starch and lower levels of other components (such as protein, fat, ash, and fiber) are preferred (Ikegwu *et al*., 2010). Table 1 shows the functional properties of the RS 5 corn (Native Corn Starch (NCS)), Stearic acid treated Corn Starch (SACS), Corn Oil treated Corn Starch (COCS) starches. Moisture, Ash, Crude fat and Crude fiber was evaluated. Functional properties are the characteristics that determine the suitability of the food material for specific purpose (Eke-Ejiofor and Owuno, 2014). The starch yield of the treated COCS and SACS 44.4 and 51.1 (%) respectively. The heat treatment affects the starch yield in SACS treated starch than the COCS starch samples. Fan Zhu and Ya-Jane Wang (2013) reported that the Starch complex yield of common starch treated with α-napthol was found to be 53.2 % which it was comparable to the COCS starch 51.1 (%). The starch complex yield of SACS is 44.4 % this starch was less than the native corn starch 51.1 (%). The moisture content of NCS, COCS and SACS was 8.62, 7.63 and 7.56 (%) respectively. Starches treated with stearic acid and corn oil shows reduced moisture content compared to native corn starch (NCS), the higher moisture level was observed in native corn starch (NCS). The moisture content of NCS, SACS and COCS was comparatively low when compared with the results of Shalimar Maize 8.45 (%) reported by Abida Ali *et al.,* (2016). These lower values of moisture content are advantageous in terms of shelf life. The moisture content of these starches was in the range generally accepted for dry products in order to obtain a desirable shelf life (Abida Ali *et al.,* 2016). The ash content of NCS COCS and SACS was 0.09, 0.16 and 0.11 (%) respectively. Normal high amylose corn starch (NCS) shows reduced ash content compared to Starches treated with stearic acid and corn oil, the higher ash content level was observed in corn oil treated starch and stearic acid treated starch. Native corn starches (NCS) was highly purified in nature than the treated starch samples, the treated starch samples slightly higher than the native starch (NCS) this may be due to the reason of addition of stearic acid and corn oil to the high amylose corn starches. Thus ash content of SACS, COCS which clearly depicts the presence of mineral content than that of native corn starches. The ash content of NCS, SACS and COCS was less comparable to the corn cultivars such as PS-43 (0.20%), shalimar maize (0.38%) reported by Abida Ali *et al.,* (2016). The relatively low values reported for ash, lipid and protein contents indicate the purity of starches and these properties met the worldwide industrial standards (Swinkels, 1985), Thomas *et al.,* 1997). The crude fibre content of NCS, SACS and COCS was 0.73, 0.48 and 0.83 respectively. The crude fibre content of COCS was higher than that of NCS and SACS starches. The addition of corn oil into the high amylose starches slightly increase the crude fibre content. compare with NCS and COCS treated starches the SACS starch less in fibre content.

The crude fat content of NCS, SACS and COCS was 0.26, 0.26 and 0.53 respectively. Ihegwuagu *et al* (2009) who reported that the fat content of Corn starch (1%) which was higher than (NCS), (SACS) and (COCS). Abida Ali (2014) who reported the crude fat content of (P-43 cultivars and Shalimar Maize) cultivars of corn starches shows 0.67 and 0.69 (%) which it was higher than NCS, SACS and COCS corn starches. There was no significant difference was observed in the fat content of NCS and SACS corn starches. Crude fat content was higher in the corn oil treated corn starches. It may be due to addition of corn oil to the corn starch slightly increased the crude fat content than the NCS and SACS corn starches. Thus crude fat content was high only in corn oil treated corn starches. NCS, SACS, and COCS have pH values of 6.19, 6.17, and 6.20, in that order. One significant physicochemical characteristic of starch that affects its uses is pH. The pH values of starch treated with stearic acid and maize oil were comparable to those of native and other modified starches. The amylose content of NCS, SACS and COCS was 33.6, 35.2, and 36.8 respectively. Han *et al*., (2003) who reported the amylose content of high amylose corn starches 35.9, 34.5 and 31.3 for

different autoclaving temperatures. Because there were more long chains in high-amylose corn starch chains, they were more prone to thermal breakdown than normal or waxy corn starch chains. Additionally, Kweon *et al*. (2000) found that long linear branches of anomalous amylopectin (38%) and regular linear amylose (33%) made up high-amylose corn starch (ae 7Wx), which included 70% amylose. According to their findings, amylomaize starch that included 50% amylose contained 30% amylose, 40% amylopectin peculiar to amylomaize, and 30% intermediate material, which did not meet the criteria for either amylose or amylopectin. SACS and COCS starches had complex indices of 66.7 and 83.4, respectively. The process that involves the development of a starch-iodine complex and the measurement of starch that is not complexed with lipids is used to quantify starch-lipid complexes and calculate the complexing index (CI). The amount of starch complexed to the iodine is correlated with the absorbance (Kaur and Singh, 2000). The helical cavity of amylose is home to linear complexing agents, such as fatty acids, monoglycerides, or linear alcohols, which typically induce its structure (Nuessli *et al*. 2003). There was a strong correlation between SACS and COCS's amylose concentration and Complex Index. The chemical composition is simple and convenient way to illustrating the purity of the starch extracts, whereby higher starch and lower contents of other components (fat, ash, fibre) are highly desirable (Ikegwu *et al*., 2010). The result indicate that the ash, fat and fibre content of SACS corn starches was comparatively less than the NCS and COCS starches which it clearly indicates that SACS is highly pure than NCS and COCS corn starches. The result also implied that NCS is less pure than COCS and SACS corn starches.

Functional Properties of Native and Treated Corn Starch

The Table 2 shows the water and oil absorption capacity of the RS 5 samples produced from different treated conditions. Water absorption capacity represents the ability of a substance to associate with water under a limited water condition (Abida Ali *et al*., 2016). The water absorption index (WAI) measures the volume occupied by the starch after swelling in excess water, and indicates the integrity of starch in aqueous dispersion Magali Leonel *et al*., (2009). Water absorption capacity (WAC) of native corn starch and treated corn starch was 1.61, 1.37, and 2.01 (g/g) respectively. The RS 5 content mainly composed of retrograded amylose content which is joined tightly by a hydrogen bond. Due to the tight bond within the insoluble crystalline structure RS 5 is not able to form a hydrogen bond with the water molecules (Sajilata *et al*., 2006). The differences in WAC of starches from different types could probably be attributed to the variation in their granule structure. The engagement of hydroxyl groups to form hydrogen and covalent bonds between starch chains lowers WAC (Hoover and Sosulski, 1986). The loose association of amylose and amylopectin molecules in the native starch granules has been observed to be responsible for high WBC (Soni *et al*., 1987). The (WAC) water absorption capacity of stearic acid treated corn starches significantly decreased levels than the native and corn oil treated starches. Hence, RS 5 of stearic acid treated corn starches in food can exert both nutritional benefit and improve the property of the food. The oil-Absorption capacity (OAC) property (Table 1) of the corn RS5 starch samples produced from different treatments. The OAC was used to measure the ability of starches to hold the oil. The oil absorption capacity observed in RS 5 of native corn starch was significantly ($p<0.05$) higher than corn oil and stearic acid treated starches. OAC is the ability of the dry starch to physically bind fat by capillary attraction and it is of great importance, as fat acts as flavor retainer and also increases the mouth feel of foods (Abida Ali *et al*., 2016). According to Hutton and Campbell (1981), food's capacity to absorb water and oil may improve sensory qualities like mouthfeel and flavor retention. Accordingly, this statement suggests that the OAC of NCS was higher than that of COCS and SACS, while the WAC of RS 5 COCS starches was higher than that of NCS and SACS. It demonstrates that the mouthfeel and flavor retention of these COCS and NCS are higher. The physical trapping of oil and the binding of fat to the apolar chain of proteins are the primary mechanisms responsible for oil absorption (Kinsella, 1979).

Functional Properties of Native and Treated Corn Starch

The results of starch swelling power of NCS, SACS and COCS at different temperatures are presented in Table 3. Swelling power of the starch granules was raised gradually from 40°C to 90°C. At higher temperatures (>70° C), a sudden increase in swelling power was observed in all the starch samples. For NCS and treated starch samples, the swelling profile exhibits a consistent general tendency of increasing with temperature. This is an indication of the granules' capacity to absorb water when heated. According to Charles *et al*. (2007), this could be explained by the

breakdown of starch granules at higher temperatures, which causes all of the amylose to be released from the amylopectin network. All of the starch samples had a strong swelling power at higher temperatures. As the temperature rises, the starch granules' absorption of water causes swelling to worsen (Charles *et al*., 2007).Given that an increase in swelling power indicates that a starch is suitable for use as a disintegrant in the pharmaceutical industry (Chowdary *et al*., 2011), NCS, SACS, and COCS seem to be better options for disintegrants in tablet formulation, particularly since tablets are made and used at temperatures where they have superior swelling properties. The application of high amylose corn starch NCS, SACS, and COCS in other industries is confirmed by the fact that high swelling power also leads to high digestibility and the capacity to use starch in solution, indicating improved dietary properties and the use of starch in a variety of dietary applications (Nuwamanya *et al*., 2010). As the temperature increased to 60°C, the solubility (%) of NCS, SACS, and COCS starch increased steadily. At increasing temperatures, the solubility gradually reduced in all of the starch samples. Solubility increased as the temperature increased because of increase in mobility of the starch granules, which facilitated dispersion of starch molecules in water. The change in functional properties of starch with respect to temperature has been attributed due to amylose and amylopectin content of the starch. The results show that increase of straight chain amylose content increases solubility of NCS, SACS and COCS starches. The solubility and swelling power of high amylose corn starch could be explained by its granule size and amylose content.

Indeed, starch with large granules swells rapidly when heated in water and water molecules are bonded to the free hydroxyl groups of amylose and amylopectin by hydrogen bonds (Singh *et al*., 2003). The swelling power and solubility was comparatively less when compared with the cassava and potato starches works reported by Eke-Ejiofor and Owuno, (2014). According to Hoseney (1987), amylose also functions as a diluent and an inhibitor of swelling, particularly when lipids are present and can form insoluble complexes with some of the amylose during swelling and gelatinization. The crystalline bundles known as micells, which are formed by hydrogen bonding between the starch molecules, have been used to demonstrate the associative binding force within the granules (Leach *et al*., 1959). When an aqueous suspension of starch granules is heated, these structures become hydrated and swelling occurs. According to Schoch and Maywald (1968), starches have been classified as high swelling, moderated swelling, restricted swelling, or highly restricted welling. High swelling starches have swelling power of approximately 30% or higher at 95°C. Their granules swell enormously and the internal bonds become fragile toward shear when the starch is cooked in water. Restricted swelling starches have swelling power in the range of 16-20% at 95°C. The cross linkages in their granules reduce swelling and stabilize them against shearing during cooking in water (Galvez and Resurreccion, 1993). The high amylose corn starch NCS, SACS and COCS starch had swelling power of 2-9% respectively. Therefore, the resulting swelling power indicated that the starch of high amylose corn starch was highly restricted type according to Schoch and Maywald (1968).

Structural analysis of Native and Treated Corn Starch

Scanning Electron Micrograph of Native and Treated Corn Starch

Using scanning electron microscopy, morphological analyses of NCS, SACS, and COCS starch granules (Fig. 1, 3, 4) showed surface alterations and granule breakage in SACS and COCS corn starches compared to NCS corn starches. High amylose NCS corn starch shows various granules shaping such as round, rod shaped and polygonal shapes. In contrast to the NCS starch granules, the SACS and COCS treated starch granules have irregular forms and rougher surfaces, while the granules' surface is smooth and free of pores and visible fissures. It might be because the combination of corn oil and stearic acid alters the surfaces of the starch granules. Significant fragmentation and a drastic change in granule form indicate that the starch granules' structural integrity was disrupted during the esterification process (Hoover, 2000). After the amylose migrated during the gelatinization process, the starch granule structures collapsed, leaving behind these irregular particles. Improved contact between the granules and the polymer matrix is made possible by the porous structure. Furthermore, as noted by Doi *et al*. (2002), the opened-up structure of starch following modification permits the starch's inherent high functionality to undergo a range of chemical modification. The properties of starch granules are affected by the presence of these proteins and lipids in or on the surface of the granules. For example, a high amount of lipids in cereals starches decreases the capacity of starch granules to bind with water, thus reducing the swelling and solubilisation of starch granules (Swinkels, 1985).

Esterification of starch may affect the morphology of the material (Steeneken, 2008). The esterification or acid treatment leads to morphological changes of starch granules including the appearance of pores and cracks on the granular surface as reported by the (Jayakody and R. Hoover, 2004). The scanning electron microscopy supported that findings of the SEM images revealed the disrupted structure of the granules after esterification (SACS and COCS) when compared with NCS starches.

Light Micrograph of Native and Treated Corn Starch

The light micrograph of NCS, SACS and CACS treated corn starch, iodinated were given in Figure (2 - 6), (7-8), (9-10). The granular structure of NCS, SACS and COCS corn starches were viewed under light microscope. The high amylose normal corn starch shows round and polygonal shaped starch granules. The high amylose normal corn starch observes the iodine solution which it turns the starch granules into light blue in colour. The shapes of the high amylose normal corn starch granules were round, polygonal and smooth particles were observed. The stearic acid treated corn starch (SACS) and corn oil treated corn starch (COCS) revealed irregular starch bodies. These irregular shapes of SACS and COCS corn starches were due to the addition of pullulunase and gelatinization treatments which either erodes or modify the shape of the starch granules or digest channels from selected points on the surface toward the center of the granule (Matsubara *et al.,* 2004). Five patterns of attack have been identified in the earlier studies by Evers (1979) who stated that the attacks were pin-holes/pepper-potting, sponge-like erosion, many medium-sized holes, distinct loci leading to single holes in individual granules and surface erosion. The iodinated starch granules of SACS and COCS were stained with iodine solution. The treated starch granules observes the iodine solution which it turn into dark blue and slightly pink in colour with irregular shaped starch granules.

SUMMARY AND CONCLUSION

Hence it was concluded that high amylose corn starch treated with corn oil was better than the NCS and SACS starches in terms of it, Chemical composition, functional and structural features. Thermal Characteristics. Compared to the B- and C-polymorphic starch granules, the RS-5 V type was much more heat stable. It was proved in this study that the treated SACS and COCS corn starches are highly heat stable than the NCS starches. The morphological alterations of starch granules, such as the emergence of pores and fissures on the granular surface, are caused by esterification or acid treatment. Scanning electron microscopy confirmed that, in comparison to NCS starches, 48 SEM pictures showed the granules' altered structure during esterification (SACS and COCS). High-amylose maize starch might be processed with FFAs to create a novel Type 5 resistant starch (RS5), which would then be employed in food formulation.

ABSTRACT

Ksharasutra is the contribution of Acharya Sushruta and has mentioned its application in Nadivrana, Arbuda, and Arshas in Sushruta Samhita. It is a safe, cost-effective, minimal hospital stay, and the chance of recurrence rate is less for treating arshas with fewer side effects. In this study, a patient suffered from 4th-degree interno-external thrombosed pile masses at 3,5,7 o'clock and 3rd-degree interno-external pile mass at the 11 o'clock position. Under spinal anesthesia , all the pile masses were ligated with Ksharasutra except at 7 o'clock internal hemorrhoid which was treated by Ksharalepa. The post-operative assessment was done daily; all pile masses had fallen by the 10th postoperative day, and the wound was healed within a month.

Keywords: Integrated Medicine, Ksharasutra, Thrombosed haemorrhoids Transfixed. Apamarga

INTRODUCTION

Arshas (hemorrhoids) are dilated veins within the anal canal in the sub-epithelial region formed by radicals of superior, middle, and inferior rectal veins and often described as varicose veins of the anus and rectum which is

considered a common disease mostly due to life style disorders, especially during advancing age [1]. Arshas is included in the eight morbidities that pose significant treatment challenges [2]. It occurs in Guda Pradesha (Anal canal). Guda is included in Sadyopranahara Marma which requires delicate management. At present, different types of treatment modalities like rubber band ligation, sclerosing injection therapy, infra-red coagulation therapy, haemorrhoidectomy, cryo-surgery, etc. are available [3]. There may associate with complications like incontinence, haemorrhage, and anal stricture [4]. Acharya Sushruta has described the ligation of Ksharasutra in Nadivrana (sinus), Arbuda, and Pratisaraniya Kshara (local application of Kshara) in the treatment of Arshas.

Case history

A 31-year-old married male, sale man by occupation, with IP no and OP no 184497/54591 visited our OPD on 24/08/2024 with complaints of previously bulged multiple masses per rectum that have turned into hard, big, painful masses which were not going inside even after pushing, following an episode of constipation associated with bleeding per rectum since yesterday.

History of Present Illness

As per the statement of the patient, he was healthy 1 year ago. He gradually noticed painless masses that used to go inside on their own after defecation, associated with occasional bleeding per rectum. Over the year, the masses had gradually grown in size and required manual pushing by the patient which he neglected and did not seek any medical advice. Since yesterday the masses had increased in size with severe pain and bleeding per rectum following an episode of constipation. Masses were not going inside even after pushing, hence he approached the Shalya Tantra department, JSS Ayurveda Hospital for further management. On enquiring, he said that his job demanded traveling on a two-wheeler up to 60km per day. On further interrogation, the patient revealed that he was not a known case of Diabetes or hypertension, but gave a history of addiction to alcohol and smoking and he had consumed non vegetarian food with alcohol on 22/08/2024 and parties till late night.

History of Past Illness

Medical history: N/K/C/O T2 DM and HTN.
Surgical history: Nothing contributory. s
Family history: All are said to be healthy.

Personal history

Diet: Mixed diet.
Sleep: 6-7 hours–Sound sleep.
Bowel: One time a day (constipated).
Micturition: 4 – 5 times a day.
Habit: Occasionally alcohol and smoking since 4 year.

Ashta sthanapariksha

Nadi - 76 bpm (Pitta-kapha)
Mala – 1 time a day.
Mutra - 4 -5 times a day.
Jihwa – Alipta.
Shabda – Prakruta.
Sparsha – Anushnasheeta.
Drik– Prakruta.
Akriti – Madhyama.

General examination

Pallor: Absent
Icterus: Absent

Cyanosis: Absent
Koilonychia: Absent
Lymphedema: Not palpable
Edema: Absent
Blood pressure: 130/90mmHg
Respiratory cycle: 16 cycles/min
Heart rate: 74 BPM

Systemic Examination
CNS
Higher mental function test: Conscious well oriented with time place person.
Memory: Recent and remote: intact
Intelligence: Intact
Hallucination/delusion/speech disturbance: Absent
Cranial nerve / sensory nerve/motor system: Normal
CVS
Auscultation: S1 and S2 heard, no murmur/added sound
RS
Inspection: B/L symmetrical
Palpation: Trachea is centrally placed and non-tender
Auscultation: B/L NVBS heard
GIT
Inspection: No scar marks, No discoloration
Palpation: Soft, non-tender.
Auscultation: Normal peristaltic sound heard
Percussion: Normal resonant sound heard over the abdomen

LOCAL EXAMINATION
On inspection
Pile mass at 3,5,7,11
Discoloration – no
Any scar mark- no
On palpation
a) Per rectal examination
Sphincter tone- Slightly laxed
Induration – absent

Pre-op
The informed written consent was taken from the patient.
The patient was advised nil by mouth from 7:30 am on the day of surgery.
Part preparation was done in the morning on the day of surgery.
A Proctoclysis enema was given in the morning on the day of surgery.
Inj. Tetanus Toxoid,0.5ml IM was given as a prophylactic measure
A sensitivity test was done with 2% Inj. Lignocaine 0.5cc subcutaneously in the morning on the day of operation.

Operative procedure
Under all aseptic precautions, the patient was made to lie in a lithotomy position after spinal anaesthesia. The operative part was painted with povidone iodine and drapped. Digital rectal examination and two-finger anal dilation was done using Lignocaine jelly (2%). The proctoscopy was done to visualize and re-assess the positions of

haemorrhoids. Apamarga ksharasutra was transfixed simultaneously at interno-external thrombosed haemorrhoids extending from 3 to 5 o'clock positions along with thrombosed external haemorrhoids at 7 o'clock position. This huge masses re-secured by tying another Ksharasutra. The distal part of the transfixed haemorrhoidal mass was excised and sent for histopathological examination. The ksharalepa was done at an internal pile mass of 7 'o'clock position. The 11 o'clock interno-external pile mass was also ligated with ksharasutra. A Diclofenac suppository was inserted followed by anal packing with Mahanarayana Taila and dressing was done.

Post-operative

The patient was kept nil by mouth for six hours and intravenous fluid of Ringer Lactate and Dextrose Normal Saline was given.
A sip of water was allowed followed by a glass of ganji after an appropriate bowel sound was heard.
Intravenous injection of metrogyl 100 ml 8 hourly for 5 days was given.
Inj. Tramadol IM was given as per the need of the patient.
Inj. Fortwin 1ml and Inj. Phenargan1ml IM were given at night on the day of surgery.

Differential Diagnosis

1.CA of Rectum
2.Rectal Prolapse
3.Proctitis
4.Haemorrhoids

Ayurvedic medication

Syp. Abhayarista 10 ml BD with 20 ml of water after food.
Syp. Drakshasava 10 ml BD with 20 ml of water after food.
Tab. Pilocid 1-0-1 ater food.
Tab. Styplon 2-2-2 after food.
Tab. Manasa mitravati 0-0-1 after food.
Sitz bath with PVK lotin with lume warm water twice a day.
Taila Purana with 10ml of jatyaditaila twice a day.

DISCUSSION

Acharya Sushruta had mentioned chaturvidha chikistha for Arshas, namely Aushadhi, Kshara, Agni, and Shastra [5]. Among these procedures, we adopted the Ksharasutra procedure because of huge thrombosed haemorrhoidal masses. Generally, the external and internal haemorrhoids are ligated all together to prevent the post operative bleeding. But in this case the mass was huge and congruent from 3 to 7 'o clock position externally where as the internal component was well demarcated between 3 to 5 ' o clock position and separately at 7 'o clock position. Hence, Apamarga ksharasutra was transfixed simultaneously at interno-external thrombosed haemorrhoids extending from 3 to 5 o'clock positions along with thrombosed external haemorrhoids at 7 o'clock position. The ksharalepa was done for internal pile mass at the 7 o'clock position. The 11 o'clock interno-external pile mass was also ligated with ksharasutra. Apamarga Ksharasutra blocks the blood flow to pile masses, leading to pressure necrosis, mechanical strangulation, then the death of pile mass, and kshara to better fibrosis of pile mass.

The masses fell on their own accord by the 10th postoperative day. The applied Apamarga Kshara on the thread acts as an anti-microbial, anti-inflammatory and promotes healing after sloughing out of pile masses. The pH of Ksharasutra is alkaline (pH-10.3); hence, it does not allow the growth of bacteria at the site of ligation. There are no postoperative complications like pain, bleeding, delayed healing, stricture formation, etc. In comparison to haemorrhoidectomy, the Ksharasutra procedure is said to be better as it has minimum post-operative complications,

minimal hospital stay, and a lesser rate of recurrence. Delayed complications like anal stricture and fecal incontinence are not found. The Ksharasutra procedure is a boon to patients suffering from Anorectal diseases because of its remarkable results when compared to the conventional methods.

Patient Perspective

The patient gave consent for the procedure and withstood the procedure well. The patient had pain and burning sensation in the post-operative area for around 5 days which had a declining trend in the Pain scale and gradually coped up well. Hemorrhoidal Masses had fallen by the 10th post-operativeday automatically. Bleeding, Pain, and burning sensation had reduced by almost 80% as per the patient's own statement. He had also quit smoking and alcohol and changed his lifestyle after the surgery & followed Pathya-Apathya as per the instructions given. The patient has recovered well after the procedure & was satisfied with the treatment provided.

CONCLUSION

The main benefits of the ksharasutra procedure include minimal tissue loss, cost-effectiveness, a shorter hospital stay, and a lower chance of recurrence. This case report discusses the successful integrated treatment of huge thrombosed internal and external haemorrhoids using Apamarga ksharasutra transfixation in a novel method where the pile masses were ligated individually. The result observed was encouraging without any complications. Further study can be carried out on the safety and efficacy of this novel technique.

ACKNOWLEDGEMENTS

The authors would like to mention and acknowledge the Department of PG and PhD studies in SHALYA TANTRA, JSS Ayurveda Medical College Mysuru for allowing me to write a case report.

ABSTRACT

Identifying software defects early is a fundamental aspect of software engineering that helps improve product quality and reduce the effort required for maintenance. This research evaluates the performance of several machine learning models for predicting defects, using datasets from NASA. Six widely used classifiers Logistic Regression, Decision Tree, Support Vector Machine (SVM), Random Forest, Gradient Boosting, and k-Nearest Neighbors (k-NN) are tested on various NASA software datasets. The study measures their effectiveness through metrics including precision, recall, F-measure, accuracy, Matthews Correlation Coefficient (MCC), and the Receiver Operating Characteristic (ROC) curve area. Findings reveal that ensemble-based algorithms, particularly Random Forest and Gradient Boosting, achieve better predictive accuracy than the other models. These results highlight the promise of machine learning techniques for enhancing defect prediction and provide valuable guidance for choosing the right algorithms in software quality assurance. Feature selection methods are also analyzed to determine their role in optimizing model accuracy. The comparative analysis offers practical insights for developers aiming to integrate defect prediction tools into their workflow. Overall, this research underscores the growing relevance of AI-driven approaches in maintaining high software reliability.

INTRODUCTION

In modern software development, ensuring software quality is critical to meeting user expectations and maintaining system reliability. One of the key challenges in this domain is the early detection of software defects, which helps reduce debugging time, lowers maintenance costs, and improves overall software performance. Traditional defect detection methods such as manual code reviews and extensive testing are often time-consuming, expensive, and sometimes insufficient for complex software systems. As a result, researchers and practitioners increasingly rely on automated methods to predict software defects effectively. Machine learning approaches have gained prominence in software defect prediction due to their capability to learn from historical data and apply discovered patterns to new software instances. By analyzing software metrics together with past defect information, ML models can classify components as defective or defect-free, supporting timely quality assurance efforts. Various algorithms such as Logistic Regression, Decision Trees, Support Vector Machines, Random Forest, Gradient Boosting, and k-Nearest Neighbors have been applied to this problem, each demonstrating different levels of performance. NASA datasets are extensively used as benchmark resources in software defect prediction research. They contain software modules characterized by multiple metrics, along with defect labels collected from NASA software projects. These publicly available datasets offer a practical foundation for evaluating and comparing the effectiveness and robustness of various machine learning algorithms. Due to the diversity of NASA datasets each representing different projects and complexity levels they offer an excellent platform for comparative analysis of predictive algorithms. This research conducts a thorough assessment of several machine learning classifiers applied to NASA datasets to identify the most accurate and reliable approaches for software defect prediction. The evaluation compares the models using performance metrics such as precision, recall, F-measure, accuracy, Matthews Correlation Coefficient (MCC), and the area under the ROC curve. By understanding the strengths and limitations of these algorithms on NASA datasets, this study aims to guide software engineers in selecting appropriate machine learning approaches tailored to their defect prediction needs. The results of this analysis are expected to contribute valuable insights into improving defect prediction systems, ultimately leading to better software quality management practices. Through efficient defect prediction, organizations can optimize their testing efforts, reduce software failures in production, and deliver higher-quality software products within budget and time constraints.

RELATED WORK

Predicting software defects is a key factor in enhancing the reliability of software systems and reducing the workload involved in testing and maintenance. Over the years, extensive research has focused on leveraging machine learning techniques for defect identification. These techniques analyze historical defect data to categorize software modules as defective or non-defective. Such classification aids in the effective distribution of testing resources and facilitates the early recognition of potential problems in the software development process. Conventional machine learning algorithms like Decision Trees, Naive Bayes, Support Vector Machines (SVM), Random Forest, and K-Nearest Neighbors (KNN) have been widely used in software defect prediction. Decision Trees are known for their simplicity and interpretability, though they may struggle with noisy datasets. Naive Bayes offers fast computation but relies on the assumption of feature independence, which may not accurately reflect real-world software data. SVMs are well-suited for classification problems. Random Forest, an ensemble-based approach, has consistently outperformed several models in past research due to its capacity to mitigate overfitting and accuracy. NASA's PROMISE repository, containing datasets like CM1, JM1, KC1, and PC1, has become a standard benchmark for evaluating software defect prediction models are commonly evaluated using labeled datasets derived from real-world NASA software projects, which serve as reliable resources for empirical research. In a comparative study by Lessmann*et.al.,*(2024), several classification techniques were applied to NASA datasets. The findings revealed that ensemble approaches, especially Random Forest, consistently outperformed other classifiers in terms of both accuracy and stability. Similarly, Khoshgoftaar*et.al.,*(2022) noted that class imbalance and noise in software metrics could significantly affect the prediction capabilities of conventional models. Recent research has focused on enhancing prediction performance through the integration of feature selection, data preprocessing, and ensemble

learning. Malhotra (2022) reviewed empirical studies on defect prediction and emphasized the critical role of data preprocessing and algorithm tuning. Feature selection techniques, such as correlation-based and wrapper-based methods, have been widely adopted to remove irrelevant or redundant features, which often lead to improved model generalization and reduced computational complexity. Hybrid and ensemble learning methods have demonstrated strong capabilities in dealing with complex defect patterns and imbalanced data distributions. These approaches integrate multiple classifiers to capitalize on their individual advantages, resulting in improved model effectiveness. For instance, combining Support Vector Machines (SVM) with Random Forest has yielded better predictive outcomes, especially in scenarios involving noisy or high-dimensional datasets. Such techniques not only enhance classification accuracy but also improve the identification of rare defective cases, which is crucial for real-world software applications. Studies have also explored the use of clustering techniques in conjunction with supervised learning to further enhance defect prediction. Clustering helps in grouping similar software modules, which can then be analyzed using classification algorithms. This semi-supervised approach has proven useful in reducing the impact of data noise and improving overall model stability. In addition, resampling methods like SMOTE are frequently employed to address the issue of class imbalance, which is a common characteristic of software defect datasets. In summary, existing literature indicates that no single machine learning model is universally superior for software defect prediction. However, ensemble and hybrid approaches generally yield better and more reliable results, particularly when applied to real-world datasets like those from NASA. The continuous evolution of preprocessing techniques, algorithmic innovations, and benchmark evaluations is essential for improving the performance and reliability of software defect prediction systems.

METHODOLOGY

The objective of this study is to evaluate the performance of various machine learning algorithms in software defect prediction, using NASA datasets as the foundation. The research follows a structured approach, including data collection, preprocessing, feature selection, model development, and performance assessment. Each step is methodically implemented to ensure accuracy, consistency, and reproducibility of the results.

Data Preprocessing

Before training the models, the data undergoes preprocessing to ensure quality and consistency. Missing values are managed by replacing them with the mean for continuous data or the mode for categorical data, and categorical variables are encoded when necessary. Numerical features are scaled through normalization or standardization, which is particularly important for models like SVM that are sensitive to the range of input values. Additionally, to address the issue of imbalanced classes where defective modules are fewer SMOTE (Synthetic Minority Over-sampling Technique) is applied to generate synthetic samples and balance the dataset.

Feature Selection

Feature selection is performed to reduce dimensionality and improve model performance. Correlation-based feature selection and mutual information are used to retain only the most relevant features. This step helps to eliminate noise and redundant data, enhancing the model's generalization ability.

ML Models

The study evaluates several machine learning models including DT, Naive Bayes, SVM, RF, and K-Nearest Neighbors. A hybrid model combining Random Forest and SVM is also developed to leverage the strengths of both algorithms. All models are implemented using Python libraries such as scikit-learn. Model performance is assessed using metrics including Accuracy, Precision, Recall, F1-Score, and ROC-AUC, with evaluation conducted through 10-fold cross-validation technique is employed to ensure statistical reliability and to avoid overfitting. Performance metrics are averaged across all folds to provide a robust comparison among the models.

Tools and Environment

The experiments are the implementation was carried out in Python utilizing libraries such as Pandas, NumPy, scikit-learn, and imbalanced-learn for data preprocessing and model development. The computations are performed on a standard computing system with adequate processing power and memory to handle the datasets efficiently. This methodology ensures a comprehensive analysis of how different ML techniques perform on real-world software defect data, offering insights into their effectiveness and practical utility. NASA Cleaned Datasets (Table.1)

RESULTS AND DISCUSSION

This section presents the evaluation outcomes of various machine learning models applied to software defect prediction using cleaned NASA datasets. Model performance was assessed through metrics such as accuracy, precision, recall, F1-score, and AUC-ROC, offering a comprehensive view of their capability to differentiate defective from non-defective software modules. CM1 Dataset Results (Table 2) JM1 Dataset Results (Table 3). The classification outcomes of several machine learning algorithms applied to the KC1 and KC3 datasets, respectively. In both datasets, Random Forest emerged as the top-performing model, achieving the highest F-measure values for both defective and non-defective classes. For the KC1 dataset, Random Forest attained F-measure scores of 92.6% for non-defective and 68.6% for defective instances, while in the KC3 dataset; these scores were 93.8% and 70.4%, respectively. Gradient Boosting also delivered robust performance, maintaining strong precision and recall across both classes and closely trailing Random Forest. The Support Vector Machine (SVM) demonstrated balanced results with solid F-measure values, especially for defective modules. In contrast, Logistic Regression and k-Nearest Neighbors (k-NN) showed weaker. These results emphasize the effectiveness of ensemble approaches, particularly Random Forest and Gradient Boosting, in handling class imbalance and improving defect prediction accuracy on NASA's KC1 and KC3 datasets. This contrast further supports the suitability of advanced ensemble techniques, which leverage multiple learners to achieve higher generalization and resilience against noise. The superior performance of Random Forest and Gradient Boosting thus not only reflects their algorithmic strengths but also their adaptability to real-world software defect datasets such as NASA's KC1 and KC3. KC1 Dataset Results (Table 4), KC3 Dataset Results (Table 5). Table 5: KC2 Dataset Results. Table 7 summarizes the classification outcomes of various ML algorithms applied to the MC1 dataset, with a focus on both non-defective and defective software modules. Among the models evaluated, Random Forest yielded the most accurate predictions, achieving a high F-measure of 94.5% for non-defective instances and 71.8% for defective ones, indicating its robustness in handling both classes effectively. Gradient Boosting followed closely, also performing well with strong precision and recall values across both classes. SVM maintained a solid balance, particularly for the defective class, outperforming Logistic Regression and k-NN in terms of F-measure. Decision Tree showed moderate performance, while k-NN and Logistic Regression were less effective in identifying defective modules, exhibiting lower recall and F-measure scores. Overall, the ensemble methods especially Random Forest stood out for their superior ability to predict software defects in the MC1 dataset. Random Forest emerged as the top performer, achieving an F-measure of 93.4% for non-defective and 69.8% for defective instances, demonstrating its strong predictive strength. Gradient Boosting followed closely, showing high precision and recall for both classes, with a 68.2% F-measure for defective samples. SVM delivered reasonable results, balancing precision and recall with a 63.6% F-measure for the defective category. Decision Tree and Logistic Regression showed average performance, while k-Nearest Neighbors (k-NN) had the poorest results, especially for defective modules, with the lowest F-measure of 55.3%. These outcomes reinforce the effectiveness of ensemble methods, particularly Random Forest, in managing class imbalance and accurately predicting defects in the MC2 dataset.

CONCLUSION

This study investigated the performance of various machine learning algorithms for predicting software defects using multiple cleaned NASA datasets. The analysis involved applying classifiers such as Logistic Regression, Decision Tree, Support Vector Machine (SVM), Random Forest, Gradient Boosting, and k-Nearest Neighbors (k-NN) across well-known datasets including CM1, JM1, KC1, KC3, MC1, MC2, MW1, and PC1–PC5. Results demonstrated

that ensemble-based methods, particularly Random Forest and Gradient Boosting, consistently delivered superior results across evaluation metrics like accuracy, F-measure, Matthews Correlation Coefficient (MCC), and ROC-AUC. These models effectively addressed class imbalance issues, improving defect detection accuracy and overall model stability. SVM also showed strong performance, especially in terms of ROC-AUC and F-measure, while k-NN performed less effectively, likely due to its sensitivity to noise and imbalanced data. These findings highlight the advantages of ensemble learning for software defect prediction, offering valuable insights for software quality assurance teams aiming to enhance early defect detection and optimize testing efforts. Future research may explore hybrid methods, deep learning architectures, and adaptive sampling techniques to further improve prediction accuracy in highly imbalanced or evolving software environments.

ABSTRACT

The present study seeks to formulate and evaluate a proniosomal gel for the topical delivery of nimesulide as a potential therapeutic intervention. Nimesulide, classified as a BCS class II drug, is employed in the treatment of osteoarthritis and inflammation. Nimesulide proniosomes were developed using the coacervation phase separation technique, which involved the combination of lecithin, cholesterol, and various grades of non-ionic surfactants. For each proniosomal formulation prepared, physicochemical properties such as size, shape, encapsulation efficiency, and drug release were evaluated. The objective of the present study was to formulate six topical proniosomal gel formulations with varying concentrations of cholesterol and surfactants. All formulations were assessed for parameters including percentage entrapment efficiency, pH, vesicle size, and in vitro drug release. The vesicles were observed to be spherical and distinct. After nine hours, the in vitro drug release was determined to be 93.59%, with formulation F6 demonstrating superior performance across all evaluation tests. When the drug release data were fitted to various kinetic models, the release from each formulation adhered to Higuchi kinetics. This study illustrates the controlled release of medication following nimesulide encapsulation in proniosomal gel and suggests that nimesulide proniosomal formulations may be utilized for topical drug delivery systems in the treatment of skin infections.

Keywords: Nimesulide, Osteoarthritis, co-acervation phase separation method, Non-ionic surfactants, soya lecithin, cholesterol.

INTRODUCTION

Skin serves as the primary barrier for the delivery of topical medications, and the stratum corneum plays a significant part in this barrier function[1]. Topical medication distribution is limited by the stratum corneum's low permeability. To get around these restrictions and provide control over the distribution of the medicine into the body, a unique drug delivery mechanism is employed[2]. Novel drug delivery methods enable sustained drug release at a predetermined rate, maintaining a comparatively constant effective medication level while minimising unwanted side effects. These cutting-edge drug delivery systems include niosomes, liposomes, lipoproteins, and microcapsules, which can break down gradually to target particular locations[3]. Topical drug administration refers to a localised method of delivering medication through the skin, vaginal, rectal, and ophthalmic routes to any part of the body. Topical drug distribution occurs via the skin, which is one of the human body's most accessible organs for topical administration[4]. Proniosomes are amorphous, free-flowing pro-vesicles that easily transform into niosomes upon hydration. They have a liquid crystalline consistency[5]. The components found in proniosomes mainly phospholipids and non-ionic surfactants have the ability to diffuse into the stratum corneum, disturbing the fluidity of the lipid bilayers producing faulty permeability barrier function to act as penetration enhancers[6]. The ratio of cholesterol to non-ionic surfactant may have an impact on the integrated drug's release properties and entrapment efficiency[7]. When applied to skin in an occlusive situation, proniosomal gel becomes hydrated with the skin's moisture and transforms into niosomes. Proniosomal gel has a lot of promise to lessen medication side effects and boost transdermal drug delivery's therapeutic efficacy[8]. One of the most frequent types of arthritis is osteoarthritis. It can affect almost any joint in the body and is linked to a deterioration of the cartilage in the joints. It commonly affects the weight-bearing joints in the hips, knees, and spine[9]. Inflammation and pain are treated with NSAIDs; however, because they increase the risk of adverse effects in the upper gastrointestinal tract and do not address the underlying pathophysiology of articular disease, they are not very effective in altering the course of the disease or improving quality of life[10]. The purpose of present study to formulate proniosomes as transporters for topical delivery of nimesulide. Proniosomes converts into niosomes upon hydration which can prove as substitute to increase poor skin penetration and residence time of the topical anti- inflammatory drugs.

MATERIALS AND METHODS

Materials

Nimesulide was obtained as a gift sample from G. R. Traders, Hyderabad, span 20, 60, 80 and Tween 80 were purchased from Karnataka Fine Chemicals, Bangalore. Phosphate buffer pH
7.4 were prepared as described in the Indian pharmacopoeia (1996).

Method of preparation

The coacervation phase-separation approach was used to create proniosomes. The following steps were included in the method, which will be carried out in dry, wide-mouthed glass containers
(i) weighing the necessary quantities of cholesterol, soya lecithin, and lipophilic surfactant; (ii) adding the drugs ingredient nimesulide, which is soluble in 100% ethanol; (iii) sealing glass containers to stop solvent loss; (iv) heating the resulting mixture in a water bath at 60–70 °C for approximately 5 minutes while shaking to completely dissolve all of the solid ingredients, particularly the cholesterol and surfactant; (v) adding distilled water that has been preheated to 60 °C (to create a clear liquid); (vi) continuing to warm the mixture at the same temperature for approximately 3 minutes while shaking moderately; and (vii) cooling the liquid mixture at to room temperature and solidifying into a white, creamy proniosomal gel, the liquid combination will be stored in the dark for characterization, getting the proniosomal gel ready.

Preparation of proniosomal gel

Carbopol 934 (1g) was soaked in 100 ml of distilled water for three hours to produce Carbopol gel 1% w/v. The mixture was then put on a mechanical stirrer set at 100 rpm to create a homogenous viscous solution.

Triethanolamine was added in little amounts (two to four drops) until the gel formed. Since 1%w/w of nimesulide is present in the proniosomal gel preparation. Preservatives such as propyl and methyl paraben were utilized.

Characterization of proniosomes and proniosomal gel

The coacervation phase separation method was successfully used to create the proniosomal gel. Several parameters were evaluated for the proniosomes that were prepared. Experimental preformulation was done to maximise the product's acceptance, safety, and stability. Investigations into drug-excipient interactions using FT-IR incompatibility were carried out.

Vesicle size analysis

Proniosome vesicle size was assessed using a SEM and an optical microscope. Under a microscope, the size of each prepared batch of proniosomes was examined[12]. Each batch's proniosomal vesicle size was measured at several locations on the slide using a little drop of proniosomal dispersion, and the average size of the proniosomal vesicles was calculated[13].

Determination of Entrapment Efficiency (EE %)

In a test tube, 0.2g of the proniosomal suspension was collected and reconstituted using 10 ml of pH 7.4 isotonic phosphate buffer. In a sonicator bath, this aqueous solution was subjected to sonication Technique[14]. Centrifugation at 3000 rpm for 30 minutes at 20 °C was used to separate drugs containing niosomes from the mixture. The UV technique was used to measure the amount of unentrapped nimesulide at 205 nm in the 1 ml of supernatant. The percentage of entrapment efficiency was calculated by the following equation[15].

$$\% EE = \frac{\text{Total drug} - \text{Unentrapped drug}}{\text{Total drug}} \times 100$$

Particle size distribution and zeta potential

Using Zeta sizer and Malvern software, the optimised formulation's zeta potential was examined at 25 °C[16]. The zeta potential was measured by dispersing electrodes in a proniosomal solution that had been diluted 100 times with double-distilled water, and setting the voltage at 1.4 V. Each sample was run 3 times and analysis was continued at 25 °C[17].

Drug content analysis

A particular amount of proniosomal dispersion (100 mg) was taken and dissolved in 100 ml of pH 7.4 phosphate buffer. For three hours, the volumetric flask containing the dispersion was shaken on a mechanical stirrer to ensure that the drug was completely soluble[18]. This solution was filtered, and a blank phosphate buffer (pH 7.4) was used for spectrophotometric estimation at 205 nm[19].

% Drug content= practical drug content/theoretical drug content ×100

Evaluation of proniosomal gel

Proniosomal gel formulations that were developed were evaluated using a number of parameters.

Physical parameters

Appearance

The produced gels' colour, homogeneity, and foreign particle presence were assessed.

pH

A digital pH meter was used to measure the pH after 2.5 g of gel were dissolved in 25 milliliters of distilled water.[20]

Spreadability studies

By pressing one gram of proniosomal gel between two clear circular glass slides, the spreadability of each batch of gel was assessed. Leaving them for five minutes allowed for maximum spreading. To express the spreadability, the diameter of the produced circle was measured[21].

Spreadability (g cm/s) (S) = M×L/T

Where, M = weight tied to upper slide, L= length moved on the glass slide, T= time taken[22].

Viscosity and rheological studies

Viscosity and rheological characteristics of proniosomal gel were determined using a spindle 64 in a Brookfield digital viscometer (Model LVDV-E, USA) [23]. The spindle was placed in a beaker containing 100 gram of the gel. At 25°C, the viscosity of the gel was determined at various angular velocities. An average run involved varying the angular velocity between 5 and 25 rpm. The viscosity was determined by averaging two observations[24].

***In-vitro* diffusion studies**

The drug diffusion test is conducted *In vitro* using a Franz diffusion cell with an egg membrane. 25 ml of 7.4 pH PBS were taken in the receiver compartment, and one gram of nimesulide- loaded proniosomal gel was taken in the donor compartment[25]. To keep the volume of the release media constant throughout the experiment, aliquots (1 ml) of the medium were taken out at 1, 2, 3, 4, 5, and 9 hours and replaced with an equivalent volume of the fresh medium PBS 7.4 pH. After passing through what-man filter paper, all samples were examined at 205 nm using a Shimadzu -1800 UV spectrophotometer (Japan)[26].

Release kinetics

The kinetics of the drug release process in each formulation were described using a variety of equations, including the Higuchi's model, the Peppas model, the zero-order rate equation, and the first order rate equation[27 28].

Stability studies

According to accelerated stability, three months of stability testing were performed on the optimized batches of nimesulide proniosomal gel. In the present research, optimized formulations were assessed for pH, drug content, and *In-vitro* drug diffusion investigations, as well as stability studies at 40°C+2°C/75% RH for the first three months[29 30].

RESULTS AND DISCUSSSION

The spectra for a 10 μg/ml solution are illustrated in Figure 1, with the maximum wavelength (λ max) of nimesulide in a pH 7.4 environment identified at 205 nm. Nimesulide adheres to Beer's law within a concentration range of 0.4 - 5 μg/ml in a pH 7.4 solution, exhibiting a regression coefficient (r2) of 0.9973 and a slope (m) of 0.1909. Figure 2 depicts the calibration curve's construction. The melting point of the drug sample was found to be 140°C using the Thiels tube method and 142.22°C via the DSC method. The results confirmed the drug's purity, meeting BP standards within the reported range of 143°C. Figure 5 presented the DSC thermograph of nimesulide. The thermogram for both the optimized formulation and the pure drug was obtained, showing an endothermic peak at 142.22°C for nimesulide. The encapsulated proniosomes optimized formulation F6 exhibited a peak at 127.50°C, lower than the pure drug's endothermic peak, indicating successful encapsulation with a carrier. The pH of nimesulide proniosomal gel formulations was found to range from 5.3 to 6.8, aligning with the typical skin pH range. The viscosities of all gel formulations were within an acceptable range. Spreadability is a crucial aspect of gel drug delivery systems, reflecting how easily the gel can be applied or spread on the skin with minimal shear stress. The spreadability values of the created gel ranged from 6.65±0.65 gm.cm/sec to 11.41±0.95 gm.cm/sec, indicating that all formulations spread easily with minimal shear stress. All six formulations had viscosities between 13940 and 21290 cps at 25 rpm. In comparison to other formulations, the F6 (21290cps) formulation was determined to have superior viscosity. In comparison to the other five formulations, the F6 formulation exhibited the highest drug content, of 94.5% , in the

developed proniosomal gel. FTIR was used to determine the compatibility of the drug excipient. The drug and polymer were the subjects of the FTIR. The polymer FTIR is shown in fig:4, while the FTIR spectra of the pure drug nimesulide revealed distinct peaks at 3277, 3085, 1587, 1515, 740, 1216, and 1315 cm^{-1}. The proniosomal formulation's FTIR spectra show the typical peaks of pure drugs, suggested that there has been no alteration in drug-polymer interaction. This suggested that the drug and the polymer utilized in the proniosome formulation are not potentially incompatible. In Figure 7, the zeta potential of the nimesulide proniosome formulation F6 was measured at –26.3 mV, suggesting enhanced stability. The surface morphology was analysed using scanning electron microscopy (SEM), and Figure 7 presents the SEM images of the proniosome formulation F6. The Malvern particle size analyzer determined the average particle size to be 267.8 nm, with a polydispersion index of 0.375 for the optimized formulation F6. Table 3 details the entrapment efficiency of each ingredient, with F1, F2, F3, F4, F5, and F6 exhibiting efficiencies of 65.86%, 68.97%, 71.80%, 61.86%, 83.25%, and 84.41%, respectively. Formulation F6 demonstrated the highest entrapment efficiency at 84.41%. This high efficiency is attributed to its elevated phase transition temperature, which facilitated the formation of a homogeneous bilayer structure, allowing for complete entrapment of the lipophilic drug. Span 20 and Tween 80 showed relatively lower entrapment efficiencies, characterized by a low phase transition temperature and a liquid state at ambient temperature. In vitro drug release studies using a Franz diffusion cell, as depicted in Figure 9, indicated the cumulative drug penetration for each formulation. Based on these results, Formulation F6 was identified as the optimal formulation, achieving a drug release of 93.59% over 9 hours. Several models, including zero order, first order, and the Higuchi and Korsemeyer Pappas model, were used to fit the results from *In-vitro* diffusion tests. The Higuchi model was determined to have the highest correlation of the optimal formulation F6 (R2=0.9813). The drug release would be caused by the super case-II transport mechanism, as shown by the n value being more than 0.89. The generated optimized formulation (F6) was subjected to accelerated stability studies for three months while being kept at 40 ± 2°C and 75 ± 5% relative humidity. Proniosomal gel formulation F6 stability studies demonstrated that the formulation is stable throughout storage, with minimal changes in pH, drug content, viscosity, and percentage cumulative drug release. The outcome of this research indicates that Proniosomal nimesulide gel formulation is applicable for treating bacterial infections locally and systematically for higher medical aid. Over all conclusion, Nimesulide loaded proniosomal gel formulations were successfully prepared by coacervation phase separation method using surfactant and cholesterol. In order to create the anti-inflammatory proniosomal for topical administration, nimesulide was employed as an anti-inflammatory medication. The six batches of proniosomal gel that were made (F1–F6) were assessed based on a number of factors, including stability, *In-vitro* release, viscosity, entrapment efficiency, and physical assessment. Out of the six proniosomal gel formulations (F1–F6), the F6 formulation was determined to be the best based on the assessment parameters' results. Indicating the extended drug release pattern of formulated proniosomal gel, the F6 formulation of proniosomal exhibits the highest percentage entrapment efficiency (84.41%) and highest drug release in 9 hours (93.59%). After three months, the proniosomal gel formulation F6 remained stable and upon hydration, formed spherical niosome vesicles.

ACKNOWELDGEMENTS

The authors are thankful to G R Traders, Hyderabad for providing gift sample for this work. And we also thankful to Mallige college of pharmacy and I wish to express my thanks to my Research guide Mrs. Suma U, S (Associate professor), Department of pharmaceutics, Mallige college of pharmacy, Bangalore for their kind support and encouragement.

ABSTRACT

The importation of pharmaceutical drugs is a critical aspect of ensuring access to high-quality medicines in global markets. However, regulatory frameworks governing drug imports vary significantly across countries, impacting market entry, compliance, and patient safety. This study explores the regulatory challenges associated with the import of pharmaceutical drugs into India and Brazil, two emerging economies with distinct yet complex regulatory landscapes. It provides a comparative analysis of the regulatory frameworks established by the Central Drugs Standard Control Organization (CDSCO) in India and the Brazilian Health Regulatory Agency (ANVISA) in Brazil. Key aspects covered include drug registration, Good Manufacturing Practices (GMP) compliance, dossier requirements, pricing regulations, timelines, and post-market surveillance. The research identifies critical bottlenecks such as lengthy approval processes, stringent documentation requirements, and evolving regulatory policies that impact international pharmaceutical trade. Additionally, the study examines recent regulatory reforms in both countries and their implications for foreign pharmaceutical companies seeking market entry. By highlighting the challenges and proposing strategic solutions, this study aims to aid pharmaceutical manufacturers, regulatory professionals, and policymakers in navigating the complexities of drug importation into India and Brazil. The findings emphasize the need for greater harmonization and streamlined regulatory processes to enhance global pharmaceutical trade and improve patient access to essential medicines.

Keywords: Regulatory Issues; India; CSDCO; ANVISA; India; Brazil; Import; Pharmaceutical products.

INTRODUCTION

The global pharmaceutical industry plays a critical role in ensuring public health and well-being by providing access to essential medications. As markets become increasingly interconnected, the import of pharmaceutical drugs has gained prominence, offering opportunities for countries to access a wider range of treatments and innovations. However, the process of importing pharmaceutical drugs is complex and subject to stringent regulatory frameworks, which vary significantly across different regions. This thesis aims to explore the regulatory issues associated with the import of pharmaceutical drugs in two major emerging markets: India and Brazil. Both countries have substantial pharmaceutical industries and are key players in the global market. Nonetheless, they face distinct challenges in regulating the import of pharmaceutical drugs, which can impact drug availability, quality, and public health outcomes. In this study, we will examine the regulatory frameworks in India and Brazil, focusing on the key regulatory bodies, import approval processes, and documentation requirements. By conducting a comparative analysis of the regulatory issues in India and Brazil, this thesis aims to identify similarities and differences in their approaches, as well as the implications for pharmaceutical companies and public health.

Historical Background

The origins of the pharmaceutical industry trace back to the early 19th century. In the United States, between 1818 and 1822, fine chemical manufacturers established factories in Philadelphia, marking the inception of large-scale drug production. Simultaneously, European companies like Merck, Eli Lilly, and Roche transitioned from supplying natural products to manufacturing drugs. Additionally, chemical companies such as Bayer and Pfizer began exploring medical applications for their products during this period.

Significance in Modern Healthcare

The pharmaceutical industry has been instrumental in medical advancements, leading to the discovery and production of numerous new drugs in industrial laboratories. These developments have significantly improved disease control and elimination, contributing to increased life expectancy and better health outcomes globally.

Economic Impact

Beyond healthcare, the pharmaceutical sector substantially influences the global economy. It drives economic growth through job creation, research and development investments, and the generation of substantial revenue. The industry's commitment to innovation not only leads to new treatments and cures but also fosters technological advancements and economic development.

Challenges and Future Outlook

Despite its achievements, the pharmaceutical industry faces challenges such as identifying new drug targets, obtaining regulatory approvals, and refining drug discovery processes. Addressing these issues is crucial for the continued advancement of disease control and elimination. In summary, the pharmaceutical industry's evolution from early drug production to its current role as a cornerstone of modern medicine underscores its importance. Its contributions to medical progress and economic growth highlight the need for ongoing innovation and adaptation to meet future healthcare challenges.

Importance of Import Regulation

Effective import regulations are crucial in ensuring the safety, efficacy, and quality of pharmaceutical drugs entering a country. For nations like India and Brazil, which have burgeoning healthcare sectors and significant pharmaceutical markets, robust import regulatory frameworks are essential to protect public health and maintain market integrity.

India's Pharmaceutical Import Regulations

The Central Drugs Standard Control Organization (CDSCO) emerged as a result of India's evolving pharmaceutical regulatory landscape. The organization's foundations were laid with the enactment of the Drugs and Cosmetics Act

of 1940, a landmark legislation introduced during British colonial rule to regulate the import, manufacture, distribution, and sale of drugs in India. Following India's independence, the Drugs and Cosmetics Rules of 1945 were formulated to provide the operational framework for implementing the Act. The organization has evolved significantly since its inception, particularly after the 1962 amendments to the Drugs and Cosmetics Act that strengthened regulatory controls following global concerns raised by the thalidomide tragedy. In the decades since, CDSCO has continually expanded its scope and authority, with major revisions to its structure and mandate occurring in the 1980s, 2000s, and most recently through the New Drugs and Clinical Trials Rules, 2019. [1]

Organizational Structure of CDSCO

CDSCO has a hierarchical structure comprising various departments and regulatory bodies:

1. Drugs Controller General of India (DCGI)
2. Headquarters (HQ) – New Delhi
3. Zonal and Sub-Zonal Offices
4. Central Drug Testing Laboratories (CDTLs)
5. Subject Expert Committees (SECs) & New Drug Advisory Committees (NDACs)
6. State Drug Regulatory Authorities
7. Pharmacovigilance Programme of India (PvPI)

India's pharmaceutical industry is one of the largest globally, both in terms of domestic consumption and export. To safeguard public health, the Central Drugs Standard Control Organization (CDSCO) oversees the import of pharmaceutical products. Key regulatory aspects include

Import Licensing: A valid import license issued by CDSCO is mandatory for importing pharmaceutical products into India. The license is granted under Form 10 of the Drugs and Cosmetics Rules, 1945.

Registration: Imported drugs must be registered with CDSCO under Form 41, serving as authorization for the importation of specific pharmaceutical products.

Brazil's Pharmaceutical Import Regulations

The Agência Nacional de Vigilância Sanitária (ANVISA), or the Brazilian Health Regulatory Agency, was established on January 26, 1999, under Law No. 9,782. This creation aimed to enhance the safety of products and services consumed by the Brazilian population, marking a significant advancement in the country's public health infrastructure.

Historical Context and Establishment

Before ANVISA's inception, Brazil's health surveillance was managed by various fragmented entities, leading to inconsistencies in regulatory practices. The 1990s saw a growing public demand for more stringent health regulations, particularly concerning the safety of consumable goods and services. In response, the Brazilian government consolidated these functions into a single autonomous agency—ANVISA—to ensure a more coordinated and effective health surveillance system.

Organizational Structure of ANVISA

ANVISA's organizational structure consists of several key components that facilitate its regulatory functions

1. Collegiate Board of Directors (DICOL - Diretoria Colegiada)
2. President-Director
3. Thematic Regulatory Departments
4. Technical Advisory Committees
5. Regional and International Cooperation Units
6. Administrative and Support Departments

Evolution and Achievements

Over the years, ANVISA has evolved into one of the most respected regulatory agencies globally. Its rigorous standards and comprehensive regulatory practices have significantly contributed to the improvement of public health in Brazil. The agency's commitment to transparency and efficiency has bolstered its reputation both domestically and internationally. Brazil, as the largest pharmaceutical market in South America, relies significantly on imported medicines to meet its healthcare needs. The country's regulatory framework, managed by the Brazilian Health Regulatory Agency (ANVISA), includes

Local Representation: Foreign pharmaceutical companies must establish a local manufacturing unit or office, or appoint a Brazilian distributor authorized to import and distribute medical products.

Product Registration: All imported pharmaceutical products must be registered with ANVISA to ensure compliance with Brazilian health standards.

These measures are designed to ensure that imported pharmaceuticals meet the country's safety and efficacy standards, protecting public health.

Challenges and Considerations

Both India and Brazil face challenges in their pharmaceutical import processes:

Complex Approval Processes: The regulatory systems in these countries can be intricate, with new drugs taking a year or more to be approved for marketing.

Tariff Implications: Import tariffs can significantly impact the cost of pharmaceuticals. For instance, in Brazil, bound tariffs on Active Pharmaceutical Ingredients (APIs) can reach up to 34%, while in India, they can be as high as 70%.

Understanding and navigating these regulatory landscapes are essential for pharmaceutical companies aiming to operate in these markets.

MATERIALS AND METHODS

The materials and methods used in this study involved a comprehensive qualitative and comparative analysis of the regulatory frameworks governing the import of pharmaceutical products into India and Brazil. Data were collected from official regulatory authority websites such as the Central Drugs Standard Control Organization (CDSCO) in India and the National Health Surveillance Agency (ANVISA) in Brazil, as well as relevant international regulatory sources like WHO and ICH guidelines. Key regulatory documents, including guidelines, acts, notifications, and import licensing procedures, were reviewed and analyzed. A systematic literature review was conducted using peer-reviewed journals, regulatory databases, and industry reports to identify common regulatory challenges, approval processes, and documentation requirements. The study employed a comparative methodology to identify similarities, differences, and potential bottlenecks in the import processes of both countries. Expert opinions from regulatory professionals and published case studies were also considered to support the findings and provide contextual insights.

RESULTS

Procedure for Import and Registration of Drugs in India

Import License

Before applying for an import license, it is essential to determine the specific regulatory requirements applicable to the product category. The import license is issued by different regulatory bodies based on the product category. For example, pharmaceuticals and medical devices require approval from the Central Drugs Standard Control Organization (CDSCO), while food products need clearance from the Food Safety and Standards Authority of India

(FSSAI). Other items, such as electronics, chemicals, and hazardous substances, may require approval from the Bureau of Indian Standards (BIS), the Directorate General of Foreign Trade (DGFT), or the Ministry of Environment, Forest and Climate Change (MoEFCC). To obtain an import license for drugs, an application must be submitted to the licensing authority using Form 8 for drugs other than those listed in Schedule X and Form 8-A for Schedule X drugs. This application can be made by either the manufacturer or their authorized agent in India, provided the agent holds a wholesale license for the sale or distribution of drugs. The application must be accompanied by a license fee of ₹1,000 for a single drug and ₹100 for each additional drug, along with an undertaking in Form 9, duly signed by or on behalf of the manufacturer. Additionally, the application must include a copy of the Registration Certificate issued in Form 41 under Rule 27-A. However, in urgent situations, the central government may grant an import license using Form 10 or 10-A without requiring a Registration Certificate under Rule 27-A, provided the reasons are documented in writing. If the original license is lost, damaged, or defaced, a duplicate copy can be obtained by paying a fee of ₹250. Once submitted, the licensing authority reviews the application to ensure compliance with regulatory standards. This may involve document verification, inspection of manufacturing facilities, and adherence to safety norms. In certain emergencies, the central government may grant an import license without requiring a Registration Certificate under Rule 27-A, provided reasons are recorded in writing. Upon receiving an application for an import license in the format specified under Rule 24, the licensing authority, once satisfied that the applicant will comply with the license conditions, may issue the import license in either Form 10 or Form 10-A, depending on the case. Unless it is suspended or cancelled earlier, the license remains valid for three years from the date of issue. To obtain a renewed license, a fresh application must be submitted at least three months prior to the license's expiry date**.** The license allows the applicant to import the specified products into India, subject to ongoing regulatory compliance and periodic renewals as required. The validity of an import license varies depending on the product and regulatory body. In most cases, the license is issued for a specified period, after which it must be renewed to continue importing the product. Renewal applications should be submitted well in advance to avoid disruptions in the supply chain. After obtaining the import license, importers must comply with all Indian import regulations, including product labelling, storage, and distribution requirements. Periodic audits and quality checks may be conducted to ensure compliance with national standards. Any violations may lead to suspension or cancellation of the import license**.**

Registration Certificate

In India, a Registration Certificate is required for certain categories of products—especially regulated goods like pharmaceuticals, medical devices, electronics, and cosmetics—before they can be imported, sold, or distributed. This certificate ensures that the product complies with Indian quality, safety, and labeling standards. Regulatory bodies such as the Central Drugs Standard Control Organization (CDSCO), Bureau of Indian Standards (BIS), and FSSAI issue these certificates depending on the product category. The first step in obtaining a registration certificate in India is to determine which regulatory authority governs your product.

- Pharmaceuticals and medical devices are regulated by the Central Drugs Standard Control Organization (CDSCO).
- Electronics and IT goods come under the Bureau of Indian Standards (BIS), particularly under the Compulsory Registration Scheme (CRS).
- Food products are regulated by the Food Safety and Standards Authority of India (FSSAI).

If you're a foreign manufacturer, you must appoint an Authorized Indian Representative (AIR) who will be responsible for communication with the regulatory body and submission of applications. The AIR must be based in India and have a valid license (e.g., wholesale license for pharmaceuticals). The application must be submitted in FORM 40.For CDSCO-regulated products, applications can be submitted through the SUGAM online portal. BIS applications are submitted via their own portal, especially for products under the Compulsory Registration Scheme (CRS)**.** Each regulatory body charges specific fees for registration and licensing. For instance

- CDSCO: ₹1,000 for a single drug and ₹100 for each additional drug (Form 8/8A), plus ₹1,500 for Form 41 (registration certificate)
- BIS: Fee depends on product type, testing, and number of variants
- FSSAI: Fee varies by license type (state/central/importer**)**

Once your application is submitted, the authority will scrutinize it. If needed, they may request additional documents or conduct an inspection.

- If everything is in order, a Registration Certificate (e.g., Form 41 under CDSCO, BIS CRS certificate, or FSSAI License) is issued.
- The registration is typically valid for 3 to 5 years, depending on the product and authority.
  Make sure to apply for renewal before expiry to avoid disruptions. Additionally, continue to comply with local labeling, safety, and distribution laws. Non-compliance may lead to suspension or cancellation of the registration.[2]

Procedure for Import and Registration of Drugs in Brazil

Importing pharmaceutical drugs into Brazil is a regulated process overseen by the National Health Surveillance Agency (ANVISA).Brazilian importers must register with the Foreign Trade Secretariat (SECEX), a branch of the Ministry of Development, Industry, Trade and Services (MDIC) via its Integrated System for Foreign Trade (Siscomex). Companies seeking to import goods into Brazil must obtain a RADAR licence. The RADAR licence grants a password to access the Brazilian Integrated Foreign Trade System (SISCOMEX). The SISCOMEX is an electronic integrated trade documentation system designed by the Brazilian Government to control and monitor the Brazilian Foreign Trade.

- Register with RADAR (Registro e Rastreamento da Atuação dos Intervenientes Aduaneiros) through Receita Federal to access SISCOMEX.
- Enables your company to submit import declarations and monitor the process.

Every pharmaceutical product must be registered before being imported, unless exempted under special regulations (like compassionate use or clinical trials).Submit the Dossier Técnico (Technical Dossier) detailing product composition, manufacturing process, safety, efficacy, and labelling.Products manufactured abroad must have Good Manufacturing Practices (GMP) approval from ANVISA, which may involve on-site inspection. Once the product is registered, an Import License (Licença de Importação - LI) is submitted via SISCOMEX. The LI includes, product details, supplier, importer, quantity, intended use, and classification. For pharmaceuticals, ANVISA must approve the LI before the goods are shipped or cleared. Pay the Sanitary Surveillance Inspection Fee associated with the importation process. The fee amount varies based on the nature of the importation and the size of the company. For instance, the consent to import samples for analysis may incur fees ranging from R$8.86 to R$177.29. Import licenses are typically valid for 90 days. Detailed fee structures can be found in ANVISA's Resolution RDC No. 222 of 2006. After submission, ANVISA will evaluate the application and supporting documents. The standard review process can take up to 365 days, while priority reviews may be completed in approximately 120 days. This evaluation includes a thorough assessment of the product's safety, efficacy, and compliance with Good Manufacturing Practices (GMP)**.** Upon approval, proceed with the customs clearance process. Ensure all import documentation is accurate and complete to facilitate the release of goods. Compliance with ANVISA's regulations is crucial to avoid delays or penalties.[3]

Registration Certificate

To market a pharmaceutical product in Brazil, a company must obtain aRegistro Sanitário(Sanitary Registration Certificate) from ANVISA (Agência Nacional de Vigilância Sanitária). The process begins with the appointment of **a** local Brazilian legal representative or subsidiary, as foreign companies are not permitted to apply directly. This local entity must possess a valid AFE (Autorização de Funcionamento de Empresa) — an authorization to operate issued by ANVISA. Once authorized, the applicant must prepare and submit a registration dossier in the CTD (Common Technical Document) format, under RDC No. 73/2016 and related ANVISA guidelines. The complete dossier includes administrative information, product composition, manufacturing data, quality control measures, stability data, and clinical or preclinical evidence depending on the product type (e.g., new drug, generic, or similar). The application is submitted electronically via the Peticionamento Eletrônico system on ANVISA's portal. Once submitted and the fee is paid, ANVISA begins the technical and regulatory review, which can take 12–24 months, depending on product complexity and regulatory backlog. If the application mets all requirements, ANVISA issues a 10-year valid

registration certificate that must be maintained and renewed. The complete dossier includes administrative information, product composition, manufacturing data, quality control measures, stability data, and clinical or preclinical evidence depending on the product type (e.g., new drug, generic, or similar). The application is submitted electronically via the Peticionamento Eletrônico system on ANVISA's portal. Once submitted and the fee is paid, ANVISA begins the technical and regulatory review, which can take 12–24 months, depending on product complexity and regulatory backlog. If the application meets all requirements, ANVISA issues a 10-year valid registration certificate that must be maintained and renewed**.** ANVISA charges fees based on the product classification and the size of the applying company. For example, the registration of a new synthetic or biological drug typically ranges from BRL 119,000 to BRL 160,000, while generics and similar medicines may cost between BRL 54,000 and BRL 80,000. Simpler products like OTC drugs have lower fees, around BRL 20,000 to BRL 40,000. Micro and small enterprises (classified as ME or EPP) are eligible for significant fee reductions, up to 90%, upon presenting proper documentation. A product's registration in Brazil can be canceled in several ways. The marketing authorization holder may request voluntary cancellation by submitting a petition via the Peticionamento Eletrônico system. Additionally, ANVISA may cancel a registration administratively if the product is not renewed within the 10-year period, is found to pose a public health risk, or if the company fails to comply with Good Manufacturing Practices (GMP), product safety regulations, or pharmacovigilance requirements. Another reason for cancellation is non-commercialization, i.e., the product is not marketed in Brazil for more than 12 consecutive months without justification.

Comparative Analysis of Import Regulations in India and Brazil

India and Brazil have established robust frameworks for pharmaceutical imports, overseen by their respective regulatory agencies, the Central Drugs Standard Control Organization (CDSCO) in India and ANVISA in Brazil. While the two countries share similarities in their focus on quality, safety, and efficacy, they differ significantly in their procedural specifics, timelines, and compliance standards. (Table 1)

CONCLUSION

Both India and Brazil have stringent pharmaceutical import regulations to ensure drug quality, safety, and efficacy. However, companies face significant challenges in navigating the complexities of each country's regulatory framework. Below are the key issues and challenges specific to both markets.

Key Issues and Challenges of Import Regulations in India and Brazil

INDIA

Regulatory Complexity

Multiple Approvals: Importers must obtain drug registration (Form 41) and an import license (Form 10). These processes are often perceived as duplicative and time-consuming. State vs. Central Authority Conflicts: Overlap in responsibilities between the CDSCO and state drug control authorities can lead to delays.

Delayed Timelines

Approval Delays: Import approvals often take 6-12 months, and delays can arise due to incomplete submissions or lack of coordination between stakeholders.

Insufficient Regulatory Harmonization

Non-Alignment with Global Standards: While India follows Schedule M for GMP compliance, it is not fully harmonized with ICH or WHO standards, leading to additional certification requirements for international companies.

Labelling Challenges

Language Restrictions: Labels must be in English, which may not align with exporting country norms.

Lack of Technological Integration

Paper-Based Systems: Despite efforts to digitize, much of the regulatory process remains manual, increasing the risk of errors and inefficiencies.

BRAZIL

Lengthy and Costly Approval Process

- ANVISA Inspections: ANVISA mandates its own GMP inspections for foreign facilities, adding costs and extending timelines. Approval may take up to 18 months.
- Stringent CTD Requirements: The Common Technical Document (CTD) format demands extensive documentation, making registration complex.

Limited Mutual Recognition

GMP Certification: Brazil's reluctance to accept GMP certifications from other regulatory authorities, unless under specific agreements, creates additional hurdles for manufacturers.

Trade Barriers

- High Import Duties: Pharmaceuticals are subject to substantial tariffs and taxes, increasing the cost of imports.
- Customs Delays: Bottlenecks at ports and extensive documentation requirements can delay market access.

Language and Labeling Issues

Portuguese Labels: All product labels and accompanying documentation must be in Portuguese, requiring translation and revalidation processes.

Complex Post-Marketing Requirements

Pharmacovigilance: Stringent post-market surveillance regulations increase compliance costs and resource allocation for the company.

COMMON CHALLENGES IN BOTH COUNTRIES

- Lack of Harmonization with Global Standards: Both countries' regulatory frameworks differ from ICH guidelines, leading to duplication in testing and documentation.
- High Regulatory Costs: Lengthy approval processes and compliance requirements raise the cost of market entry.
- Limited Transparency: Importers often face challenges in navigating opaque regulatory requirements, leading to delays and inconsistencies. (Table 2)

India and Brazil, as emerging pharmaceutical markets, present significant opportunities but also unique challenges for pharmaceutical imports. Both countries aim to protect public health through robust regulatory frameworks. However, the complexities, delays, and stringent requirements often impede timely access to essential medicines and increase costs for manufacturers.

Key Takeaways

1. Regulatory Diversity: India's reliance on the CDSCO and Brazil's dependence on ANVISA reflect differing approaches to drug safety and efficacy standards. India's fragmented system involves state and central coordination, whereas Brazil has centralized oversight but requires ANVISA's specific GMP compliance.
2. Harmonization Gaps: Both countries lack full alignment with global standards like ICH, WHO-GMP, and PIC/S, necessitating additional certifications for international companies.
3. Approval Timelines: Long timelines—6-12 months in India and 12-18 months in Brazil—contribute to delays in market entry.
4. High Regulatory Costs: Repeated inspections, dossier preparation, and compliance with unique local requirements increase operational costs**.**
5. Customs and Language Barriers: Inefficient customs clearance and mandatory labeling in local languages (English for India and Portuguese for Brazil) further complicate imports.

Recommendations

1. Harmonization: Aligning national standards with global frameworks like WHO, ICH, and PIC/S could reduce duplication and improve efficiency.
2. Digitalization: Both countries should invest in digitized systems for faster processing and greater transparency.
3. Collaboration: Strengthening collaborations between regulatory authorities and industry stakeholders can streamline procedures and reduce bottlenecks**.**

[Table 1 : Comparison Table of Import Regulations in India and Brazil

Aspect	India	Brazil
Regulatory Agency	CDSCO	ANVISA
GMP Standards	Schedule M / WHO GMP	ANVISA-specific GMP
Registration Format	Form 41 (simpler than CTD)	CTD dossier
Inspection Requirements	Limited, accepts foreign certifications	Frequent, often ANVISA-led
Timelines	~6-12 months	~12-18 months
Labeling Language	English	Portuguese
Climatic zone	Zone IV	Zone IV

Table 2: Comparison Table of Challenges in Both India and Brazil

Challenge	India	Brazil	Remarks
Regulatory Complexity	Multiple approval steps involving CDSCO and state authorities	Stringent ANVISA registration and inspection requirements	Both countries have extensive and sometimes overlapping regulatory requirements.
Lengthy Approval Timelines	Drug import approvals take 6-12 months	Approvals can take 12-18 months, especially for biological products	Long timelines increase the cost and delay market access for manufacturers.
GMP Certification Issues	Requires alignment with Schedule M; limited international harmonization	ANVISA insists on its own inspections; limited recognition of foreign GMP certificates	Lack of mutual recognition adds to complexity and costs for global manufacturers.
Language and Labeling	Labels must be in English	Labels and documents must be in Portuguese	Language localization is mandatory, increasing compliance requirements.
High Regulatory Costs	Compliance costs due to manual processes and non-standardized regulations	Costs are higher due to ANVISA inspections and complex dossier requirements	Regulatory compliance is resource-intensive in both countries.
Customs and Import Delays	Delays due to manual procedures and lack of digital integration	Delays from customs bottlenecks and extensive documentation requirements	Inefficient customs processes hinder timely product availability.
Pharmacovigilance Compliance	Mandatory post-marketing surveillance and reporting	RDC No. 4/2009 enforces stringent pharmacovigilance systems	Both require robust post-market safety monitoring, increasing operational demands.
Trade Barriers	High tariffs and non-tariff barriers for some drugs	High import duties and taxes on pharmaceutical products	Both countries impose tariffs that raise the cost of imports.

ABSTRACT

One of the most promising methods for enhancing the biopharmaceutical performance of weakly water soluble pharmacological substances, particularly for natural products, is the use of drug nanosuspensions, a universal formulation technique for better drug delivery of pharmaceuticals with hydrophobic properties. The purpose of this review was to provide an overview of the major technological challenges in the development of nanosuspensions, including the in vivo study of the systemic administered nanosuspensions, guidelines for stabilizer screening, and methods for achieving intravenous target delivery. Additionally, the difficulties of using nanosuspensions to transport natural goods were also covered and debated. As a result, it aimed to offer guidance and support for the creation of nanosuspensions, the use of stabilizers, the controllability of targeted delivery of the herbal products nanosuspensions, and the predictability of in vivo studies.

Keywords:

INTRODUCTION

Herbal products have long been utilized as alternative treatments for a range of illnesses with comparatively less side effects, and they are a significant source of therapeutically useful molecules worldwide[1].Recently, they have drawn interest for the identification of novel therapeutic agents.These natural compounds have considerable pharmacologic al activity, but because of their limited water solubility, they have low bioavailability, which results in subtherapeutic drug concentrations.Gris-PEG, a sustained-release tablet containing griseofulvanin nanosuspensions, was the first medicine to be commercialized using nanosuspensions in 1995.There are now around 20 products on the market for nanosuspensions, with parenteral and oral being the two main ways of drug administration. Analgesia, schizophrenia, antifungal, anti-inflammatory, and other areas are among the many indications[2]. The main benefits

of using nanosuspensions in pharmaceutical technology for herbal product delivery include improving skin surface permeation for transdermal drug delivery and increasing the rate of dissolution and saturated solubility, which improve bioavailability for oral administration. Two factors contribute to the increased penetration of the skin's surface. According to Fick's first law, the nanosuspensions' greater saturation solubility produced a greater concentration gradient and a greater diffusive flow into the skin as compared to the micronized drug powders. Additionally, because there are a lot of nanosuspensions particles, the medicine may be more equally spread across the skin's surface, which results in a more even concentration gradient distribution[3]. For the oral administration of herbal products, nanosuspensions may be used. Drugs in nanosuspensions are mostly administered orally to increase the bioavailability of insoluble drugs; individual differences have a significant impact on drug absorption[4]. First off, nanosuspensions have a comparatively strong adherence to the gastrointestinal mucosa because of their tiny particle size and large specific surface area, which prolongs their retention period in the gastrointestinal system. The absorption rate and degree are raised when the medication is released at the adsorption site, its saturation solubility rises, and the electrochemical gradient in the intestinal wall and plasma increases[5]. TriCor tablets made with fenofibrate nanosuspensions technology could be consumed either fed or fasted. Fenofibrate must be administered with food prior to TriCor's release in order to ensure adequate absorption. When fenofibrate is taken with food, its absorption differs by about 35% compared to when it is taken alone. Drugs can dissolve more quickly and completely in the gastrointestinal tract and be absorbed more readily by the body thanks to nanosuspensions dosage forms[6]. At a reduced dosage, the authorized 48 mg and 145 mg TriCor tablets can accomplish the same level of efficacy as the earlier 54 mg and 160 mg tablets, respectively. Additionally, it is more convenient for patients to take the TriCor tablets with or without food. The new pills are still taken once day. The initial dosage of 54 mg and 160 mg of TriCor tablets was replaced with 48 mg and 145 mg tablets at the same cost. Thus, the nanosuspensions technique abolished the dietary effect on fenofibrate bioavailability. Despite there aren't any herbal products available on the market yet, the nanosuspensions technology can undoubtedly remove the impact of fasting or non-fasting on the bioavailability of natural products[7]. Additionally, nanosuspensions could be used for the injectable administration of natural goods. In order to prevent the negative reactions brought on by organic solvents, the formulation of the nanosuspensions only requires a tiny amount of surfactants as stabilizers. Human capillaries have a diameter of roughly 2 μm, while nanosuspensions that are injected into blood typically have a size range of 0.1–1 μm, which helps prevent vascular embolism[8]. The ability of nanosuspensions to load drugs is comparatively high. For drugs whose efficacy is measured by AUC and adverse reactions by Cmax, the pH changes of the nanoparticles after they are phagocytosed by macrophages in the circulatory system could also be utilized to achieve slow and controlled release when the drug is administered subcutaneously or intramuscularly[9].

Approach for nanosuspensions preparation

Smart Crystal Method

A particular nanosuspension formulation intended for cutaneous applications is the main focus of smart crystal technique. The description emphasizes that this approach is distinct and not typical of other approaches utilized in the research or field, using the results from this formulation as an example. The summary essentially highlights the uniqueness of the smart crystal approach when it comes to dermal nanosuspension formulations. As demonstrated in the production of rutin nanocrystals, this technique blends high-pressure homogenization with low-energy pearl milling. When applied to human volunteers' skin, a nanosuspension containing 5% rutin in the form nanocrystals showing 500-fold more antioxidant activity than a 5% water-soluble rutin-glycoside derivative. A nanocrystal containing active rutin, as a nanocrystal, leads to higher gradient between the topical formulation and the skin [10].

Media Milling Nanocrystals

High-shear media mills or pearl ball mills are used to create nanosuspensions. A milling chamber, a milling shaft, and a recirculation chamber make up the mill. After that, the medication is sent through the mill, which has tiny pearls or grinding balls in an aqueous solution. As the temperature is properly regulated, these balls rotate at a very high shear rate as they pass through the grinding jar's interior, striking the sample on the wall on the other side. The combined actions of impact and friction result in a significant reduction of particle size[11]. Materials like zirconium oxide, aluminum oxide sintered in ceramic, or tightly cross-linked polystyrene resin with exceptional abrasion

resistance are used to make the milling medium or balls. A planetary ball mill is a equipment that may achieve a particle size below 0.1 μm (PM100 and PM200; Retsch GmbH and Co., KG, Haan, Germany). A Zn-Insulin nanosuspension with particle size of 150 nm was created by wet milling technique[12].

High-Pressure Homogenization Method

Using the high-pressure homogenization (HPH) approach, which relies on the use of significant shear pressures, a solution is ejected from cavities and used to scatter drug crystals in order to carry out the cavitation process. Two homogenization concepts that are commonly used in conjunction with certain homogenizers that follow these principles are microfluidization and piston-gap homogenization[13]. The HPH technology can be separated into two categories based on the homogenization concept and technique: microfluidization and piston-gap homogenizers. The jet principle, put forth by Haynes in 1992, serves as the foundation for the microfluidization technology. The Z-type to Y-type reform has been applied to the microfluidic reactor channels. The main factors limiting HPH in pharmaceutical industrial applications are the small reaction channel, the high number of homogenization cycles (some patents describe as many as 75), and the high percentage of micron particles in the final product, particularly for drugs with relatively low hardness of the homogenization target[14]. In the mid-1990s, a new method for preparing nanosuspensions—piston-gap homogenizers—was created based on the potential issues with media milling and the microfluidization principle. Based on the various dispersed phases, the piston-gap homogenizers can be classified as either non-water phase homogenization (Nanopure) or water phase homogenization (Dissocubes). The initial iteration of piston-gap homogenization technology is called Dissocubes. But since this uniformly distributed phase is a water phase, drying and water removal are the factors that need to be looked into in order to govern the production of the next product. Certain medications of low melting points require drying treatment using expensive freeze-drying technologies[15]. The aforementioned drawbacks are addressed by the piston-gap homogenization technology for the creation of nanosuspensions, and the non-aqueous phase homogenization may distribute the medication in both the oil phase and the aqueous solution of PEG or glycerol. Gelatin soft capsules might be immediately inserted into drug nanosuspensions made by homogenizing oil or PEG 400/ PEG 600 as a dispersive phase. The non-aqueous dispersion phase is advantageous for drug storage and enhances the stability of some drug nanosuspensions with significant chemical instability, such hydrolysis. These drugs may be tailored into a dosage form that is redilution-ready prior to clinical use. For intravenous administration, the drug nanosuspensions that use glycerol-water as a dispersed phase could be diluted into an isotonic suspension with water[16].

Nanoedge Method

The foundation of nanoedge technology is the combination of homogenization and precipitation. The drugs are first dissolved in an organic solvent and for precipitation, this solution is then mixed with a miscible anti-solvent. Because of its poor solubility in the water-solvent mixture, the medication precipitates. Quick precipitation and high-pressure homogenization are combined to create high-shear processing, which goes hand in hand with this precipitation method[17].

Microemulsion technique

The emulsion, which is created by employing a somewhat water-miscible solvent as the dispersed phase, can also be made into nanosuspensions by simply diluting it. Drugs that are partially water miscible or soluble in volatile organic solvents can be used using the emulsion technique. Nanosuspensions can also be created using microemulsion templates. Surfactants or cosurfactants stabilize microemulsions, which are dispersions of two immiscible liquids, like water and oil, thermodynamically. The medication can be saturated through close drug mixing and is either loaded into the internal or preformed phase of the microemulsion. Using the microemulsion process, glieofulvin nanosuspension is made with lecithin, butyl lactate, water, and the sodium taurodeoxycholate salt[18].

Precipitation Method

A common technique for creating submicron particles of medications that are poorly soluble is the precipitation method. This approach involves dissolving the drug in a solvent, then solution is mixed with another solvent that

renders the drug insoluble when surfactant is present. When a solution is quickly added to a solvent, usually water, the medication in the solution becomes supersaturated and forms an ultrafine amorphous or crystalline form. This process includes crystal growth and nuclei production, both of which are mostly temperature-dependent. The main prerequisites for creating a stable suspension with the smallest possible particle size are a high nucleation rate and a low crystal growth rate [19].

Nanosuspensions Herbal products

Curcumin nanosuspensions

Turmeric rhizome (*Curcuma longa*) is the primary source of curcumin (diferuloylmethane), a polyphenolic chemical that is utilized extensively as a nutraceutical ingredient in food and drink products. Anticancer, antiviral, antioxidant, anti-inflammatory, antibacterial, hypoglycaemic and antirheumatic qualities are among curcumin's health advantages. [20]However, its clinical use and therapeutic impact are limited by its poor oral bioavailability, stability, and water solubility[21]. Curcumin decrases the toxicity of heavy metals like lead and cadmium by binding with them. This characteristic of curcumin explains why it protects the brain. Curcuminoids are components of turmeric, primarily curcumin, demethoxycurcumin, and bisdemethoxycurcumin. These substances are all not very soluble in water. Curcumin's primary disadvantages, including instability, low solubility, poor bioavailability, and rapid metabolism, significantly restrict its therapeutic use. It has been tried to make curcumin fully dispersible in an aqueous medium by using nanosuspension-based delivery[22]. When compared to native curcumin, curcumin nano-formulations exhibit more anticancer efficacy. Curcumin nanoparticles of about 100–200 nm in size can be produced using polymer nanoparticles based on PLGA, which is a biodegradable and biocompatible polymer. While appropriate surface coating permits escape from macrophage absorption, this particle size range is sufficiently tiny to permit intracapillary transit. Numerous studies have been conducted on these curcumin nanoformulations using animal and cell culture models. Dendrimer-based nanoparticles can create a curcumin nanoformulation that has the capacity to selectively kill human neurotumor cells while maintaining biological activity[23]. The formulation has a zeta potential of -25 mV, a modest diameter (211 nm), and low polydispersity (0.06). On Caco-2 and HT-29-MTX cell lines, the prepared nanosuspensions demonstrated a lower cytotoxicity profile and better chemical stability at pH values that resemble the gastrointestinal tract as compared to the solubilised curcumin. This formulation of redispersible curcumin nanosuspensions might open up new possibilities for curcumin oral dosage. When curcumin/TPGS nanosuspensions or curcumin/Brij78 nanosuspensions were administered, the oral bioavailability of curcumin increased by several times respectively, in comparison to suspension. [24] Targeting curcumin to the hair follicles as a unique method of transdermal delivery may create a depot from which the active ingredient is released into the hair follicle and have a significant therapeutic impact on the management of skin conditions. Investigations were conducted on the ability of curcumin nanosuspensions to penetrate hair follicles and the impact of gels in which the nanosuspensions are suspended[25]. The gels were loaded with various characteristics, including viscosity, lipophilicity and polarity. Using comparable concentrations of the nanosuspensions and evaluated for their capacity to direct the nanosuspensions into the hair follicles. It was discovered that regardless of the kind and concentration of gelling agent used, all gels loaded with nanosuspensions demonstrated an effective uptake of the nanosuspensions into the hair follicles [26].

***Scoparia dulcis* nanosuspension**

This plant species is mostly used to treat inflammation, kidney stones, diabetes, hypertension, stomach ailments, analgesia, and fever. Alcoholic extracts of Scoparia dulcis are employed in this investigation. The best technique for creating a polyherbal nanosuspension is ionic gelation. Qualitative phytochemical screening was used to identify the phytochemicals contained in the extract. Carbohydrates, tannins, flavonoids, saponins, steroids, terpenes, and phenols are all present in the alcohol extract. A herbal nanosuspension was made by varying the chitosan content. Ionic gelation was the technique utilized to create the nano suspension. Sodium benzoate is used as a preservative and PEG as a stabilizer. In addition to stomach ailments, kidney stones, hypertension, diabetes, and inflammation, the findings offer scientific proof for the traditional use of *Scoparia dulcis* herbal nanosuspension for analgesic, antipyretic, and urinary problems. Following the scale-up investigations of the optimized formulation, clinical and human trials must be conducted[27].

***Phyllanthus amarus* nanosuspensions**

About 800 species of *Phyllanthus amarus*, a plant belonging to the Euphorbiaceae family, may be found worldwide in tropical and subtropical regions. It is frequently utilized in traditional Indian medicine and as dietary supplements to treat a variety of physiological conditions, including liver diseases. In both cultivated and waste areas, *Phyllanthus amarus*, a branching annual glabrous herb, is a common weed. Its absorption following oral administration may be restricted due to the poor water solubility of its main ingredients, such as flavanoids and lignans. Thus, *Phyllanthus amarus* nanosuspension was created to increase the drug's solubility. The ethanolic extract of Phyllanthus amarus extract (PAE) and its nanoparticles (PAN) were investigated for their hepatoprotective effects on acute liver damage caused by paracetamol in Sprague-Dawley rats. By lowering levels of aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, and bile salts, it was discovered that an oral dose of PANs that is five times lower than the oral dose of PAE had a comparable hepatoprotective effect. Rat liver biopsy analyses corroborated these biochemical evaluations[28].

***Coriander sativum* nanosuspensions**

Since coriander (*Coriandrum sativum* L.) is an annual herb, an extract was made from the entire plant. Although they have different flavours and purposes, the plant's seeds, leaves, and roots can all be eaten. Because the leaves of coriander are perishable, it can be utilized as a complete plant and processed to improve the flavour of ripe fruits before adding it to various meal preparations. [29] The coriander plant is a great source of nutritious components and minerals. Due to its many health advantages and ability to prolong food preservation, coriander is also well-known for its anti-oxidant, anti-diabetic, anti-mutagenic, anti-anxiety, and antibacterial activity, as well as its analgesic and hormone-balancing properties.[30] The primary cause of a drug's removal from the market is hepatotoxicity. The study examined the hepatotoxic effects of a nanosuspension containing extracts from *coriander sativum*. According to the results, the nanosuspension significantly reduces the hepatotoxic liver damage caused by carbon tetra chloride in male Wistar albino mice[31].

Baicalin nanosuspensions

Baicalin, a naturally occurring flavonoid that is isolated from the dried root of Scutellaria baicalensis Georgi, is one of the most widely used bioactives in Chinese medicine and has been utilized extensively in China from ancient times. It has numerous positive health impacts on people and can be used to treat a range of illnesses either by itself or in combination with other medications[32]. Baicalin is a possible therapeutic medication for the treatment of stroke and Alzheimer's disease because of its herbal, which might protect and improve cerebral ischemia reperfusion as well as protect nerve and endothelial cells[33]. Nevertheless, this substance is nearly insoluble in water and poorly soluble in ethanol. Its insolubility has long been a significant issue limiting its use in medicine.

***Cuscuta chinensis* Nanosuspension**

A popular traditional remedy for supporting the kidneys and liver is *Cuscuta chinensis*. This parasitic plant is a member of the Convoluceae family. It is frequently used as an aphrodisiac, pain reliever, anti-aging, and anti-inflammatory. Its absorption following oral administration may be restricted due to the poor water solubility of its main ingredients, such as lignans and flavonoids. Therefore, to increase the drug's solubility, the nanosuspension approach was employed[34]. Ethanolic extract (CE) of *Cuscuta chinensi* was studied for its hepatoprotective and antioxidant properties in relation to acetaminophen-induced hepatotoxicity in rats. The hepatoprotective activity of an oral dose of *Cuscuta chinensis* nanosuspension, which is five times lower than the oral dose of Cucuta chinensis extract, was found to be comparable. Furthermore, superoxide dismutase, catalase, glutathione peroxidase, and malondialdehyde were all markedly elevated by the antioxidant activities of CE and CN. Additionally, the results demonstrated that Cuscuta chinensis nanosuspension had more effective hepatoprotective and antioxidant effects than Cuscuta chinensis extract[35].

Quercetin nanosuspensions

Fruits, vegetables, and therapeutic herbs all naturally contain quercetin, a polyphenolic flavonoid. Quercetin is frequently used as a nutritional supplement and phytochemical medicine to prevent and treat a variety of illnesses

because of its most notable dietary antioxidants and pharmacological activities. Quercetin, one of the most well-known dietary antioxidants, is said to have positive health effects, such as preventing osteoporosis, some types of cancer, heart and lung conditions, and aging, without any indication of toxicity, carcinogenicity, or genotoxicity associated with ingestion[36]. The enhanced dissolve performance and significantly increased dissolution rate of freeze-dried quercetin nanosuspensions were due to the increase in surface area and solubility brought about by the reduction in particle size. The physical mixture, the freeze-dried quercetin nanosuspensions, and the coarse medication all dissolved at cumulative rates of 52.30%, 53.07%, and 70.90% within 120 minutes, respectively[37]. Nanosuspensions pharmaceutics technology has the potential to improve not only the dissolution and, thus, the oral bioavailability of the herbal product, but also the transdermal efficiency. By using the wet media milling technique quercetin nanosuspensions was stabilized by taking Tween 80 and Poloxamer 188 showed encouraging accumulation in the skin layers and biocompatibile in human keratinocytes and the capacity to mitigate the oxidative effect of hydrogen peroxide on cells[38].

***Berberine* nanosuspensions**

The active component of *Coptis berberine* is an alkaloid that is an isoquinoline derivative and has a variety of pharmacological actions. Berberine and its derivatives as well as when combined with other pharmaceutically active substances or in formulations, have applications in a number of therapeutic areas, including diabetes, depression, cancer, inflammation, hypertension, and numerous infectious diseases. But because of its low oral bioavailability, berberine's therapeutic use is restricted[39]. In diabetic mouse models, the antidiabetic effects of Berberine nanosuspension were assessed in comparison to the effectiveness of bulk Berberine. Furthermore, by changing comparing berberine and metformin, the berberine nanosuspension demonstrated greater hypoglycemic, total cholesterol, and reduction body weight. Thus, using a nanosuspension to administer berberine is a viable method of treating type 2 diabetes[40]. Malignant cancers like hepatocarcinoma pose a serious threat to human life. The anti-hepatocarcinoma properties of berberine nanosuspension were assessed in vitro and in vivo in comparison to the effectiveness of bulk berberine. While in vivo studies also demonstrated greater anticancer activity, berberine nanosuspension had notable inhibitory effects against human HepG2 and Huh7 cells. Therefore, a promising method of treating hepatocarcinoma is to give berberine as a nanosuspension[41].

Silybin nanosuspensions

In order to shield the liver from oxidative stress and chronic inflammatory processes, silybin, a hepatoprotective herbal medication, has been used extensively in clinics to treat hepatitis. Its benefits include a certain therapeutic impact and less negative side effects. Additionally, silybin has a variety of biological activities, including antioxidant and anticancer properties. Its low water solubility and, as a result, low oral bioavailability are characteristics of silybin[42]. Therefore, the development of silybin products is currently hampered by its poor water solubility and restricted gastrointestinal absorption[43]. In addition to the standard dose form, multifunctional PEGchitosan-stabilized silybin nanosuspensions could also be delivered via smart nanocaged carriers[44]. The b-poly(ε-caprolactone)-methoxypoly(ethylene glycol) (mPEG-b-PCL) For the manufacture of silybin nanosuspensions, methoxypolythylene glycol-grafted chitosan (PEG-CS), a multifunctional stabilizer and propargyl modified were used as nanocaged carriers. Using an anti-solvent precipitation technique, two silybin nanosuspensions formulations like PEG-CS and nanocaged nanosuspensions were prepared. The nanocaged nanosuspensions were found to have exceptional stability. Additionally when compared to the solution group, the AUC of the nanocaged and PEG-CS nanosuspensions increased by 5.54 and 2.58 fold, respectively. As a result, the technology of nanocaged nanosuspensions, which has superior stability, enhanced dissolving velocity, and relative bioavailability, may be suggested as a practical and effective method for the delivery of medications that are water insoluble. The viability of employing smart nanocaged carrier technology in herbal medicine has also been investigated[45].

Camptothecin nanosuspensions

Topoisomerase is a DNA enzyme that is inhibited by the cytotoxic quinoline alkaloid camptothecin. It was extracted from the stem and bark of the tree *Camptothecia acuminate,* which is used in traditional medicine to cure cancer. In early clinical trials, camptothecin shown impressive anticancer activity, but it also had poor solubility and a high rate

of adverse medication reactions[46]. The study examined the anticancer activity of camptothecin nanosuspension both in vitro and in vivo, as well as its dose-dependent toxicity in comparison to topotecan. The MTT assay was used to examine the cytotoxicity of camptothecin nanosuspension and topoecan against MCF-7, HCT-8, and PC-3 cells; the HCT-8 xenograft model was used to assess the antitumor activity in vivo; and changes in body weight and relative organ weight were used to examine the dose-dependent toxicity in vivo during the treatment. When applied to MCF-7 cell lines, camptothecin nanosuspension exhibits approximately six times the in vitro cytotoxicity activity of TPT, almost the same anticancer activity and less toxicity. Camptothecin nanosuspension is a unique prospective formulation with minimal toxicity and strong antitumor activity, according to the data[47].

Resveratrol nanosuspensions

After being identified in 1924, resveratrol, a non-flavonoid polyphenol natural product was extracted from *Veratrum grandiflorum* roots in 1940. Resveratrol, an antitoxin released by plants during times of stress or pathogen attack, was also discovered in grape leaves in 1976. It is known as phytoalexin because resveratrol synthesis rose dramatically in response to UV light, mechanical stress, and fungal infection[48]. D-α-tocopherol polyethylene glycol 1000 succinate (TPGS) and folate modified distearoylphosphatidyl ethanolamine-polyethylene glycol-folate (DSPEPEG-FA) were utilized as stabilizers and target delivery carriers to create two resveratrol nanosuspensions that are RSV-NA nanosuspension and RSV-NB nanosuspension, that were made using the antisolvent precipitation method[49].

CONCLUSION

An overview of advancements in the effectiveness of nanosuspensions technology for the delivery of natural products is given in this review. Topics covered include methods for preparing nanosuspensions, typical formulations of herbal product nanosuspensions, screening guidelines for stabilizers, the effects of stabilizers and particle size on the in vivo study of the nanosuspensions administered intravenously as well as how to accomplish intravenous target delivery. An essential strategy for enhancing the effectiveness of insoluble active ingredients in herbal products is the use of nanosuspensions. Although this drug delivery technology has advanced significantly in recent years, there are still numerous issues with stabilizer selection and use, the in vivo drug delivery process, targeted drug delivery and other areas and there is a lack of basic research.

ABSTRACT

Gymnastics is a demanding sport requiring strength, power, agility, flexibility, balance, coordination, and cardiovascular endurance, but it also carries a high risk of injury, particularly with its growing popularity. This study aimed to predict injuries among Indian male gymnasts aged 18–30 using the Gymnastic Male Functional Measurement Tool (GFMT). A total of 45 participants were selected based on specific criteria, and data were collected through consented demographic details, injury-related questions, and performance of the 10 GFMT tests. Descriptive analysis using SPSS v21 revealed a mean age of 24.16 years and an injury prevalence of 18%. The shoulder (75%) was the most frequently impacted area, followed by the lower back and ankle (25%), with the neck, upper back, and elbow each accounting for 13% of cases. Athletes who sustained injuries showed lower GFMT scores than their uninjured counterparts, reflecting decreased performance efficiency. The study found that poor GFMT scores correlate with higher injury risk, suggesting it is a useful predictive tool. Inadequate training and lack of proper cool-down routines were also highlighted as contributing factors to injury.

Keywords: Gymnast, GFMT tool, Indian gymnast, Injury, Prediction.

INTRODUCTION

Sports contribute significantly to physical fitness, mental well-being, and overall quality of life. Regular participation improves cardiovascular endurance, muscular strength, flexibility, and coordination while also promoting personal growth and psychological development[1]. However, sports involving intense physical demands also come with a risk of injury. Injury patterns vary depending on the sport, training intensity, age, and experience [2, 3]. Gymnastics, one of the most demanding sports, requires a combination of strength, agility, flexibility, and balance [4]. The repetitive, high-impact nature of gymnastics increases the risk of both acute and overuse injuries [5]. As the sport gains popularity, injury prevention has become a growing concern, especially since many gymnasts start intensive training at a young age[6, 7]. Male gymnasts often face high training volumes, leading to common injuries in the shoulders, back, neck, and ankles due to repeated loading and extreme ranges. These injuries can interrupt training, limit performance, and lead to long-term consequences[8-10]. Early detection of risk factors is, therefore, essential for injury prevention, and field-based screening tools are useful in assessing physical readiness and limitations [11]. The Gymnastic Functional Measurement Tool (GFMT) is a sport-specific assessment designed to evaluate critical physical attributes in gymnasts[12, 13]. The male version includes ten practical tests that assess strength, flexibility, agility, balance, and endurance using accessible equipment. These tests reflect the physical demands of gymnastics and help identify potential risk factors[11, 14]. Lower scores in specific tests may signal performance limitations that could increase injury risk. Thus, the GFMT is not only valuable for performance evaluation but also for predicting injuries [11]. Understanding injury risk in gymnasts also requires consideration of regional differences in physical characteristics and training conditions. Indian gymnasts may differ from athletes in other regions, making localized data essential. This study focuses on injury prevalence among Indian male gymnasts and evaluates the GFMT's utility in predicting injury within this population, intending to inform safer training practices and personalized conditioning programs. The study's significance lies in its potential to provide relevant insights into injury patterns and to support the development of targeted interventions. By using the GFMT as a screening tool, coaches and healthcare professionals can better guide gymnasts toward improved safety, performance, and long-term athletic development. The primary aim of this study is to predict injuries among Indian male gymnasts aged 18 to 30 years using the Gymnastic Male Functional Measurement Tool (GFMT), helping to strengthen injury prevention strategies through functional assessment.

METHODOLOGY

This correlational study aimed to examine the relationship between physical performance and injury prediction in male gymnasts. Using purposive sampling, 45 gymnasts aged 18–30 years were recruited from coaching centers across Surat. Participants had a minimum of six months of active training and were excluded if currently injured, recovering from recent injuries (<3 months), or outside the age/experience range. The study was conducted over six months (October 2023 to April 2024) with prior ethical approval and informed consent. Data collection was divided into three parts. First, gathered demographic and injury-related information, including training experience, competition level, injury history, and protective measures. The another is Male Gymnastic Functional Measurement Tool (MGFMT), which mainly incudes different ten sport-specific tests targeting agility, flexibility, strength, balance and endurance. Tests included the rings hold, handstand push-ups, star excursion balance, over-grip pull-ups, vertical jump, hanging pike, shoulder flexibility, splits (left, right, and middle), agility, and handstand duration. Standard procedures and basic equipment (e.g., tape measure, stadiometer, stopwatch) were used for all tests. (Fig: 1 to Fig: 8) Each test targeted specific physical capacities: the rings hold and push-ups assessed upper body and core strength; the star excursion balance test evaluated dynamic balance; pull-ups tested muscular endurance; the vertical jump and hanging pike assessed leg power and core flexibility, respectively. Related to range of joints and flexibility of lower body, the quantification is being carried out by shoulder flexibility and split test. Agility and handstand endurance were measured through directional sprints and time held on parallel bars. (Table-1) Raw scores were interpreted per GFMT scoring criteria and analyzed statistically. The results aim to determine GFMT's predictive validity in identifying injury risk and guiding prevention strategies among Indian male gymnasts.

RESULT

A total of 45 Indian male gymnasts aged 18–30 years participated in this study. The mean age was 24.16 ± 3.02 years, with average height and weight of 1.70 ± 0.08 m and 65.18 ± 8.17 kg, respectively. Based on BMI, 37% of participants were underweight, 60% were within the normal range, and 4% were classified as obese. Most participants (62%) had less than one year of experience in gymnastics, and the majority (75%) competed at the district level. Regarding injury prevalence, 18% of the participants reported gymnastics-related injuries, with the shoulder (75%) being the most commonly affected site, followed by the ankle (25%), lower back (25%), neck (13%), and upper back (13%). Knee, wrist and head injuries were less reported. Training frequency analysis showed that both injured and non-injured athletes commonly trained 3–5 days per week. All participants performed warm-ups, while cool-downs were slightly more common in the non-injured group (95%) compared to the injured group (87%). Protective equipment use was reported by 50% of injured and 49% of non-injured athletes. When comparing performance on the Male Gymnastic Functional Measurement Tool (GFMT), non-injured athletes had consistently higher mean scores across most of the 10 test components except the agility, as shown in table 2.

DISCUSSION

The present study aimed to predict injuries among Indian male gymnasts aged 18–30 years using the Gymnastic Male Functional Measurement Tool (GFMT), providing valuable insights into how performance-based field testing can help identify injury risk. With an injury prevalence of 18%, the results are slightly lower than those reported in earlier studies, such as the 24% prevalence among male gymnasts documented in 2015[15], which may be attributed to differences in training intensity, competition level, or preventive practices. The most frequently injured site was the shoulder (75%), followed by the ankle and lower back (25% each), with less frequent injuries reported in the neck and upper back. These findings align partially with those of prior studies, such as the 2021 systematic review[6], which noted high injury rates across upper limbs, the trunk, and lower limbs in gymnasts. The findings of the present study affirm the GFMT's effectiveness in forecasting injury risk at specific sites based on performance outcomes. Athletes who sustained injuries consistently exhibited lower average scores on the majority of GFMT components, particularly those assessing shoulder function (such as ring hold, shoulder flexibility, over-grip pull-ups, and handstand push-ups, back and trunk (hanging pike and pull-ups), and ankle (vertical jump, splits, and star excursion balance).This indicates reduced strength, endurance, balance, and flexibility in injured gymnasts, reinforcing that those physical inefficiencies directly correlate with higher susceptibility to injury. In line with Bostjan Jakse's research[16], which emphasized the role of body composition and tailored training in athlete performance, this study also revealed that 37% of participants were underweight and 4% were obese, which may reflect inadequate nutritional support or inconsistent training loads—factors that could influence injury risk. Furthermore, most participants had less than one year of experience and primarily competed at the district level, which may suggest a developmental stage where physical conditioning and technical adaptation are still maturing. Bostjan also noted that a structured training schedule is crucial for safe progression[16]; in this study, most injured athletes trained only 3–4 days a week, whereas a higher proportion of non-injured gymnasts trained up to 6 days weekly, suggesting better physical adaptation and workload management. The importance of recovery routines was also evident: although all athletes performed warm-ups, cool-downs were more common among non-injured athletes (95%) than injured ones (87%), consistent with the understanding that proper recovery reduces post-exercise stress and injury risk[17].

The use of protective equipment was similar in both groups, indicating that while protective gear is standard practice, it alone may not be sufficient without proper conditioning and recovery strategies. Notably, the agility test was the only GFMT component where injured athletes performed marginally better, possibly due to its emphasis on cardiovascular and speed elements rather than muscular strength or flexibility. This further supports the need to emphasize strength and balance training in injury prevention programs. As the GFMT has demonstrated good reliability and construct validity[11, 14], its continued application in gymnastic screening—especially among populations like Indian male gymnasts, for whom limited data currently exists—can greatly support injury

prevention. By pinpointing individual physical weaknesses and adjusting training to correct them, coaches and sports medicine practitioners can boost athlete safety, minimize injury-related downtime, and improve overall performance. These findings validate the role of sport-specific functional assessment tools like GFMT in structured athlete management and highlight the importance of integrating them into regular practice, especially in high-risk sports like gymnastics. This study had a few limitations. It included only male Indian gymnasts, so the findings may not apply to female athletes. The sample size was small and limited to gymnasts from Surat, which may affect the generalizability of the results. Additionally, the study did not differentiate between types of gymnastics, which may have influenced the injury patterns observed. Future studies are recommended with larger sample sizes to improve data reliability and avoid saturation. Research should also include Indian female gymnasts to understand gender-specific injury patterns. Additionally, comparing different assessment tools could help identify the most effective method for injury prediction. Studies focusing on specific gymnastics disciplines and their associated injury risks would also provide more targeted insights.

CONCLUSION

There is 18% prevalence of injury among Indian male gymnast, where, using male GFMT tool the injury can be predicted for the Indian male gymnast, as lesser the score for the items, less the efficiency to perform the task leading to lack of specific strength and ability leading them to lend up with the injury. Also, lack of specific training and not carrying out proper cool down can be a factor for getting injured while performing gymnastics.

ABSTRACT

Coogan-Reese syndrome, also referred to as Cogan-Reese syndrome or Iris Nevus Syndrome, is a rare and distinct disorder within the Iridocorneal Endothelial [ICE] syndromes. These conditions are typically unilateral, nonhereditary, and are characterized by the abnormal proliferation and migration of corneal endothelial cells, which form a membrane-like structure that disrupts the anterior segment of the eye. This disruption can lead to secondary glaucoma by obstructing the drainage of aqueous humour. Coogan-Reese syndrome is distinguished by its characteristic features, including pigmented nodules or diffuse pigmentation of the iris, progressive iris atrophy, corectopia, and peripheral anterior synechiae. These abnormalities contribute to elevated intraocular pressure and visual impairment. The exact aetiology of Coogan-Reese syndrome remains unclear, though both genetic susceptibility and environmental factors, such as viral infections, have been suggested as possible contributors. Recent diagnostic advancements, including anterior segment optical coherence tomography [AS-OCT] and ultrasound biomicroscopy [UBM], have significantly improved the ability to identify the characteristic features of this syndrome. Differential diagnoses include conditions with overlapping clinical features, such as Fuchs' Heterochromic Iridocyclitis, neovascular glaucoma, and neurofibromatosis type 1. Management of Coogan-Reese syndrome primarily focuses on controlling secondary glaucoma and corneal oedema through both medical and surgical interventions. Initial treatment typically involves topical intraocular pressure-lowering medications; however, in refractory cases, procedures like trabeculectomy, glaucoma drainage devices, or cyclophoto coagulation may be necessary. Corneal transplantation techniques, such as Descemet's Membrane Endothelial Keratoplasty [DMEK] or Penetrating Keratoplasty [PK], are considered for severe corneal decompensation. Despite these treatments, the progressive nature of the disease necessitates ongoing monitoring and multidisciplinary care. The prognosis of Coogan-Reese syndrome varies depending on the severity of glaucoma and

corneal involvement. Early diagnosis and proactive treatment can preserve vision; however, the aggressive and often treatment-resistant nature of the condition underscores the need for further research to develop improved therapeutic strategies. This review article was prepared through a comprehensive process to gather, evaluate, and synthesize relevant information from a wide range of scientific sources. A systematic search was conducted across multiple databases, including PubMed, Google Scholar, and Scopus, using key terms such as "Coogen-Reese Syndrome," "clinical features of Coogen-Reese," "genetic basis of Coogen-Reese," and "treatment of Coogen-Reese" to ensure broad coverage of the existing literature. To maintain the relevance and quality of the sources included, specific inclusion and exclusion criteria were applied. Peer-reviewed articles, case reports, and clinical studies that addressed the pathophysiology, diagnosis, treatment, and outcomes of Coogen-Reese Syndrome, with a focus on both adult and paediatric populations, were included. Studies providing original data, systematic reviews, or meta-analyses were prioritized. Exclusion criteria consisted of studies on unrelated disorders, articles in languages other than English, and opinion pieces or unpublished data lacking clinical evidence or peer review. This review provides a comprehensive overview of the pathophysiology, clinical presentation, diagnostic strategies, differential diagnosis, treatment modalities, and prognosis of Coogan-Reese syndrome, thereby enhancing the understanding and management of this complex ocular disorder.

Keywords: Coogen Reese Syndrome, Iridocorneal, Syndrome, atrophy, genetic, nodules.

INTRODUCTION

Coogan-Reese syndrome, also referred to as Cogan-Reese syndrome or Iris Nevus Syndrome, is a rare and distinct disorder within the broader category of Iridocorneal Endothelial [ICE] syndromes. ICE syndromes are a group of unilateral, nonhereditary conditions characterized by abnormal proliferation and migration of corneal endothelial cells [1]. These aberrant endothelial cells possess the unique ability to form a membrane-like structure that extends across the anterior chamber, affecting critical ocular structures, including the iris and trabecular meshwork [2]. This pathological extension of endothelial cells disrupts the normal anatomy and function of the anterior segment of the eye, often leading to secondary glaucoma, as the aqueous humor drainage pathway is compromised [3]. Coogan-Reese syndrome stands out among ICE syndromes due to its distinct iris-related manifestations. The defining feature of this syndrome is the presence of pigmented nodules or a diffuse, patchy pigmentation across the anterior surface of the iris. This pigmentation creates an irregular, speckled pattern that is often readily visible during clinical examination, and it may vary in intensity over time [4]. As the condition progresses, patients typically experience worsening iris atrophy, corectopia [a condition where the pupil is displaced from its normal central position], and an irregularly shaped pupil. These changes can lead to significant cosmetic concerns and visual disturbances, further complicating the clinical management of the condition [5]. In addition to these iris abnormalities, peripheral anterior synechiae [PAS] may develop, where pathological adhesions form between the iris and cornea. This can exacerbate the elevation of intraocular pressure, contributing to the progression of glaucoma [6]. The precise aetiology of Coogan-Reese syndrome remains elusive, although it is generally believed to arise from a combination of genetic susceptibility and environmental factors [7]. Viral infections, particularly those caused by herpes simplex virus or Epstein-Barr virus, are thought to play a role in triggering the condition in individuals with a predisposition to ICE syndromes [8]. Advances in diagnostic imaging techniques, such as anterior segment optical coherence tomography [AS-OCT] and ultrasound biomicroscopy [UBM], have revolutionized our ability to diagnose Coogan-Reese syndrome with greater precision. These tools allow clinicians to visualize the subtle changes in the anterior segment and differentiate this syndrome from other similar ocular conditions [9]. This review provides an extensive examination of the pathophysiology, clinical manifestations, diagnostic approaches, differential diagnosis, treatment strategies, and prognosis of Coogan-Reese syndrome. By delving into these aspects, we aim to enhance the understanding and management of this complex ocular disorder.

Historical Background

Coogan-Reese syndrome, a rare ocular disorder, was first described in the mid-20th century and is recognized as a distinct subtype within the broader spectrum of Iridocorneal Endothelial [ICE] syndromes [10]. This condition owes its name to ophthalmologists James D. Coogan and Albert Reese, who were pivotal in identifying and characterizing the unique iris abnormalities and associated ocular complications that set it apart from other forms of ICE syndrome[11]. Unlike related conditions such as Chandler syndrome, known for corneal oedema and endothelial abnormalities, and Essential Iris Atrophy, which involves progressive thinning and distortion of the iris, Coogan-Reese syndrome is distinguished by the presence of nodular or diffuse pigmented lesions on the iris surface[12]. These distinctive features, along with its potential to cause glaucoma and other vision-threatening complications, underscore its clinical importance [13]. The detailed observations and pioneering work of Coogan and Reese contributed significantly to the understanding and classification of ICE syndromes, paving the way for further research into their pathophysiology and management.

Pathophysiology

The hallmark of ICE syndrome, including Coogan-Reese syndrome, is an abnormal proliferation of the corneal endothelium, a thin layer of cells on the inner surface of the cornea [14]. Normally, these cells help maintain the cornea's clarity by keeping it dehydrated. However, in Coogan-Reese syndrome, these cells multiply and start to act like epithelial cells, a transformation known as epithelial-like metaplasia [15].This leads to a series of problems in the eye, including corneal swelling, iris abnormalities, and glaucoma [16].This abnormal proliferation spreads from the corneal endothelium to the iris and the trabecular meshwork, resulting in various clinical manifestations

Corneal Endothelial Dysfunction: The proliferating endothelial cells lead to corneal edema as they lose their ability to maintain proper fluid balance in the cornea [17].

Trabecular Meshwork Involvement: The abnormal endothelial cells can spread into the trabecular meshwork, obstructing aqueous humour outflow and leading to secondary glaucoma [18].

Iris Changes: In Coogan-Reese syndrome, the abnormal endothelium migrates over the iris, leading to the formation of pigmented nodules or diffuse pigmentation, along with progressive iris atrophy and pupil distortion [corectopia] [19]. The exact cause of Coogan-Reese syndrome is still unknown, but some studies suggest that a viral infection, especially the herpes simplex virus [HSV], might trigger the disease [20]. HSV could potentially change the behavior of the corneal endothelial cells, leading to their abnormal growth and spread. However, this theory remains controversial, and not all cases of ICE syndrome show clear viral involvement [21].

Clinical Features

Coogan-Reese syndrome is a rare condition with distinct clinical features primarily affecting the iris and corneal endothelium. It typically manifests in middle-aged adults, with a higher prevalence observed among females [22]. The disease is almost exclusively unilateral, impacting only one eye, and belongs to the broader spectrum of Iridocorneal Endothelial [ICE] syndromes [23].

Pigmented Iris Nodules [Iris Nevi]

The defining feature of Coogan-Reese syndrome is the presence of pigmented nodules on the surface of the iris, commonly referred to as iris nevi. These nodules vary widely in size, shape, and number, imparting a distinct spotted or bumpy texture to the iris [24]. Occasionally, instead of discrete nodules, there may be diffuse pigmentation of the iris, creating a uniformly darker appearance. Patients might notice these changes cosmetically, with alterations in iris color or texture being particularly striking. The pigmented nodules are not only a diagnostic hallmark but also contribute to the unique visual presentation of the condition [25].

Iris Atrophy and Corectopia

As the disease advances, the iris undergoes progressive atrophy, characterized by thinning and the development of holes in the iris stroma. This deterioration frequently leads to corectopia, a displacement or distortion of the pupil. Corectopia is a hallmark sign of ICE syndromes and may cause visual disturbances or contribute to patient concern over aesthetic changes [26]. Additionally, the iris can form abnormal adhesions to the cornea, termed peripheral anterior synechiae, which can further distort the normal anatomy of the eye and exacerbate functional impairments [27].

Corneal Edema

Dysfunction of the endothelial cells in Coogan-Reese syndrome impairs their ability to maintain corneal deturgescence, resulting in corneal oedema [28].This oedema manifests clinically as blurred vision, glare, and halos around lights, particularly noticeable in dim settings. Corneal clarity may deteriorate over time, and patients often describe a sensation of visual "haze." The degree of corneal oedema can fluctuate, worsening in the presence of elevated intraocular pressure [IOP] or other stressors to the eye [29].

Secondary Glaucoma

Secondary glaucoma is a frequent and potentially sight-threatening complication of Coogan-Reese syndrome. Abnormal endothelial cells proliferate and invade the trabecular meshwork, leading to obstruction of aqueous humour outflow and a consequent rise in IOP [30]. This type of glaucoma is typically aggressive and refractory to conventional medical management, often necessitating surgical intervention to control IOP and preserve vision [31]. The coexistence of glaucoma and corneal oedema amplifies the risk of vision loss, underscoring the importance of early diagnosis and vigilant monitoring [32].

Diagnosis

The diagnosis of Coogan-Reese syndrome is primarily clinical, based on the characteristic ocular findings. A thorough eye examination is essential to identify the key features of the syndrome. Diagnostic tools and tests include:

Slit-Lamp Examination: This reveals the characteristic pigmented nodules or diffuse iris pigmentation. The slit-lamp examination also helps identify corneal oedema and assess the degree of iris atrophy and corectopia. The corneal endothelium may exhibit a "hammered silver" or "beaten metal" appearance, indicative of endothelial abnormalities [33].

Gonioscopy: Gonioscopy is used to evaluate the anterior chamber angle of the eye, which is the area responsible for draining aqueous humour from the eye [34]. In Coogan-Reese syndrome, the trabecular meshwork is often covered by abnormal endothelial cells, which can be detected during gonioscopy. This blockage is what leads to the development of glaucoma. This test is essential in evaluating the extent of angle closure caused by the abnormal cells and anterior synechiae formation. [35]

Specular Microscopy: Specular microscopy provides an in-depth assessment of the corneal endothelium.In patients with Coogan-Reese syndrome, the endothelial cells appear irregular and lose their typical hexagonal shape, which is key to maintaining the cornea's transparency [36]. This abnormality is often described as having a "hammered silver" or "beaten metal" appearance [37].

Intraocular Pressure [IOP] Measurement: Regular monitoring of IOP is critical, as glaucoma is a common and potentially sight-threatening complication of the syndrome [38].

Anterior Segment Optical Coherence Tomography [AS-OCT]: This non-invasive imaging technique can provide detailed cross-sectional images of the cornea, iris, and anterior chamber angle. This tool helps in assessing the structural changes in the eye, including the presence of synechiae [iris sticking to the cornea] and corneal edema [39].

Differential Diagnosis

Coogan-Reese syndrome must be carefully differentiated from other ocular conditions that share overlapping features, to ensure accurate diagnosis and effective management. The following conditions are particularly relevant:

Fuchs' Heterochromic Iridocyclitis [FHI]: This condition is characterized by chronic, mild uveitis, which frequently presents with heterochromia and cataract formation. Unlike Coogan-Reese syndrome, FHI does not exhibit the nodules on the iris or the severe glaucoma that are hallmarks of Coogan-Reese syndrome [40]. Additionally, the inflammation in FHI is typically low-grade and non-granulomatous, with the absence of peripheral anterior synechiae or endothelial changes [41].

Neovascular Glaucoma [NVG]: NVG is a type of secondary glaucoma caused by the growth of abnormal new blood vessels on the iris and trabecular meshwork [42]. While NVG may mimic the synechiae observed in iridocorneal endothelial [ICE] syndromes, including Coogan-Reese syndrome, its underlying cause is often distinct, typically linked to retinal ischemia or systemic conditions such as diabetes mellitus or central retinal vein occlusion [43]. Unlike Coogan-Reese syndrome, NVG is primarily associated with severe underlying vascular pathology rather than primary endothelial dysfunction [44].

Neurofibromatosis Type 1 [NF1]: NF1 is a genetic disorder that may present with Lisch nodules, which are pigmented, benign hamartomas found on the iris. While Lisch nodules superficially resemble the iris nodules seen in Coogan-Reese syndrome, they do not result in the corneal changes, peripheral anterior synechiae, or secondary glaucoma that are characteristic of Coogan-Reese syndrome [45]. NF1 is typically accompanied by other systemic manifestations, such as café-au-lait spots and neurofibromas, which further aid in differentiation [46].

Management

The management of Coogan-Reese syndrome primarily targets the control of secondary glaucoma and the reduction of corneal oedema, with a combination of medical and surgical treatments. The condition is complex, and its progression requires careful monitoring and individualized care. Below is an overview of the treatment strategies and their respective roles in managing this rare disorder.

Medical Therapy for Glaucoma

The primary goal of medical therapy is to lower intraocular pressure [IOP] to prevent optic nerve damage and vision loss [47]. Initial treatment usually consists of topical medications aimed at reducing IOP. Common classes of drugs include

Prostaglandin Analogs: These medications, such as latanoprost, are effective at lowering IOP by enhancing the outflow of aqueous humour through the uveoscleral pathway.

Beta-blockers: Agents like timolol reduce aqueous humour production, thereby lowering IOP. However, they may not be as effective in advanced stages of ICE syndrome due to the progressive nature of the trabecular meshwork obstruction.

Carbonic Anhydrase Inhibitors [CAIs]: Drugs such as dorzolamide reduce aqueous humor production, helping control IOP.

Despite the initial benefits, these medications may become less effective over time due to the progressive and obstructive nature of the trabecular meshwork in ICE syndrome, requiring additional interventions [48].

In addition, hypertonic saline eye drops are used to reduce corneal oedema by drawing excess fluid from the corneal stroma. Although this provides temporary relief, it does not address the underlying causes of corneal swelling and is typically a short-term measure [49].

Surgical Intervention for Glaucoma

When medical management fails to adequately control IOP, surgical interventions may be necessary. These procedures aim to either improve aqueous humour drainage or decrease its production [50]. The following are commonly considered surgical options:

Trabeculectomy: This filtration surgery creates a new drainage pathway for aqueous humor to reduce IOP. However, its effectiveness is limited in ICE syndrome due to endothelial cell proliferation and fibrosis at the surgical site, which can obstruct the drainage mechanism [51].

Glaucoma Drainage Devices [GDDs]: When trabeculectomy is not effective, the implantation of drainage devices, such as the Ahmed valve or Baerveldt implant, may offer a better alternative. These devices create a controlled outlet for aqueous humour, thereby helping to maintain adequate IOP levels. GDDs are often more successful in patients with ICE syndrome due to the reduced risk of trabecular meshwork obstruction and endothelial proliferation [52].

Cyclophotocoagulation: This laser procedure involves the selective destruction of the ciliary body to reduce aqueous humor production. It is typically reserved for refractory cases of glaucoma that do not respond to medical or conventional surgical treatments. Cyclophotocoagulation can be an effective tool in controlling IOP in severe, treatment-resistant cases [53].

Management of Corneal Oedema

Corneal oedema, a hallmark of Coogan-Reese syndrome, can lead to significant visual impairment if not properly managed. The primary aim is to reduce swelling and preserve corneal clarity:

Hypertonic Saline Eye Drops/Ointments: These agents help temporarily reduce corneal oedema by drawing excess fluid from the corneal stroma, providing short-term relief [54].

Corneal Transplantation: In cases where corneal oedema becomes severe and leads to significant vision loss, a corneal transplant may be required. There are two primary types of corneal transplants considered:

Descemet's Membrane Endothelial Keratoplasty [DMEK]: This selective transplant involves replacing only the damaged endothelial cells of the cornea. DMEK has shown promising results in patients with ICE syndrome, as it focuses on the specific layer affected by the condition [55].

Penetrating Keratoplasty [PK]: For advanced cases where the damage to the cornea is more widespread, a full-thickness corneal transplant may be necessary [56]. PK is considered when DMEK is not an option or in cases with more significant corneal scarring [57].

Monitoring and Follow-Up

Given the progressive nature of Coogan-Reese syndrome, continuous monitoring is essential to ensure optimal management and timely intervention. Patients should undergo regular assessments of the following:

Intraocular Pressure [IOP]: Frequent monitoring of IOP is necessary, as glaucoma progression can lead to optic nerve damage and vision loss [58].

Corneal Health: Regular evaluation of corneal thickness and swelling helps guide treatment decisions, particularly with respect to managing corneal oedema [59].

Visual Acuity: Regular tests of visual function are crucial to monitor any changes in vision and determine the need for surgical interventions [60]. Long-term follow-up is critical, as the disease can progress despite treatment. Ongoing

management requires a multidisciplinary approach, involving both glaucoma and corneal specialists, to address the complex interplay of intraocular pressure and corneal health in Coogan-Reese syndrome [61].

Prognosis

The prognosis for Coogan-Reese syndrome [also known as Iridocorneal Endothelial [ICE] syndrome] can vary significantly depending on the severity and progression of associated complications, particularly those involving glaucoma and corneal changes [62]. Early detection of elevated intraocular pressure [IOP] and prompt, effective management are crucial for preserving vision. However, glaucoma related to ICE syndrome can be particularly challenging to manage due to its tendency to be resistant to conventional treatments [63]. This necessitates the use of advanced, often multifaceted therapeutic strategies, including medical therapy, laser procedures, and sometimes surgical intervention [64]. In cases where corneal clarity is markedly compromised, corneal transplantation may become an essential treatment to restore vision. While corneal grafting can effectively improve visual outcomes, it carries substantial risks, including graft rejection and the recurrence of endothelial dysfunction, which can result in further corneal decompensation. Additionally, the progression of ICE syndrome itself may lead to complications that complicate the success of such procedures [65]. The potential for significant vision loss is particularly high in the advanced stages of the disease, making early diagnosis and proactive, individualized treatment plans critical[66]. The implementation of a personalized approach to managing Coogan-Reese syndrome is vital to optimizing visual outcomes and enhancing the long-term prognosis. Given the complexity of the condition, patients should undergo regular, thorough follow-up appointments to monitor disease progression and adjust treatment regimens as necessary. Even with aggressive interventions, the condition may continue to evolve, requiring careful attention [67]. A multidisciplinary approach that includes collaboration between ophthalmologists, corneal specialists, and glaucoma experts is essential to manage the complex and often unpredictable course of the syndrome. This collaborative effort helps ensure that patients receive the most appropriate and effective care, improving their chances of maintaining functional vision and reducing the risk of further complications [68].

Future Directions and Research Perspectives

Advances in Imaging Techniques

The evolution of ocular imaging has significantly enhanced the diagnosis and monitoring of Coogan-Reese Syndrome [CRS]. Traditional slit-lamp biomicroscopy remains a cornerstone of clinical assessment, but newer modalities such as anterior segment optical coherence tomography [AS-OCT] and ultrasound biomicroscopy [UBM] have improved our ability to visualize the intricate changes in the anterior segment.

Anterior Segment Optical Coherence Tomography [AS-OCT]: AS-OCT is a non-invasive imaging technique that offers high-resolution cross-sectional images of the anterior segment [69]. It is particularly useful in assessing the abnormal corneal endothelial proliferation characteristic of ICE syndromes, including Coogan-Reese syndrome [70]. Future advancements in AS-OCT may provide automated detection and quantification of endothelial membrane progression, allowing for early intervention before significant complications arise [71].

Ultrasound Biomicroscopy [UBM]: UBM is a high-frequency ultrasound technique that allows detailed visualization of the anterior chamber angle, including peripheral anterior synechiae [PAS] formation and trabecular meshwork abnormalities [72]. This imaging method plays a crucial role in differentiating Coogan-Reese syndrome from other ICE variants. Further refinements in UBM technology could enhance real-time imaging capabilities, improving clinical decision-making [73].

Specular and Confocal Microscopy: Specular microscopy enables the assessment of endothelial cell morphology, revealing characteristic changes such as cell polymorphism, pleomorphism, and abnormal migration [74]. Confocal microscopy further aids in visualizing endothelial proliferation, distinguishing Coogen-Reese Syndrome from other endothelial pathologies [75].

Artificial Intelligence in Imaging Analysis: Machine learning and AI-based algorithms are being explored for the automated analysis of anterior segment images. These technologies have the potential to improve diagnostic accuracy, predict disease progression, and assist in individualized treatment planning [76].

Genetic and Molecular Studies

Despite extensive research, the exact genetic basis of Coogan-Reese syndrome and other ICE syndromes remains unclear. Recent research suggest that a combination of genetic predisposition and environmental triggers [such as viral infections] contributes to disease development. Future genetic and molecular research could offer critical insights into the pathogenesis of this disorder.

Potential Genetic Markers: Some studies have suggested an association between polymorphisms in endothelial cell-related genes and the development of Coogan-Reese syndrome. The role of mutations in genes regulating endothelial cell adhesion, proliferation, and apoptosis is currently under investigation [77].

Role of Viral Infections: The association between herpes simplex virus [HSV] and Epstein-Barr virus [EBV] with ICE syndromes suggests a possible viral-mediated mechanism in endothelial cell dysregulation. Further studies using viral DNA/RNA sequencing and immunohistochemical analysis of corneal tissues could clarify the role of viral infection in triggering disease onset [78].

Molecular Pathways in Endothelial Cell Transformation: Research into the molecular mechanisms underlying corneal endothelial cell migration and proliferation is crucial for developing targeted therapies. Potential areas of interest include exploring the involvement of TGF-β signalling, endothelial-mesenchymal transition [EMT], and matrix metalloproteinases [MMPs] in disease progression [79,80].

Emerging Therapeutic Approaches

Current treatments for Coogan-Reese syndrome primarily focus on managing intraocular pressure [IOP] and preventing complications like secondary glaucoma. However, novel therapeutic strategies targeting the underlying disease process are being explored.

Targeted Pharmacological Therapy

Rho-Kinase [ROCK] Inhibitors: These medications, such as ripasudil and netarsudil, have shown promise in improving aqueous outflow and reducing intraocular pressure. Future research may evaluate their role in modifying endothelial cell behaviour to prevent disease progression [81].

Anti-Fibrotic Agents: Since ICE syndromes involve abnormal endothelial fibrosis, drugs targeting fibrotic pathways [such as pirfenidone or anti-TGF-β therapies] could be investigated for their potential to slow disease progression [82].

Anti-Viral Therapies: Given the suspected viral etiology, long-term antiviral therapy [e.g., valganciclovir or acyclovir] may be considered for patients with a history of viral infections to prevent further endothelial damage [83].

Stem Cell Therapy and Regenerative Medicine

- Research into corneal endothelial cell regeneration using induced pluripotent stem cells [iPSCs] or ex vivo cultured endothelial cells holds promise for future treatment options [84].
- Tissue-engineered endothelial cell grafts or gene-edited endothelial transplants could potentially restore normal corneal function in advanced cases [85].

Gene Therapy and RNA-Based Interventions

- Advances in gene-editing technologies like CRISPR-Cas9 may offer potential solutions for correcting genetic mutations associated with ICE syndromes [86].

- RNA-based therapies, such as small interfering RNA [siRNA] or antisense oligonucleotides, could be designed to target specific molecular pathways involved in endothelial cell proliferation [87].

Minimally Invasive Glaucoma Surgery [MIGS]

- MIGS procedures, including microstents and canaloplasty, are being increasingly explored as safer and less invasive alternatives to traditional trabeculectomy for glaucoma associated with Coogan-Reese syndrome [88].
- Future advancements in implantable microdevices with sustained drug delivery mechanisms could offer long-term IOP control with minimal surgical risks [89].

CONCLUSION

Coogan-Reese syndrome is an uncommon yet severe subtype of Iridocorneal Endothelial [ICE] syndrome, distinguished by the presence of iris nodules, corneal endothelial dysfunction, and secondary glaucoma [90]. This rare condition presents a considerable diagnostic and therapeutic challenge due to its progressive nature and the complex interplay of ocular structures involved. The progressive damage to the corneal endothelium and the development of glaucoma can lead to significant visual impairment if not promptly and effectively managed [91]. Early diagnosis and proactive management are critical to preserving vision and minimizing complications. Diagnosis often relies on clinical examination and imaging modalities, such as anterior segment optical coherence tomography [AS-OCT] or specular microscopy, which aid in identifying characteristic changes in the corneal endothelium and iris architecture. Therapeutic strategies primarily focus on controlling intraocular pressure [IOP] to mitigate glaucoma-related damage, typically through medical therapy, laser procedures, or surgical interventions like trabeculectomy or glaucoma drainage devices [92]. Corneal edema resulting from endothelial dysfunction often necessitates corneal transplantation, such as Descemet's stripping endothelial keratoplasty [DSEK] or penetrating keratoplasty [PKP], particularly in advanced cases. Despite these interventions, long-term outcomes may remain guarded due to the progressive and recurrent nature of the disease [93]. While current management is largely palliative, aimed at stabilizing IOP and addressing corneal complications, there is growing interest in advancing treatments through a better understanding of the underlying pathophysiology [94]. Research into endothelial cell therapy, regenerative medicine, and the molecular mechanisms driving ICE syndromes offers hope for novel, more effective therapies in the future. Emerging technologies, such as tissue-engineered corneal grafts and targeted gene therapy, may revolutionize the care of patients with Coogan-Reese syndrome, potentially improving both visual outcomes and quality of life [95].

Methods for Locating, Selecting, Extracting, and Synthesizing Data

In the preparation of this review article on Coogen-Reese Syndrome, a structured and comprehensive approach was utilized to gather, evaluate, and synthesize relevant information from a diverse range of scientific sources. A systematic search strategy was implemented across multiple established scientific databases, including PubMed, Google Scholar, and Scopus, to ensure the inclusion of high-quality, peer-reviewed articles. The search terms used encompassed a broad spectrum of relevant phrases, such as “Coogen-Reese Syndrome,” “clinical features of Coogen-Reese,” “genetic basis of Coogen-Reese,” and “treatment of Coogen-Reese,” which were combined in various ways to maximize the retrieval of pertinent literature. To ensure that only the most relevant and reliable sources were included in the review, specific inclusion and exclusion criteria were applied during the selection process. The inclusion criteria prioritized peer-reviewed articles, case reports, and clinical studies that provided in-depth insights into the pathophysiology, diagnosis, treatment, and outcomes of Coogen-Reese Syndrome. Special attention was given to studies that focused on both adult and pediatric populations diagnosed with the disorder. Articles that presented original data, systematic reviews, or meta-analyses were considered most relevant and were given preference during the selection process. Conversely, exclusion criteria were set to eliminate sources that were not directly related to Coogen-Reese Syndrome. Studies focusing on unrelated ocular or systemic disorders were excluded, as well as articles published in languages other than English due to the language limitations of the review process. Additionally, opinion pieces and unpublished data lacking peer review or clinical evidence were excluded to

maintain the rigor and quality of the sources considered. This comprehensive approach ensured that the literature included in the review was not only relevant and scientifically sound but also provided a broad and balanced view of the current understanding of Coogen-Reese Syndrome. By systematically gathering and synthesizing data from a range of sources, this review offers a thorough and up-to-date summary of the clinical, genetic, and therapeutic aspects of this rare ocular disorder.

ABSTRACT

This project investigates the formulation and evaluation of antioxidant-based topical products: a cream, lotion, and gel face wash. The aim is to develop formulations with enhanced antioxidant properties to combat oxidative stress in the skin, contributing to improved skin health and appearance. The different pharmaceutical formulations are prepared with synthetic chemicals but there are side effects. Herbal formulation is safer and having customer acceptability. That's why we are formulating the antioxidant cream, gel. and facewash there may be other herbal formulations but formulation with pineapple is less.
The aim is to develop formulations with enhanced antioxidant properties to combat oxidative stress in the skin, contributing to improved skin health and appearance. The formulations were prepared using Bromelain, isolated from pineapple with an antioxidant property. Each formulation was designed to suit all skin types and applications. The cream is for intense hydration and long-lasting effects, the lotion is for light and non-greasy application, and the gel face wash is for an effective cleansing effect. The products were subjected to physicochemical tests to assess stability, pH balance, viscosity, and antioxidant capacity. In vitro assays, such as DPPH, are used to measure antioxidant activity. Additionally, preliminary skin irritation tests and sensory evaluations were performed to confirm the safety and acceptability of the products. All three formulations demonstrated good stability and acceptable pH levels. The antioxidant activity varied among the products. The cream was rich and

moisturizing, suitable for dry skin. The lotion provided moderate hydration with a lighter feel, making it suitable for normal skin. The gel face washes effectively cleansed while providing antioxidant benefits, suitable for all skin types. The antioxidant cream, lotion, and gel face wash successfully incorporated antioxidants and showed potential results. Further studies could focus on optimizing the formulations and testing their effectiveness through long-term use.

Keywords: *Ananas comosus*, antioxidant property, moisturizing cream, lotion, gel face wash.

INTRODUCTION

Pineapple is a tropical fruit, a member of the Bromeliaceae family. It is mostly consumed raw but can also be processed into juice, drinks, jams, and jellies (1). The *Ananas comosus* is a herbaceous perennial that may reach heights of 1.0 to 1.5 meters (3.3 to 4.9 feet), while it can occasionally reach much higher heights. The plant itself is visually striking, with a short, stocky stem and stiff, waxy leaves (2). When it blossoms, the separate fruits of the flowers come together to form a pineapple. Commercial growers "Following the first fruit, the main stem's leaf axils produced side shoots, which are known as suckers by Commercial growers(3). Pineapple is one of the most beneficial fruits for producing value-added compounds such as antioxidants, organic333 aci33ds, bromelain, Sesquiterpene, and phenolic compounds, according to its physicochemical makeup and nutritional value (4). Pineapple stems are the source of the potent chemo-responsive proteolytic enzyme bromelain. It is isolated and purified using various techniques and contains several thiol endopeptidases (5). Though scientists have also shown that it has antibacterial and anticancer properties, it is most typically utilized as an anti-inflammatory medication. (6)

MATERIALS USED

DPPH Solution, Bee wax, Methyl Paraben, Glycerin, Petroleum Jelly, Tween 80, SLS, Carpool 934, Borax, Liquid Paraffin, Rose Oil, Castor Oil, Cetyl Alcohol, Sodium Benzoate, Triethanolamine, Ethanol were taken from different manufacturer like Sigma Aldrich, Nice Chemicals, CDH Ltd, Loba Chemicals, Himedia, Changshu Song sheng, Fine chemical. Different Instruments are used like Lyophilizer Labard Instruchem, Centrifuge Machine, Vinayak Enterprise, Magnetic Stirrer, Remi, Electronic Balance, Mettler Toledo MF204, pH meter, IR Spectroscopy, Bruker Alpha II, BOD incubator, Vinayak Enterprise, Brookfield Viscometer, AMETEK Brookfield, Hot air Oven, Vinayak Enterprise.

METHODS

Preparation of extract

Fresh fruit of pineapple (*Ananas comosus*) was purchased from the markets in and around Barasat, West Bengal, India. Slices of the pineapple peels were removed. Next, chop the core from the pineapple into small pieces. These small pieces were put into the mixer grinder for smashing. After complete smashing the extract was filtered through a gauge. The filtrate of pure juices of pineapple is collected in a container. The extracted juice is subjected to Lyophilization for 3 days and we get a shiny and sticky substance (7).

Antioxidant Study of Pineapple Extract

Ethanol was added into the filtered juice at 1:4 ratio and stored for 8h at 8°C then centrifuged at 15000RPM for 25 min. Obtained Sediment was dried at 30°C. 40 µg/mL DPPH solution was prepared and absorbance was measured at 200-400 nm. Five different concentrations of Vitamin C solution and pineapple extract were added into 40 µg/mL DPPH solution. Mix it properly. Then the mixture was placed in a dark cabinet for 30 minutes. The absorbance was

checked at 517 nm by using UV- VIS spectrophotometer. The blank solution was Ethanol. Percentage of inhibition activity was performed by using formula (8).

% of inhibition = (ADPPH - Asample / ADPPH) × 100% Preparation of cream

All water-soluble ingredients (Table 1) (Borax, and pineapple extract) dissolved in water, serving as an Aqueous phase. All ingredients (Bees wax and Liquid paraffin) which were oil soluble mixed at 75°C±5°C in separate beakers. The oil phase was then poured into the aqueous phase slowly with vigorous stirring. Finally, other ingredients like Rose oil and preservatives were added with continuous mixing (9). The cream that was prepared is shown in Fig 1.

Determination of antioxidant capacity of cream

Cream was dissolved in ethanol and three different concentrations of Cream and Vitamin- C solution. 40 µg/mL DPPH solution was made and absorbance was checked at 200-400 nm. After that, three different concentrations of Cream solution and Vitamin- C solution were added into the DPPH solution and incubated for 30 min at 30˚C. The absorbance of the solution was measured at 517 nm using a UV-visible spectrophotometer. Ethanol was used as a blank. The free radical scavenging activity was calculated using the following formula (10).Figure 1(a) represents the pineapple cream.

% of inhibition = (ADPPH - Asample / ADPPH) × 100%

Preparation of Lotion

The ingredients used in the preparation of cream are listed in Table 2. Oil in water(O/W) emulsion of 1% and 2% of drugs were prepared (11). The emulsifier (glyceryl monostearate) and other components which are oil soluble components i.e sunflower oil, (mineral oil, cetyl alcohol petroleum jelly) were dissolved in the oil phase (part A) and heated up to 80℃. Extract and water-soluble components glycerine, propylparaben. methylparaben, were solubilized in (part B) and heated up to 80˚C. Once heated, Until the emulsifier cooled, the aqueous phase was gradually added to the oil phase while being continuously stirred. (12). When the temperature dropped to 45˚C, the perfume was added. Figure 1(b) represents the pineapple cream.

Determination of antioxidant capacity of lotion

Lotion was dissolved in ethanol and prepare three different concentrations of Lotion and Vitamin- C solution. 40 µg/mL DPPH solution was prepared and absorbance was measured at 200-400 nm. After that, three different concentration of Lotion solution and Vitamin- C solution was added into the DPPH solution and incubate for 30 min in 30˚C. The absorbance of the solution was measured at 517 nm using a UV-visible spectrophotometer. The blank was ethanol. Using the formula below, the percentage of scavenging activity was determined. (10,13)

% of inhibition = (ADPPH - Asample / ADPPH) × 100%

Preparation of Gel face wash

The ingredients used in the preparation of cream are listed in Table 3. Carbopol 934 was dissolved in distilled water and left overnight for shock. After that extract, Sodium Lauryl Sulphate (SLS) / Tween 80 and preservative was added with continuous stirring. Then Triethanolamine was added as a pH adjuster(14).The figure 1(c) represents the gel face wash.

Determination of antioxidant capacity of gel face wash

40 µg/mL DPPH solution was prepared and absorbance was measured at 200-400 nm. Three different concentrations of Vitamin C solution and gel face wash solution were added into 40 µg/mL DPPH solution. Mix it properly. After that, the mixture was incubated for half an hour. At 517 nm, the absorbance was determined using a UV-VIS spectrophotometer. The blank solution was Ethanol. Percentage of scavenging activity was calculated by using formula (10, 13)

% of inhibition = (ADPPH – A sample / ADPPH) × 100%

Evaluation of Cream

Sensory assessment of cream

The formulated cream was evaluated at time of preparation by its organoleptic properties lick color, odor texture etc (15). Results are listed below Table. 4.

Determination of pH cream

Digital pH meter was calibrated using standard buffer solution.0.5 g cream was dissolved in 50 ml distilled water and determined the pH (16).

Determination of Viscosity of cream

The viscosity of the cream formulation was determined by Brookfield viscometer by using LV- 4 spindle. The adaptor was filled with the cream formulation and viscosity was measured.

Spread ability studies of cream

The spread ability refers to a cream's ability to cover the skin evenly. This quality is determined by the amount of time, in seconds, it takes for two slides to glide off the cream, held between them, under a specified weight. The faster the two slides separate, the better the Spread ability. Two pairs of standard-sized glass slides were collected. After that, a slide of appropriate size was chosen and the cream mixture was applied to the slide (17). Next, another slide was positioned on top of the mixture. After that, a weight or specific load was added to the top slide to evenly press the cream between the two slides into a thin. Next, the weight was taken off and any extra formulation sticking to the slides was scraped away. The weight attached to it allowed the upper slide to slip off freely due to gravity. The duration for the upper slide to slide off was recorded. The data was presented in table 4.(18)

Spreadability = (m*l)/t
m = weight tied to the upper slide (2g)
l =length of glass slide (7.5cm)
t =time taken in seconds.

Stability Studies of Cream

Stability testing of drug products begins as a part of drug discovery and ends with the demise of the compound or commercial product. To assess the drug and formulation stability, stability studies were done. The ICH guidelines were followed for conducting the stability investigations. The cream is placed in a bottle and stored for two months at 40 ± 2 °C and 75 ± 5% relative humidity. Samples were examined for viscosity and physical characteristics at the conclusion of the investigations (19). The Spreadability of the cream is tabulated in table 5.

Homogeneity of cream

Through touch and visual inspection, the homogeneity of the formulations was evaluated.

Removal of cream

The cream's ease of removal was assessed by using tap water to wash the region that received the cream application.

After feel effect of cream

After applying a certain quantity of cream, the degree of emolliency, slipperiness, and residue were assessed.

Evaluation of Lotion

Organoleptic evaluation lotion

The formulated lotion was evaluated by its organoleptic properties lick color, odor texture etc.

Determination of pH

Digital pH meter was calibrated using standard buffer solution. 0.5 g lotion was dissolved in 50 ml distilled water and determined the pH.

Determination of Viscosity

The viscosity of the lotion formulation was determined by Brookfield viscometer by using LV- 4 spindle. Lotion formulation was poured into the adaptor and viscosity was measured

Spreadability refers to a lotion's ability to cover the skin evenly

This quality is determined by the amount of time, in seconds, it takes for two slides to glide off the lotion, held between them, under a specified weight. The faster the two slides separate, the better the Spreadability. Two pairs of standard-sized glass slides were collected. After that, a slide of appropriate size was chosen and the lotion mixture was applied to the slide. Next, another slide was positioned on top of the mixture. After that, a weight or specific load was added to the top slide to evenly press the lotion between the two slides into a thin layer. The data are depicted in Table 7. Next, the weight was taken off and any extra formulation sticking to the slides was scraped away. The weight attached to it allowed the upper slide to slip off. The duration for the upper slide to slide off was recorded (20).and ends with the demise of the compound or commercial product. To assess the drug and formulation stability, stability studies were done. The stability studies were carried out as per ICH guidelines. The lotion is filled in a bottle and kept in a humidity chamber maintained at 40 ± 2 °C / 75 ± 5 % RH for two months. At the end of studies, samples were analyzed for the physical properties and viscosity. The Spreadability of the lotion is tabulated in table 5.

Homogeneity

Through touch and visual inspection, the homogeneity of the formulations was evaluated.

Removal

By using tap water to wash the area where the lotion was applied, the lotion's ease of removal was assessed.

After feel

After applying a certain quantity of lotion, the degree of emolliency, slipperiness, and residue were assessed.

Greasiness

In this instance, the lotion was applied to the skin's surface as a smear, and its oiliness or grease- like consistency was assessed.

Evaluation of Gel face Wash

Organoleptic evaluation

The formulated gel face wash was evaluated by its organoleptic properties lick colour, odour texture etc.

Determination of pH

Digital pH meter was calibrated using standard buffer solution. 0.5 g gel face wash was dissolved in 50 ml distilled water and determined the pH.

Determination of Viscosity

The viscosity of the gel formulation was determined by Brookfield viscometer by using LV-4 spindle. gel formulation was poured into the adaptor and viscosity was measured.

Stability Studies of Gel Face wash

Drug product stability testing starts during the drug discovery process and concludes when the chemical or commercial product degrades. Stability studies were conducted to evaluate the stability of the medication and

formulation. The ICH guidelines were followed for conducting the stability investigations. The cream is placed in a bottle and stored for two months at 40 ± 2 °C and 75 ± 5% relative humidity. Samples were examined for viscosity and physical characteristics at the conclusion of the investigations. The Spreadability of the lotion is tabulated in table 5.

Homogeneity
Through touch and visual inspection, the homogeneity of the formulations was evaluated.

Removal
By using tap water to wash the area where the gel face was applied, the gel has ease of removal was assessed.

After feel
After applying a certain quantity of gel face wash, the degree of emolliency, slipperiness, and residue were assessed.

RESULT

According to the literature review, the DPPH solution's maximum wavelength was 517 nm. The DPPH solution was changed to reveal antioxidant activity (21). The DPPH solution turns from purple to yellow, and the color's intensity increases and is directly correlated with the moles of the stabilized molecule present. Stability testing of drug products starts with drug discovery and ends with the demise of the compound or commercial product. Antioxidants derived from plants, such as bromelain, shield the body against illnesses caused by free radicals with minimal to no adverse effects. By stopping the oxidative chain reaction, which prevents oxidative damage, antioxidants reduce oxidative stress (22). The antioxidant activity of vitamin C and crude pineapple extract is presented in Table 6. The DPPH solution's color changes from purple to yellow, and the amount of the stabilized molecule present exactly correlates with how intense the color is. Antioxidants derived from plants, such as bromelain, shield the body against illnesses caused by free radicals with minimal to no adverse effects. By stopping the oxidative chain reaction, which prevents oxidative damage, antioxidants reduce oxidative stress (23). Table 6: Determination of antioxidant activity of vitamin C and Crude Pineapple extract

Determination of antioxidant capacity of lotion
The color of the DPPH solution transitions from purple to yellow, with the intensity of the color being directly correlated with the moles of the stabilized molecule present. Antioxidants derived from plants, such as bromelain, shield the body against illnesses caused by free radicals with minimal to no adverse effects. By stopping the oxidative chain reaction, which prevents oxidative damage, antioxidants reduce oxidative stress (24, 25). The data are depicted in table no 09. Antioxidants derived from plants, such as bromelain, shield the body against illnesses caused by free radicals with minimal to no adverse effects. Antioxidants reduce oxidative stress by stopping the oxidative chain reaction, which prevents oxidative damage (26).

Determination of pH of the cream
The pH of the cream was shown to be between 6.4 and 7.9, which is a suitable range for the pH of skin. All of the lotion formulations had pH values that were closer to skin pH. The results are listed below in Table 8.

Determination of viscosity of cream
The cream's viscosity, which ranged between 40000 and 33000 cps, suggests that it may be readily distributed with little shear. The viscosities of the all three formulations are given in Table 8.

Homogeneity of cream
The extracts are distributed uniformly throughout the cream in all formulations, which is determined by touch and visual appearance.

Removal of cream

All three cream formulation was applied on the skin and were easily removed by washing with tap water.

After feel effect of cream. The change of different organoleptic properties of different formulation are shown in Table 9. The amount of residue left behind, the cream's emolliency, and its slipperiness were all deemed satisfactory after application.

Determination of pH of the lotion

The lotion's pH was found to be between 6.4 to 7.6, which is a suitable range for the pH of skin. All of the lotion formulations had pH values that were closer skin pH. The result is listed below.

Determination of viscosity of lotion

The lotion's viscosity, which ranged between 150000 and 380000 cps, suggests that it may be readily distributed with little shear. The viscosity of the all three formulations is given in Table.

Homogeneity lotion

The extracts are distributed uniformly throughout the lotion in all formulations which is determined by touch and visual appearance.

Removal of lotion

All three lotions applied on skin were easily removed by washing with tap water.

After feel effect of lotion

After applying the lotion, it was determined that the emolliency, slipperiness, and amount of residue left were all satisfactory.

Determination of viscosity of gel face wash

The viscosity of the gel face wash, which ranged between 5209 and 5630 cps, suggests that it may be readily distributed with little shear.

Homogeneity of gel face wash

The formulations are distributed uniformly throughout the gel face wash in all formulations which is determined by touch and visual appearance.

Removal of gel face wash

The all three gel applied on skin was easily removed by washing with tap water.

After feel of gel face wash

Washing with tap water made it simple to remove all three gels that had been applied to the skin.

Following gel face wash feel: Following gel face wash application, it was found that the amount of residue left, emolliency, and slipperiness were all acceptable.

FTIR Study

From the FTIR Spectrum of Crude Bromelain the peak was observed at 3328.81 cm^{-1} which represents N-H bond and represents amino group and having enzyme or protein in nature (27). The 2124.10 cm^{-1} peak shows presence of C≡C triple bond which represents alkyne group contain organic compound like monounsaturated hydrocarbon and 1635.89 cm^{-1} peak shows presence of C=N or cyano or nitrile group containing compound like amine, imine and nitrile compound (28).

The FTITR study of Cream

The pineapple cream F1 shows peak at 2920.27 cm^{-1} and 2851.66 cm^{-1} which represents presence of Strong OH bond containing compound like aldehyde, carboxylic acid or ketone and incorporation of that group with amino group (29). The next peak shows at 1461.67 cm^{-1} and 1376.87 cm^{-1} which shows presence of aromatic benzene ring which is the mother molecule of every compound. The 720.75 cm^{-1} peak shows presence of C-H (methyl group) containing compound (30). The pineapple cream F2 shows peak at 2918.98 cm^{-1} and 2850.72 cm^{-1} which reflect the presence of C-H stretching which suggests that the presence of Aliphatic hydrocarbons means the presence of compounds such alkenes(31).At peak 1736.89 cm^{-1} represent C=O stretching which indicates the presence of esters, aldehydes, ketones, or carboxylic acids. The next peak shows at 1462.09 cm^{-1} and 1376.89 cm^{-1} which shows presence of aromatic benzene ring which is the mother molecule of every compound. The C-O stretches at 1279, 1167, and 1048 cm^{-1} further indicate functional groups such as esters or ethers.

The 720.33 cm^{-1} peak shows presence of C-H methyl group containing compound (32)

The IR spectrum suggests the presence of Free hydroxyl groups (3778 cm^{-1}) and amine groups (3339 cm^{-1}), indicating isolated alcohols or phenols and primary or secondary amines or amides, respectively. Aliphatic hydrocarbon chains (2923 and 2854 cm^{-1}), suggesting the presence of methylene and methyl groups. The presence of Carbonyl group (1715 cm^{-1}), characteristic of esters, ketones, or aldehydes. C-O stretching at 1106 and 1035 cm^{-1} pointing to alcohols, ethers, or esters (33). The IR spectrum of Pineapple lotion F2 suggests the presence O-H stretching at 3774.82 cm^{-1} is associated with alcohols and phenolic substances (34). At 3353.21 cm^{-1} presence of N-H stretching indicate that the presence of primary amines. C=O stretching at 1641.06 cm^{-1} indicate the presence of amides. The IR spectrum suggests that the sample likely contains hydroxyl groups (indicating alcohols or phenols), aliphatic hydrocarbons (alkanes), carbonyl groups (ketones, aldehydes, carboxylic acids, or esters), alkenes or aromatic rings, and ethers or esters. The broad and strong O-H peak, along with the distinct carbonyl and C-H stretching vibrations.

FTIR Spectrum of Pineapple Gel Face Wash (F1)

FTIR spectrum of Pineapple Gel Face Wash (F1) shows the broad peak around 3300 cm^{-1} suggests the presence of O-H stretching vibrations, typical of hydroxyl groups found in alcohols or phenols. Aliphatic hydrocarbons are indicated by the peak close to 2920 cm^{-1}, which is typical of C-H stretching vibrations. The strong and sharp peak around 1633 cm^{-1} corresponds to C=O stretching vibrations, which is typical of carbonyl groups present in compounds such as ketones, aldehydes, carboxylic acids, or esters. The IR spectrum displays the broad absorption around 3347 cm^-1 suggests the presence of hydroxyl (O-H) groups, typical of alcohols or phenols. Aliphatic hydrocarbons are shown by the peak near 2926 cm^-1, which corresponds to C-H stretching vibrations. C=O stretching vibrations are characterized by a strong peak at about 1633 cm^-1, which indicates the presence of carbonyl groups such as those found in ketones, aldehydes, carboxylic acids, or esters. Additional peaks around 1031 cm^-1 suggest C-O stretching vibrations, indicating the presence of ethers or esters(35).

FTIR Spectrum of Pineapple Gel Face Wash (F3)

The FTIR spectrum shows key absorption peaks at 3346.86 cm^{-1}, 2360.41 cm^{-1}, 1632.39 cm^{-1}, 1214.47 cm^{-1}, and 692.23 cm^{-1}. The prominent broad peak around 3346.86 cm^{-1} typically indicates O-H or N-H stretching, suggesting the presence of alcohols, phenols, or amines. The peak near 2360.41 cm^{-1} could be attributed to C≡N stretching or CO_2. The peak at 1632.39 cm^{-1} is likely due to C=O stretching vibrations from carbonyl groups or amide bands. The peak at 1214.47 cm^{-1} suggests C-O stretching, possibly from esters, ethers, or carboxylic acids(36).

DISCUSSION

This study successfully formulated and evaluated three antioxidant skincare products: a cream, lotion, and gel face wash, utilizing pineapple extract for its antioxidant properties. The aim was to assess and compare the antioxidant capacity, pH, viscosity, and stability of each formulation. The antioxidant capacity of the formulations was determined using IC_{50} values, which reflect the concentration required to inhibit 50% of free radicals. The IC_{50} value

for the pineapple extract was shown to be 41.67 μg/mL. With an IC_{50} value of 44.10 μg/mL, the lotion had the highest antioxidant capacity among the developed formulations, closely approximating the antioxidant strength of the pineapple extract itself. The gel face wash followed with an IC_{50} value of 47.19 μg/mL, demonstrating substantial antioxidant activity. The cream, while effective, showed a slightly lower antioxidant capacity with an IC_{50} value of 50.84 μg/mL. These results suggest that the lotion is the most effective in retaining antioxidant properties, making it potentially beneficial for enhancing skin protection against oxidative stress. The pH and viscosity of the formulations were also evaluated to ensure compatibility with the skin and ease of application. The cream exhibited a pH range between 6.4 to 7.9 and a viscosity range of 33,000 to 40,000 cps, indicating that it is well-suited for skin application and can be easily distributed with moderate shear. The lotion, with a pH range from 6.4 to 7.6 and a higher viscosity range of 150,000 to 380,000 cps, offers a thicker consistency, which is ideal for more intensive miniaturization. The gel face wash had a pH range of 6.4 to 7.5 and a lower viscosity range of 5,209 to 5,630 cps, suggesting it is easily spreadable and suitable for cleansing while maintaining compatibility with the skin's natural pH balance (37). FTIR (Fourier Transform Infrared) spectroscopy provided further insights into the chemical composition of the formulations, confirming the presence of functional groups associated with antioxidant activity. The cream showed peaks indicating the presence of aldehyde, carboxylic acid, ketone, aromatic benzene ring, and methyl groups. The lotion's FTIR spectrum revealed hydroxyl, amine, carbonyl, and aliphatic hydrocarbon chains. The gel face wash demonstrated the presence of hydroxyl, aliphatic hydrocarbons, and carbonyl groups, supporting the incorporation of antioxidant compounds.

CONCLUSION

In conclusion, this project demonstrated that the formulated cream, lotion, and gel face wash successfully utilized the antioxidant properties of pineapple extract, each offering distinct benefits for skin care. The lotion showed the highest antioxidant capacity among the products, suggesting it can effectively protect the skin from oxidative damage. The cream, with moderate antioxidant activity and excellent moisturizing properties, is particularly suitable for dry skin. The gel face wash provides effective cleansing while offering antioxidant protection, making it suitable for daily use on various skin types. These formulations offer a range of options for different skincare needs and preferences, contributing valuable antioxidant benefits. Overall, this project highlights the potential of pineapple extract in developing antioxidant-rich skincare products. Future studies could focus on evaluating the long-term effectiveness and user satisfaction of these formulations to further improve and adapt them for wider use.

ABSTRACT

AIM: To estimate and compare the incidence of post operative pain after irrigation activation using Conventional needle irrigation , Passive ultrasonic irrigation (PUI) and Sonic irrigation methods during root canal therapy using Visual Analogue Scale. Thirty patients with symptomatic irreversible pulpitis in maxillary or mandibular molars were selected for the study. The teeth were randomly assigned to three groups depending on the final irrigation technique applied. In Group 1 (conventional needle irrigation), a 27-gauge needle was used to perform the irrigation. In Group 2, Sonic agitation was done using endoactivator (Dentsply). It is device operating at 10,000 rpm and 3-5 mm vertical strokes. In Group 3, Passive ultrasonic irrigation was done using an ultrasonic device (Satelec). The tips in all groups were fitted 2mm short of working length. Volumes of 5ml 2.5% of NaOCl, 2ml 17% of EDTA, were used for 1 minute. Teeth were then obturated with gutta-percha and a resin containing sealer using the lateral compaction technique. Postoperative pain was evaluated at 6, 12, 24, and 48 hours, as well as after 1 week, using the Visual Analogue Scale (VAS). At 24 h, the severity of pain experienced by patients in the NI group was found significantly higher compared to the patients in the Sonic and Ultrasonic group ($P < 0.05$). Significant difference was found between groups at 24 h ($P < 0.05$). At 48 h pain continued to

decrease in all groups, the sonic irrigation group demonstrated lower values in VAS scale than the needle irrigation group. The highest PP scores were noted at 6 h in all groups and observed to diminish over time. At 6 h, 12h, 24 h and 48 hours, no significant difference was found among the groups in relation to pain intensity ($P > 0.05$). Within the limitations of the present study, the highest recording of Post op pain at the end of the 24th h was detected in the NI group and the lowest in the Sonic and Ultrasonic group. In all the irrigation methods, the pain showed a decrease after 24th h and the difference between the PP levels related to the irrigation methods disappeared. This study provides valuable insights into the effectiveness of different irrigation activation techniques in minimizing postoperative pain following root canal treatment. By identifying the most effective method, clinicians can improve patient comfort and treatment outcomes, contributing to enhanced patient satisfaction and adherence to endodontic procedures.

Keywords: Conventional needle irrigation, EDTA, Irrigation activation, Passive ultrasonic irrigation, Postoperative pain, Root canal treatment, Sodium hypochlorite, Sonic irrigation, Symptomatic irreversible pulpitis, Visual Analogue Scale,

INTRODUCTION

Successful endodontic treatment means effectively cleaning out the infected or dead pulp and removing any harmful microorganisms from the root canal system[1]. Clinically, it is defined by the lack of symptoms, sinus tract, swelling, and radiographically by normal periodontal ligament space or a progressive reduction in the size of the periapical radiolucency over follow-up periods[1]. The discomfort experienced following endodontic therapy is known as post-endodontic pain[1,2]. Both patients and dentists find it to be an uncomfortable scenario[1,2]. Post-treatment endodontic pain has been reported to occur in approximately 16% to 25% of cases. It usually appears in the first 24 to 48 hours following obturation and goes within few hours, however it can sometimes last for many days[2]. A number of factors can affect the likelihood of pain following root canal therapy: inadequate instrumentation; irrigant extrusion; intracanal dressing extrusion; hyperocclusion; missed canals; preoperative pain; periapical pathosis; apical debris extrusion; and apical patency at the time of root canal preparation[3]. Most authors used different endodontic materials and techniques, as well as varied criteria for defining and assessing post-endodontic pain. Pain perception is mainly subjective and variable. Because of its ease of use, the visual analogue scale (VAS) is frequently employed to describe the degree of pain. A 100-mm line with two endpoints representing no pain and the worst pain served as the VAS intensity rating[3]. Sodium hypochlorite (NaOCl) is frequently employed as an irrigant owing to its excellent antimicrobial activity and its effectiveness in breaking down organic matter. The activation of such irrigant using different techniques makes the areas that are difficult to access such as curved canals, dilacerated canals, calcified canals easily accessible. Conventional manual irrigation using a syringe and needle has been shown to be ineffective at delivering irrigant to places with limited access, like the apical and isthmus regions[3,4]. Passive ultrasonic irrigation (PUI) involves moving an ultrasonic tip that has been placed inside the canal, 2 mm short of the WL, passively up and down so as not to bind with the root canal walls[3,4]. The Endo Activator tips increase the activity of irrigation solutions without causing any dentin cutting The tips enables the safe activation of intracanal solutions and has the ability to activate intracanal fluid[3,4]. The purpose of this study is to evaluate and compare the incidence of postoperative pain with the application of conventional needle irrigation, passive ultrasonic irrigation, endoactivator during root canal therapy.

MATERIALS AND METHODS

This study was conducted in the Department of Conservative Dentistry and Endodontics, RDC,Loni after IEC approval.

Inclusion Criteria

- Teeth with symptomatic irreversible pulpitis (pulp vitality test will be done using EPT)
- Fully mature multirooted teeth. (will be assessed radiographically and clinically)
- Age: 18 to 65 years
- Systemically healthy patients
- Teeth with enough crown structure for adequate isolation
- Restorable teeth undergoing endodontic treatment

Exclusion Criteria

- Patients with systemic diseases, including diabetes, auto-immune disease, and cancer.
- Immunodeficient Patients
- Teeth with calcified canals, root resorption, immature/open apex, or previous root canal treatment.
- Teeth with severe damage.
- Teeth presenting with a sinus tract or associated periapical abscess
- Patients who have previously taken any medication.

A preoperative radiograph was taken to examine the periodontal and periapical tissues. The procedure began with the administration of local anesthesia, followed by rubber dam isolation of the teeth. Carious lesions were eliminated, and conventional access to the root canal system was achieved with diamond burs under continuous water irrigation. An apex locator was used to determine the working length (WL), which was subsequently verified by digital radiography using a 10k initial apical file. Initial filing was performed up to 25k hand files, followed by rotary filing of each canal using the Hero Gold Rotary file system. The instrumentation sequence followed the manufacturer's guidelines and involved using 4% taper files in sizes 20, 25, and 30, followed by 6% taper files in sizes 20, 25, and 30, in a crown-down technique. Copious irrigation was performed between the use of each file with 2.5% sodium hypochlorite and normal saline. A final rinse with 17% EDTA was used to irrigate all root canals for one minute, and they were then dried with sterile paper points. Thirty patients with maxillary or mandibular molars diagnosed as symptomatic irreversible pulpitis were selected. "The allocation of teeth into three groups was done randomly, based on the final irrigation procedure applied."

Group1: Conventional needle activation (control group).

Group2: Passive ultrasonic activation.

Group3: Sonic activation (Endoactivator)

In Group 1 Conventional needle irrigation was used, employing a 27-gauge needle.

In Group 2 Sonic agitation was done using endoactivator (Dentsply). It is device operating at 10,000 rpm and 3-5 mm vertical strokes.

In Group 3 Passive ultrasonic irrigation was done Using an ultrasonic device (Satelec)

The tips in all groups were inserted 2mm short of working length

Volumes of 5ml 2.5% of NaOCl, 2ml 17% of EDTA, were used for 1 minute

Teeth were then obturated with gutta-percha and a resin-based sealer using the lateral compaction technique

Postoperative pain was evaluated at intervals of 6, 12, 24, and 48 hours, as well as after one week, using the Visual Analogue Scale (VAS).

Patients to be asked to describe their pain experience using one of five well defined categories as

0-No PAIN

1-3- Mild pain

3-5- Moderate pain

5-9- Severe pain

10- Worst possible pain

RESULTS

- At 24 h, the severity of pain experienced by patients in the NI group was found significantly higher compared to the patients in the Sonic and Ultrasonic group ($P < 0.05$). Significant difference was found between groups at 24 h ($P < 0.05$)
- At the 48-hour mark, the sonic irrigation group demonstrated a significantly lower VAS score compared to the needle irrigation group.
- The highest PP scores were noted at 6 h in all groups and observed to diminish over time.
- At 6 h, 12h, 24 h and 48 hours, no significant difference was found among the groups in relation to pain intensity ($P > 0.05$).
- **6 hours**: All groups experienced the highest pain, with no statistically significant difference.
- **12 hours**: Pain began to decrease in all groups, with no significant difference among them.
- **24 hours**: Needle Irrigation (NI) group had significantly higher pain than Sonic and Ultrasonic groups ($P < 0.05$).
- **48 hours**: Pain continued to decrease in all groups, showed a significantly lower VAS score in the sonic irrigation group than in the needle irrigation group.

DISCUSSION

Apical extrusion of debris or irrigants varies depending on the root canal irrigation method used. Any irrigation delivery system that minimizes the risk of extrusion into periapical tissues benefits both the patient and the clinician by reducing postoperative discomfort[7]. However, the available data regarding debris and irrigant extrusion using different irrigation methods are primarily limited to in vitro studies. Furthermore, to the best of our knowledge, no study has evaluated the effect of different irrigation agitation techniques on the incidence and severity of postoperative pain (PP) after root canal treatment (RCT) in symptomatic molar teeth. This study aimed to compare the effects of various irrigation agitation methods on PP severity following RCT. Postoperative pain (PP) is largely subjective and can be affected by a variety of factors. Measuring subjective variables presents a considerable challenge, leading to the use of various scales and methods to assess PP [8]. The Visual Analog Scale (VAS) (100 mm) ranging from 0 to 10 was used to measure PP intensity. The VAS is simple, valid, reliable, and widely used in previous studies evaluating PP after RCT [9,10]. To minimize errors, the scale was described in detail to patients, who were also assisted in recording preoperative pain conditions to ensure familiarity with the scale. Limitations in evaluating PP arise due to differences in study designs, including variations in preoperative tooth conditions and treatment protocols [11]. To address these concerns, only teeth diagnosed with symptomatic irreversible pulpitis treated in a single visit were included. The potential effects of infected necrotic pulps and the use of intracanal medicaments were excluded. Standardization was maintained across all groups, including the use of a consistent irrigation agitation technique. A previous study by Rodríguez-Figueroa *et al*. [12] compared irrigant extrusion using passive ultrasonic irrigation (PUI), the EndoActivator system, and needle irrigation (NI), concluding that PUI and EndoActivator tips positioned within 1 mm of the working length (WL) appeared to be relatively safe. Based on these findings, PUI and EndoActivator tips within 1 mm of the WL were used in this study. It is well established that radiologic and electronic root canal measurements may not always correspond [15]. In this study, WL determination was achieved using an electronic root canal length measurement device and confirmed radiologically. This approach helps clinicians confine preparation within the root canal system, reducing the risk of over-instrumentation, which is considered a primary factor in postoperative discomfort. Several studies suggest that variables such as age, sex, and preoperative pain significantly impact PP [16,17]. However, no significant differences among demographic variables and preoperative pain scores between the groups were found, allowing these factors to be excluded from consideration. PP scores following RCT were significantly higher in certain groups at the 6- and 24-hour time intervals, leading to the rejection of the null hypothesis. Previous studies have evaluated the extent of apical extrusion associated with different irrigation approaches.. Karataş *et al*. [18] compared the effects of NI, sonic activation (SA), and PUI on apical debris extrusion and found no significant differences among these methods. Yost *et al*. [19] assessed the extrusion of NaOCl using both the EndoActivator and a conventional needle, finding that both

methods resulted in comparable levels of extrusion. Azim *et al*. [20] compared the volumes of irrigants extruded apically using different irrigation methods in an artificial model simulating clinical conditions and found that NI and EndoActivator methods resulted in similar volumes of extrusion. Boutsioukis *et al*. [23] investigated the effects of PUI and SA on irrigant extrusion using a newly developed method. Pain scores were highest in all groups within the first 6 hours, followed by a significant reduction at subsequent observation intervals of 24, 48, and 72 hours, and at 7 days. This pattern aligns with previous studies examining the duration of PP after RCT [21, 22]. Further studies are necessary to evaluate the influence of additional variables on PP.

CONCLUSION

Within the limitations of the present study, the highest recording of Post op pain at the end of the 24th h was detected in the NI group and the lowest in the Sonic and Ultrasonic group. Across all irrigation techniques, pain levels decreased after 24 hours, and the differences in postoperative pain associated with each method were no longer evident.

List of abbreviations
PP – Postoperative Pain
PUI – Passive Ultrasonic Irrigation
VAS – Visual Analogue Scale
WL – Working Length
NI – Needle Irrigation
NaOCl – Sodium Hypochlorite
EDTA – Ethylene diaminetetra acetic Acid
RCT – Root Canal Treatment
EPT – Electric Pulp Testing
RCT – Root Canal Therapy
RPM – Rotations Per Minute
G – Gauge (Needle Size)
mm – Millimeter
h – Hours

ABSTRACT

This study evaluates the performance of three machine learning models Logistic Regression, Random Forest, and Support Vector Machine in predicting lung cancer risk based on demographic and lifestyle factors. Using a dataset of 60 individuals with features including age, smoking habits, alcohol consumption, and residential area quality, compare model performance through various metrics and provide comprehensive data visualizations. The Random Forest classifier demonstrated superior performance with 88.3% accuracy, SVM is 85%and Logistic Regression is 81.7%. Our findings predict that ensemble methods may be particularly effective for medical risk prediction tasks with moderate-sized datasets.

Keywords: Lung Dataset, Data Pre-processing, Logistic Regression, SVM, Random Forest.

INTRODUCTION

Lung cancer continues to be one of the most prevalent and deadly malignancies worldwide, accounting for a significant portion of cancer-related morbidity and mortality. While tobacco smoking remains the predominant risk factor, accounting for approximately 85% of cases, emerging research highlights the growing significance of environmental exposures, genetic predispositions, and lifestyle factors in lung carcinogenesis. Recent epidemiological studies demonstrate notable shifts in disease patterns, including increasing incidence rates among never-smokers and changing histological profiles. Concurrently, advances in screening modalities and the

implementation of tobacco control policies have shown promising results in early detection and prevention. This paper synthesizes current evidence on the multifactorial etiology of lung cancer, examines contemporary trends in disease epidemiology, and evaluates the effectiveness of various prevention and early detection strategies. The analysis aims to provide a comprehensive understanding of this complex disease and inform future public health initiatives and clinical approaches to reduce the global burden of lung cancer.

LITERATURE REVIEW

Siegel *et al*. (2023)provides an updated statistical overview of cancer incidence, mortality and survival rates in the United States. The authors highlight key trends in lung cancer, emphasizing the impact of smoking and early detection. The study serves as a comprehensive resource for understanding current cancer epidemiology and is widely cited in public health research. Islami *et al*. (2021) This study quantifies the proportion of cancer cases and deaths linked to modifiable risk factors, such as smoking, alcohol use, and obesity. The findings underscore the significant role of tobacco in lung cancer mortality and advocate for stronger preventive measures. The research supports policy interventions aimed at reducing exposure to carcinogens. Alberg *et al*. (2022)this review explores the epidemiology, diagnosis, and management of lung cancer. It discusses risk factors, including smoking and environmental exposures, and provides clinical guidelines for early detection. The study is a key reference for pulmonologists and oncologists. O'Keeffe *et al*. (2021) This meta-analysis in *BMJ Open* examines gender differences in lung cancer risk among smokers. The authors conclude that smoking poses a similar relative risk for both men and women, contradicting earlier beliefs about gender-based susceptibility. The study reinforces the universality of smoking-related lung cancer risks. Malhotra *et al*. (2021)this global study identifies smoking as the leading risk factor for lung cancer across diverse populations. It also highlights regional variations in lung cancer incidence linked to tobacco use patterns, air pollution, and occupational hazards. Jha and Peto (2022)This evaluates the global impact of smoking, cessation, and tobacco taxation on lung cancer rates. The authors argue that higher taxes and anti-smoking policies significantly reduce mortality, providing evidence for public health strategies. Tindle *et al*. (2021)Using data from the Framingham Heart Study, this research demonstrates that cumulative smoking exposure strongly predicts lung cancer risk, even among former smokers. The study emphasizes the long-term benefits of quitting smoking early. Bade and Dela Cruz (2020)This review in Clinics in Chest Medicine summarizes the latest findings on lung cancer etiology, with a focus on smoking and emerging risk factors like radon and genetic predispositions. It serves as a primer for clinicians. De Groot *et al*. (2021)This article discusses epidemiological shifts in lung cancer, including rising adenocarcinoma rates and the impact of screening programs. It highlights the need for targeted prevention strategies. Smith and Winstanley (2022)this study links stricter tobacco policies (e.g., advertising bans, smoke-free laws) to declines in lung cancer mortality. It provides empirical support for legislative action. Wakelee *et al*. (2021)This research focuses on lung cancer in never-smokers, identifying second hand smoke, radon, and genetic factors as key contributors. It challenges the stereotype that lung cancer only affects smokers. Pesch *et al*. (2022)A pooled analysis of case-control studies, this paper quantifies the risk of lung cancer subtypes (e.g., squamous cell, adenocarcinoma) associated with smoking intensity and duration. Thun *et al*. (2023)This study tracks 50-year trends in U.S. smoking-related mortality, showing declines due to reduced smoking rates but warning of persistent disparities among low-income populations. Travis *et al*. (2021)A landmark classification system for lung adenocarcinoma, endorsed by major respiratory and oncology societies. It standardizes diagnostic criteria for researchers and pathologists. Ezzati and Lopez (2022)This study estimates global deaths attributable to smoking in 2000, highlighting tobacco's role in preventable mortality and advocating for international tobacco control. Lortet-Tieulent *et al*. (2021)This study analyzes lung cancer trends by histological subtype, noting a rise in adenocarcinoma among women. It calls for gender-specific research on smoking and lung cancer.

RESEARCH METHODOLOGY

Data Collection

The dataset taken from kaggle, which is used to predict the lung disease detection. The dataset consists of Name, Surname, Age, Smoke, AreaQ, Alkhol and Result.

Data-Pre-processing

In figure 1, The dataset shown contains information on 59 individuals with 7 attributes for each. These attributes include personal identifiers such as Name and Surname, along with health-related and environmental factors like Age, Smokes, AreaQ , and Alkhol. Result is the target variable, indicates that lung disease affected means 1 and not affected means 0

Model Evaluation

In the model evaluation, the three models are compared for the prediction of the lung disease such as Logistic Regression, Random Forest, and Support Vector Machine (SVM). In this work, Random Forest shows the improved performance of among all the models. Its provide the better results in the performance of the evaluation of the model.

RESULTS AND DISCUSSIONS

Correlation Map

The Result (lung disease presence) has a strong positive correlation with Age (0.64), Alkhol (0.81), and Smokes (0.37), suggesting these features are significant contributors to predicting lung disease. In contrast, AreaQ has a strong negative correlation with Result (-0.75), implying that poorer air quality (lower AreaQ) is associated with a higher likelihood of disease. In figure 2, displays a feature correlation matrix visualized as a heatmap, which illustrates the pairwise correlation coeff. Features like Name and Surname show negligible correlation with all other variables and are irrelevant for prediction. Overall, this matrix is useful for identifying the most influential features for building an effective predictive model.

Results of Cancer Status

Each subplot shows the distribution or correlation between two variables, with data points color-coded by cancer lung disease status pink for Result = 1 and teal for Result = 0. In figure 3, apair plot in scatter plot matrix that visualizes relationships between various features in the dataset based on lung disease status that is Result.

Comparison of Models

In figure 4, a comparison of model accuracies for lung disease prediction using three different machine learning algorithms that is Logistic Regression, Random Forest, and Support Vector Machine. Among the models evaluated, the Random Forest model achieves the highest accuracy, close to 0.88, indicating its superior performance in correctly predicting disease outcomes. Logistic Regression follows with an accuracy of approximately 0.85, while the SVM model performs the least effectively with an accuracy around 0.83.

Overall Performance Metrics

In Table 1, summarizes the performance of three machine learning models Logistic Regression, Random Forest, and Support Vector Machine used for lung disease prediction. In this, the Random Forest model shows the highest performance, achieving the highest accuracy of 88.3%, precision of 87.5%, recall of 88.9%, F1-score with 88.2%, and ROC-AUC with 0.89. The SVM model performs moderately well, with an accuracy of 85% and balanced precision, recall, and F1-score is 83.3%, along with a ROC-AUC of 0.86. Logistic Regression, while still fairly effective, lags slightly behind with an accuracy of 81.7%, precision of 80.0%, recall of 77.8%, F1-score of 78.8%, and a ROC-AUC of 0.82. In this results, Random Forest is the most reliable and accurate model for detecting lung disease among the three.

CONCLUSION

The analyses of the lung disease prediction task using machine learning techniques using dataset, consisting of health and lifestyle attributes such as age, smoking frequency, alcohol consumption, and environmental factors, which shows strong correlations between lung disease and features like age, alcohol use and area quality. The correlation matrix and pair plot confirm that these features are significant predictors, while identifiers like names and surnames hold no predictive value. Model comparison through accuracy and performance metrics reveals that the Random Forest classifier consistently outperforms both Logistic Regression and SVM. It achieves the highest scores across all key metrics accuracy (88.3%), precision, recall, F1-score, and ROC-AUC indicating its robustness in correctly identifying both positive and negative cases of lung disease. SVM shows moderate performance, and Logistic Regression, while still effective, is the least accurate among the three. Overall, the findings predict that Random Forest is the most suitable model for this classification task.

ABSTRACT

A good menstrual health plays a vital role in determining the future reproductive life of a female. Although being so important, it is often an under-looked aspect, when it comes to adolescent wellbeing, particularly in low and middle income countries like India. In India, there have been significant progress towards creating public health awareness but still menstrual problems among adolescents are deeply rooted in cultural stigma, poor health literacy and skimpy healthcare access. This review attempts to extract vital excerpts from the existing literature on Indian adolescents' menstrual health, identifying key gaps in research, exploring strengths and limitations of the existing policy initiatives and also evaluating the practices related to menstrual health. This was achieved by comprehensively reviewing peer reviewed articles, data from Government policy documents as well as the grey literature from various non-governmental organizations. The focal point of this review was adolescent menstrual irregularities, their psychosocial and lifestyle factors with their health seeking behavior in terms of the existing policy frameworks. This review findings highlight that in spite of growing awareness about menstrual health and management, there still persists critical gaps in both evidence and action.

Keywords: Menstrual health, Indian Adolescents, Menstrual irregularities, Psychosocial impact, Lifestyle factors, Health seeking behavior, Public health policy.

INTRODUCTION

Adolescence in humans is a crucial period of growth and development involving pivotal changes and adaptations in one's physical, physiological, psychological and social environments. It is a period which marks the transition from pre-reproductive to reproductive maturity. Menarche, the female's first menstrual period, often occurring during adolescence, serves as a significant milestone of reproductive wellbeing. Menstruation is a major biological event, which not only influence a girl's reproductive health, but have additional significant implications for her educational participation, mental wellbeing and social interactions[1,2]. India, housing over 253 million adolescents, where nearly 47% of them are females, menstrual health continues to be a profoundly overlooked matter[3]. To make things worse, menstrual health in India has always been a bounded issue, often encircled by sociocultural taboos and myths[2]. Empirical evidence highlights that a substantial proportion of Indian adolescent girls experience several menstrual irregularities such as dysmenorrhea, menorrhagia, irregular menstrual cycles, premenstrual syndrome and others, which often result in psychosocial distress among them[4]. Additionally, studies have also shown that majority of the adolescent girls with menstrual health related complaints, do not actually seek formal medical care, but instead rely on self-medication or home remedies. These treatment seeking behaviors were attributed to hesitation, shyness, lack of correct information and a shortage of adolescent friendly care options[5,6]. Menstruation and its related irregularities have a considerable impact on the academic performance of adolescent girls and highly account for their school absenteeism[7,8,9]. The worldwide understanding surrounding menstrual health has progressively broadened to encompass a multidimensional framework that includes hygiene, sanitation, menstrual irregularities, mental wellbeing and access to adolescent friendly healthcare services. However, in the Indian context, the adoption of this holistic perspective still remains in an emergent stage. The government of India have definitely made a positive attempt to work upon these aspects by introducing certain policies/programs. However these policies/programs largely focus on menstrual hygiene, with very skimpy focus on broader aspects such as mental support, nutritional need and various social determinants of menstrual health[9]. The researcher presents this review which forms a part of a larger mixed method research project currently underway in Gujarat, India, which aims to explore psychosocial and lifestyle correlates of menstrual irregularities and treatment seeking behavior of adolescent girls. This review attempts to synthesize existing evidence on menstrual health among Indian adolescents, critically evaluate any gaps in public health policies and programs and advocate for a more holistic and integrated approach to menstrual health from adolescent centered perspective.

Current Research Landscape

Prevalence and Distribution of Menstrual Irregularities

Studies across the country consistently suggest that there exists a heavy burden of menstrual irregularities among adolescents, with about 50-75% of them having suffered from at least one type of irregularity[5,10,11,12]. A meta-analysis done among Indian adolescent girls identified the pooled prevalence irregularities like dysmenorrhea, premenstrual syndrome, oligomenorrhoea, menorrhagia and polymenorrhoea to be among the highest[13]. Although menstrual irregularities are rampantly prevalent, yet they are failed to be adequately reported, often due to the socio-cultural beliefs surrounding it, which stigmatize and inhibit the open discourse around menstruation.

Psychosocial Impact

Menstruation in Indian context, is continually surrounded by several centuries old cultural restrictions and taboos. Menstruating females are considered as impure[2]. Discussing about it openly is often stigmatized. This has led to a feeling of shame, hesitance and misinformation among the female demography, specially the adolescents. Researches have shown strong association between menstrual disorders and various psychosocial factors like anxiety, stress, social isolation and body image issues[14,15]. Skipping school is a commonly cited collateral reaction to menstrual discomfort[7,8,15]. Additionally, lack of proper sanitary facilities in schools, worsened the school attendance during menstruation. A study done in the capital of India found that girls remained absent from schools citing reasons like anxiousness, embarrassment, shame along with lack of private place to manage periods in school, lack of adequate water supply and waste disposal system and lack of a separate bathroom for the girls[16]. A systematic review and

meta-analysis on management of menstrual hygiene among Indian adolescent girls reported that a quarter of them missed school during menstruation due to the lack of proper washrooms[17].

Lifestyle and Behavioral Determinants

Empirical evidences strongly suggest that lack of physical activities, a bad sleep routine and unhealthy eating habits have a strong association with menstrual irregularities[4,13]. Research has also indicated that menstrual problems were more prevalent among adolescent girls with high BMI[12,13,18].

Health-Seeking Behavior and Barriers to Care

In spite of the widespread prevalence of menstrual irregularities among Indian adolescents, there is a strikingly low utilization of healthcare services. Instead of taking professional help, girls were found more comfortable to confide their menstrual related problems with their mothers and friends[14,15,18]. Barriers like hesitance, prevailing stigma, lack of knowledge and lack of access to health care facilities, influenced the treatment seeking behavior of girls.

Methodological Gaps in Research

Most of the studies done in this area are predominantly cross sectional and focusses on school going adolescents. Large gap exists in findings related to adolescents not going to school as well as girls with disabilities. Additionally, studies involving the qualitative exploration of the experiences of such adolescents is minimal. This is a pivotal aspect when it comes to the in-depth understanding of the dynamic interrelationship that exists between various determinants of menstrual health.

Policy Landscape

National Initiatives and Government Programs

In order to address the disparities noted in the equitable access to menstrual healthcare services, the Government of India has introduced several national initiatives which primarily focusses on improving adolescent menstrual health. Two such prominent schemes are the Menstrual Hygiene Scheme (MHS), also known as the Scheme for Promotion of Menstrual Hygiene and the Rashtriya Kishor Swasthya Karyakram (RKSK). The Ministry of Health and Family Welfare launched MHS in the year 2011, with the main goal of benefitting adolescent girls by increasing their awareness as well as by increasing their access to high quality sanitary napkins and ensuring their safe disposal in an environmentally friendly manner[19]. The Accredited Social Health Activists (ASHAs) were also trained under this initiative, to play a pivotal role in distributing sanitary napkins along with creating awareness regarding menstrual hygiene management[20]. This scheme was a commendable step towards empowering adolescent girls. However, its impact was constrained by irregular supply of the sanitary napkins and minimal subsidies[21]. In 2014, RKSK was also introduced, whose one of the core strategy focused on improving adolescent menstrual health which was integrated within the sexual and reproductive health related component. Despite its holistic approach, RKSK faced its own challenges like lack of trained counsellors, procurement issues and inadequate participation of adolescents[22,23]. In the education sector, the Ayushman Bharat-School Health Programme has also included the component of menstrual health. However the programme too have faced considerable implementation gaps, with many of its intended interventions failing to materialize at ground-level[24].

Policy Gaps and Systemic Challenges

Despite the notable policy advances made by India in addressing menstrual health among adolescents, programmatic challenges such as being narrowly focused, having limited adolescent engagement, being underfunded with inconsistent percolation till grass-root level, have all collectively undermined the effectiveness of these initiatives.

Public Health Practice Landscape

Public Health Interventions: Successes

Over the past decade, India has proactively worked upon bettering the menstrual health of adolescents. The government has shown immense perseverance by adopting innovative models and methods in order to facilitate

better implementation of its various initiatives. By collaborating with Non-Governmental organizations, the country has successfully attempted to expand its services like distribution of sanitary pads, raising awareness and fighting against stigmatization, to the actual needful demography[24].

Public Health Practice: Programmatic Gaps

In spite of significant strides in promoting menstrual health, the actual impact of various initiatives have been restricted by several pressing shortcomings. These include being excessively fixated on distribution of sanitary products with limited attention to the physical, emotional and social aspects of menstrual health; insufficient supportive infrastructure in schools; limited focus on adolescents who are outside the formal education system; insufficient training and coordination among stakeholders involved in implementation[22,23,24].

Challenges in Health Workforce

Under the various initiatives aimed to address adolescent menstrual health, several challenges persists as highlighted by various studies. It is reported that the frontline workers - primarily ASHAs and Peer educators - are often not able to sustain their efforts effectively due to factors such as inadequate supply of sanitary pads for distribution, workforce shortages compounded with overburdened existing taskforce and insufficient refresher training opportunities, both in frequency and duration[21,22,23,24].

Call for Holistic and Equity Centered Approaches

To have a lasting effect, menstrual health must be approached with dignity, inclusion and must be recognized as a fundamental public health right. To achieve this would require additional efforts like robust implementation frameworks, active community engagement, a well-resourced and empowered taskforce and holistic care that caters both physical and psychosocial wellbeing.

Key Recommendations

At the moment, efforts towards menstrual health among Indian adolescents reflect a fragmented understanding based approach, with weak integrated systemic actions. The recommendations outlined in table 1, aims to support the creation of a transformative framework that embeds menstrual health within the bigger agenda of dignified and inclusive public health.

CONCLUSION

The dimension of adolescent menstrual health has recently picked up its momentum in the Indian subcontinent. Although the last decade has witnessed increased attention through various policies and programs, the discourse around menstrual health remains predominantly focused on hygiene and access to sanitary napkins. The critical concern of understanding the complex multifaceted interplay of biological, psychological and socio-cultural factors that usually affect adolescent girls, is often over-looked. Additionally, research in this domain remains scattered, with limited focus on psychosocial dimension and treatment seeking behavior. This review has attempted to synthesize the existing evidence on Indian adolescents' menstrual health, advocating for a more holistic approach that repositions adolescent menstrual health from a mere hygiene issue to an integral human right and public health priority.

Table1: Key Recommendations for advancing adolescent menstrual health

Recommendation	Strategy
Redefine Menstrual Health	Expand from a hygiene issue to a holistic health and human right matter. Should also address menstrual irregularities, associated mental health, reproductive health awareness and psychosocial support.
Prioritize Adolescent focused research	Conduct and invest in multitude of scientific inquiries involving adolescents, particularly those from the over-looked demography like out of school adolescents.
Scale up school based Menstrual Health efforts	Ensure trained taskforce, adequate supplies, supportive infrastructure, inclusive education; Strengthen existing Adolescent Friendly Health Clinics; Support for frontline workers.
Targeted and Inclusive support	Enhance more inclusive efforts targeting adolescents who are outside the formal education system, have disabilities or belong to marginalized section.
Involvement of male counterpart	Engage male stakeholders like teachers, fathers and community leaders in the challenging journey of de-stigmatizing menstrual health and fostering social acceptance, through menstrual health initiatives.
Strengthen monitoring system	Promote independent monitoring and evaluation of both Government and Non-Government led actions. Establish built in feedback mechanism for continuous improvement.
Partnerships for United action	Foster collaborations between sectors like health, education, digital media and youth empowerment to develop and deliver sustainable menstrual health solutions.

ABSTRACT

This literature overview," Navigating Product Licensing in the EU: AN approximate Overview," It delves into the Central, Decentralized, and multiple Recognition proceedings, breaking down their respective edges, minuses, and felicitous for multi-hued groups of pharmaceutical substances and drugs. The document emphasizes the intention of EMA to preside over the Central approval route; attributes and resemble as sanction time, disbursement, executive expenditure, and post-marketing guidance are juxtaposed across these strategies. It similarly recognizes novel tendencies and the obstacles in regularizing administrative necessities across EU constituent nations. It suggests fields for coming breakthroughs in optimizing these operations, leveling to upgrade demand obtain ability, mitigating interval-to-demand, and keeping up public security within the EU.

Keywords: Product Licensing consent, EMA, Central approval route Proceeding, Decentralized nonsupervisory proceeding, multiple Recognition route, European Union official cadre, Safety regulation, Post-market guidance.

INTRODUCTION

Product licensing consent proceedings serve as fundamental perspectives for pharma health care regulating system, governing how medications are approved and launched for different regions. In the EU, the purpose of these proceedings is not only to ensure the integrity, efficiency, and safeguarding of the medications but also to accelerate

the accessibility of innovative treatments to patients across the member states. Considering the society well-being impacts, these procedures are complex and dynamic and both scientifically supported and legally organized.
The EU establishes four unique routes for acquiring marketing authorization:

1. Central approval route Proceeding,
2. Decentralized non-supervisory proceeding,
3. Multiple Recognition route, and
4. Nationalized proceedings.

Designed for the Pharma formulations and directive goals, For instance, Central approval route Proceeding is compulsory for Novel treatments, advanced therapies, and drugs for rare or neglected diseases (orphan drugs), while decentralized and multiple recognition proceedings are typically adopted for generic products and widely accepted products targeting market access in multiple regions. This assortment allows organizations Agility in developing product introduction strategies, yet, it contributes to a more complex administrative landscape. The EMA and NCA significantly contribute to the structure of the administrative landscape by Administer assessments and sector frameworks by the chosen regulatory strategy.

Overview of the EU administrative framework

Approaches are essential in the pharmaceutical firm, as they confirm that only safe, effective, and premium-quality drugs are introduced to the market. It entails a detailed exhaustive examination of a medicine's quality, safety, and efficacy before public sale, forming a key pillar of public health safeguarding. A Simplified, Fast-tracked authorization method can substantially cut down time-to-market for Cutting-edge therapies, serving the needs of industry stakeholders and patients, In need of fast access to new therapeutic solutions. To address the varying characteristics of pharmaceutical products, the EU implements multiple authorization pathways, namely the Central approval route Proceeding, Decentralized non-supervisory Proceeding (DCP), and Multiple Recognition Proceedings (MRP). Each of these routes provides different advantages in terms of regulatory efficiency, adaptability, and scope of market entry—factors that are especially important considering the wide range of medicinal products, such as biologic, generics, and orphan medicines.

The Role of the European Medicines Agency (EMA)

Central to Eu's administrative frame, it was EMA, which oversees the assessment and Supervisory control of therapeutic agents. These pathways are especially important for novel treatment modalities addressing unmet medical needs those addressing critical social well-being. The EMA's role goes beyond initial examination, encompassing for the continuous Medicinal product oversight post-authorization, conducting data-driven reviews, and offering regulatory guidance to pharma regulatory and EU states. By maintaining strict analysis and Therapeutic risk assessment procedures, administration upholds the safe use, superiority, and effectiveness criteria necessary for medications to enter and remain in the EU market. This not only safeguards community well-being but also supports modernization by accessibility of emerging medical interventions. Eu's legislative structure—led by the EMA—provides a well-defined, transparent, and scientifically robust environment for the pharmaceutical sector. This system strikes a crucial balance between assuring patient well-being and facilitating timely access to indispensable medications.

SCOPE, PURPOSE AND CONTEXT OF REVIEW

Aim: To deliver a concise comparative assessment for Eu's primary marketing authorization procedures, by highlighting their procedural steps, timelines, costs, and regulatory obligations. It offers stakeholders practical insights for selecting the most suitable pathway based on product type and strategic goals.

Source Selection: Relevant peer-reviewed literature, EMA and European Commission guidelines, and regulatory reports from 2015–2024 were included. The focus was on materials discussing regulatory timelines, benefits, requirements, and challenges of each MA route.

Inclusion and Exclusion Criteria: Included sources provided substantial insight into EU MA procedures for pharmaceuticals. Excluded were outdated documents or those unrelated to human medicinal products (e.g., cosmetics, food, or veterinary fields).

Data Analysis: A qualitative, comparative approach was applied. Key themes were extracted to evaluate timelines, regulatory complexity, cost, flexibility, and post-marketing obligations for each pathway.
Outcome: The synthesized findings equip with an understandable, strategic overview of EU marketing authorization processes, guiding companies in selecting appropriate regulatory routes for efficient and compliant market access.

Overview of Product Licensing Procedures in the EU
Central Approval Route Proceeding
It was a streamlined process overseen by the EMA. It is specifically designed to simplify the Endorsement of pioneering and high-impact therapeutic formulations over the EU and the EEA.

Scope and Applicability: Mandatory for Biotech-derived medicines, ATMPs, orphan drugs, medicines for specific conditions, Encompassing malignancies, neuro-degenerative conditions, endocrine disorders, immunological diseases, and viral infections like HIV/AIDS. Permissible to other forward-thinking treatment that represents the major strides in clinical, regulatory, or technological domains.

Process Overview: An application was submitted directly to EMA, the CHMP conducts the legislative assessment. If the CHMP issues a favorable standpoint, EC grants a single and unified license throughout EU.

Key Benefits: Once granted, the authorization applies uniformly to all EU member states and promotes regulatory uniformity, particularly for high-tech or novel products through centralized Pharmacovigilance and post-marketing surveillance.

Decentralized Non-supervisory Proceeding
It was intended for medications that are still waiting for the consent in any EU state; this route enables pharma industries to simultaneously obtain MA in multiple countries, offering both flexibility and efficiency.

Scope and Applicability: Used for products which are under review in any EU state, often selected for reliability looking into extend the multiple segments.

Process Overview: The contender submits a single consent form to multiple EU states, one country is designated as the RMS, which conducts the systematic examination and oversees the procedure and the other involved countries are known as CMS. If RMS provides an assessment report, which the CMS must either accept or raise objections to within a defined time-frame.

Key Benefits: Cost-efficient than applying for separate national authorizations across all nations, expands market reach while maintaining flexibility and offers a lower regulatory burden.

Multiple Recognition Route Proceeding
It allows a medication, once approved in one constituent state of EU, to extend its provision to other EU states, which offers streamlined approach to gain endorsement across multiple nations based on initial local acceptance.

Scope and Applicability: Used when a medicinal product has already received consent in a single EU state, whereas other states that wish to sell the medication to recognize the initial consent which are typical to register well-established medicament's and generics with Established inclusion in one country.

Process Overview: The product primary license in a RMS and contender claims the appreciation of this endorsement by the CMS. These countries required embracing the RMS / raise exceptions undoubtedly handed within specified duration. It facilitates evaluation compared to initial endorsements.

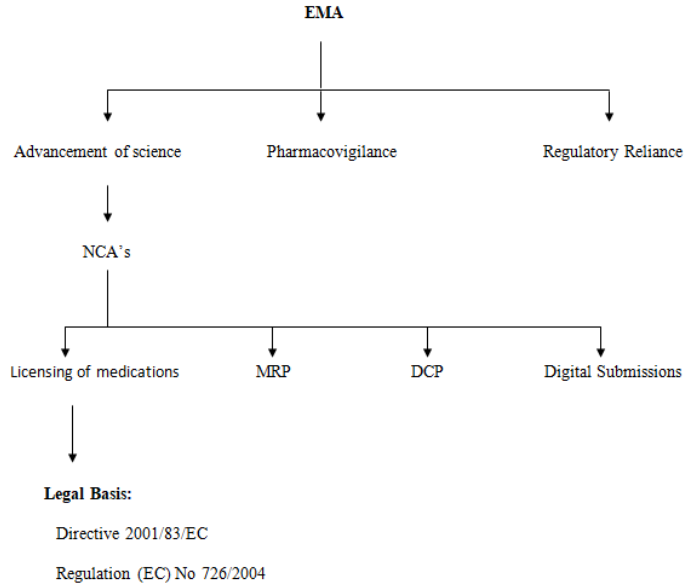
Key Benefits: Delivers an productive way to develop distribution of outcomes that already endorsed in one constituent of EU, constricts organizational duties, as the supplies has previously subjected to consideration in RMS, accelerates enrollment into further segments within the EU/EEA.

Nationalized Proceedings

It was the foundational route within the EU, used when a product is purposed to justified in just one constituent state of EU. Unlike other EU-wide proceedings, the NP was strictly confined to the country where the application is filed and does not permit access to additional member states.

Scope and Applicability

- A country-specific legislative pathway, valid for member jurisdiction where the request is lodged.
- Commonly chosen for generic medications or niche materials not aiming for immediate broader product access.
- Suitability of materials in a market with restricted coverage or those does not fulfill prerequisites for other centralized or decentralized procedures.



Process Overview: Entrant sends the Proposal to the NCA concern state; the NCA evaluates the product's security, therapeutic potency, and reliability by national compliance standards. Upon approval, medications merely market and sold in that defined boundaries.

Key Benefits

- A simpler and enhanced cost-effective route compared to wider EU approaches.
- Potentially faster endorsement timelines for commodities that do not require multinational access.
- Ideal for initial entry into a local market where a single-country authorization meets the commercial objectives.

Regulatory Authorities and Legal Framework In Pharmaceutical Regulation

EU Administrative

i.e.,

EMA

It plays a central role in coordinating the advancements for medicinal compounds even it also supervises Pharmacovigilance, ensuring that the risks of medicines are continuously assessed even after they are marketed.

NCA's

National administrative bodies in each EU state that accountable for proceedings related to MA. They play a significant role in the Multiple Recognition Proceedings and Decentralized Proceedings, helping facilitate the approval of medicines across multiple countries in the EU.

Legal Framework

EMA Regulatory activities and NCAs are operated under the Directive 2001/83/EC and EC - No 726/2004.

Directive 2001/83/EC sets out the regulatory structure for manufacture and distribution of therapeutic agents and materials within EU.

Regulation (EC) No 726/2004 outlines the centralized proceedings for legislative medications, which is particularly important for high-priority or complex medicines, such as biologics.

Recent Updates

Legislative Reliance: This concept allows administrative bodies to rely on the evaluations of other trusted regulators when making decisions about medicine, making the process better optimized and fostering international cooperation.

Digital Submissions: There has been an important turn to the digital submissions for regulatory approvals, which allows faster, more efficient processing of registration, reducing the burden on both administrative bodies and pharmaceutical companies. Comparative study of EU Authorization proceedings (Table 1)

Comparative Analysis with Global Regulatory Authorities

In the global regulatory landscape, the European Union (EU), United States (US FDA), and Japan (PMDA), India (CDSCO) represents four most influential regulatory systems. Each authority follows a distinct framework with its own benefits, challenges, and strategic approaches for Pharmaceutical approval.

U. S

FDA: US follows a single centralized marketing authorization system for all states.

Pathways

Standard Review

Expedited Pathways, including

Hasten: For critical medical conditions with unmet needs.

BTD: For interventions with preliminary evidence of Considerable advancement.

Accelerated Approval: Permitted on the basis of alternate endpoints.

Priority Review: Review in a span of 6 months instead of the standard 10 months.

Example: 'Keytruda' **(**pembrolizumab**)**: Received Breakthrough Therapy status for multiple indications.

Japan

PMDA centralized regulatory authority under the Ministry of Health, Labour, and Welfare, where Pre-submission consultations are mandatory.

Expedited Programs

i. Sakigake specification: For innovative products with initial stages in Japan.
ii. Priority Review and Conditional Approval are available based on urgency and medical need.

Example: Opdivo (nivolumab)**:** First approved in Japan for melanoma under priority review.

European Union

EMA with **NCAs**, the hybrid system combining a centralized agency with the decentralized national routes via NCAs**.**

Pathways

- Centralized Procedure(Mandatory for high-tech drugs),
- Decentralized and Mutiple Recognition(flexible national expansion),
- National Procedure (for single-country marketing).

Facing challenges like multiple legal frameworks (e.g., Directive 2001/83/EC, Regulation 726/2004), Linguistic diversity**:** Requires translations and national labeling adaptations, more complex coordination**:** RMS/CMS discussions in DCP/MRP.

Example: Zolgensma (onasemnogene abeparvovec)**:** Approved via centralized procedure.

India

CDSCO under Ministry of Health and Family Welfare works closely with state-level drug controllers and the Drug Consultative Committee. Offers a single national endorsement framework, where the Drug Controller general of India (DCGI) is capable for the authorization of drugs and biologics, Application, human studies, requires endorsement from the DCGI.

Expedited programs

Hasten: For drugs that fulfill neglected restorative needs or for life-threatening conditions.

Priority Endorsement: Required for quicker to get basic medicines.

Import Permitting: For imported drugs, the CDSCO has particular authorizing rules that guarantee item quality.

Examples: Covaxin: Endorsed beneath crisis utilize authorization by CDSCO with fast-track strategies amid the pandemic; Remdesivir: Affirmed beneath the same assisted pathways for COVID-19 treatment.

Global Regulatory Authorities Comparison (Table 2)

DISCUSSION

- The selection of a product licensing route is guided by the components characteristics, target markets, and prior regulatory experiences.
- The CP excludes the access for member states of EU through a single application, but involves greater complexity, time, and administrative effort.
- The DCP and MRP are more economical options, ideal for generics and well-established medications seeking selective market entry.
- Common challenges include inconsistent interpretations among member states, approval delays from CMS, and adaptation to refining digital expectations.
- New digital requirements, like eCTD format and use of PLM Portal, require pharmaceuticals to upgrade their administrative submission systems.
- Regulatory trends are shifting toward convergence, with increased use of reliance models and efforts to achieve digital harmonization across EU jurisdictions.
- These changes aim to simplify processes, enhance coordination, and support more efficient, faster outcomes approvals over Europe.

CONCLUSION

Comprehending the perspectives for EU product licensing applications were important for pharma industries. Focused on streamline enhancement and make their products available. Alternative options, like Central approval, Decentralized, and Multiple Recognition Proceedings, are each tailored to various kinds of pharma medications and endorsement strategies. A clear comprehension frame helps regulatory bodies and administrators make well-informed decisions, leading to faster approvals and even most productive entry into demand. Adopting digital technologies alongside adaptive licensing is modernizing the administrative frame, and facilitating accelerated and simplified legislative proceedings. Co-exist to align with EU benchmarks, these advancements were extremely streamlined processes, accelerate time-to-market, and rely on broader acceptance to advanced therapies for public. Carefully aligning administrative strategy with the medication and its demand expectations, it is the key to gain consent and attaining commercial viability. With regulatory enhancements and digital adoption on the rise, the EU is paving to approach agile and efficient pharma licensing procedure which supports immediate approaches to therapies for both the plant and public. Hence the transformation in regulation was scheduled for drive-in pharma progress and growth, making it possible to health care recipients for benefiting from reliable and effective therapies without undue waiting.

LIST OF ABBREVIATIONS

EU: European Union
EMA: European Medical Agency
CP: Central approval proceedings / centralizes procedure
DCP: Decentralized non-supervisory proceedings
MRP: Multiple recognition proceedings / mutual recognition procedure
NP: Nationalized proceeding / national procedure
NCA: National competent authorities
MA: Marketing authorization
EEA: European economic area
ATMPs: Advanced therapy medicinal products
CHMP: Committee for medicinal products for human use
RMS: Reference member states
CMS: Concerned member states
EC: European commission
CMDh: Coordination group for mutual recognition and decentralized procedures for human
CTD: Common technical document
IRIS: Integrated European industrial risk reduction system
eAF: Electronic application form
OTC: Over the counter
CDSCO: Central drugs standard control organization
FDA: Food and drug administration
US: United states
PMDA: Pharmaceuticals and medical devices agency
BTD: Breakthrough therapy designation
PLM: Product life cycle management.

ABSTRACT

Presently an evaluation was made on the effects of pesticide phoskillin specific body tissues of the common freshwater fish, *Oreochromis mossambicus*. The experimental fishes were 6.1±0.1cm in length and 5.78±0.8 mg in weight on average. Fishes were subjected to four distinct concentrations (0.1 - 0.4 ml/L) at various time intervals *viz*., 6 hrs, 12 hrs, 24 hrs, 36 hrs, 48 hrs, 60 hrs, 72 hrs, 84 hrs, and 96 hrs. After 96 hrs exposure, fish under a 0.2 ml/L concentration exhibited 50% mortality and the eyes and skin were completely damaged. The protein, carbohydrate and lipid-contents of phoskill-ingested fish showed a significant difference ($p>0.05$) against control-without phoskill ingested fish at different time intervals. The RBC and WBC counts were found to be decreased in phoskill treated fish blood (when compared to control group) for96hrs exposure. The blood parameters were reduced in phoskill ingested fishes *viz*; Total protein- 13.64±0.37%; Glucose - 115.4±1.62% and Granulocytes - 1.8±0.06%. Histology revealed the significant deformations found in gill and liver of tilapia fish. Gene expression results showed that myostatin gene was inhibited in phoskill treated fish compared to control fish. Phoskill ingested fish showed a reduced enzyme activity (TAA, Ache, and CAT) being significantly different ($p>0.05$), while total peroxide (TPX), TBARS and SOD were significantly increased ($P>0.05$) in fish tissues compared to control fish. In view of recent findings, further-more

experimental works are required so as to safely use these pesticides and to estimate the impacts of agricultural pollution on freshwater invertebrates.

Keywords: Toxicity, *Oreochromis mossambicus*, Biochemical composition, Haematology, Histology, Myostatin, Antioxidants.

INTRODUCTION

The vast majority of research on pesticide effects on fish has been limited to their testing for acute toxicity with fish mortality as the endpoint. The effects of pesticides on fish could include everything from altered physiology, biochemistry, behaviour, growth and reproduction to death. Recent population growth of human has put pressure on the world's agricultural system, and now, the main goal of most nations is to increase the food production to meet the demands of a growing human population which is predicted to increase to be about 10 billion by 2050[1, 2]. Meanwhile, a variety of harmful compounds, most notably the use of pesticides and fertilizers by agricultural sector, severely contaminate both the freshwater and terrestrial ecosystems [3]and which has become a major issue on a global scale. Pesticides typically runoff into the reservoirs or drainage systems from agricultural areas during rainfall or irrigation processes [4]. The three main ways that aquatic organisms are being exposed to pesticides are;(i) through the skin, (ii) through breathing, (iii) orally; aquatic organisms typically become exposed to pesticides during their feeding on pesticide-contaminated prey or by drinking contaminated water.

The aquatic environments inhabit a variety of animal and plant species, including fishes, amphibians, plants, and invertebrates. The pesticides can have both directly and indirectly an impact on these organisms; the direct effect being the physiological changes within an organism [5]. For instance, the exposure of pesticides to water fleas causes their demise, which can be regarded as a direct effect of pesticides, and it may produce a dramatic rise in the biomass of algae due to the relaxation from grazing pressure, which is regarded as a secondary effect. Globally, herbicides mostly 'glyphosate' are being used to manage both the terrestrial and aquatic weeds, and in recent years, its usage has been found to be increased. And thus, it has been well recognized that this herbicide has a harmful impact on non-target animals in aquatic environs [6]. Of late, pesticides are a necessary component of modern life because they are utilized to get rid of dangerous pests. In theory, they should only be dangerous to the intended organisms, but emerging research provides evidence that industrial chemicals, pesticides, heavy metals, and other toxic compounds interfere with the normal functioning of many species, including humans and aquatic organisms. Pesticides that are found in drinking water at higher concentrations are required to be banned towards public safety. It's important to keep industrial and agricultural wastes from being dumped into the aquatic environs and the regular monitoring of trace elements in water and other consumables are essential [7].

There have been reports of fish deaths in India as a result of water pollution and the pesticides are considered to be a quick aquatic-contaminant. Depending on the pesticide's solubility, once it enters the aquatic environment, it may stay there for several days to weeks, that could cause mass mortality as well as morphological, physical, biochemical, and behavioural changes in aquatic organisms. Further, the pesticide overdose can cause the organisms reduction in growth, and reproductive capacity and would find it more difficult to adjust to environmental changes [8]. In addition to the ichthyofauna, the aquatic invertebrates such as zooplankton are also being impacted by pesticide contamination. Since the fish and other aquatic animals are commercially valuable species, maintaining the biological balance of the aquatic ecosystems and maximizing the fish-yield solely depends on the careful management and protection of their natural habitats [9]. The most significant cause of aquatic pollution is thought to be pesticides, their metabolites, and consequences of their decomposition. Numerous research examined the insecticides' toxicological concerns like; alteration in oxygen consumption, damages in biomolecules and enzymes, histopathology and health-status of animals. Researchers focus on pesticide effects on ecosystems, particularly on their biota has increased in recent years as the sciences of ecology and ecotoxicology have made rapid progress/advancements in relation to fishes. Numerous recent studies have examined the effects

of various types of pesticide on fish biology [10, 11]. Despite the availability of abundance of scientific data on the toxicity of malathion to *Oreochromis* in India, nothing is known about how this pesticide affects the biochemical, antioxidant and enzymatic-characteristics of *Oreochromis mossambicus*. The aim of the current study was to assess the effects of the pesticide, phoskill at sub-lethal doses on certain antioxidant activities, hematological, biochemicals and histological characteristics in specific body tissues of the common freshwater fish, *Oreochromis mossambicus*.

MATERIALS AND METHODS

Species selection

The *Oreochromis mossambicus*, often known as the *Tilapia mossambica,* is a member of cichlidae family of freshwater fishes. The fish adapts well to lab conditions and is an economically important one. *Mosambique tilapia* is good for aquaculture since it is not very difficult to produce and gather. It has a substantial body with a long dorsal and is packed along the sides. The front portion of the animal bears spines to balance the body. Males have a larger mouth than females due to sexual dimorphism, and its scales are cycloid type. The adults can grow to a length of around 35 cm. Dorsal blade with 10 to 13 fragile beams and 15 to 18 spines. Due to ecological and reproductive weights, hostage and naturalized populations may vary in size and color. It is an omnivorous fish that live both saline water and fresh water as well as in new waters.

Experimental Design

The samples of tilapia fish, *Oreochromis mossambicus* (n=300; Length - 10+0.5cm; Weight - 20+1gm) were obtained from the Azhiyar fish farm, Pudukkottai District (India) and they were stocked at density of 15 numbers in each plastic bucket (10L). To supply constant aeration for all buckets, the air compressors were individually connected with each bucket to avoid hyperactivity – physical injuries and stress. The photoperiod was maintained at 12:12 hours L:D cycle. Fishes were fed with commercial pellet-feed at3% of body weight, thrice a day (9 am, 1 pm and 5 pm).Varied concentrations from 0.2 to 2.0 ppm were prepared and used for toxicity studies in fishes, *O. mossambicus* according to OECD Guidelines with slight modifications (OECD, 1992).

Toxicity Study

The 96-hour half-lethal concentration (LC_{50}) was determined by following the method (Islam et al., 2021).Five plastic containers with a 10L capacity each and tap water were kept with the fish (n=15).The dechlorinated tap water was used and maintained at a constant temperature, aeration, and feeding. The five distinct phoskill concentrations (ml/L), *viz*; 0.2 ml/5L, 0.4 ml/5L, 0.6 ml/5L, 0.8 ml/5L and 1 ml/5L were fixed and without the addition of phoskill served as a control. Fish deaths were noted at 24, 48, 72, and 96 hours. Throughout the experiment, fish activity was observed together with changes in water temperature, pH, and dissolved oxygen. The test was performed at three times and acute toxicity test's $LC_{50/96}$ hrs mortality values were calculated.

Analysis of Biochemical Composition

The protein, carbohydrate, and lipid-contents of fish were estimated as per the methods of Lowry *et al.* [12], Roe [13] and Folch *et al.*[14] respectively. For protein, the dried samples were precipitated in ethanolic mixture and the samples were kept in undisturbed condition for blue color formation (which was made by biuret reaction). Then the mixture would react with phosphomolybdic - Phosphotungastic of Folin reagent which represents the protein. Then the samples were used for spectrophotometric analyses at 630 nm and Bovine Serum Albumin (BSA) used as standard.

The carbohydrate concentration was estimated with the help of TCA extraction. Primarily, the simple hydrolyzed carbohydrates are being converted as sugars and diluted in hydrochloric acid as hot acetic medium. Then the glucose was dehydrated into hydroxyl-methyl furfural and this mixture was kept in undisturbed condition for the formation of green color (followed by spectrophotometric analyses at 630 nm) and glucose used as a standard. Lipid

was analyzed by chloroform-methanol method. Fish sample (10mg) was taken in test tube having 5ml chloroform and methanol mixture (2:1) and incubated at room temperature for 24 hrs. Filtrated the mixture using filter paper in 10 ml pre-weighed beaker and kept on hot plate. Calculated the beaker weight as prior and end of experiment to know the lipid content present in the sample.

Hematological Analysis

Fishes were collected from the experimental system for haematological analysis. Blood samples were collected from sub-lethal treated individuals at 24hrs intervals. Each treated fish was gently wiped with a dry cloth to remove water. Caudal peduncle was cut with a razor and the blood was collected in a vial containing EDTA (anticoagulant). The blood was mixed well with EDTA solution by using a glass rod and the sample was used for following estimations. Oxygen carrying capacity of blood was calculated by multiplying the haemoglobin content with 1.25, oxygen combining power of Hb/g [15].

Histological Analysis

The major steps involved in histological analysis are; fixation, tissue processing, decalcification and section cutting [16] and staining [17].

Molecular Analysis in Phoskill Treated Fish

Genomic DNA extraction and isolation from phoskill treated fish was carried out as per the protocol of Vemulawada Chakrapani *et al.* [18]. The extracted DNA was analyzed using PCR technique and the PCR amplified product was studied mainly on myostatin gene expression. The DNA extraction, amplification and gene expression studies were carried out in PAR Lab, Tiruchirappalli, Tamil Nadu (India).

Antioxidant Enzymes Study

In phoskill-treated tilapia fish *Oreochromis niloticus*, antioxidant and their enzyme activities were investigated. Total antioxidant capacity was determined in fish samples by Hamed *et al.* [19]. Superoxide dismutase (SOD) activity was determined by its capacity to prevent the formation of a red product from the nitroblue tetrazolium dye's degradation to phenazine methosulphate [20]. Based on the ability of 3,5-dichloro-2-hydroxybenzene sulfonic acid to quickly stop the hydrogen peroxide breakdown reaction catalyzed by CAT and react with the remaining hydrogen peroxide to produce a yellow product, catalase (CAT) was identified [21]. Acetylcholinesterase (AChE) enzyme activity was calculated using the Ellman *et al.* [22] technique. For five minutes in an ice bath, homogenate (50 mg/mL) was produced in 0.1 M phosphate buffer, pH 8.0. As a standard, glutathionine was used. Esterbauer and Cheesman's approach [23] was used to measure the estimation of thiobarbituric acid reactive compounds (TBARS) in order to assess lipid peroxidation.

Statistical Analysis

Results were expressed as mean + standard error of mean (SEM) of three observations. The obtained data were subjected to ANOVA-test using GraphPad Prism through Duncan's Multiple Range Test (DMRT). The differences between the various treatments found at $p<0.05$ have been considered to be significant.

RESULTS

In the quarantine tank, a total of 300 tilapia fishes were stocked. The fishes were 6.1±0.1cm in length and 5.78±0.8 mg in weight (on average). Morphometric characters of the fishes were measured and the findings are presented in Table-1.

Toxicity Experiment

The fishes were subjected to four distinct concentrations (0.1 - 0.4 ml/L) at various time intervals *viz*., 6 hours, 12 hours, 24 hours, 36 hours, 48 hours, 60 hours, 72 hours, 84 hours, and 96 hours (Fig. 1).The fish subjected to 0.1 ml/L pesticide phoskill for 84 hours had slowed their swimming and died in 20% mortality. After 96 hours of exposure, fish under a 0.2 ml/L concentration showed 50% mortality, and their eyes and skin were completely damaged. Gradually, the concentration was raised 0.3 ml/L, the fish's skin and tail began to erode, resulting in 80% mortality. Fish exposed to 0.4 ml/L concentration experienced 100% mortality; the entire body was affected, and the color of gill region changed red to pale yellow. The highest number of fatalities was recorded at concentration 0.4 ml/L. Based on 50% fish mortality rate, the LC_{50} concentration was determined to be 0.2 ml/L.

Biochemical Composition

The protein, carbohydrate, and lipid-contents of muscle samples in phoskill - ingested fishes shown in Fig. 2 and which showed decreased values of 11.53±0.25, 2.17±0.15, 6.10±0.11 mg/gm in relation to control-without phoskill ingested fishes were; 20.45±0.43, 3.46±0.04, 10.3±0.3 mg/gm at different time intervals of exposure; 24, 48, 72 and 96 hrs, respectively. ANOVA results revealed that protein and carbohydrate contents of control fish has significantly different with experimental fish ($P>0.05$), except lipid contents of control fish has not significantly different with experimental fish ($P<0.05$).

Liver protein, carbohydrate and lipids contents were analyzed in control and phoskill ingested fish, *Oreochromis mossambicus* (Fig. 3). The total protein content in liver of normal fish was found to be; 9.82±0.03, 8.2±0.02, 7.27±0.25 and 7.07±0.15 mg/gm and total protein levels were decreased in 50% sublethal treatment fishes were found to be; 7.2±0.26, 6.05±0.51, 5.70±0.15 and 4.80±0.05 mg/gm during 24, 48, 72 and 96 hrs of exposures. The mean control values of carbohydrate content in liver tissues were varied between 9.94±0.04, 8.63±0.15, 8.13±0.15 and 7.10±0.08 mg/gm. Similar trend of results were obtained in LC_{50} of 0.2ml/L phoskill treatment fishes *viz*; 6.80±0.06, 4.78±0.14, 3.28±0.17 and 2.92±0.13 mg/g at 24, 48, 72 and 96 hrs of exposures respectively. Liver total lipid concentration was decreased in phoskill exposed fishes against control fishes. Lipid levels in normal fish were found to be 12.65±0.15, 14.9±0.30, 17.53±0.35 and 20.1±0.26 mg/gm and decreased lipids content in LC50 treated groups were; 14.27±0.31, 12.5±0.2, 10.09±0.27, 8.63±0.15 mg/gm of phoskill treatment at 24, 48, 72 and 96 hrs respectively. ANOVA results shows the protein and carbohydrate contents of control fish has significantly different with phoskill treated fish ($P>0.05$) and lipid contents has not significantly different ($P<0.05$) with phoskill treated fish.

The fish kidney biochemical contents were analyzed (Fig. 4) and depicts the amounts of total proteins recorded were; 6.45±0.03, 5.21±0.02, 4.12±0.15 and 3.42±0.02 mg/gm in kidney tissues of normal fish. Total protein values declined in kidney tissues of LC_{50} treated groups were; 4.3±0.17, 3.52±0.21, 2.65±0.03 and 1.20±0.03 mg/gm at different time intervals of exposures; 24, 48, 72 and 96hrs respectively. Kidney carbohydrates levels were found to be less in experimental fishes *viz*; 5.19±0.04, 4.86±0.02, 3.85±0.02 and 3.48±0.06 mg/gm due to sublethal (LC_{50} value-0.2ml/L) toxicity as against the mean control carbohydrate values *viz*.5.67±0.16, 4.39±0.03, 4.25±0.04 and 3.85±0.04 mg/gm at 24, 48, 72 and 96 hrs of exposures. Kidney total lipids levels were also decreased on the exposure of LC_{50} phoskill toxicity *viz*; 7.46±0.14, 6.05±0.14, 5.21±0.19 and 4.06±0.05 mg/gm, compared with mean total lipids obtained were; 4.83±0.03, 6.4±0.2, 7.83±0.15, 8.2±0.2 mg/gm in kidney of normal fish at 24, 48, 72 & 96 hrs of exposure.

Figure 5 illustrated the phoskill-ingested tilapia fish's biochemical profiles in relation to control fish**.** Protein levels were decreased in LC_{50} treated groups *viz*; 4.66±0.04, 3.56±0.02, 2.43±0.03 and 1.16±0.11mg/gm at 24, 48, 72 and 96hrs of treatment when compared with devoid of phoskill ingested fish. Likewise, gills carbohydrates values decreased in sublethal (LC_{50} value-0.2ml/L) exposed fish *viz*; 4.34±0.05, 3.15±0.04, 2.61±0.06 and 2.12±0.03 mg/gm as compared to control fish gill carbohydrate levels 5.34±0.03, 6.52±0.06, 7.65±0.15 and 8.23±0.03 mg/gm at 24, 48, 72 and 96 hrs exposures respectively. Similarly, lipids contents were decreased in the gills, when fishes treated with LC_{50} (0.2ml/L) phoskill. Gills contained 7.73±0.08, 6.57±0.04, 5.66±0.06 and 5.1±0.2 mg/gm of total lipids on exposure to 0.2ml/L phoskill effect when compared to total lipids in the gills of normal fish 6.33±0.13, 7.03±0.25, 8.43±0.11 and 8.60±0.03 mg/gm at 24, 48, 72 and 96 hrs of treatment. ANOVA results expressed the protein and lipid contents of control has

not significantly different with phoskill treated fishes at $p<0.05$ and carbohydrate mean of control fish has significantly different with phoskill treated fish at $p>0.05$.

Hematological Features

Experimental data obtained on blood characteristics of *O.mossambicus* exposed to 0.2ml/L sublethal concentration of LC_{50} for 24, 48, 72 and 96 hrs are presented in Table 2.

The results showed a decrease in total RBC^{s} with respect to increases in exposure periods(hours).The blood RBC counts (2.18±0.38 x10^{6}/µL) reduced in phoskill (0.2ml/L) exposed fishes at different time intervals (24,48,72and96hrs), whereas control fish have high RBC counts (2.65±0.28 x10^{6}/µL) in blood. Similarly, the least WBC counts (3.58±0.21 x 10^{6}/µL) found in phoskill (0.2ml/L) treated fish blood when compared to control group WBC counts 3.78±1.05 x 10^{6}/µL during 96hrs exposure. The subsequent parameters reduced in phoskill treated fishes were total protein-13.64±0.37%; glucose - 115.4±1.62% & granulocytes - 1.8±0.06% against without treated phoskill fishes.

Histology

In the present study, Tilapia fishes showed five pair of gill arches. In the control group (Fig. 6a), four pairs of slender gill arches form two lines and these two lines are joined to each other at the base by a gill septum. The last pair of gill arches generally transforms into the pharyngeal bone and does not play a role in respiration. The surface of the gill lamellae is covered with simple squamous epithelial cells and many capillaries are separated by pillar cells that run parallel along the surface. Primary gill lamellae consist of centrally placed rod like supporting axis with blood vessels on either side. The secondary lamellae, also termed as respiratory lamellae are highly vascularized and covered with a thin layer of epithelial cells. Blood vessels are extended into each of the secondary gill filaments.

In the treatment group (Fig. 6b), the structure of gill arches was damaged and affected the primary and secondary lamellae. Pillar cells shape and erythrocytes function was altered. On exposure to sublethal concentration (of phoskill), the most significant changes were observed *viz*; lamellar shortening, lamellar necrosis, telangiectasis, lamellar clubbing and the changes observed were architectural loss necrosis, desquamation of epithelial layer hyperplasia and lamellar telangiectasis. In control group (Fig.6c), the liver exhibited a normal architecture with hepatocytes by presenting a homogenous cytoplasm and a large central or sub central spherical nucleus. The important histological changes observed in phoskill treated groups (Fig. 6d) were pyknotic nuclei, clear cell foci, necrosis and also caused heavy damage in glycogen vacuoles and Kupffer cells of the liver samples.

Molecular Analysis of Phoskill Treated Fish

Real-time reverse transcription polymerase chain reaction (RT-PCR) analysis of phoskill treated tilapia, *Oreochromis mossambicus* were studied. Myostatin gene (MSTN gene) and β-actin (as a reference gene) was performed (Elbialy *et al.* 2016) using the following primers for Myostatin gene exon1 forward primer: 5'GCATCTGTCTCAGATCGTGCT3' and reverse primer 5'TGCCATCATTACAATTGTCTCCG3' and β-actin (Pang *et al.,* 2013) forward primer 5'CAGCAAGCAGGAGTACGATGAG3' and reverse primer TGTGTGGTGTGTGGTTGTTTTG. The cDNAs used as the template for Real-time PCR system (Agilent Technologies, Santa Clara, CA, USA). The amplification blots of MSTN gene in muscle of tilapia are shown in Fig.7and observed the expression levels of tilapia fish MSTN gene in muscle tissue are shown in Fig. 8.The myostatin gene expression analytical results are shown in Table-3 and the relative differences in gene expression were calculated using threshold cycle (CT) values that were first normalized to those of *O. mossambicus* β- actin house-keeping gene and by using ΔCT value of muscle as a calibrator using the $2^{-\Delta\Delta CT}$ method as previously described by Livak and Schmittgen (2001).

Antioxidant Enzyme Activities

Total antioxidant activity (TAA) and antioxidant enzymes (Ache, TBARS, CAT & SOD) analysis clearly demonstrated that TAA, Ache and CAT enzyme activities were significantly ($P<0.05$) reduced in phoskill treated

fish while total peroxide (TPX), TBARS and SOD enzymes activities were significantly enhanced (P<0.05) in gill and muscle tissues of phoskill treated fish after exposure to sublethal doses compared with control fish (Table-4).

DISCUSSION

Presently, the freshwater fish, *Oreochromis mossambicus* was subjected to sublethal doses of pesticide phoskill at 96 hrs exposure altered the biochemical nature of biomolecules *viz*; total proteins, carbohydrates and lipids in the selected body organs (muscle, gill, liver and kidney) were studied. The present investigation showed a significant decrease in carbohydrate-content in all the tissues studied. The present study results illustrates the carbohydrate metabolism of *Oreochromis mossambicus* suggest that glycogen being a ready source of energy, reduction in glycogen may probably due to its more rapid breakdown (glycogenolysis) which could release the glucose in circulatory system to meet the increased energy demand in a stressed condition. Another possibility for reduction in the glycogen level may be due to glucose 6-phophate, which is located in the membrane of endoplasmic reticulum as a consequence of phoskill treatment, as opined by Jaroli and Sharma [24].

Many earlier researchers have reported a similar trend of decrease in carbohydrate [25, 26]. On the other hand, some other workers have reported that the sublethal concentration of certain organophosphate pesticides caused glycogenolysis, which caused hyperglycemia in African food fish, *Tilapia mossambica* and the Indian catfish, *Heteropneustes fossilis* [27, 28]. However, Remia *et al.* [29] have reported that the elevation of carbohydrates might be due to stress induced by insecticides as physiology of organisms with the help of corticosteroids. Analysis of such biochemical parameters could help to identify target organs of toxicity as well as the general health status of fishes. It may also provide an early warning signal about the stress on animal such as *Oreochromis mossambicus*. The source of these parameters is the indicators responding to the environmental effects and which can also serve as markers for toxicant exposure and effect in fish.

Proteins are important organic substances required by organisms for tissue building and they can play an important role in energy metabolism [29, 30]. The present toxicity-study showed significant decrease in protein content in the fish tissues analyzed. The percentage of protein content was decreased in liver tissue and such reduction of protein may be due to the proteolysis and increased metabolism under toxicant stress [29]. Kumar and Saradhamani [31] have reported significant decreased protein content in all the tissues of fish, *Cirrhinus mrigala* upon its pesticide exposure. The fish's physiological ability to cope up for pesticide stress, requires a lot of energy (to overcome), is also indicated by the decreases in protein content as seen in current study's phoskill-intoxicated fish. Protein metabolism may have been stimulated by the energy demand. The current study results can be compared with earlier reports such as those of Sastry and Siddiqui [32] in *Channa punctatus*, Sabita Borah [33] in freshwater teleost, *Heteropneutes fossilis*, Rao [34] in *Oreochromis mossambicus*, *Oreochromis niloticus* was studied by Bose *et al*. [35], *Channa punctatus* by Ganeshwade [36], and *Oreochromis mossambicus* by Lakshmanan *et al*. [37] proved the decreased protein content was found in phoskill treated fish, when compared to control group.

The four bodily organs of *Oreochromis mossambicus* chosen for this study viz; the muscle, kidney, liver and gills have shown lower total lipid levels as a result of sublethal toxic doses of phoskill. The reductions in total lipids (mg/gm) might have been brought out by stress, which is mobilized to meet the energy demand, lipolysis, or mitochondrial injury caused by hazardous chemicals that may have been present in phoskill pesticide. The results of previous investigations on *Channa punctatus*, *Clarias batrachus*, and *Gambusia affinis* [38] have all supported the present findings. The toxicity of phoskill may have affected fatty acid metabolism, which is another explanation for the drop in total lipid concentration. For example, Benli *et al.* [39] studied in Nile tilapia *Oreochromis niloticus*, while Mathivanan [40] reported in *Oreochromis mossambicus*, Padmini *et al.* [41] investigated in grey mullet, *Mugil cephalus*. Present study histological analysis of control fish-gills revealed a typical structural organization of the lamellae. But the fish exposed with pesticide phoskill exhibited a number of histological changes like hypertrophy, lifting of the

epithelial linings from the surfaces of secondary lamellae, and in a few locations, lamellar epithelium degeneration, deformations in the gill and liver of tilapia fish.

One of the most widely cultivated fish species in world is the Nile tilapia, *Oreochromis niloticus* [42]. The development of striated skeletal muscle, which makes up 40-75% of body mass in tilapia and other cultured fish species, is crucial [43]. In most teleost fish, white tissue makes up more than 90% of all the muscle tissues. As a result, changes in body mass are mostly caused by variations in the growth of muscle [44]. The majority of fishes expand their tissues through muscular hyperplasia and hypertrophy, which are governed by several regulatory agents like myostatin. Most fish have indeterminate muscular growth that takes place through hyperplasia and hypertrophy [45]. New muscle fibres are recruited to cause hyperplasia, and old muscle fibres are expanded to cause hypertrophy [46]. The size distribution of muscle fibres is altered by variations in the relative contribution of various mechanisms. These adjustments are crucial because genetic and environmental factors have an impact on variances in fibre diameter and quantity, which have an impact on productivity [47].

As a result of environmental factors such as temperature [48], oxygen levels, and diet composition, differences in the distribution pattern of muscle fibre size have been reported between different species [49, 50]. The size of the fibres is also influenced by the stage of development, with bigger diameter fibres being more common in adult Tilapia and smaller diameter fibres being more prevalent in early fish stages [51, 52]. Regulation by growth factors, in particular myostatin, a member of the super family of transforming growth factors (TGF-b), which also contains elements that negatively limit the growth of muscles, is another crucial factor [53]. According to Seiliez *et al*. [53] and Langley *et al.* [54], myostatin regulates the proliferation and differentiation of myogenic precursor cells, which are necessary for the creation of striated skeletal muscle in fish. Contrary to mammals, teleost fishes have at least two paralogs, MSTN-1 and MSTN-2, that are responsible for the transcription of myostatin [55]. In various fish species, myostatin activity has been investigated, and previous research has demonstrated that this ability to suppress growth and increase muscle mass primarily occurs through hyperplasia, hypertrophy, or both [56]. Developmental stage, temperature, and dietary constraints are a few examples of the intrinsic, environmental, and other factors that influence the myostatin gene [57]. In reality, environmental influences may change how some genes express themselves [58]. The expression of various genes for tilapias' adaptability and tolerance to this circumstance may be modulated by high alkalinity stress, according to those researchers. In an effort to control muscle growth, culture-environmental factors may have an impact on myostatin gene expression. Myostatin gene activity, which prevents the development of skeletal muscle was shown to be lower in fish treated with phoskill than in control fish in the current study. The myostatin gene is crucial for the biomass of fish muscles.

Reactive oxygen species (ROS) and oxidative stress are known to be induced by pesticides in fish [59]. The activity of the antioxidant enzymes (Ache, SOD, and CAT) is frequently employed to evaluate the risk of pesticides because they prevent oxidative stress [60]. Oxidative stress affects aquatic organisms when there is an excessive synthesis of reactive oxygen species (ROS), which can degrade biomolecules [61]. In the current study, phoskill pesticide exposure to fish resulted in enzyme activities (TAA, Ache, and CAT) being significantly decreased ($P>0.05$) in phoskill treated fish while total peroxide (TPX), TBARS and SOD enzyme activities were significantly increased ($P>0.05$) in liver, gill and muscle tissues of phoskill treated fish after exposure to sublethal doses compared to control fish. Activity of antioxidant enzymes in fish gill tissue reveals an adaptive response to pesticides. Aquatic species are guarded against oxidative stress by catalase (CAT), a crucial antioxidant enzyme [62]. Pollutant-induced cellular transcription mechanisms or mRNA degradation can also prevent organisms from producing enzymes. In the current study, freshwater fish *O. mossambicus* that have been exposed to pesticide phoskill exhibit substantial changes in non-enzymatic (Ache, TBARS, SOD & CAT) activities as well as biochemical (protein, carbohydrate, and lipid) parameters. Changes in biochemical markers in the current study may offer a useful tool to evaluate the water quality polluted with various pesticides. It is abundantly obvious from the altered antioxidant indicators that pesticide phoskill caused oxidative stress in the fish.

CONCLUSION

Aquatic toxicity-discipline is relatively a new and still evolving discipline, originating from the concern for the safety, conservation and protection of aquatic environments and it is an off-shoot of toxicology field, since degradation of water mass is caused mainly by anthropogenic toxicants dumped into the water bodies by human activities, directly or indirectly. The purpose of this study was to determine how the pesticide phoskill affect the histological, biochemical, and haematological (blood properties) changes in body tissues of the freshwater teleost, *Oreochromis mossambicus*. The fish's respiratory physiology and chemical components (blood parameters and biomolecules) are demonstrated to be disrupted by pesticide phoskill, which causes cell damage (histology) and finally fish mortality. When organisms are exposed to pesticides over an extended period of time, they offer a persistent health danger to people. Hence, consuming these deadly fish would pose a serious threat to human population. Therefore, it is essential to regularly test the levels of pesticide residues in food and people in order to ascertain the population's exposure to these chemicals.

ACKNOWLEDGEMENT

The authors thank The Principal, Nirmala College for Women (Autonomous), Coimbatore-18 and authorities of the Bharathidasan University, Tiruchirappalli-24, for the facility provided. MPEDA-Rajiv Gandhi Centre for Aquaculture, Sirkazhi-115 is gratefully acknowledged for the histopathological assay facility provided.

ABSTRACT

Pulmonary drug delivery has emerged as an efficient approach for treating respiratory diseases due to its targeted delivery, rapid onset of action, and minimized systemic side effects. Conventional inhalation therapies, including metered-dose inhalers, dry powder inhalers, and nebulizers, often suffer from low drug deposition efficiency, rapid clearance, and lack of sustained release. To overcome these challenges, nanocarrier-based pulmonary drug delivery systems have been developed, utilizing liposomes, polymeric nanoparticles, solid lipid nanoparticles, dendrimers, and inorganic nanoparticles. These nanocarriers improve drug bioavailability, enhance retention in the lungs, and offer controlled drug release. Surface modifications such as PEGylation and ligand functionalization further improve lung-selective deposition while reducing macrophage uptake. However, challenges remain, including mucociliary clearance, alveolar macrophage uptake, formulation stability, aerodynamic properties, and regulatory hurdles. Recent advancements, including stimuli-responsive nanocarriers, biodegradable mucoadhesive systems, and AI-assisted design, are paving the way for personalized pulmonary nanomedicine. Additionally, inhalation device integration with nanocarriers, including dry powder inhalers and nebulizers, is critical for optimizing drug deposition and patient compliance. Future perspectives focus on gene and mRNA delivery, eco-friendly nanocarriers, and the clinical translation of nanotechnology-based inhalable therapeutics. While significant progress has been made, further research

and regulatory standardization are essential for the commercialization of inhalable nanocarrier therapies. This review highlights the advances, challenges, and future directions of nanocarrier-based pulmonary drug delivery, emphasizing its potential in treating chronic respiratory diseases such as asthma, COPD, cystic fibrosis, and lung infections.

Keywords: Nanocarriers; pulmonary drug delivery; inhalable nanoparticles; controlled release; bioavailability; lung targeting.

INTRODUCTION

Pulmonary delivery is a modern and very efficacious method of delivering drugs to ICU patients because of its advantages such as targeted delivery, fast action and minimum side effects to the rest of the body [1]. The drug is quite popular for treating asthma, chronic obstructive pulmonary disease, cystic fibrosis, lung infections as well as pulmonary hypertension [2]. Lungs have a big surface area, which is rich in blood vessels and alveoli, and the barrier between the alveoli and the blood capillaries is rather thin as well; therefore, drug absorption is very efficient, and the effect of drugs is experienced instantly [3]. Pulmonary drug targeting does not undergo first pass metabolism in the liver as is the case with other routes such as oral or intravenous administration; this means that the drug is rapidly made available in the body for its main action. The administered doses of inhaled drugs are relatively smaller compared to those of the systemic route due to the reduced risk of systemic toxicity and better compliance by patients. These make pulmonary drug delivery as one of the most suitable methods of action for localized and systemic illnesses [4]. Nonetheless, there are several drawbacks of conventional inhalable drug formulations that linger and hamper the effectiveness of inhaled therapy [5]. The common pulmonary drug delivery systems include the metered-dose inhalers, dry powder inhalers, nebulizers, and so on that present low drug deposition efficacy [6]. When using MDI to deliver medication a considerable proportion of the drug is deposited in the oropharyngeal region, exhaled or removed through mucociliary clearance leaving little to reach the lower respiratory tract. This inefficient deposition sometimes requires higher doses, which are often repeated, and, as a result, dose-related side effects and treatment load in a patient [7]. Moreover, the small sized drugs are quickly removed from the lungs by macrophages and enzymatic breakdown in the lining fluid of the alveoli reducing the lung tissue concentration and therapeutic effect [8]. Still, there are some drawbacks of conventional pulmonary formulations as there is no controlled and sustained release of the drug and the therapeutic effects are not achieved in the long term and redosing is necessary.

Such challenges necessitate optimization of drug depositions, retention in the lungs and attainment of long term therapeutic effects [9]. Studies on nanocarriers have shown a great promise to overcome the problems associated with conventional inhalable drug delivery systems [3]. Such systems include lipid carriers such as liposomes, polymeric systems like nanoparticles, solid lipid nanoparticles, micelles and dendritic polymers which present some superiority over conventional pulmonary drugs [10]. They possess a small size that enables them to penetrate deep in the lungs and to deposit the drug uniformly on the alveolar surfaces which enhance the bioavailability of the drug and the effectiveness of the administered treatment [3]. This has shown that it is possible to engineer nanocarriers in such a way that they shield the drugs from any enzymatic degradation, increase the delivery time of the drugs within the lungs and also ensure that the drugs are released in a controlled and slow manner [11]. Other factors including PEGylation and ligand targeting can also be used to improve the lung selective deposition of the drug along with reducing recognition by alveolar macrophages [12]. Due to the versatility that is achieved by the availability of properties in the nanocarrier, there is the possibility of delivering small molecules, proteins, nucleic acids and even gene therapies making inhalable nanomedicine useful in the treatment of chronic respiratory diseases and lung infections [13]. This review aims to concentrate on the development of nanocarrier-based pulmonary drug delivery systems which enable the inhalation of the drugs. It gives a detailed over of the various nanocarrier systems, the properties and use in improving drug delivery effectiveness. It also enlists the major struggles associated with

effective design of inhalable nanocarriers comprising of stability of particles, aerodynamic properties, safety factors and regulatory issues. Further, it also discusses about creating new possibilities with the help of adding nanotechnology to inhalation devices and about establishing new horizon in the respiratory disease treatment through developing new drug delivery system. To this end, this review has tried to identify some of the important issues which would help in giving a direction as to how nanotechnology based pulmonary drug delivery could be a game changer in respiratory therapeutics.

Types of Nanocarriers For Pulmonary Drug Delivery

Nanocarriers have highly impacted the delivery of drugs to the lungs by increasing the solubility, stability and release rate of the particular drug [3]. They display attributes such as small size, which allows them to penetrate deep into the lungs, a factor that allows for uniformity of drug dispersion and prevention of drug compounds from being metabolized enzymatically. The nanocarriers that have been investigated for pulmonary delivery include polymeric, lipid-based, inorganic and composite and hybrid systems, with their respective merits and demerits [10].

Polymeric Nanoparticles

Polymeric nanoparticles are preferable for pulmonary drug delivery since they are biodegradable, and their release rate can be controlled while the loading of the drug can be maximized [20]. These nanoparticles are prepared from synthetic or natural polymers for the purpose of improving the stability of the drug as well as developing a controlled drug delivery system [21]. Among all the nanoparticles prepared through various polymers, PLGA-based nanoparticles are more prevalently investigated because of their approval from the FDA, biocompatibility, and the capability to provide prolonged drug release [22]. Chitosan-based nanoparticles, biopolymers of natural chitin, have mucoadhesive character to prolong drug duration in the lungs. Other polymers used include polycaprolackton, poly ethylene glycol, poly (lactic acid) as well as alginic acid; each has its advantages in terms of solubility and bioavailability of the targeted drug [23]. Polymeric nanoparticles prevent drugs from undergoing degradation by enzymes hence making their release duration lengthy leading to lesser dosing. Also, they can be further functionalized with targeting ligands, PEGylation or charge alteration to enhance lung-selective delivery of a drug [24]. Nonetheless, it is important to note that the control of particle size is crucial as the size of particles less than 200 nm is phagocytised by alveolar macrophages and particles with a size of 1-5 μm are more effective in achieving high lung deposition. They include toxicity of the polymers, slow biodegradation of some of the polymers used and careful formulation strategies in order to achieve the set goals of drug delivery [5].

Lipid-Based Nanocarriers

Lipid based nanocarriers are characterize by a number of benefits including biocompatibility, ability to dissolve the drugs and stability in pulmonary drug delivery systems [25]. They replicate the characteristics of natural biological membranes and are biocompatible to be useful in lung delivery of drugs. Of all the lipid based nanocarriers, liposomes and solid lipid nanoparticles (SLNs) are the most investigated systems [26]. Liposomes are membranous structures made of phospholipid double layer and have the ability to accommodate both polar and non polar chemical substances [27]. This is due to their biodegradable nature, non toxic and their efficiency in fusing with cells from the lung epithelial category [28]. Liposomes can be made to release the drug in a controlled and targeted manner by modifying the surface, using polymers, or changing charge characteristics in an attempt to target the lungs specifically [29].The main components of SLNs are stearic acid, triglycerides, and glyceryl monostearate have characteristics of improved drug stability, slow drug release, and controlled drug diffusion. For this reason, SLNs exhibited more increased resistance to enzymatic degradation as compared with the conventional lipid formulations. Thus, the main hindrances in formulation are lipid oxidation and nanoparticle aggregation.Lipid-based nanocarriers can be easily aerosolized using nebulizers, dry powder inhaler, pressurized metered dose inhaler and thus signifying inhalation therapy. They may lack a strong drug-loading efficiency especially for hydrophilic drugs and may require stabilizers to avoid degradation of the drug during storage or transport [30].

Inorganic Nanocarriers

Inorganic nanocarriers have attracted much interest in pulmonary drug delivery because they are more rigid in structure, which would make them more stable within the delivery system, and the surface chemistry can easily be controlled and the drug release kinetics can be well regulated as well [31]. These nanocarriers include high drug stability, size can be changed and functionalized with targeting moieties for site specific drug delivery [32]. Gold nanoparticles have demonstrated outstanding properties such as stability, capability of being functionalized and theranostic properties where they could be used in diagnosis as well as treatment. They can be designed to be non-toxic to the tissues of the lungs and to release the drugs directly to the target site [33]. Silica nanoparticles especially mesoporous silica nanoparticles have been widely used for drug loading and release due to its large surface area and adjustable pore size [34]. The polymeric microparticles can be made to be sensitive to certain physiological stimuli like pH or enzyme activity so that drug is only released in a controlled manner. However, biocompatibility and long-term safety is an issue since inorganic nanoparticles might deposit in the lungs and can cause toxicity. More studies proposing their chemical nature, the way they behave in lung tissues, and their applicability in the formulation of inhalable drugs are necessary [35].

Hybrid Nanocarriers

Biomimetic hybrid nanocarriers combine the features of polymeric, lipid-based, and inorganic systems and can provide multiple functions, including higher stability, sustained release, and better biocompatibility [36]. Such systems are particularly flexible and generic and can be designed for site-specific, active and individualized drug release [37]. Copolymer liposomes are multifunctional particles that combine only sensitivity to lipids with the polymer capacity to control and maintain drug release in the lungs for a longer duration [38]. These nanoparticles are of core shell system in which the polymeric core offers stability and release control and the lipidic shell offers biocompatibility and cellular internalization [39]. Nanomicelles as self-assembled of amphiphilic surfactants are perfect for enhancing dissolution of poorly soluble drugs for pulmonary delivery [40]. They have very low toxicity and reasonable lipophilicity and bioavailability but have very short residence time in lungs which requires further refinement [41]. The stimuli-responsive nanocarriers belong to the hybrid nanocarriers that are capable of responding to external stimuli such as pH conditions, enzyme activity or oxidative stress for drug release [42]. These smart systems improve the effectiveness of therapy minimizing side effects and can be considered as one of the prospects of individual inhalation treatment. Despite these advantages, the formulation of hybrid nanocarriers is not easy, the cost of their preparation is relatively high and there is still a great deal of concern about their stability in the large-scale applicability in clinical settings. The future prospects of developments in this research area are hence concerned with enhancing the efficiency of such nanocarrier formulations, the effectiveness of formulating and delivering the aerosols, and lastly, uncovering the long-term safety of the inhaled drugs [43].

Advances in Inhalable Nanocarrier Technologies

The development of inhalable nanocarrier device in the last few years has marked a new page in pulmonary drug delivery by providing enhancement in drug deposition, targeting and controlled release of drug. Such developments are intended to address the problems pertaining to efficacies of classic inhalation treatments and to enhance therapeutic effects of regimens applied in respiratory diseases [44].

Surface Modification for Improved Retention and Targeting

Modification of the surface of nanocarriers has been identified as one of the most effective ways of increasing the circulation time and targeting of nanocarriers in the pulmonary system [3]. When the surface of nanoparticles is coated with specific ligand such as antibodies, peptides or small molecules target lungs or specific receptors within the lungs can be obtained [29]. It enhances the effectiveness of the administered drugs and also reduces the negative impact within the remainder of the body. For example, functionalization of nanocarrier with transferrin or folate ligands which leads to receptor mediated endocytosis in lung cancer cells thus increasing drug concentration at the tumor site. Also, coating of the surface with polymers such as polyethylene glycol (PEG) may minimise the opsonisation and hence enhance phagocytosis by the alveolar macrophages hence enhancing the residence time of nanocarriers in the lung [45].

Mucoadhesive and Biodegradable Nanocarriers

The advancement in mucoadhesive nanocarriers was proved to be beneficial to enhance the delivery of a drug to the lungs [46]. These nanocarriers are intended to be anchored to the mucus layer that exists around the respiratory tract to ensure prolonged duration of drug presence in the affected area and increased absorption [47]. Chitosan and many of its derivatives have always been preferred because of their mucoadhesive properties owing to their electrically positive charges that enable them interact with the electrically negative charges of the mucosal membranes [48]. In addition, the choice of biodegradable materials for construction of nanocarrier minimizes the potential for chronic inflammation and toxicity after performing its role of drug delivery. This biodegradability is especially crucial when it comes to pulmonary uses because the tissues involved in that human organ are very delicate and may lead to inflammation if they come into contact with materials that the body recognizes as foreign [49].

Smart and Stimuli-Responsive Nanocarriers

Stimuli-responsive nanocarriers give better prospects in pulmonary drug delivery. Such stimuli-sensitive systems can deliver the medicine in response to change in pH, temperature or the presence of specific enzymes which can be active only at the site of the disease [50]. For instance, at the regions of the lungs that have become inflamed, the pH being slightly acidic, it is possible to design nanocarriers that release the anti-inflammatory agents at the right location. Likewise, enzyme-sensitive nanoparticles can also be developed to release the incorporated drug in the presences of matrix metalloproteinases that are up regulated in disease affected lung tissues. This level of control is beneficial in imparting a precise onset and duration of activity with drugs, which increases the therapeutic index and decreases side effects [51].

Controlled and Sustained Release Formulations

It is essential to have controlled and long-term drug release in the lungs to keep the levels high enough to produce sustained drug effects and requiring minimal dosing frequency and compliance [52]. Nanocarrier design has improved, its formulation come with controlled releasing system, so that the drugs can be slowly released. For example, the fusion of drugs into polymeric systems permits the delivery of the therapeutic ingredient dispersed in the matrix as the polymers disintegrate. Also, applying perform coatings, that involves the deposition of the polymer layers of the drug, which gathers drug in the form of layers leads to slow release of the drug. They are quite useful in chronic conditions such as asthma or COPD because it is crucial to maintain constant drug concentration in the bloodstream [53].

Challenges in Pulmonary Nanocarrier Drug Delivery

However, there are challenges that still need to be overcome in order to acknowledge the safety, effectiveness, and translation of inhaled nanocarrier-based pulmonary drug delivery. The complex biological environment which prevails in the lungs, certain problems related to the stability of the formulation, and concerns considered by the regulative authorities are the most critical factors which may restrain the spread of such systems. Alleviating these challenges is critically important in order to achieve the realization of employing nanocarriers in clinical conditions of respiratory diseases [58].

Physiological Barriers

The human respiratory system has developed several barriers in order to safeguard the lungs and other attached tissue from any foreign matter, including drug-bearing nanocarriers [59]. Mucociliary escalator is made up of a layer of mucous and lining cells covered with cilia and helps get rid of particles inhaling the air by moving the mucus constantly. Although this is a natural defense mechanism that is itself highly important for the health of lungs, this reduces the time that nanocarriers can remain in the lungs, thus reducing the time that drugs can be absorbed and hence their effectiveness in treatment. Another type of physiological barrier is alveolar macrophages, which removes the substance. Alveolar macrophage therefore are specialized cells, which are ready to identify and dispose invading particles that arrive at the deep lung. A lot of these nanocarriers have a diameter of below 200 nm and are aggressively taken up by these immune cells, thereby being cleared before reaching the affected area. Although

PEGylation, or ligand coating for instance, would minimize the rates of clearance by macrophages, few more solutions must still be enhanced for lung targeting [60].

Formulation and Stability Issues

It is even more challenging to develop inhalable nanocarriers that remain stable enough during storage and transportation up to the time of administration. Nanoparticles are prone to agglomeration and alteration with time affecting particle size, surface characteristics, and release mechanism of the drug. It can be of vital importance to keep the formulation rather stable and to ensure the physicochemical properties to read out alike all the time [61]. Another issue is the behavior of nanocarriers and lung surfactants, which change the characteristics and deposition profiles of the drug. In the formulation, the drug-polymer interactions as well as drug-lipid interactions may influence the stability and release profiles of the nanocarrier system hence demanding characteristic pre-clinical studies. The formulation of aerosolized nanocarriers must also fit the delivery system eg dry powder inhaler, nebulizers or metered dose inhaler, so that the drug will disperse properly on inhalation [62].

Particle Size Optimization and Aerodynamic Properties

It is noteworthy that the appropriate particle size and the ability of particles to reach deep into the lungs in a timely manner remain critical. In order that nanocarriers reach the depths of the lungs, they must not exceed 1–5 micrometers in diameter. If droplet particles are greater than 5 μm they can impact on the trachea and bronchus, in other cases, particles smaller than 1 μm are expelled before deposition [63]. Besides size, shape and mass density also play a part in determining the efficiency in which particles are deposited in the lung system. It has been found that, in general, both rod-like and porous nanoparticles are taken up better thus have longer half-life in lungs as compared to spherical ones. Besides, through optimization of the surface charge and design of the engineered nanocarriers, their deposition and penetration in deep lung tissues can be further improved. Nonetheless, it continues to be difficult to engineer nanocarriers that have an optimal aerodynamic properties and the ability to support high drug loading [64].

Safety, Biocompatibility, and Toxicity Considerations

Sustainability of the inhalable nanocarriers is an important factor in their medical applicability superseding that safety and biocompatibility are of prominence. It is to be noted that both polymeric and lipid based nanoparticles are generally considered biodegradable and biocompatible; however, serious issue of long term accumulation with non biodegradable inorganic nanoparticles cannot be neglected. Some materials can remain in the lungs for long duration like gold and silica nanoparticles which can cause inflammation or fibrosis [65]. Also, solvents, surface-active agents, and other additives employed in nanocarrier preparations may themselves be toxic to the lungs. As a result, in-vitro and in-vivo toxicity tests must be conducted to determine the impact of nanocarriers on lung cells and their ability to trigger inflammation response, as well as circulation in the bloodstream. Another important consideration is bioactivity of nanocarriers to evade the host's immune system may cause unwanted immune response with undesirable complications. Coating the surfaces and biodegradable polymers enhance the safety features but further research must be carried out before clinical application [61].

Regulatory and Clinical Translation Challenges

Nevertheless, progress has been lacking in the development of nanocarrier-based inhaled drug delivery systems because of problems associated with approval of such systems for clinical application. Several regulatory agencies across the globe possess their guidelinesfor nanomedicine approval such as the FDA and EMA, and they require clinical data on safety, efficacy, and stability of the product. In contrast, the nanocarrier requires other tests slightly different from a conventional drug, which are the nanoparticle distribution, degradation rate, and accumulation of nanocarriers in lung tissue, thus making the approval process lengthy and costly [66].One of the major issues is that it is usually challenging to prepare nanocarrier formulations that can be scaled up and reproduced. Preparation of nanocarriers on an industrial scale entails selecting a very specific particle size, drug encapsulation rate and stability, which can be sometimes hard to accomplish [67]. Third, there may be a concern from the public and therefore it

contributes to low utilization of nanotechnology based therapies that will require more promotion and awareness to be developed [68].

Nanocarrier - Inhalation Device Integration

The successful delivery of nanocarrier-based therapeutics to the lungs hinges not only on the design of the nanocarriers themselves but also on their effective integration with inhalation devices. This ensures that the therapeutic agents get to the target sites in the respiratory system and also increase the surface area on which the production can be done [58].

Overview of Inhalation Devices for Nanocarrier Delivery

Inhalation devices play a very crucial role when it comes to delivering nanocarrier-based drugs to the desired organ, in this case the lungs. These tools consist of DPIs, nebulizers as well as pMDIs. Every device has its techniques or attributes concerning the dispersion of the drug and the choice depends on the properties of the nanocarrier formulation as well as the requirement for the medications to be delivered [69].

Dry Powder Inhalers vs. Nebulizers vs. Pressurized Metered-Dose Inhalers

Dry Powder Inhalers (DPIs): DPIs provide drugs in a powder form and depend on the patient's inspiratory force to expel the powder into smaller particles that the patient can easily inhale. They do not require the hand-breath synchronization, and this makes them breath-actuated. However, DPIs demand sufficient inspiratory flow rate and this may not be in the reach of patients with severe respiratory ailments. In formulating the nanocarriers for DPIs, it is important to factor the flowability and stability of the powder [70].

Nebulizers: Most of the nebulizers produce aerosols from liquid formulations utilization of compressed air, Ultrasonic waves or vibrating mesh. They are most useful where patients can find it hard to use the inhalers such as kids or those in acute respiratory disease. which can make them suseptical to certain nanocarrier formulations wherein nebulizers can achieve delivery of large volumes of medication over duration of time. However, they are normally larger in size, not so mobile and easy to maintain as the portable models [71].

Pressurized Metered-Dose Inhalers (pMDIs): These ones dispense a particular amount of medicine through the use of a propellant in the aerosol technology. They are small in size, can be moved easily from one place to another and administer drugs very quickly. However, it is not that effective or simple to use because the patient must coordinate the hand and breathing during operation. It is for this reason that spacer devices can be employed to address this problem. According to article four and five, formulation of nanocarriers in pMDIs requires compatibility with propellants and achieving of stability of the suspension [69]. All these inhalation devices possess their merits and demerits, which are as follows: Several factors for the selection of the device includes the disease state of the patient, the type of formulation of the nanocarrier and the targeting area of drug delivery within the respiratory tract.

Aerosolization Techniques and Optimization Strategies

Effective aerosolization of nanocarrier formulations is crucial for ensuring that the therapeutic agents reach the target sites within the lungs. Optimization strategies include:

Particle Engineering: Modifying the physicochemical properties of nanocarriers, such as size, shape, and surface characteristics, to enhance aerosolization efficiency and lung deposition.

Formulation Additives: Incorporating excipients like dispersing agents or stabilizers to improve the stability and dispersibility of nanocarrier formulations.

Device Calibration: Adjusting device parameters, such as airflow rates and nozzle designs, to optimize the generation of aerosols with desirable particle size distributions.

Patient Training: Educating patients on proper inhalation techniques to ensure effective delivery of the medication to the lungs. By carefully considering the interplay between nanocarrier formulations and inhalation devices, and implementing appropriate optimization strategies, it is possible to enhance the efficacy of pulmonary drug delivery systems [72].

Future Prospects and Emerging Strategies

The field of inhalable nanocarrier-based pulmonary drug delivery system is gradually expanding, and there are several promising strategies which can further improve the therapeutic result of respiratory diseases. New promising approaches are as follows: nanomedicine for personalization, gene and mRNA delivery, integrating AI, and green approaches, and clinical translation [73,74].

Personalized and Precision Nanomedicine Approaches

The concept of personalized nanomedicine relates to the use of nanoparticles in relation to the individual patient where different parameters are considered, including but not limited to genetic factors and disease manifestation. Getting nanocarriers which could selectively transport particular drug or therapeutic agent to certain parts of the lungs will increase the efficiency and, by the same token, decrease side effects. In this approach, it is essential to produce nanocarriers that will be able to interact with specific molecular indicators present in a patient's respiratory system in order to deliver medication [75].

Gene and mRNA Delivery via Inhalable Nanocarriers

The targeting of selected genes and mRNA to the lung tissues provided a great potential in treating various pulmonary diseases such as genetic disorders, cancers, etc. With such carriers, these nucleic acids can be protected from degrading and can easily target the cells in the respiratory tract. Several investigators have also illustrated that AI constructed nanoparticles could transport mRNA to the target cells at the diseased areas and so advance treatment for lung cancer and cystic fibrosis conditions [76].

Artificial Intelligence in Nanocarrier Design

There is a new trend that AI is being adopted for enhancing nanocarrier design and applied functions. AI systems have the ability to learn from massive data and therefore the course to the appropriate nanocarrier combinations as well as structures suitable for certain therapeutic uses. This way improves the agenda of the nanocarrier based drug delivery systems and also minimizes the time of development. For instance, AI has also been applied in developing nanoparticles for drug delivery which have increased on their efficiency as well as targeting abilities [77].

Sustainable and Eco-Friendly Nanocarrier Development

There is an increase in the interest for green and environmentally friendly nanocarriers in the current world. Scientists are determined to develop methods of using non-toxic and environment-friendly materials for the fabrication of nanocarriers that can biodegrade invariably. This encompasses the use of natural polymers and the development of nanocarriers that have an environmentally friendly decomposing component once they have executed their therapeutic functions [78].

Clinical Translation and Commercialization Trends

There are many barriers associated with the transition of a developed concept from laboratory to clinic such as the approval by the regulatory agencies, production in large scale, and market availability. Newer strategies that are current in this area include attempts made to establish standard procedures on characterization of such nanocarriers so as to allow standardization in production as well as random clinical trials to evaluate the safety and effectiveness of such nanocarriers extensively. Cooperative actions between the professors, representatives from the companies and organizations, and the regulatory bodies are significant in ensuring the commercialization of the I-needs novel inhalable nanocarrier-based therapies [79].

CONCUSION

Nanocarrier-based pulmonary drug delivery systems present a promising alternative to conventional inhalable formulations by enhancing drug deposition, bioavailability, and controlled release. The ability of nanocarriers to penetrate deep into the lungs, avoid enzymatic degradation, and provide sustained release makes them highly suitable for treating respiratory diseases. Various nanocarrier types, including liposomes, polymeric nanoparticles, solid lipid nanoparticles, and dendrimers, have demonstrated potential in improving pulmonary therapeutics. However, challenges such as mucociliary clearance, macrophage uptake, formulation stability, and regulatory approval remain key obstacles. Recent advancements in stimuli-responsive nanocarriers, biodegradable and mucoadhesive systems, and AI-driven nanocarrier design are pushing the boundaries of inhalable nanomedicine. Future directions focus on personalized therapies, gene and mRNA delivery, and eco-friendly nanocarrier development. While significant progress has been made, further research is required to optimize formulation strategies, overcome physiological barriers, and facilitate clinical translation for widespread application in respiratory disease treatment.

ABBREVIATIONS

Table 1: Classification of Inhalable Nanocarriers and their Properties

Nanocarrier Type	Composition	Advantages	Limitations	References
Liposomes	Phospholipids, cholesterol	Biocompatible, protect drugs from degradation, controlled release	Short stability, potential aggregation, high production cost	[14]
Polymeric Nanoparticles	Biodegradable polymers (PLGA, chitosan)	Sustained drug release, targeted delivery, improved lung retention	Risk of polymer toxicity, complex formulation	[15]
Solid Lipid Nanoparticles	Lipids (stearic acid, triglycerides)	Increased drug stability, controlled drug release, biocompatible	Potential for drug expulsion, limited drug-loading capacity	[16]
Nanomicelles	Amphiphilic surfactants or block copolymers	Enhance solubility of hydrophobic drugs, rapid lung absorption	Prone to rapid clearance, requires optimized surfactant selection	[17]
Dendrimers	Highly branched polymers	Precise drug loading, tunable surface chemistry, targeted delivery	High synthesis cost, potential cytotoxicity	[18]
Inorganic Nanoparticles	Silica, gold, carbon-based materials	High drug stability, good pulmonary retention, potential for imaging	Possible accumulation in lungs, safety concerns	[19]

Table 2: Recent Advances In Inhalable Nanocarrier-Based Therapies

Nanocarrier Type	Modification/Feature	Therapeutic Application	Key Benefits	References
Polymeric Nanoparticles	PEGylation for reduced clearance	Lung Cancer Therapy	Enhanced tumor targeting and prolonged circulation time	[54]
Lipid-Based Nanocarriers	Ligand-functionalization for targeted delivery	Asthma Management	Improved drug deposition in inflamed airways	[55]
Inorganic Nanocarriers	pH-responsive release mechanisms	Tuberculosis Treatment	Targeted drug release in acidic environments of infection sites	[56]
Hybrid Nanocarriers	Mucoadhesive surface coating	Cystic Fibrosis Therapy	Increased retention time in mucus-covered lung tissues	[57]

ABSTRACT

Physical activity and fitness by age and gender have implications for understanding the etiology of obesity in youth and for suggesting approaches for prevention and treatment. Females are less physically active and less fit than males at all ages. 6MWT is an inexpensive in general submaximal exercise test generally used to quantify the functional exercise capacity in clinical population. The test is frequently used in adults and is increasingly being utilized in children and in adolescents population as well. It has been used in assessment of subject with pulmonary, cardiovascular etc. This study is needed to assess how physical activity influences heart rate recovery (HRR) after a 6-minute walk test in school-going adolescents. Understanding HRR can help evaluate cardiovascular fitness, detect potential health risks early, and promote healthier lifestyles in young individuals. A total of 80Adolescent were taken and they were divided into two groups. Group 1 n=15 subjects (physicallyactive) and Group 2 n=15(sedentary) subjects. Students were instructed to perform six min walk test. Heart rate recovery was calculated between groups. As the data was not normally distributed non parametric Man Whitney U test was used to compare heart rate recovery between both the groups. Result shows that will comparing between groups, physically active children have significant heartrate recovery as compared to sedentary students

(p< 0.004). Present study concluded that physically active students were having faster heart rate recovery as compared to sedentary students thus preventing future cardiovascular risk factors

Keywords: Heart rate recovery, 6 MWT, Physical Activity, Adolescents.

INTRODUCTION

Cardiovascular fitness is a critical component of overall health, particularly during adolescence—a pivotal period marked by significant physical and physiological development. In recent years, there has been growing concern about the increasing prevalence of sedentary behaviours among school-going adolescents, which may predispose them to various cardiovascular risks. Heart Rate Recovery (HRR), defined as the rate at which the heart rate declines after exercise, serves as a valuable indicator of autonomic function and cardiovascular health. An accelerated HRR reflects robust parasympathetic reactivation and overall cardiac fitness, whereas a delayed HRR may signal autonomic dysfunction and heightened cardiovascular risk[9]. The Six-Minute Walk Test (6MWT) is a submaximal exercise assessment widely utilized to evaluate functional exercise capacity across diverse populations. It measures the distance an individual can walk over six minutes on a flat, hard surface, providing insights into their aerobic endurance and cardiovascular efficiency. In paediatric populations, including adolescents, the 6MWT has been employed to establish normative data and assess functional capacity[10]. Engagement in regular physical activity is known to enhance cardiovascular fitness, improve autonomic balance, and facilitate more rapid HRR post-exercise. Studies have demonstrated that individuals who participate in consistent physical training exhibit improvements in HRR, indicative of better exercise tolerance and cardiac health[11]. Conversely, sedentary lifestyles during adolescence have been associated with diminished cardiovascular efficiency and delayed HRR, underscoring the importance of physical activity in promoting cardiac autonomic function. While extensive research has been conducted on HRR in adult populations, there is a relative paucity of data focusing on adolescents, particularly in the context of the 6MWT. Given the unique physiological changes occurring during adolescence, it is imperative to understand how physical activity influences HRR in this demographic. Such insights could inform targeted interventions aimed at enhancing cardiovascular health and mitigating future cardiovascular risks among school-going adolescents.

This thesis aims to investigate the effect of physical activity on HRR following the 6MWT in school-going adolescents. By examining the relationship between habitual physical activity levels and HRR, this study seeks to elucidate the potential of HRR as a non-invasive marker for cardiovascular fitness in adolescents. Furthermore, the findings may contribute to the development of school-based physical activity programs designed to improve cardiovascular outcomes and promote long-term health in this vulnerable age group. In conclusion, understanding the interplay between physical activity and HRR in adolescents is of paramount importance in the context of public health. By addressing this knowledge gap, the present study endeavours to provide evidence-based recommendations for fostering cardiovascular fitness through physical activity, ultimately aiming to reduce the burden of cardiovascular diseases later in life. These data on variations in physical activity and fitness by age and gender have implications for understanding the etiology of obesity in youth and for suggesting approaches for prevention and treatment. Females are less physically active and less fit than males at all ages.

It is generally accepted that the gender difference in fitness is related to body fat, muscle mass, and haemoglobin concentration, but the relatively new data on gender differences in physical activity suggest that the role of physical activity should be considered more carefully. For Males, aerobic power per kilogram body weight remains virtually unchanged throughout youth become less and less active. When physical activity standards for youth are proposed, it must be assumed that activity levels decrease with age. Especially regarding physical activity, one would expect female youth to have higher levels of obesity than males. All other factors being equal, the contribution of physical activity to the risk of obesity would be expected to increase with age as activity decreases in both gender group, but

more so in females. Health benefits of physical activity for children and adolescent, it is vitally important to have accurate information on the epidemiology of physical activity in youth[1]. Here is substantial evidence linking the number of hours of TV viewing and being overweight or obese in children and adolescent. For example, in a representation sample of 7216 children aged 7 to 11 years, TV watching and video game use were risk factors for being overweight(17% to 44% increased risk) or obese(10% to 61%). The authors emphasized the need to examine more than a single sedentary behaviour (ie, TV viewing), particularly because not all sedentary behaviours have been associated obesity[2]. After achieving peak workload, all the patients spent at least two minutes in a cool-down period during treadmill testing at a speed of 2.4 km (1.5mil) per hour and a grade of 2.5 percent. This period was considered the recovery period. The value for recovery of heart rate was defined as the reduction in the heart rate from the rate at peak exercise to the rate one minutes after the cessation of exercise. The mechanisms by which impaired heart rate recovery confers an increases risk of death, even among patients without heart failure myocardial perfusion defects, are not clear. Imai *et al*. examination the physiologic characteristics of heart-rate recovery after exercise in health adults, athletes, and patients with chronic heart failure[5]. they demonstrated that, in all three group, vagal reactivation was the principal determinant of the decrease in heart rate during the first 30 seconds of recovery and that this mechanism was independent of age and the athletes but was blunted in patients with heart failure and was completely abolished by the administration of atropine[3].

MATERIALS AND METHODS

This Prospective Observational Study study was conducted on 80 school going adolescence (N=80). Informed consent was taken to the individuals who were participating in the study. Data was collected from the various centres of Ahmedabad, Gujarat. All the individuals were recruited according to the inclusion and exclusion criteria. Students were divided into two groups. Group 1 n=40subjects (physically active) and Group 2 n=40(sedentary) subjects. Students were instructed to perform six min walk test. Heart rate recovery was calculated between groups

Materials

- Sphygmomanometer
- Pulse oximeter
- Stop watch
- Bottles
- Measure tape
- Pen
- Chalk
- Book
- Chair

The Inclusion Criteria

- Normal Healthy Adolescent
- Age Group between 6 to 18 Years
- Both Male and Female Are Included
- Who wereAble to perform 6 MWT.

The Exclusion Criteria

- Those Students Who were Participating in Other Sports Activity
- Students who had underwent any past surgery since last 6 months
- Students presented with any type of neurological disorder, congenital heart disease etc.,
- Students not welling to participate.

PROCEDURE

Physical Activity Assessment
Physical activity levels will be assessed using
Physical Activity Questionnaire for Adolescents (PAQ-A) – a validated self-report tool.
Pedometer-based step count analysis – to objectively measure daily activity levels.

Participants will be classified into two groups
Active Group: Engaging in at least 60 minutes of moderate-to-vigorous physical activity per day.
Sedentary Group: Engaging in less than 60 minutes of physical activity per day.

6-Minute Walk Test (6MWT)
The 6MWT will be conducted following the American Thoracic Society (ATS) guidelines
- Conducted in a 30-meter indoor corridor with minimal external interruptions.
- Participants will be instructed to walk as far as possible for 6 minutes at a self-paced speed.
- Standardized encouragement will be provided at specific time intervals[8].

Heart Rate Measurement
Resting Heart Rate (RHR): Measured using a digital heart rate monitor after 5 minutes of seated rest.
Post-6MWT Heart Rate: Measured immediately after the test and at 1-minute, to assess HRR.
HRR Calculation: -HRR1 = Peak HR - HR at 1 min post-exercise

RESULT

The result was done from SPSS software 20 version.

Demographic data
In group 1, 18(45%) were male and 22(55%) were female and in Group 2, 26(65%) were male and 14(35%) were female. Table 1 showing data of Demographic. An Unpaired T test was used to compare the pre and post data of individual. The mean ± SD distribution for heart rate recovery (HRR) for the adolescents was physically active (Group A) was 23.95 ± 2.783 and sedentary individuals was 16.07 ± 4.42 (Group B). Shows the data of Group 1 and Group 2 Heartrate Recovery Rate (Figure 1)

DISCUSSION

The present study aimed to evaluate heart rate recovery (HRR) among physically active adolescents and compare it with their sedentary counterparts. The findings revealed a significant difference in HRR between the two groups, with physically active adolescents demonstrating a notably faster recovery ($p < 0.00001$). This suggests that regular physical activity has a substantial impact on autonomic regulation and cardiovascular efficiency. A lowered resting heart rate in active individuals is primarily attributed to an increase in parasympathetic activity and a minor reduction in sympathetic discharge. Regular exercise enhances vagal tone, leading to a quicker return to baseline heart rate post-exercise. The accelerated HRR observed in the physically active group further supports the role of training in optimizing autonomic function. Conversely, sedentary students exhibited a delayed HRR, indicating reduced parasympathetic reactivation and prolonged sympathetic dominance. This imbalance may contribute to long-term cardiovascular risks if not addressed early in life. HRR is considered an essential prognostic marker of cardiovascular health, with delayed recovery being linked to an increased risk of cardiovascular diseases, metabolic disorders, and autonomic dysfunction. Several factors influence HRR, including exercise intensity, cardiorespiratory fitness, autonomic nervous system (ANS) modulation, hormonal changes, and baroreflex sensitivity. Physical training has been shown to enhance cardiac vagal tone, which facilitates quicker HRR. The improved efficiency in

autonomic regulation observed in active adolescents underscores the benefits of regular physical activity in promoting cardiovascular health. These findings highlight the need for structured physical activity programs in schools to enhance cardiovascular fitness and autonomic balance among adolescents. HRR post-exercise can serve as a simple yet effective tool for assessing cardiovascular health, encouraging early interventions to reduce future health risks associated with sedentary lifestyles.

CONCLUSION

The present study concluded that physically active students demonstrated significantly faster heart rate recovery (HRR) compared to their sedentary counterparts, indicating better autonomic function and cardiovascular efficiency. Faster HRR is primarily attributed to enhanced parasympathetic reactivation and reduced sympathetic dominance, which play a crucial role in maintaining heart health. In contrast, sedentary students exhibited delayed HRR, suggesting impaired autonomic regulation that may contribute to an increased risk of cardiovascular diseases in the future. HRR is a well-established prognostic marker of cardiovascular health, with slower recovery post-exercise being associated with higher risks of hypertension, obesity, and metabolic disorders. Regular physical activity strengthens the cardiovascular system by improving vagal tone, increasing baroreflex sensitivity, and enhancing cardiac autonomic balance. These physiological adaptations contribute to a more efficient heart rate regulation, ultimately reducing long-term cardiovascular risk. Given the significant impact of physical activity on HRR, encouraging adolescents to engage in regular exercise is crucial for promoting lifelong heart health. Schools should implement structured physical education programs that emphasize aerobic and endurance training to enhance cardiovascular fitness. Early interventions focused on increasing physical activity levels in adolescents can help mitigate future cardiovascular risks, fostering a healthier generation with improved overall well-being.

Limitation

- More sample size can be administered
- Factors such as diet, sleep pattern was not administrated in the study
- Other outcome measures such as fatigue was not assessed

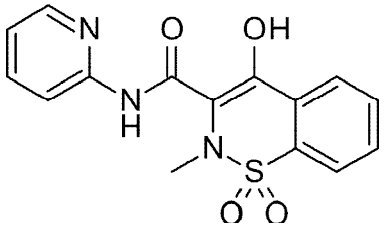
ABSTRACT

A powerful member of the oxicam class of non-steroidal anti-inflammatory medicines (NSAIDs), piroxicam has attracted a lot of interest due to its wide range of effectiveness in treating inflammatory conditions. For chronic illnesses such rheumatoid arthritis, osteoarthritis, and ankylosing spondylitis, Piroxicam provides a practical and efficient treatment alternative due to its lengthy half-life and once-daily dosage. As part of its pharmacodynamic profile, it inhibits the cyclooxygenase (COX)-1 and COX-2 enzymes, which lowers the production of prostaglandins that cause fever, discomfort, and inflammation. Piroxicam also shows promising results in postoperative inflammation and acute musculoskeletal injuries. Despite its therapeutic advantages, gastrointestinal and renal adverse effects must be carefully considered, especially when using it for an extended period of time. The pharmacological adaptability of Piroxicam, its therapeutic uses, and the risk-benefit analysis that is essential for maximizing patient outcomes in the treatment of inflammatory diseases are all highlighted in this review.

Keywords: Piroxicam, NSAID, Rhumatoid arthritis, Osteoarthritis

INTRODUCTION



Piroxicam refers to anti-inflammatory agents with anti-aggregating, analgesic, and antipyretic effects [1]. In addition to post-traumatic pain, gout, neuralgia, myalgia, soft tissue inflammation, and inflammatory viral illnesses of the upper respiratory tract, piroxicam is utilised to treat a number of musculoskeletal disorders [2]. Piroxicam works by mechanism inhibiting the COX-1 and COX-2 systems as depicted in figure 1, which are involved in the metabolism of arachidonic acid. Piroxicam is known for its high oral absorption rate and its ability to have an impact for up to one day following the initial dosage. Thus, piroxicam can be given one to two times a day, depending on the manner of dose [3]. New medications being created in contemporary pharmacology based on piroxicam. Additionally, the

mechanisms of action are examined in relation to the age group [4]. Mechanism of Piroxicame [Figure 1]. Piroxicam is an anti-inflammatory drug that is both popular and in great demand. The pharmaceutical dose form is one of the many factors that greatly influence the patient's tolerance, pharmacokinetics, and ease of administration of the medicine. Tolerance and ease of administration also play a significant role in a patient's commitment to therapy. Compliance is therefore essential to the treatment's effectiveness. Since they can make oral administration easier and improve patient comfort, low-soluble or insoluble chemicals in the liquid dose form are important[5]. Piroxicam comes in a number of dosage forms, including pills, suppositories, capsules, and gels for topical application. Seven firms, with their origins in Germany, Poland, Bulgaria, and the Russian Federation, are registered in the CIS nations. It should be highlighted that the limited selection of oral forms provided by these manufacturers is due to their comparable excipient makeup. Fluid forms are now preferred by doctors when prescribing oral dose forms. [6]. The current development of a fluid dosage form of piroxicam presents an essential issue in this respect. With consideration for excipients, patient preferences, and pharmacological factors, this development would expand the selection of piroxicam medication variations. Piroxicam is also utilized as a suspension because it is very insoluble in water [7]. There are a number of characteristics that set suspension apart from other dosage forms. These include the solid fraction's high dispersibility, the therapeutic impact starting sooner than with tablets and other solid dose forms, the therapeutic effect lasting longer than with solutions, and patient simplicity of use. In different dose forms, piroxicam suspensions make up no more than 1.5% of the overall amount of the drug. These low numbers can be explained by the fact that suspensions are generally kinetically and aggressively unstable, which dictates the specifics of suspension preparation and storage. Research into alternative drug delivery mechanisms in the human body is therefore relevant since the effective dose forms of piroxicam that are now accessible are unstable when stored. The purpose of the study is to investigate the gastrointestinal tract's unique piroxicam kinetics in ex vivo tests. An alternate and perhaps more effective method of delivering piroxicam to the gastrointestinal tract lumen during oral administration is to use a theoretically appropriate material, such as pectin and zein-based hydrogels. The study aimed to: [a] examine the kinetics of piroxicam releases from hydrogel-based drug delivery systems in gastrointestinal settings during a rat experiment; [b] compare the experimental outcomes based on the dry matter mass, mass index of piroxicam, and ratio of zein and pectin; and [c] calculate the time interval for which 50% of piroxicam is released in gastrointestinal tract-simulation conditions.

Description

Piroxicam is 4-hydroxy-2-methyl-N-(2-pyridyl)-2H-1,2-benzothiazine-3-carboxamide-l,l-dioxide.

Structure

Appearance, Color, Odor, Taste

Piroxicam is a colourless, odourless, bitter crystalline powder.

Synthesis

Starting with sodium saccharin, the first one uses chloroacetic acid esters to alkylate it at nitrogen. After alkoholysis and a Dieckmann ring closure, the base catalyses the rearrangement of the 5-membered intermediate to produce 3-Acyl-2H-1,2-benzothiazin-4(3H)-one-l, 1-dioxide. When N-Methyl derivative reacts with methyl iodide, it is easily obtained. After that, the product is treated with the proper amine in refluxing xylene to produce the matching carboxamide [8].

Pharmacokinetics

When taken orally or recally, piroxicam is easily absorbed. It builds up after many doses and reaches a stable level in around seven days. With a half-life of around 40 hours in humans, the medication undergoes substantial metabolism to produce metabolites that appear to be inert. Peak plasma levels are reached around two hours following a single oral dosage and 5.5 hours following rectal administration of suppositories or 2U. Because of piroxicam's long plasma half-life, plasma concentrations stay rather constant over the following 24 to 48 hours. 99.3% of piroxicam is bound to plasma proteins at doses ranging from 5 to 30 g/ml. Patients with rheumatoid arthritis can absorb piroxicam through their synovial fluid, where it can reach quantities of around 40% of those seen in plasma. Since piroxicam is so strongly protein-bound, it may displace other medications that are also protein-bound. The simultaneous administration of antacids and aspirin has no effect on its absorption or distribution.

Metabolism

The available information indicates that piroxicam undergoes substantial metabolism in humans through a variety of pathways, including amide hydrolysis, cyclodehydration, glucuronide production, 5'-pyridine ring hydroxylation, decarboxylation, ring contraction, and N-dealkylation. Scheme 3 displays the known piroxicam metabolic routes. The main metabolite in humans is metabolite B, which is created when the pyridyl ring is hydroxylated. It can exist free or in conjugation with glucuronic acid. In terms of prostaglandin synthetase inhibition, the metabolite is at least 1000 times less potent than piroxicam [9]. Within the first eight days following treatment, over 10% of a single oral dosage of piroxicam is found in the urine unaltered. Piroxicam's half-life is prolonged because of its poor clearance rate; in healthy patients, it is typically estimated to be 38 hours, with a range of 31 to 56.7 hours. Neither dosage nor plasma concentration seem to have any impact on half-life. The rat appears to hydroxylate the pyridyl ring at the para-position to form metabolite B, whereas the dog's primary mechanism is the synthesis of the cyclodehydrated metabolite [A]. Up to 60% of a daily dosage of the latter molecule is found in urine and faeces, making it the primary human metabolite, whether free or conjugated with glucuronic acid. In addition, laboratory animals produce ring contraction, deamidate, and decarboxylate in different proportions. These latter mechanisms appear to have little influence on human behaviour. Laboratory animals show no discernible anti-inflammatory effects from any of piroxicam's metabolites. Together with their extremely low plasma concentration at or below the limits of analytical detection], the metabolites' lack of activity supports the theory that piroxicam is inherently active and that its metabolites have no role in that activity. It appears that the special mix of functional groups that piroxicam has is necessary for its effect. Piroxicam can be formulated in various novel dosage form as shown in figure 2 and table 1.

Sublingual tablet system using low doses of Piroxicam

In this technique, piroxicam and a bioadhesive substance are applied to water-soluble carrier particles during dry mixing. In theory, the pill breaks down rapidly into the ordered units made up of the bioadhesive component, piroxicam, and carrier. At first, these units stick to the mucosa. Piroxicam dissolves with the water-soluble carrier particles as they progressively disintegrate. This method combines the bioadhesive retention of the medication in the oral cavity with the best possible exposure of the active ingredient to the dissolving solution. The rate of dissolution in the gastrointestinal (GI) tract frequently regulates the oral absorption rate of poorly soluble, highly permeable (class II) medications, such as piroxicam. Thus, in addition to permeability, a drug's solubility and dissolving behaviour are important factors that determine its oral bioavailability. Because of the prolonged interaction between the medicine and the GI mucous, this undesirable quality may further increase the amount of GI damage. Consequently, it is a perfect fit for evaluating the MFD tablet's potential for dissolving stability.

Transdermal Drug Delivery System

A popular and effective non-steroidal anti-inflammatory medication, piroxicam has the potential to be delivered topically. Using a Keshery Chein diffusion cell, the penetration of piroxicam from a reservoir-type transdermal gel formulation based on proniosomes over excised rat abdomen skin was examined. The flow was significantly better than with the control gel composition. The size of the generated niosomes and the entrapment effectiveness of the lipid vesicles were assessed. It was shown that formulations based on Span 60 generated the smallest and most efficient vesicles, whilst those based on Span 80 generated the least efficient vesicles. Lecithin's addition improved

entrapment efficiency even further. The traditional method of making proneosomes used sorbitol and maltodextrin as the basis. We used scanning electron microscopy to examine the proniosomes' morphology. The maximum flow of 35.61 g/cm2/h was attained, and the transdermal system based on proniosomal gel was 7.39 times more effective than the control gel. Anti-inflammatory research showed that piroxicam might be delivered using a transdermal drug delivery method based on proniosomes. When compared to the control, the carrageenan-induced rat paw inflammation was significantly reduced. S4 and S6, the niosomes made with spans, exhibited the highest percentage of entrapment, at 90.4% and 94.8%, respectively. Niosomes from S4 were found to be bigger than those from S6, according to the particle size study. Because they tend to fuse more easily, vesicles of a smaller diameter are thought to penetrate the skin more effectively. Compared to S4, the niosomes of S6 were smaller, showed greater entrapment effectiveness, and had a larger surface area. Due of their limited entrapment effectiveness, S2 niosomes were not pursued for more research. Span 40 niosomes were found to create bigger niosomes, however piroxicam vesicles from Span 60 had a greater entrapment effectiveness and were therefore chosen; this was likely due to its low permeability and high transition temperature [24]. Additionally, lecithins were attempted to be included. Drug entrapment was discovered to be improved by the addition of egg lecithin. Since lecithin improves permeability, its inclusion is likewise warranted. By adding lecithin, the percentage of drug entrapment increased to 96.1%. Lecithin increases hydrophobicity, which causes vesicles to become smaller when it is incorporated. Drug leakage is likely prevented by the creation of a more compact and well-organised bilayer. The anti-inflammatory trials' findings demonstrated that lecithin vesicles based on span 60 (S6L) significantly decreased paw oedema. The percentage inhibition was greater than that of the carbopol gel containing piroxicam. *In vitro* investigations show a delayed release, which can be explained by the short fall found with formulations based on sorbitol and maltodextrin. It has been investigated and assessed how well piroxicam penetrates proniosomes of different kinds and compositions of nonionic surfactants in vitro. High effectiveness piroxicam entrapment was achieved within the vesicles' lipid bilayers. Based on the experimental results, it is possible that surfactants promote penetration or that the vesicles fuse with the stratum corneum's intercellular lipid and transport the medicine from the vesicles to the skin. The presence of lecithin most likely facilitates the process. Proniosomes can therefore transport piroxicam and most likely additional medications.

Self-microemulsifying drug delivery system (SMEDDS)

SMEDDS promotes the absorption of lipophilic medicines in vivo and increases their dissolution in vitro. The droplet size of the SMEDDS system ranges from 20 to 200 nm. The purpose of the solubilisation capacity was to look at SMEDDS for piroxicam. Due to differing intermolecular interactions between the medication and SMEDDS components, different medicines in the current investigation had varied stable SMEDDS formulations. SMEDDS's tiny droplets improve the pace at which medications dissolve and their bioavailability. The simplicity of production and scalability are two other significant benefits of SMEDDS [25]. A solid self-microemulsifying drug delivery system was created by filling a hard gelatin capsule with a liquid self-microemulsifying drug delivery system that included Neusilin US2. The optimised formulation contains 27.58 percent Transcutol-P, 44.16 percent Cremophor EL, and 28.26 percent Capmul MCM. The findings demonstrated that piroxicam's drug release profile from the self-microemulsifying drug delivery formulations was superior to that of piroxicam powder in its pure form. Piroxicam was quickly and completely released. It is anticipated that solid self-microemulsifying drug delivery systems, once packed in hard gelatin capsules, will be a viable method of delivering a liquid formulation in solid dosage form. Formulations were assessed for drug release experiments conducted in vitro. In comparison to pure drug, it demonstrated an improvement in the rate of drug release. An indicator of better solubility and dissolution rate of the pure medication is the enhanced in vitro dissolution from the S-SMEDDS. Consequently, S-SMEDDS is a promising piroxicam system [26].

Nanosponge Formulation

PXM nanosponge (PXM-NS) formulations were made with β-cyclodextrin and carbonyldiimidazole as a cross linker. Three ratios of β-cyclodextrin to crosslinker and three drug to nanosponge ratios were investigated. The particle size, zeta potential, physical compatibility, and in vitro release of piroxicamnanosponge formulations were all evaluated. For the best recipe, stability tests were conducted at three different temperatures. Lastly, research on the ideal

formula's pharmacokinetic characteristics and in vivo analgesic effectiveness was done. Particle), polydispersity index, zeta potential, and %EE were shown by the optimised PXM-NS formula (PXM-NS10). When compared to the unformulated medication, the dissolving testing revealed a significantly higher quantity of PXM dissolved. The nanosponge demonstrated acceptable stability for ninety days at four and twenty-five degrees Celsius, according to stability tests. Studies on in vivo pain management confirmed that mice's analgesic response to PXM was significantly improved, and that PXM-NS10's relative bioavailability was 1.42 times higher than that of commercial tablets. An promising method for improving Piroxicam's solubility and, consequently, its bioavailability is to create nanosponge under ideal circumstances [27]. The addition of PXM to β-cyclodextrinnanosponge improved its analgesic efficacy. To find the best nanosponge formula for PXM, twelve PXM-nanosponge formulations were created utilising three ratios of β-cyclodextrin to cross linker and three ratios of drug to nanoponge. The ideal ratios were discovered to be 1:2 for the medication and 1:8 for the β-cyclodextrin to crosslinker. Using these formulation parameters significantly enhanced the PXM in vitro solubility and dissolution testing. In comparison to commercial tablets, the optimal nanosponge formulation of PXM demonstrated a significant increase in analgesic effectiveness and in vivo pharmacokinetic bioavailability. The study demonstrated that a nanosponge prepared under ideal circumstances can increase Piroxicam's analgesic action [27].

Ionic Liquids Nanoemulsion Loaded with Piroxicam for Drug Delivery System

In order to create the ionic liquid-in-oil nanoemulsions (IL/o NEs) system, two different ionic liquid types were used: 1-butyl-3-methylimidazolium hexafluorophosphate [Bmim][PF6] and 1-hexyl-3-methylimidazolium chloride [Hmim][Cl], with varying mass ratios with Tween-80/Span-20 1:1, 1:2, 2:1, and 2:3. To obtain the optimal outcome for the NEs system, they underwent stability testing prior to characterisation, rheology behaviour, and release investigation. High stability against separation, creaming, sedimentation, and flocculation is demonstrated by the high content of Tween-80 in the NE formulation. The pH value, zeta potential, and droplet sizes for each formulation were taken into consideration within the ranges of 4.72 to 5.50, -37.3 to -55.3 mV, and 100 to 500 nm, respectively. Images of the nanoemulsions obtained by transmission electron microscopy showed spherical droplets. Rheological analyses revealed that both ionic liquids exhibited non-Newtonian shear thinning behaviour at low shear rates up to 14 S-1 of NE. The dialysis bag approach was utilised to examine the in vitro drug releases by the insertion of Piroxicamnanoemulsions. The drug permeation showed that the ionic liquid had 93% of the drug released, and the optimal surfactant ratio was 2:1. It is determined that the NEs made from ionic liquids have high promise as a Piroxicam medication delivery vehicle [28]. Piroxicam, a medication that is only weakly soluble in water, can be administered using IL/o NEs. Using hydrophilic IL, and hydrophobic IL, it was possible to successfully substitute water in nonaqueous emulsions. The optimal ratio of combination surfactant Tween-80/Span-20 is 2:1, according to the formulation of NEs for both ionic liquids. Additionally, stability experiments demonstrate that IL/o NEs have high chemical and physical stability. The outcomes of the encapsulation efficiency test showed that both ILs were capable of dissolving the medication and encapsulating it in NE micelles. Apart from this, both ILs exhibit outstanding physicochemical characteristics, which produced the greatest penetration of Piroxicam in the in vitro release assay. Shear thinning for both ILs was shown by IL/o NEs for the rheology investigation. But in terms of stability, physicochemical characteristics, and in vitro release analysis, the formulation produced the best results. IL/o NEs are therefore seen to have promising potential for Piroxicam medication delivery.

Nanoemulsifying Drug Delivery System

Based on the solubility research and pseudo-ternary phase diagram, the optimised formulation of liquid SNEDDS (L-SNEDDS) was chosen. It was made up of soybean or coconut oil/Tween 80/Transcutol HP (12/80/8%w/w). Following their adsorption onto adsorbents, optimised L-SNEDDS and liquid supersaturatable (L-sSNEDDS) preparations were created as immediately compressed tablets. The creation of a nanoemulsion and the presence of the drug in an amorphous state with hydrogen bond interaction between the drug and SNEDDS components may be the cause of the enhanced drug dissolution rate in the solid supersaturatable preparation (S-sSNEDDS). The oral bioavailability of piroxicam from S-sSNEDDS was much better than that of the pure drug (PP) and its commercial counterpart (Feldene®) (CD), according to in vivo pharmacokinetic experiments conducted on eight healthy human volunteers. In comparison to PP or CD, S-sSNEDDS had a relative bioavailability of around 151.01% and 98.96%, respectively.

The findings obtained confirm that S-sSNEDDS is a potential drug delivery method to increase piroxicam's oral bioavailability. An approach that shows promise for increasing piroxicam's oral bioavailability and dissolving rate is the new self-nanoemulsifying drug delivery system (SNEDDS). HPMC-E15's addition to liquid SNEDDS and subsequent transformation into solid dosage form successfully prevent drug precipitation and provide an extra option in the quest to enhance product design, manufacturing, performance, and viability. Its benefits also include quick drug dissolving, simple preparation, and the use of non-toxic excipients. S-sSNEDDS has also been shown to increase the drug's oral bioavailability in in vivo pharmacokinetic experiments. This might be because of the combined mechanism of nanoemulsion dispersion with a greater surface area. As a result, the newly created formulation (S-sSNEDDS) would be beneficial in terms of its quick beginning of action, particularly in painful situations when an immediate analgesic impact is needed [29].

Piroxicam Encapsulated Niosomes

Compared to alternative medication delivery methods, niosomes provide a number of benefits. The stability problem, which is a major disadvantage for niosomes, is yet unclear. The stability of niosomes was the main focus of this investigation. Niosomes were loaded with piroxicam, the medication that was selected as the model. Different versions of the original niosome formulation were made, and niosomes were made using the thin-film approach. For three months, the samples were kept at either 25°C±2°C/60% RH±5% RH or 5°C±3°C. Niosomes were observed under an optical microscope, and the drug leakage percentage, particle size and distribution, zeta potential, and drug release patterns were ascertained. Piroxicam was released continuously thanks to niosome composition. At a level of 1.56–6.63%, drug leakage from stored niosomes was noted. But when niosomes were stored, their particle size grew. Neither physical shape nor time had any impact on the zeta potential values. Drug release patterns and quantities were quite comparable for the original formulation and all niosome forms; however, there was a modest reduction in drug release levels with time. This suggests that when niosomes age, they become stiffer. Although lyophilisedniosomes at 5±3°C were shown to provide the best storage conditions in this investigation, the use of an appropriate cryoprotectant and an optimisedlyophilization procedure should be further assessed [30].

GellanNanohydrogels: Novel Nanodelivery Systems for Cutaneous Administration of Piroxicam

Gellan conjugated with either riboflavin or cholesterol was used to test the viability of employing gellannanohydrogels (Ge-NH) as a delivery mechanism for the cutaneous administration of piroxicam (PRX). A 50% w/v Transcutol aqueous solution, a saturated aqueous drug solution, and a commercially available PRX plaster were used as controls in the in vitro skin penetration tests into the human epidermis. To shed light on the Ge-NHs permeation process, confocal microscopy, ATR-FTIR spectroscopy, circular dichroism, and a dynamometer-assisted extrusion experiment were used. According to skin penetration experiments, Ge-NHs slow down the permeation process in comparison to the controls while also improving PRX retention in the epidermis. NHs have the ability to pierce the stratum corneum before slowly dissolving and spreading across the viable epidermis to reach the spinosum layer. To sum up, NHs offer a fresh approach to addressing the epidermis's weakly permeable substances, which will enhance the treatment of cutaneous diseases. According to the findings of this study, Ge-NHs may be helpful in transporting and improving the skin penetration of insoluble and weakly permeable pharmaceutical ingredients. The data acquired indicates that they can enter intact in the upper layers of the skin and undergo a progressive disassembly process by diffusion in the deeper layers of the epidermis, albeit further research is necessary to fully understand their mode of action. The potential for internalisation in epidermal cell lines and the capacity of GeRfv-NHs to localise the medication in the epidermis make these nanosystems useful for developing novel therapeutic approaches for the treatment of dermatological diseases. It is important to note that these formulations may be the last dose form used for pharmacological molecules to be delivered topically. In fact, we have shown in a prior study that it is possible to deliver additional nanocarriers—namely, ultraflexible liposomes and nano-emulsions—by a straightforward spray. Since the nanogel solution may be supplied as is, this method should be beneficial as it avoids dilutions that could lower its concentration or cause the loaded medicine to diffuse outside the nanocarrier. In fact, the process of preparation produced a suspension where the drug is both free in the suspension medium and loaded in the nanogel, resulting in a saturated state that prevents drug leakage from the nanocarrier. The in vitro skin permeation experiment employing the saturated solution shows that, in the particular

case of PRX, the penetration pattern of PRX-loaded Ge-NHs is significantly greater than the penetration of the solubilised fraction through the human epidermis [31].

Drug Interactions

Few studies have been conducted expressly to ascertain how piroxicam interacts with other commonly used medications; however, piroxicam has not been demonstrated to interact pharmacokinetically with digoxin, aspirin, or antacids that contain aluminium hydroxide either by itself or in combination with magnesium hydroxide. The anticoagulant action of acenocoumarin has been shown to be enhanced by piroxicam, as demonstrated by changes in the Quick test in four out of two participants. A patient using 20 mg of piroxicam per day was reported to have had toxicity due to elevated plasma concentrations of lithium. When piroxicam was stopped, the concentration of lithium dropped from 1.5 to 1.0 mmol/L. After starting piroxicam two weeks before his third round of treatment for lymphocytic lymphoma, a patient experienced acute uric acid nephropathy [32].

Piroxicam in therapy

Piroxicam has been shown in clinical trials, some with large patient populations, to be an effective analgesic and anti-inflammatory treatment for rheumatoid arthritis, osteoarthritis, ankylosing spondylitis, and acute pain in musculoskeletal conditions and episiotomy. Piroxicam has been found to be a good substitute for aspirin, aloxiprin, indomethacin, phenylbutazone, ketoprofen, diclofenac, and sulindac in rheumatoid arthritis and for aspirin, naproxen, fenbufen, indomethacin, diclofenac, and sulindac in osteoarthritis, according to comparative studies. These trials demonstrate that it is generally effective and tolerable enough to compare well with such medications. Piroxicam appears to be beneficial in treating acute gout, according to open research, yet it is unclear how it compares to other regularly used medications. The half-life of piroxicam is greater than that of other non-steroidal anti-inflammatory medications, and it works best when taken once daily, which has been demonstrated to increase patient adherence to the medication. Typically, the medicine is well tolerated at doses of 20 mg or less per day; nevertheless, when used for extended periods of time, the gastrointestinal system is less tolerant of larger quantities [40 mg per day). Not all individuals can benefit from the newly developed non-steroidal anti-inflammatory medications, even though they are typically better tolerated than aspirin, indomethacin, or phenylbutazone. Now a well-known member of this class, piroxicam ought to be taken into account in addition to other medications of its kind when determining which medication is best for each patient [33].

DISCUSSION

Piroxicam, a non-steroidal anti-inflammatory medication (NSAID) that belongs to the oxicam class, has shown notable effectiveness in treating a number of inflammatory conditions. Its pharmacokinetic profile, which includes a lengthy half-life of roughly 40 to 50 hours, makes once-daily dosage easier and improves patient compliance, especially for chronic illnesses like osteoarthritis and rheumatoid arthritis.According to clinical research, piroxicam, when taken daily at a dose of 20 mg, is as effective as other NSAIDs such as aspirin, indomethacin, and naproxen in treating osteoarthritis and rheumatoid arthritis. 844 individuals with a range of inflammatory disorders participated in a Phase IV study conducted in India, and Piroxicam showed a good response rate of 82% to 96% across a number of measures, including pain, tenderness, and edema [34].Piroxicam's non-selective suppression of cyclooxygenase enzymes may result in gastrointestinal (GI) adverse effects despite its therapeutic advantages. According to a Norwegian study, the upper gastrointestinal tract—including peptic ulcers and hemorrhages—was implicated in 73 out of 83 likely adverse responses to Piroxicam. However, despite being linked to a higher risk than meloxicam, a worldwide meta-analysis of 75 randomized clinical trials revealed that Piroxicam did not significantly vary from other NSAIDs in terms of serious GI events. This also Co-administration with gastroprotective medications such proton pump inhibitors or H2 antagonists is advised to reduce GI risks, particularly in patients with a history of GI issues. To reduce negative effects, cautious patient selection and monitoring are also essential. In summary, piroxicam is still a useful NSAID for treating inflammatory diseases since it provides convenient once-daily dosing together with efficient symptom control. Although gastrointestinal side effects are a worry, treatment

results can be maximized with careful patient selection and preventative measures. Its safety profile could be improved and its therapeutic efficacy increased with more investigation into other formulations and delivery methods [35]. An effective treatment for both acute and chronic inflammatory conditions is piroxicam, a common NSAID that belongs to the oxicam class. Once-daily dosing is made possible by its lengthy elimination half-life (about 40–50 hours), which enhances patient compliance, a crucial aspect of managing chronic conditions like osteoarthritis and rheumatoid arthritis. Piroxicam's therapeutic effectiveness is widely established. In comparison to other NSAIDs such as ibuprofen, naproxen, and diclofenac, comparative studies have demonstrated that it offers comparable or better symptom management (JAPI, 1989). Additionally, it has shown successful in treating a variety of rheumatic illnesses, musculoskeletal injuries, and postoperative pain.

CONCLUSION

Although piroxicam is still a powerful and adaptable NSAID for inflammatory diseases, new drug delivery technologies can increase its therapeutic usefulness. These developments give patients who need long-term anti-inflammatory treatment a safer option in addition to better therapeutic results. For these formulations to be validated and incorporated into standard therapeutic practice, future clinical trials will be essential.

Table 1: Literature shows Piroxicam can be formulated in different dosage form with lots of advantages and applications:

Sr. No.	Novel Delivery System	Description	Advantages	Applications	Reference
1	Nanoparticles	Piroxicam encapsulated in polymeric/lipid nanoparticles	Enhanced bioavailability, sustained release	Targeted delivery, chronic inflammation	10
2	Niosomes	Non-ionic surfactant-based vesicles containing piroxicam	Improved permeability, reduced side effects	Topical and transdermal delivery	11
3	Microspheres	Biodegradable polymer-based microspheres	Controlled release, site-specific delivery	Injectable formulations, intra-articular delivery	12
4	Liposomes	Phospholipid bilayer vesicles encapsulating piroxicam	Biocompatibility, improved solubility	Topical, oral, and parenteral routes	13
5	Solid Lipid Nanoparticles (SLNs)	Piroxicam incorporated into solid lipid matrix	High stability, controlled drug release	Oral and topical anti-inflammatory therapy	14
6	Transfersomes	Ultra-deformable vesicles enhancing skin penetration	Enhanced transdermal delivery, reduced GI toxicity	Transdermal patches, arthritis treatment	15
7	Proniosomes	Dry formulations converted into niosomes upon hydration	Improved stability over niosomes	Easy storage, used in transdermal systems	16
8	Hydrogel-based Delivery	Piroxicam loaded into hydrophilic polymer networks	Controlled release, improved skin retention	Topical applications for localized pain relief	17
9	Mucoadhesive Buccal Films	Thin films applied to buccal mucosa	Bypasses first-pass metabolism, rapid onset	Buccal drug delivery for systemic anti-inflammatory effect	18
10	Microemulsions	Piroxicam solubilized in oil-water mixtures stabilized by surfactants	Enhanced solubility and absorption	Topical and oral formulations	19
11	Ethosomes	Soft, malleable vesicles with high ethanol content	Improved skin penetration, suitable for deep dermal delivery	Transdermal systems, arthritis pain relief	20
12	Cubosomes	Nanostructured liquid crystalline particles	High drug-loading capacity, sustained release	Oral, topical, and ocular delivery	21
13	Dendrimers	Branched, tree-like nanocarriers	High drug loading, targeted delivery potential	Intravenous delivery, anti-inflammatory applications	22
14	Floating Drug Delivery Systems	Low-density formulations that float in the stomach	Prolonged gastric residence, sustained drug release	Oral delivery, especially for gastric inflammation	23

ABSTRACT

Kala Sharira is a significant topic in the curriculum for first-year BAMS students, thoroughly elaborated in the *Sushruta Samhita*. References to this concept are also found in other classical Ayurvedic texts such as the *Charaka Samhita*[1], *Ashtanga Hridaya*[2], *Ashtanga Sangraha*[3], *Bhavaprakasha*[4], and *Sharngadhara Samhita*[5]. Despite its importance, students often struggle to comprehend the concept of *Kala Sharira*. In the context of *Sharirasthana*, the term *Kala* refers to the membrane that separates *Dhatu* (body tissues) from its corresponding *Ashaya* (body cavities or spaces). The revised NCISM syllabus emphasizes innovative teaching methodologies alongside traditional classroom lectures. This study explores ways to enhance the effectiveness of classroom teaching and improve students' understanding of *Kala Sharira*. Traditional classroom lectures involve structured verbal explanations, discussions, and supplementary written materials like notes or handouts. In contrast, audio-visual teaching incorporates multimedia tools such as videos, slides, and animations to make learning more engaging and impactful. The findings reveal that integrating audio-visual aids with traditional lectures significantly improves students' comprehension and retention of the subject matter. By combining auditory and visual elements, concepts are illustrated more effectively, making the lessons more relatable and easier to grasp. This approach highlights the value of incorporating multimedia tools to create more dynamic and enjoyable learning experiences in Ayurvedic education.

Keywords: *Kala Sharira*, Lecture, Animation, Audio-Visual

INTRODUCTION

Acharya Sushruta, regarded as the pioneer of *Rachana Sharira* (anatomy), introduced the concept of *Kala Sharira* in the fourth chapter of *Shaareerasthana*. This principle is a unique contribution to Ayurvedic science. *Kala* refers to a membrane or boundary that separates *Dhatu* (tissues) from their corresponding *Ashaya* (spaces or cavities). *Dhatu*includes not only the seven primary tissues but also the *Tridosha* and *Trimala*, as they contribute to the structural and functional integrity of the body. *Ashaya* denotes the specific spaces or regions where the *Dhatus* are located and supported.[6] The *Kala* in the body are arranged in layers, resembling the concentric rings of a tree. There are seven distinct types of *Kala*: *Mamsadhara Kala*, *Raktadhara Kala*, *Medodhara Kala*, *Shleshmadhara Kala*, *Pureeshadhara Kala*, *Pittadhara Kala*, and *Shukradhara Kala*.[7] Each type of *Kala* plays a crucial role in maintaining the structural equilibrium of the body. Beyond serving as structural boundaries, these *Kala* also perform specialized functions, making them an integral yet often underappreciated aspect of Ayurvedic physiology. Education involves imparting knowledgeand cultivating wisdom in learners through a structured learning process. Teaching aids play a vital role in enhancing the teaching-learning experience. The chalk-and-board method has long been the most commonly used traditional approach to teaching. In this method, key points and sentences are written on the blackboard, and relevant diagrams are illustrated using chalk to support the lecture. In recent times, PowerPoint presentations have also become a widely accepted component of traditional teaching methods. These presentations tend to engage learners more effectively compared to the chalk-and-board approach, as their visual appeal captures attention and encourages active listening. The advancement of technology has revolutionized teaching and learning, introducing innovative dimensions to the educational process. Integrating technology into the classroom starts when educators design lessons that incorporate digital tools in purposeful and engaging ways. Effectively combining teaching aids with appropriate methodologies enhances the overall learning experience, creating a more dynamic and enriching educational environment.[8] Audio-visual learning extends teaching beyond traditional classroom settings and moves away from the conventional chalk-and-talk approach. These aids enhance the learning process by engaging multiple senses, creating more stimulating and effective educational experiences by integrating elements such as images, animations, videos, sounds, text, and other interactive features. There by audio-visual tools offer diverse and dynamic presentations. Animations, in particular, provide the capability to visually represent microscopic entities like bacteria, viruses, atoms, and molecules. This innovation transforms the teaching and learning process, allowing abstract concepts and intangible phenomena to be vividly illustrated and easily understood by learners. Even though non-lecture activities are given more importance in the revised syllabus, they are mainly limited to group discussions, self-learning, seminars, and practical classes. Therefore, this study aims to evaluate the extent to which the audiovisual teaching method enhances students' understanding of the topic when integrated with classroom lectures.

MATERIALS AND METHODS

The study employed a cross-sectional design. A video was created using a suitable application, focusing on the concept of *Kala Sharira*. Initially, a traditional lecture using PowerPoint presentation was delivered to a group of 54 first-prof students of BAMS degree. After the session, feedbacks were collected to assess their understanding of the topic. After a period of 6 months, the animation video of the topic was provided for the same group. The students were asked to give feedback regarding the effectiveness in understanding the topic. The responses from both the feedbacks were evaluated and compared to measure the effectiveness of each teaching method.

Study sample

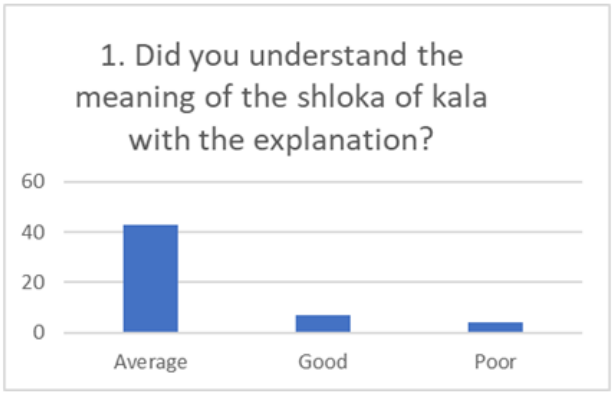
54 students of first professional B.A.M.S degree from ayurveda colleges in Kerala.

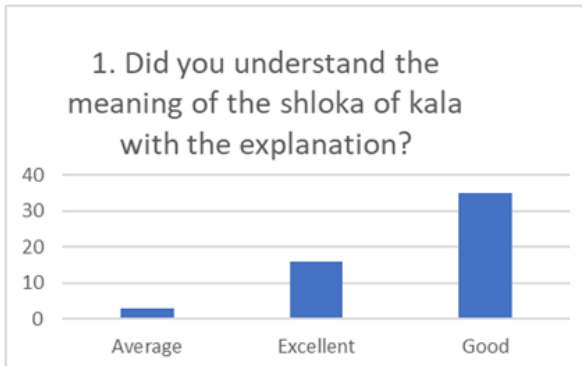
RESULTS

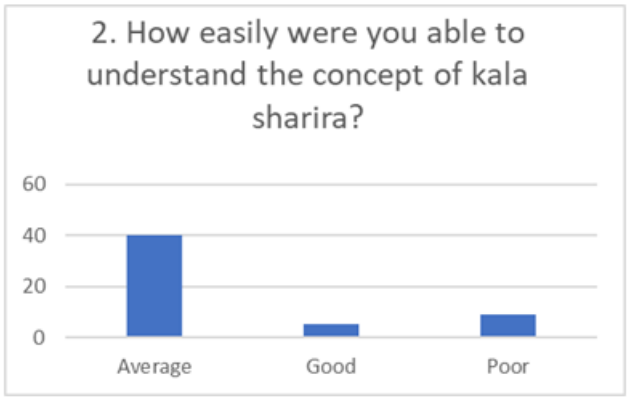
This study was designed to assess the effectiveness of integrating audiovisual aids into the learning process. The findings reveal a noticeable improvement in understanding the topic. This indicates that audio-visual classrooms significantly enhance knowledge acquisition when incorporated with conventional textbook-based learning.

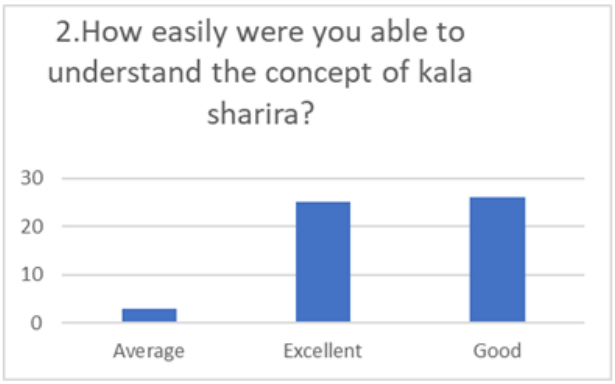
Statistical analysis

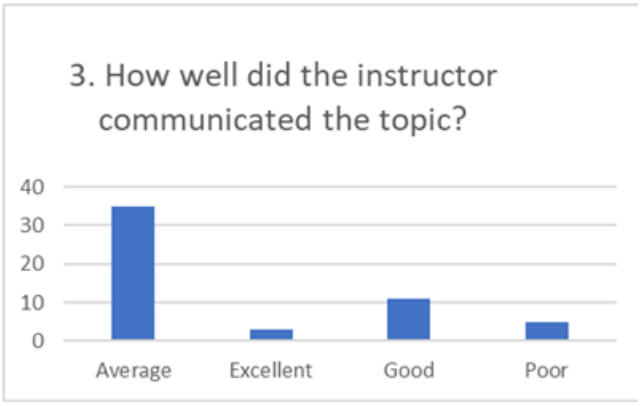
The response graph from 54 participants were analysed. The graph shows that the understanding and retention level improved when the study tool is incorporated in the teaching. The students found the class as more interesting with the study tool.

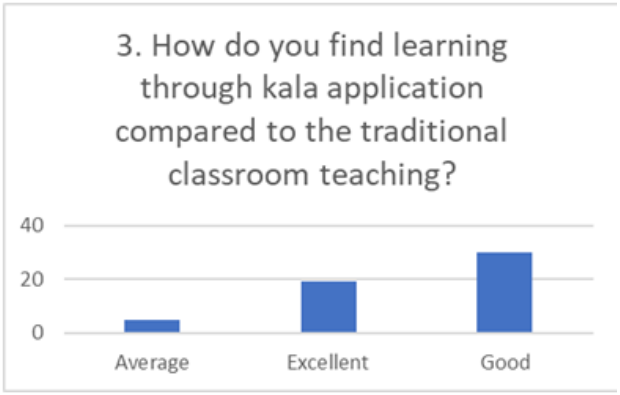




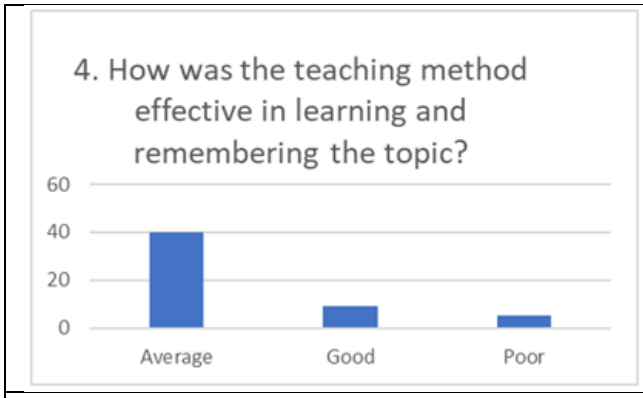








DISCUSSION



Kala Sharira is a crucial topic in Ayurvedic anatomy (*Rachana Sharira*), but understanding the concepts solely through the traditional study of Samhitas can be challenging. While the texts provide various similes to aid comprehension, elaborating on these through conventional lectures often falls short. Effective teaching involves employing diverse strategies to enable the students to grasp complex ideas and develop essential skills. The choice of teaching methods greatly influences learning outcomes. When teachers employ appropriate methods, they enhance the teaching-learning process, promote better understanding, and facilitate desired changes in students. Incorporating technology into the curriculum offers innovative approaches to teaching and promoting higher-order thinking skills. Audiovisual tools, for instance, support visualization and better interpretation of abstract concepts, making them valuable in explaining topics like *Kala Sharira*. This study highlights the importance of adopting technology-driven methods to optimize classroom learning experiences. The concept of *Kala Sharira*, as explained in the Samhitas through various similes, is often difficult for students to comprehend using traditional classroom methods such as lectures, blackboard teaching, or simple PowerPoint presentations. However, the use of audiovisual tools has been found to significantly improve students' understanding and retention of the topic. These tools facilitate a more engaging and effective delivery of complex concepts. The application of audiovisual aids in teaching *Kala Sharira* demonstrates their potential to enhance not only this subject but also other areas of study, making classroom teaching more effective overall. By encouraging an interactive and visually enriched learning environment, audiovisual tools play a pivotal role in modern education, bridging gaps in traditional methods and fostering deeper comprehension among students.

ABSTRACT

Medical students face significant psychological and intellectual challenges due to the high demands of medical education. These challenges often manifest as stress, burnout, insomnia, depression, and reduced cognitive performance, which can impact both academic success and future clinical competence. This review aims to examine the mental and intellectual health needs of medical students by analysing existing literature and traditional health frameworks, including Ayurvedic principles. A narrative review was conducted using structured searches in PubMed, Google Scholar, and institutional reports. Classical Ayurvedic texts such as Charaka Samhita and the Bhagavad Gita were also reviewed. Thematic synthesis was employed to categorize findings into mental health challenges, intellectual development, stressors, and preventive strategies. High levels of psychological distress, including anxiety (up to 43.7%) and depression (17–25%), are common among medical students. Academic pressure, sleep deprivation, and competitive environments are major contributing factors. Intellectual wellness, often neglected, is essential for cognitive growth, problem-solving, and academic performance. Ayurvedic perspectives emphasize holistic mental well-being through self-discipline, mindfulness, and balance in lifestyle. There is an urgent need to integrate mental and intellectual wellness frameworks into medical education. Promoting self-awareness, stress management, and intellectual development can enhance academic performance and personal well-being among medical students.

Keywords: Medical Students, Psychological and Intellectual Challenges, Medical Education, Ayurvedia, Pubmed, Charaka Samhita, Bhagavad Gita

INTRODUCTION

The World Health Organization defines health as a state of complete physical, mental, and social well-being not merely the absence of disease or infirmity. In traditional Indian medical systems, Acharya Sushruta similarly emphasizes the holistic nature of health, describing a healthy person as one whose physiological systems are balanced, whose mind and senses are content, and whose soul is at peace. Mental health, in modern terms, refers to emotional, psychological, and social well-being. It affects how individuals think, feel, and behave, as well as how they cope with stress, relate to others, and make choices. Intellectual health, while less frequently addressed, is equally vital. It involves maintaining cognitive functioning, engaging in creative pursuits, and continuously developing knowledge and skills for effective decision-making and lifelong learning. Medical students represent a uniquely vulnerable population due to the intense academic, emotional, and professional pressures they face. Research has consistently shown a high prevalence of depression, anxiety, burnout, and sleep disorders among this group. For example, studies have reported that up to 17% of medical students experience moderate to severe depression, while nearly half exhibit signs of academic burnout. Such mental health challenges are further compounded by intellectual fatigue, poor time management, and a lack of structured coping mechanisms. The modern medical curriculum, though rigorous, often neglects the mental and intellectual well-being of students. While institutions may provide academic support, structured programs addressing holistic development including emotional resilience, mindfulness, and cognitive wellness are rare. Additionally, classical Indian philosophical and Ayurvedic teachings offer timeless insights into self-regulation, balanced living, and the cultivation of intellect, which remain underutilized in modern education. This narrative review aims to critically explore the mental and intellectual health needs of medical students, synthesizing data from biomedical literature, educational surveys, and classical Indian knowledge systems. The objective is to provide a comprehensive framework for understanding these challenges and to offer integrative solutions that may inform educational policy and wellness programming.

METHODS

Design and Approach

This study was conducted as a structured narrative review, synthesizing both contemporary literature and classical Indian philosophical texts to examine the mental and intellectual health needs of medical students. While not a systematic review, this narrative approach employed transparent and structured methodology to ensure analytical rigor and thematic coherence.

Sources of Data

A comprehensive search was performed across the following sources:
Electronic Databases: PubMed, Google Scholar, ScienceDirect
Keywords Used: "mental health in medical students", "burnout", "academic stress", "intellectual health", "Ayurveda and mental well-being", "student wellness in medical education"
Institutional Reports: Council of Medical Education, WHO mental health publications
Classical Texts: Selections from Charaka Samhita, Bhagavad Gita, and other authoritative Ayurvedic sources relevant to mental and intellectual well-being
The search included English-language publications from the past 15 years and key classical Sanskrit translations with verified interpretations.

Inclusion Criteria

- Studies involving undergraduate or postgraduate medical students
- Articles or reports discussing psychological stress, burnout, cognitive impairment, or wellness programs in medical education
- Classical Ayurvedic texts discussing mental and intellectual wellness

Exclusion Criteria

- Articles without relevance to either mental or intellectual health
- Studies focusing solely on physical health outcomes without correlation to cognitive or emotional domains

Data Extraction and Synthesis

Relevant literature was reviewed in full and thematically coded into four core domains:

1. Mental health challenges among medical students
2. Intellectual well-being and cognitive development
3. Contributing stressors and risk factors
4. Preventive and integrative solutions, including traditional knowledge

A thematic analysis approach was employed to group findings under conceptually meaningful subheadings, and a synthesis was performed to identify recurring patterns and integrative frameworks.

RESULTS

Thematic analysis of literature and classical sources revealed five major domains relevant to the mental and intellectual health of medical students: (1) psychological morbidity, (2) academic stress and lifestyle patterns, (3) intellectual health and cognitive resilience, (4) traditional perspectives on mental wellness, and (5) existing and proposed interventions.

Psychological Morbidity in Medical Students

A significant body of literature underscores high levels of psychological distress in medical students. The prevalence of depression ranges from 17% to 30% in Indian and international studies, while anxiety disorders affect 28–43% of medical students globally [1–3]. Burnout defined by emotional exhaustion, depersonalization, and reduced personal accomplishment affects up to 49% of medical students by mid-training [4,5]. A 2021 meta-analysis by Puthran *et al*. found that 33.8% of medical students globally experienced depressive symptoms [6]. The risk of suicidal ideation was reported to be significantly higher among medical students than in the general population, with some reports suggesting they are up to 3 times more likely to die by suicide [7]. Sleep disorders are also highly prevalent. Up to 88.6% of students report sleep disturbances, including pre-, mid-, and post-insomnia [8]. Sleep deprivation due to late-night study and continuous academic load contributes to mood disorders and poor cognitive function.

Academic Stress and Contributing Lifestyle Factors

Major stressors identified include:

- Academic overload
- Performance pressure and fear of failure
- Time constraints and poor time management skills
- Sleep deprivation
- Lack of extracurricular or recreational breaks
- Peer competition and lack of faculty support

Studies from Russia and India consistently show that academic stress peaks during exam sessions and clinical rotations [9,10]. One Indian cross-sectional study found that 38% of students reported chronic fatigue, and over 33% slept fewer than six hours per night during exam periods [11].

Substance misuse and **eating disorders** have emerged as maladaptive coping mechanisms in some students, further worsening mental health and disrupting intellectual performance [12].

Intellectual Health and Cognitive Challenges

Intellectual health, though often neglected, is critical to effective learning, problem-solving, and academic success. Poor intellectual wellness manifests as

- Inability to concentrate

- Memory lapses
- Poor academic confidence
- Burnout-related cognitive dulling

Research shows that high levels of stress impair executive functioning and working memory, both essential for mastering complex medical subjects [13,14]. Moreover, the fear of judgment, intense competition, and lack of emotional support can lead to imposter syndrome, adversely impacting cognitive growth. Despite the emphasis on cognitive performance in medical training, structured interventions to enhance intellectual wellness (e.g., curiosity, lifelong learning, meta-cognition) remain largely absent.

Ayurvedic and Philosophical Insights on Mental and Intellectual Health

Classical Indian texts offer profound insights into balanced living, mental purity (sattva), and intellectual discipline (buddhi). In the Charaka Samhita, Acharya Charaka highlights the unity of mind and body

"मनसोज्ञानविज्ञानवैराग्यस्मृतिसमाचरिभिः" – Mental stability, knowledge, wisdom, and memory are integral to health. The Bhagavad Gita also addresses mental resilience through detachment, self-discipline, and self-awareness. The concept of Sattva is seen as the purest mental state one that fosters clarity, wisdom, and emotional stability. Ayurveda emphasizes that imbalances in doshas (Vata, Pitta, Kapha) affect mental faculties. Practices like meditation, pranayama, sattvic diet, and dinacharya (daily routine) are prescribed to maintain psychological equilibrium.

Preventive and Supportive Strategies

Modern evidence and traditional knowledge converge on several strategies for promoting mental and intellectual health

Mindfulness meditation: Reduces cortisol levels and improves attention span [15]
Yoga and pranayama: Improve mood, reduce anxiety, and enhance cognitive flexibility [16]
Time management training: Leads to better academic performance and reduced burnout [17]
Peer and faculty mentoring programs: Improve emotional well-being and academic engagement [18]
Inclusion of wellness modules: Institutions incorporating resilience training and emotional intelligence report improved outcomes [19]

DISCUSSION

This review synthesizes findings from contemporary literature and classical health systems, highlighting the urgent need to address the mental and intellectual well-being of medical students. The evidence demonstrates that the prevalence of psychological distress including depression, anxiety, burnout, and sleep disorders is consistently higher in medical students than in the general population or other academic groups [1,2].

Psychological Distress: An Overlooked Epidemic

The demanding nature of medical education creates a fertile ground for psychological morbidity. In line with the meta-analysis by Rotenstein *et al*., which reported depressive symptoms in over one-third of medical students globally [7], Indian studies have found similar trends, with additional cultural and institutional stressors such as academic hierarchy, parental pressure, and stigmatization of mental illness [4,5]. Furthermore, the risk of suicidal ideation and self-harm behavior is concerning. Studies by Dyrbye *et al*. and others have shown that the suicide risk in medical students is two to three times higher than in the general population [1,20]. This alarming statistic calls for comprehensive institutional mental health policies, early screening, and access to care.

Intellectual Health: The Silent Variable

Intellectual health, encompassing curiosity, analytical thinking, creativity, and self-directed learning, is often overlooked in traditional academic metrics. However, this review finds that cognitive burnout is as critical as emotional burnout. Stress impairs the prefrontal cortex, reducing executive functions such as decision-making,

attention, and working memory [21,22]. A study by Durning *et al*. emphasized that cognitive overload during clinical rotations directly affects medical reasoning and memory retrieval [23]. Moreover, the "hidden curriculum" implicit pressures and norms within medical schools often discourages open intellectual inquiry and creativity, fostering a culture of rote learning and performance anxiety [24].

Bridging Tradition and Modern Mental Health

Ayurvedic concepts offer a holistic framework for balancing mind, intellect, and behavior. The principle of *Sattva* promotes clarity, mindfulness, and equanimity mental qualities shown to buffer against stress-related cognitive impairment [25]. Mindfulness-based interventions rooted in Eastern traditions have been shown to reduce cortisol, improve attention, and mitigate symptoms of anxiety and depression [26,27]. Similarly, the concept of *Buddhi* (intellect) aligns with modern neurocognitive constructs. The cultivation of *Buddhi* through structured routine (*Dinacharya*), mindful discipline (*Yama-Niyama*), and *Swadhyaya* (self-study) enhances metacognition and self-regulation [28,29].

Institutional and Preventive Interventions

Numerous studies highlight the effectiveness of evidence-based interventions to address these challenges:
Mindfulness-based cognitive therapy (MBCT) improves concentration and reduces depression recurrence [30].
Yoga and physical exercise have been associated with better academic performance and emotional balance [31].
Resilience training and **emotional intelligence workshops** are increasingly adopted by forward-thinking medical schools [32,33].
The success of programs like Vanderbilt's "Mind-Body Medicine Elective" and Saint Louis University's "Wellness Curriculum" demonstrates the feasibility and scalability of such interventions [34,35]. Moreover, peer-support groups, faculty mentorship, and stress-reduction modules have all shown positive outcomes in terms of student engagement, retention, and satisfaction [36].

The Need for Policy Integration

Despite overwhelming evidence, wellness remains peripheral in most medical curricula. A review by Slavin *et al*. found that fewer than 20% of medical schools had structured, longitudinal wellness programs [35]. There is a need for

- Mandatory mental health orientation in the first year
- Embedded counseling access without stigma
- Scheduled "wellness breaks" and digital detox hours
- Integration of Ayurvedic mindfulness or lifestyle electives

The National Medical Commission (NMC) in India has the opportunity to lead in this regard by mandating psychological health modules under the Attitude, Ethics and Communication (AETCOM) program [37].

Limitations of This Review

This narrative review, while structured, is limited by its reliance on secondary data. No primary or survey-based data was collected. Although thematic synthesis and diverse source triangulation were used, systematic bias may be present in the selection of articles or interpretations of traditional texts.

CONCLUSION

Mental and intellectual well-being are indispensable components of a medical student's overall health and academic success. The high prevalence of psychological disorders such as depression, anxiety, burnout, and sleep disturbances among medical students globally and in India specifically underscores a systemic failure to prioritize mental wellness in medical education. Equally concerning is the widespread neglect of intellectual health, including cognitive resilience, critical thinking, and sustained curiosity, which are crucial for both personal growth and professional competence. This review has demonstrated that medical students operate in environments fraught with academic

overload, emotional stress, and insufficient psychosocial support. It has also highlighted the underexplored yet powerful potential of traditional health systems especially Ayurvedic concepts like *Sattva* and *Buddhi* in restoring balance and promoting holistic wellness. There is a clear and urgent need to integrate structured mental health screening, cognitive wellness programs, mindfulness practices, and emotional resilience training into the medical curriculum. Policy reforms at institutional and national levels, including incorporation of mental health education under modules like AETCOM, are critical steps toward cultivating a generation of physicians who are not only clinically competent but also emotionally intelligent and intellectually thriving. A healthy medical student is more likely to become a compassionate and capable physician. Ensuring their mental and intellectual well-being is not merely an academic concern it is a public health imperative.

Table 1. Prevalence of Key Mental Health Issues in Medical Students (Selected Studies)

Mental Health Issue	Reported Prevalence	Source/Study	Country
Depression	17% – 33.8%	Puthran *et al*., 2021 [6]	Global
Anxiety	28% – 43.7%	Zaid *et al*., 2018 [3]	UAE
Burnout	35% – 49%	Ishak *et al*., 2013 [4]	USA
Insomnia/Sleep Deprivation	33% – 88%	Kalmbach *et al*., 2019 [8]	USA/India
Suicidal Ideation	Up to 11%	Rotenstein *et al*., 2016 [7]	Global

Table 2. Ayurvedic Concepts and Their Relevance to Mental and Intellectual Health

Ayurvedic Concept	Description	Modern Interpretation	Relevance
Sattva	Mental purity, clarity, peace	Emotional balance, mindfulness	Promotes resilience and cognition
Buddhi	Intellect, decision-making	Executive function, rational thinking	Essential for learning and judgment
Ahar-Vihar	Diet and lifestyle	Nutritional psychiatry, lifestyle medicine	Supports neurocognitive functioning
Dinacharya	Daily routine	Circadian hygiene, sleep-wake cycle	Reduces fatigue, improves focus
Mano-nigraha	Control over the mind	Cognitive control, emotional regulation	Prevents impulsivity and distraction

REVIEW ARTICLE

A Review of Siddha Medicines for the Management of *Valippu Noi* (Epilepsy)

ABSTRACT

The Siddha system, one of the oldest streams of Indian medicine, provides a unique and in-depth approach to managing neurological disorders such as epilepsy, referred to in classical texts as Valippu Noi. In contrast to modern treatments that primarily aim to control seizures, Siddha therapies seek to correct the underlying imbalance among the three vital energies Vatham, Pitham, and Kabam. This review was carried out to systematically gather and document Siddha based formulations and therapeutic methods used for Valippu Noi. Data was compiled through the study of classical Siddha texts from various well-established libraries in Tamil Nadu. A total of 59 internal medicines and 14 external therapies were identified, including preparations such as kudineer (decoctions), chooranam (powders), mathirai (tablets), and Ennai (medicated oils). Many of these are attributed to notable Siddhars, reflecting the deep traditional roots of the system. External treatments largely involve medicated oil applications and fomentation techniques aimed at restoring balance in the humors. The review aims to provide a foundation for integrative neurological care and promote further clinical validation of these traditional formulations.

Keywords: Siddha Medicine, Valippu Noi, Epilepsy, Herbal Formulations, Neurological Disorders

INTRODUCTION

The Siddha medical tradition is a time-honoured healing system with deep roots in Tamil culture, developed and enriched by generations of Siddhars. Unlike modern healthcare, which often focuses on diagnosing and treating symptoms, Siddha medicine prioritises disease prevention and maintaining equilibrium among the three bodily humors Vatham, Pitham, and Kabam. It integrates herbal and mineral medicines, dietary practices, external therapies, and lifestyle adjustments to promote long-term health. Among the conditions discussed in classical Siddha literature, Valippu Noi, closely resembling epilepsy, is considered a significant neurological disorder. Terms such as Isivu, Iluppu, and Muyal Vali are used to describe seizure-like events, often linked to an imbalance in Kabam, usually along with disturbances in Vatham and Pitham(1). Factors such as stress, hereditary tendencies, prolonged illness, and fatigue are believed to contribute to the condition. Common symptoms described include sudden loss of consciousness, limb convulsions, foaming at the mouth, and facial distortions (2). In modern neurology, epilepsy is understood as a chronic brain disorder marked by recurrent seizures due to abnormal electrical activity. Causes may vary from genetic and metabolic issues to head trauma or infections. While Siddha and modern approaches differ in theory and practice, Siddha medicine offers comprehensive care by strengthening the nervous system and addressing root imbalances. However, many Siddha remedies for epilepsy remain unexplored in scientific literature. This study aims to compile and classify such formulations for future research and potential therapeutic application.

MATERIALS AND METHODS

A detailed literature search for the formulation of valippu noi was done in the library of the National Institute of Siddha, Library of Govt. Siddha Medical College, Palayamkottai, Government Siddha Medical College, Chennai, Siddha Central Research Institute Library, Chennai, The Connemara Public Library, Chennai, The Anna Centenary Library, Chennai, and Saraswathi Mahal Library, Thanjavur. In these libraries the keywords used to collect the formulations are Ilupu, Isivu, Valippu Noi, vali, and muyal vali. In that formulations were collected and analysed with the help of MS Office.

RESULTS

The study results showed that there are 32 Siddha literature evidences dealing with valippu noi. Mostly these books were written by Agasthiyar in his Agasthiyar Vaithiya Rathina Churukkam, Agasthiyar 2000, and Agasthiyar Vaithiya Pillai Tamil. From our documentation, 59 internal medicines were classified under various forms, such as kudineer – 4, chooranam – 1, kirutham – 2, rasayanam – 1, ilagam – 2, ennai – 11, maathirai – 10, mezhugu – 4, pathangam – 1, chenduram – 10, parpam – 7, kattu – 2, chunam – 1, karuppu – 2, and karpam – 1. The external medicines are 14 and were classified under the form, such as thailam – 9, anjanam – 1, nasiyam – 2, pugai – 1, and kallikam – 1. The formulation of internal and external medicines for Valippu Noi is detailed in Table 1 & 2.

DISCUSSION

This review comprehensively analyzed Siddha medical formulations traditionally used in the management of Valippu Noi (epilepsy). The vast array of internal and external medicines compiled from classical Siddha literature highlights the depth of traditional knowledge in treating neurological disorders, particularly seizure-related conditions. The classical classification of Valippu Noi into different types like Kakkai vali, Muyal vali, and Muppini vali aligns with modern classifications of epilepsy such as generalized, reflex, and partial seizures. This correspondence provides a useful framework for exploring integrative approaches to epilepsy care. A total of 59 internal formulations and 14 external therapeutic options were identified, spanning various dosage forms such as kudineer (decoction), mathirai (tablet), mezhugu (wax-based), ennnai (medicated oil), chooranam (powder), pathangam, chenduram, parpam, and karpam. The multi-herbal and mineral compositions in these preparations

reflect a sophisticated system of formulation that balances the three vital humors—Vatham, Pitham, and Kabam. This tridoshic approach is rooted in the Siddha principle that neurological disturbances often stem from Kabam derangement, compounded by Vatha-Pitha imbalance. Notably, several herbal ingredients used across these formulations—such as Bacopa monnieri (Brahmi), *Withania somnifera* (Amukkura), *Centella asiatica* (Vallarai), and *Acorus calamus* (Vasambu)—are pharmacologically validated for their anticonvulsant, neuroprotective, and anxiolytic properties. These plants exhibit multiple CNS activities including modulation of GABAergic, serotonergic, and cholinergic systems, supporting their inclusion in antiepileptic regimens. Studies cited in this review demonstrate antioxidant, adaptogenic, and nerve-stabilizing effects that could reduce neuronal excitability and seizure frequency. The inclusion of formulations containing minerals and metals (e.g., Parpam, Chenduram, Karuppu, Kattu) reflects Siddha's unique Rasa pharmacology. However, these metallic preparations warrant careful toxicological evaluation and standardization to ensure safety, especially when transitioning into clinical research and integrative healthcare models. The external therapies—especially medicated oils like Kasthuri ennai, Maantha ennai, Kalingathi ennai, and nasal applications (Nasiyam)—serve dual purposes. They not only address localized symptoms but are believed to assist systemic balance via olfactory and transdermal absorption. Pugai (fumigation) and Anjanam (collyrium) offer additional therapeutic avenues for reflex epilepsy and behavioral manifestations. Despite the extensive documentation of these formulations, there is a notable lack of systematic pharmacological studies and clinical trials validating their efficacy and safety. Most existing evidence is anecdotal or derived from traditional practice. Bridging this gap requires multidisciplinary collaboration involving pharmacognosy, phytochemistry, toxicology, and clinical pharmacology. Another challenge is the standardization of raw materials, preparation methods, and dosage forms. Variability in these aspects can affect therapeutic outcomes and reproducibility. Adopting PLIM (Pharmacopoeial Laboratory for Indian Medicine) standards for quality control and Good Manufacturing Practices (GMP) can greatly enhance the reliability and acceptability of Siddha formulations in contemporary settings. Furthermore, the integration of traditional diagnostic concepts with modern clinical assessment could provide more individualized and holistic treatment protocols. Understanding patient constitution (Udaliyal), humor imbalance (Uyir Thathukkal), and seasonal variations (Kaala Maruthuvam) remains essential in tailoring Siddha-based epilepsy management.

CONCLUSION

This review highlights the therapeutic richness and diversity of Siddha medical formulations in managing Valippu Noi (epilepsy). Drawing upon classical texts and categorizing numerous internal and external preparations, the study reaffirms the historical depth of Siddha knowledge in neurological care. Many of the herbal ingredients have demonstrated pharmacological actions such as anticonvulsant, neuroprotective, and antioxidant effects. Additionally, the Siddha system's tridosha-based pathophysiology aligns meaningfully with modern understandings of seizure subtypes. However, the absence of standardized protocols and rigorous clinical trials remains a barrier to mainstream integration. There is an urgent need for further scientific exploration including preclinical, toxicological, and human studies to evaluate efficacy and safety. By bridging the traditional formulations with modern research methodologies, Siddha medicine can evolve as a complementary approach in epilepsy care. The documentation presented here serves as a foundation for advancing that integration.

ACKNOWLEDGEMENT

The authors also thankful to the faculties of Department of Maruthuvam, National Institute of Siddha, Tambaram sanatorium, Chennai, for providing their support.

Ethical Approval

As the present study is a Literature review, it does not involve the use of human or animal subjects and therefore, ethical clearance is not applicable.

Funding
The author(s) received no financial support for the research, authorship and/or publication of this article

Conflict of Interest
The author(s) declared no potential conflicts of interest with respect to the research,

Table 1: Formulations of Internal Medicines For *Valippu Noi* (Epilepsy)

INTERNAL MEDICINE	PREPARATORY MEDICINE	INDICATION
Kudineer	*Vallipukukudineer[5]*	Valippu noi (Epilepsy)
	Kunmam, vaanthi, valippu, vaaineerooralukukudineer[5]	*Vaanthi* (Vomiting), *Kumatal* (Nausea), *Valippu noi* (Epilepsy) *Gunmam* (Gastric ulcer),*Vaai neerooral*(Hypersalivation)
	Muyal valippu kudineer[5]	*Muyal valippu* (Reflex epilepsy)
	Sethuma sura kudineer[3]	*Kaasam*(Cold),*Erumal*(Cough), *Suram*(Fever), *Valippu noi* (Epilepsy), *Kuralkammal* (Hoarseness of voice)
Chooranam	*Kakkai valippu neengachooranam*[24]	*Kakkai valippu* (Grandmal epilepsy)
Kirutham	*Maha mega kirutham*[9]	*Kalladaipu*(Renalcalculi) *Muyal valippu* (Reflex epilepsy), *Perumbadu* (Menorrhagia), *Vellai noi* (Leucorrhoea), *Neerkiricharam*(Urinary tract infection), *Kshayam*(Tuberculosis), *Erumal* (Cough)
	Kandangathiri kirutham[7]	*Muppini vali* (Partial adversiveseizure),*Gunmam*(Gastric ulcer)
Rasayanam	*Chithiramoolarasayanam*[15]	*Paandu* (Anaemia), *Kuttam* (Leprosy), *Valippu noi* (Epilepsy), *Meganoi* (Syphilis), *Gunmam*(Gastric ulcer)

Ilagam	*Kandangathiri legiyam*[3]	*Gunmam*(Gastric ulcer), *Valippu noi* (Epilepsy), *Peenisam*(Sinusitis), *Megavettai*(Gonorrhea)
	Mulli muti legiyam[7]	*Kudarpuzhu*(Worm infestation), *Valippu noi* (Epilepsy)
Ennai	*Neikottaanpalathennai*[12]	*Muppini vali* (Partial adversive seizure)
	Kasthuri ennai[12]	*Valippu noi* (Epilepsy), *Karapan* (Eczema), *Iraippu*(Asthma)
	Kaalakini thailam[12]	*Sanni* (Delirium), *Valippu noi* (Epilepsy)
	Maanthaennai[3]	*Valippu noi* (Epilepsy), *Seriyamai* (Dyspepsia)
	Viluthiennai[3]	*Valippu noi* (Epilepsy), *Kudarpuzhu* (Worm infestation)
	Kalingathiennai[3]	*Valippu noi* (Epilepsy), *Gunmam*(Gastric ulcer), *Karapadhasoolai* (Peripheral neuritis)
	Anjennaithailam[15]	*Valippu noi* (Epilepsy), *Neerandam* (Hydrocele), *Sanni* (Delirium)
	Thalagathailam[16]	*Sanni* (Delirium), *Valippu noi* (Epilepsy)
	Sagalavalippukusudarthailam[10]	*Sanni* (Delirium), *Valippu noi* (Epilepsy)
	Nimba ennai[10]	*Sanni* (Delirium), *Valippu noi* (Epilepsy)
	Aegamulithailam[25]	*Kuttam* (Leprosy), *Meganoi* (Syphilis), *Megavettai* (Gonorrhea), *Muyal vali* (Reflex epilepsy), *Perumbadu* (Menorrhagia), *Peenisam* (Sinusitis), *Sanni* (Delirium), *Kandamalai* (Cervical lymphadenopathy), *Madhumegam* (Diabetes mellitus)
Maathirai	*Vishnu chakaramathirai*[6]	*Sanni* (Delirium), *Valippu noi* (Epilepsy), *Vikkal*(Hiccups)
	Karrupuvishnuchakaramathirai[8]	*Valippu noi* (Epilepsy), *Neerandam* (Hydrocele), *Gunmam* (Gastric ulcer), *Pakkavadham* (Hemiplegia), *Keelvayu* (Arthritis), *Suram* (Fever)
	Yogarasamaathirai[6]	*Kaasam* (Cold), *Erumal*(Cough), *Sanni* (Delirium), *Valippu noi* (Epilepsy), *Gunmam* (Gastric ulcer), *Kshayam* (Tuberculosis)
	Suriya prabaimaathirai[6]	*Sanni* (Delirium), *Valippu noi* (Epilepsy), *Uppusam*(Bloating), *Suram* (Fever), *Seriyamai*(Dyspepsia)
	Korosanaimaathirai[3]	*Valippu noi* (Epilepsy)
	Swarna chinthamanimaathirai[12]	Kshayam (Tuberculosis), *Erumal* (Cough), *Valippu noi* (Epilepsy),*Meganoi*(Syphilis)

ABSTRACT

Malicious software often known as invader malware, is metamorphic and polymorphic by its nature, suggesting that it may modify the program as it escalates. Malicious programs that steal users' personal information, send data to elicit deductions, utilize a surge in privilege to manage the control, and so on, inflict severe harm on end users. Furthermore, the diversity in the number of their variations significantly impairs the efficiency of existing defenses, which mainly utilize signature-based approaches and are unable to identify previously discovered malicious executables. Malware group variations have common behavioral traits that identify their source and intent. Malware detection is critical to computer security. For extracting harmful traits, modern machine learning algorithms have been based on domain expertise. Furthermore, many possible traits can be employed, and manually identifying the optimal attributes is time-consuming and complex, especially considering the various nature of malware. Due to inadequate security design as well as the unique properties of IoT devices, such as processor architectural heterogeneity, IoT malware detection has quite complexities, particularly in identifying cross-architecture IoT malware. As a result, in recent years, the security community has focused its research on this issue of IoT malware detection. This study provides an outline of malware detection techniques, the types of malware, and the advantages of malware analysis. The systematic review will provide a thorough comprehensive index of strategies to assist in the conflict over malicious information.

Keywords: Malware analysis and detection, IoT malware, Android system, Machine Learning, Hypervisor

INTRODUCTION

Malware is an unauthorized, harmful initiative intended to cause chaos for the user and the system it is installed on. Viruses, Trojans, backdoors, spyware, crypto-lockers, and ransomware are examples to name a few. Malware assaults have risen substantially in recent years, demonstrating that many businesses, from huge multinational firms with high-security budgets to low businesses with individuals, are unable to safeguard themselves from the attackers adequately [12]. Android is an open-source mobile OS software that runs on a wide range of devices. According to Google, 1.2 million Android devices are enabled every day. As reported by Cisco [1], 98 percent of malware is targeted at Android users. In general, the Android OS is vulnerable to security flaws or threats. Spyware, Trojans and phishing apps are among the malware types putting the user's data and device in danger. The Internet of Things (IoT) [23] is a technology in which a collection of interconnected devices exchange data via a wireless connection without the need for human involvement. Monitoring device actions [5] to develop behavioral fingerprints or profiles is one method that has gained attraction in detecting malware-infected devices. Machine Learning (ML) [29] is the earliest and most plausible solution to the malware categorization challenge, and it has been used to solve various attacks. A classifier model is built using pattern recognition to understand the malware behavior and propagation techniques. ML has traditionally been used in anomaly-based detection approaches in which the training and detecting or testing phases [19] are the most important steps to detect malicious behavior. Cyber security [38] is critical in defending against the attacks that arise in secure computing. Virtual Machine Introspection (VMI) technique [37] is another way to solve cyber security problems. In Virtual Machine Monitor (VMM) the security firewalls are paralyzed to get the key information of the host running machine, the semantic perspective of an OS in the host virtual machine could be assembled using low-tier contemplation semantics. Malware detection procedures using VM are illustrated in Fig.1. Cloud Computing [10] Cyber security researchers deal with attacks that exploit legitimate cloud services in attempts to access sensitive data. Cloud malware attacks cloud computing-based systems with malicious code and service.

Preliminaries

Introduction to Malware

Malware (also known as malicious software) is software that is meant to harm users, businesses, computers, and communications systems. Malware can disable internet access, harm an operating system, steal a user's password, and other personal information, and encrypt vital documents on a computer before demanding a ransom. Most antivirus engines detect and classify malware by scanning files regularly and matching their signatures to those of known malware. Human antivirus professionals (also known as malware defenders) analyze the collected malware samples to produce malware signatures. Malware signatures [18] might be filenames, text strings, or byte code regular expressions. Signature-based approaches, on the other hand, can only detect traditional malware that doesn't differ much. Categories of malware are classified into three types, as indicated in Fig.2.In a piece of fiction, malware plays a crucial part. The fiction could be in the form of audio, video, game, or something else entirely; malware, like viruses, plays a vital role. In fiction, the hackers find several infections some of which are described in Table 1.

Malware analysis is usually classified into one of three categories [11].

- Static Malware Analysis
- Dynamic Malware Analysis
- Hybrid Malware Analysis

Malware Types

Malware encompasses a wide range of harmful software including viruses, worms, rootkits, Trojan horses, backdoors, botnets, spyware, adware, and ransomware. Malware versions are categorized depending on certain characteristics such as propagation mechanisms, infection types, and so on. Table 2. Depicts the types of malware.

Patterns of Malware attacks

Despite harmful software may be grouped into numerous categories, malicious software is difficult to review. The following are examples of generic malware attacks [18]

- Infiltration of currently active operations.
- Mutates are created as well as acquired.
- Monitoring the stability of the network.
- System services can be started and stopped.
- Re-modelling of the executables.
- Re-modelling of the root path.

Android Malware Detection Analysis Techniques

Android malware is malicious software that attacks mobiles and wireless-enabled devices which results in system crashing and private details being destroyed or exposed. According to the survey, Android malware detection analysis methodologies are classified into three types: static analysis, dynamic analysis, and hybrid analysis. Numerous sorts of Android Malware Detection Techniques are shown in Fig 3. In malware threats, the major purpose of static analysis is to investigate permissions, its application's software, components, resources, and signatures. The APK file contains all the data about the application. The APK file is used for static analysis. The permissions, resources, code, services, and other data are taken and evaluated properly from the APK file. For static analysis [1], there are several tools available including jd-gui, aapt, apktool and dex2jar.

Classification of Malware by Malicious Behaviors

Malware uses certain characteristics to carry out destructive operations, but it also uses other behaviors to evade detection or hide its presence. Focusing on malware behavior rather than malware kind is more significant for analytical reasons. It should be highlighted that after studying binary code and knowing about its behavior, it is much simpler to categorize it into the appropriate malware category and describes the behavior of malware [12].

Study on Static and Dynamic Malware Analysis

Malware analysis involves the study of determining how a suspicious file or a URL behaves and what its aim is. The analysis output aids in detecting and mitigating the possible threat. In this section, a full comparison of different malware analyses is presented from the perspectives of IoT Malware, Android System, Machine Learning, and Hypervisor. Evanson *et al*. [24] proposed an employing technique of Haralick picture texture characteristics with ML classifiers such as Random Forest (RF), Naive Bayes (NB), and K-Nearest Neighbor (KNN) to analyze and identify IoT malware. Code compression, Code encryption, IP identification, User interaction, Data identification, Environmental awareness, Code obfuscation, and timing are the popular IoT malware evasion strategies [23]. With a focus on IoT malware detection, Abawajy *et al*. [8] mentioned the feature selection issue like a quadratic programming challenge and then investigated the effectiveness of frequently adopted filter-based datasets. Rey *et al*. [5] discuss the opportunities that federated learning opens up in terms of IoT malware detection, as well as the security challenges that come with the proposed solution. To ensure model authenticity and quality, Yulei *et al*. [22] propose a unique user Local Neural Network (LNN) that enables local access and a smart sensing signed agreement that allows integration through the blockchain network. Sercan *et al*. [35] explain how to categorize Android malware samples into groups. Prerna *et al*. [2] proposed a generic malware detection technique. The proposed method [31] elaborates on the difficulties that can be encountered while using existing tools and techniques. As a result, a robust obfuscation-resistant malware detector is required. Qing *et al*. [42] discuss the Android app composition, analyses the source of static features, and present an analysis of Android malware static detection. Yue Liu *et al*. [21] provide a thorough examination of the use of Deep Learning (DL) in Android malware investigation. The research also looks at the state of DL-based Android malware countermeasures.

Machine Learning

ML is used to conduct a statistical examination of detection procedures. Malware detection strategies [32] can be classified in a variety of ways based on mobile malware-based techniques, classical, ML-based approaches, deep

learning-based techniques, and PCs. Daniele *et al*. [4] explain how ML works on malware research using Windows systems, specifically for the study of Portable Executables and their goals. Neil *et al*. [15] claimed that the experiment findings showed that the strings feature set had attained a high level of accuracy for this dataset and that these detectors execution times looked tractable making them appropriate for application in large-scale malware analyzers. This research reviews on ML-based android malware detection algorithms [19]. Welsh's t-test [20] is used to determine the uniqueness of spectrograms and DWT coefficients from diverse malware. Preeti *et al*. [3] introduce VMShield, a contemplation stateful firewall for safeguarding virtual domains within cloud-based portals that aim to detect malware in cloud architecture. The suggested AMD framework [10] functionality has been tested in the cloud with the most recent malware datasets. Finally, this examines the proposed framework's ability to meet VM security criteria.

IoT Malware

DEAM or Depthwise Efficient Attention Module [36] is a novel as well as simple Convolution Neural Network (CNN) focus module that is introduced and coupled including a DenseNet to create an innovative malware detection and family heuristic approach. Nazar *et al*. [13] propose a methodology for aggregating numerous platform-independent models with non-overlapping statistics combined into a single model continuously. As devices work on well before network infrastructure [33], such as the Mirai Malware Attack, the scope for cyber-attacks on IoT Infrastructure was immense. A novel automation algorithm-based technique [25] for identifying Mirai is presented and performed. For reliable and rapid malware detection, Zhaoqi *et al*. [27] proposed a unique and low-cost technique to extract features, as well as an efficient deep neural network architecture.

Android System

To identify malware from trusted programs a unique detection method was suggested. The proposed work interpreted each sequence like a phrase in the syntax and then built a signaling on the Long Short-Term Memory (LSTM) classifier [16] asserting that system call patterns like high-level languages, include semantics. Following that, two similarity scores were produced using these models. DroidEvolver[7] seems to be an Android malware detection strategy which can update itself instantly and persistently while identifying malware without the need for human interaction. This paper proposed a quick malware detection system for Android combining a variety of features: FAMD is an acronym for Fast Android Malware Detector [9]. Yucming *et al*. [28] reveal how contrastive learning was used to enable obfuscation-resistant malware analysis. PermPair[26] a novel detection approach was developed to produce and analyze networks across malicious as well as regular extracts by retrieving access matches out of a user's folder.

Machine Learning

Malware detection relies on a combination of Changed Registry Keys, Summary Information, APIs and DLLs. Cuckoo sandbox [11] is used for dynamic attack detection and provides high accuracy. This research presents a dynamic malware detection method that uses memory investigations to retrieve destructive artifacts in memory and integrate those using data acquired throughout malware processing. Pre-modeling methods [40] are employed for classifiers before the validation set which consists of the data set on ML algorithms. Zhixin *et al*. [6] use ML to investigate a promising strategy for hardware-assisted malware detection. The most serious threat to Cyber-Physical Systems (CPS) is being infected with malware that turns them into botnets. Following botnets are the two new types of malware that have been identified: DoS and advanced persistent threats. The utmost malware strikes within those modules, the most enticing processes for detecting attacks in cyber-physical frameworks or the prospective cables of investigations only with maximum effect about the near future [17]. This evaluates several reflective posts and summarizes the results acquired, as well as the most familiar cyberattacks in these modules are classified. Matthew *et al*. [30] collected information across multiple permission levels within another operating system to better identify possible variations.

Hypervisor

This study suggested retaining a list of the features in storage access patterns at the hardware level by applying window-based trait computation [14]. This research paper proposes a new dataset for cloud IDS implementation based on VM Introspected data. Using the Virtual Machine Introspection (VMI) approach [38], the dataset was produced on virtualization by combining malware behavior with benign trial activation artifacts. Jian *et al*. [37] propose a new malware detection approach in order to increase virtual machine privacy and ensure the overall security infrastructure Using Memory Forensics Analysis (MFA) and Virtual Machine Introspection (VMI) technologies, this study extracts a variety of data from virtual machine core, the hypervisor layer and the hardware overlay. Leon *et al*. [39]introduce a method for analyzing malware within the context of the operating system.

Literature Review on Hybrid Malware Analysis

Roopak *et al*. [34] suggested a novel hybrid malware detection method that relies on Tree Augmented Naive Bayes (TAN) that exploits implicit interrelations between crucial static and dynamic characteristics these were essential by a platform's execution. To ensure the effectiveness and productivity for large-scale Android malware detection, the research work presents a hybrid approach based on CNN and Deep Auto-Encoder (DAE) [41].
Comparative Analysis on Static and Dynamic Analysis

Comparative Investigation for Static and Dynamic Analysis

Detailed Comparative Investigation for Static Analysis on IoT, Android, Machine Learning and Hypervisor are tabulated in Table 3, Table 4, Table 5 and Table 6 respectively. Similarly, Detailed Comparative Investigation for Dynamic Analysis on IoT, Android, Machine Learning and Hypervisor are tabulated in Table 7, Table 8, Table 9 and Table 10 respectively.

Reverse Engineering

Reverse engineering is a process of analyzing a malicious code to determine its structure components, elements, and behavior. The advantage of reverse engineering is that it enables one to observe the hidden behavior of the file under analysis, which is unable to be done by simply running it. In static malware analysis, commencing analysis of any given problem by identifying the characteristics related to it and analyzing the behavior from those features without directly involving the analysis in execution. The benefit of static analysis is that, without actually executing it, it provides us with a clear understanding of how it will impact the environment. Static analysis of malware can be aided by a variety of tools, including decompilers, disassemblers, source code analyzers, and other tools that support extracting vital features from malicious code. It is not required to have a controlled environment to do static analysis on malware. Static analysis examines the malware code to nearly predict its characteristics and features. To mitigate static analysis, the malware author applied methods like binary obfuscation and packing. In a dynamic analysis, the malware's complete activity and impact on the environment are monitored as it runs. Debuggers, registry monitors, file system monitors, network sniffers, and API call tracers are tools that contribute to the dynamic analysis of malware. The code that needs to be executed in the case of dynamic analysis is corrosive and uncertain. The reversing environment must be isolated from the other hosts on the network. Due to the strong separation between the guest operating system in a virtual machine and the host operating system, even if the virtual machine is infected with malware, it has no impact on the host operating system while reverse engineering is worked out in a VM.

CONCLUSION

This study examined core characteristics/parameters and several malware analysis methodologies. The proposed work makes three major contributions. First, malware analysis preliminaries are suggested, which comprise malware and its classifications, malware attack forms, significance, and issues related to malware categorization and composition analysis. Second, a Literature review on static and dynamic malware analysis from the perspectives of the Android system, Machine Learning, the Internet of Things, and the Hypervisor. Third, a comparative evaluation is conducted for current malware classification and composition analysis methodologies, arranging them according

to the suggested taxonomy. This work highlighted the advantages of these findings based on the mechanism, detection study, and processing time, which can be employed to enhance future work efficiency.

Table 1: Malware by Fiction

Sl. No.	Name of the Malware	Function
1.	Digimon Fusion	A bunch of kids is transported to another digital domain and given the duty of saving the digital society from wickedness
2.	Digimon Data Squad	
3.	Digimon D-Cyber	
4.	Digimon Adventure	
5.	Digimon Adventure 02	
6.	Digimon Adventure tri	

Table 2: Types of Malware

Type	Function	Example
Ransomware	Until the ransom is paid, the victim's access to data is disabled	RYUK
Spyware	without the users' knowledge, gathers information on user activities	DarkHotel
Adware	promotes intrusive ads	Fireball
Trojans	conceals itself to be desired code	Emotet
Rootkits	allows hackers to take control of a victim's device remotely	Zacinlo
Bots	unleashes a barrage of attacks	Echobot
Keyloggers	tracks the keystrokes of individuals	Olympic vision

Table 3: Static Malware Analysis on IoT

Sl. No	Paper Ref. No	Aim	Proposed Methodology/ Algorithm/ Techniques	Methodology/Algorithm/ Techniques Used	Dataset Used	Software Tools Used and Platform	Performance Metrics	Advantages
1	[8]	To assess and classify malware in IoT, Texture features and conventional machine learning classifiers are used.	For IoT malware, the roc curve and PR analysis are used tocritique the Haralick texture features for each picture	Haralick images and Machine Learning Classifiers	Open Data Institute node-Trento	VirusTotal	95\% accuracy	Haralick features have been used to evaluate trained models
2	[23]	Beaucoup strategies are used to mitigate a black hole assault in IoT malware detection	Malware was separated into fundamental structure, low-level activity, and high-level behavior	Trust-based scheme and HCP	AMPds Datasets	Not Mentioned	Not Mentioned	Various malware evasive techniques were discussed
3	[22]	To detect IoT malware a quadratic programming problem is solved using a filter-based	The characteristic ensemble selection Approaches are presented employing filter-based features extraction	Filter-based feature selection methods	AndroZoo and VirusShare	WEKA 3.8 and VirusTotal	More than 95 %	The best selections of features are used to minimize the space and time complexity of classification

		feature selection algorithm	approaches					
4	[5]	A framework is presented to employ federated learning to detect malware that affects IoT devices	N-BaIoTFederated Learning methodology is used in the proposed technique.	MINIBATCH AGGREGATION and MULTI-EPOCH AGGREGATION	N-BaIoT datasets	VirusTotal	97 % Accuracy	Following the federated approach, it had been proved that data privacy was ensured without sacrificing model performance
5	[35]	To aggregate many user-trained networks using non-overlapping into one model, a blockchain-based aggregation approach is utilized	Decentralized Learning using Blockchian is used in the proposed IoT multi- feature deep learning model	Compose deep learning scores of the public blockchain and DroidBot Emulator	Bluestack, DroidKin dataset and Andro - MalShare	Not Mentioned	Federated Block chain achieves 98.62% accuracy	When uploading and downloading programmes from the Internet,to assess if it is harmless or malicious, a blockchain request is used

Dynalog file.				identifying malware, resulting in increased security for IoT devices.
3	[13]	To perform classification and detection technique for MIRAI malware attack network forensic is implemented.	Random Forest Algorithm is derived to detect MIRAI malware in IoT devices	Random forest [Gini Index], Tree Importance Decision.	Scan attack dataset	PT-838 Provision devices	95.01% of accuracy	The selection of the appropriate features furthermore aids in producing high detection accuracy.
4	[33]	To identify MIRAI Malware a unique Automation Algorithm-based strategy is implemented using python.	The evaluation of various models, including reliable model that gives accuracy in identifying malware and a classifier that generates huge TP data and a high F-1 value for technique to work.	Artificial Neural Network, Multi-layer perceptron	BIG 2015 Dataset	Matlab 2018b and python	92.8% of accuracy	The model comparison yielded a precise estimation with high precision for classifying malware.
5	[25]	Including an efficient deep neural network architecture for accurate and speedy malware detection, a unique and low-cost technique is adapted.	Gated-CNNs is implemented which allows the selection of important and relevant information with language tasks, it competes against recurrent classifiers.	Hash functions, Deep Neural Network	SecureAge Dataset	Cuckoo sandbox and Virtual Machines	98.80% of accuracy	Every API call's wide hash characteristics must be transformed, multiple gated-CNNs are used.

Table 8: Dynamic Malware Analysis on Android

Sl. No	Paper Ref. No	Aim	Proposed Methodology / Algorithm/ Techniques	Methodology / Algorithm/ Techniques Used	Dataset Used	Software Tools Used and Platform	Performance Metrics	Advantages
1	[27]	To distinguish malware from trusted applications, a categorization on the	LSTM model-based classifiers are used to demonstrate the effectiveness of the proposed system.	LSTM Classifier, Maline model to generaten-gram model	Not mentioned	Android Framework and Real mobile Devices.	93.7% of accuracy	Extensive trials were carried out in order to assess the proposed algorithm.

		Long Short-Term Memory (LSTM) autoencoder is used.						
2	[16]	An Android malware detection solution which can update itself dynamically while detecting malware without the need for human intervention.	DroidEvolvertechnique is used to detect android malware.	Regularized Dual Averaging (RDA), DroidEvolver: Passive Aggressive(PA), Adaptive Regularization of Weight Vectors (AROW).	VirusTotal	Apktool kit	92.9% of accuracy	DroidEvolver does not require retraining or true labels to update it.
3	[7]	To create a framework which combines variety of feature set to detect android malware	FAMD : Fast Android Malware Detector is a frame work used to detect Android malware.	Integrate features permission with Dalvik opcode features from various operating systems, CatBoost classifiers	Android Drebin Project	Androguardplatform	97.40 % of accuracy	Employing CatBoost as classifier, the outcome significantly increased accuracy.
4	[9]	A contrastive learning is used to enable obfuscation-resistant malware analysis.	IFDroid a novel contrastive learning- based robust and interpretable android malware classification system.	Grad-CAM++, SupCon Loss function	Genome project and FalDroid	ResNet-18	98.2% of accuracy	The extensive testing results show that IFDroid outperforms seven cutting-edge Android malware classification systems.

5	[28]	A detection technique that creates and analyses representing malware and regular datasets derived from access sets retrieved from an application's root folder.	PermPair creates and examines visualizations for malware and regular samples exporting from an application's root folder.	Graph merge algorithm	Genome, Drebin and Koodous	Apktool kit	accuracy of 95.44 %	The proposed method outperformed eleven popular mobile anti-malware apps, according to the results.

Table 9: Dynamic Malware Analysis on Machine Learning

Sl. No	Paper Ref. No	Aim	Proposed Methodology/ Algorithm/ Techniques	Methodology/ Algorithm/ Techniques Used	Dataset Used	Software Tools Used and Platform	Performance Metrics	Advantages
1	[24]	To create a malware detection framework which relies on a combination of various Cuckoo sandboxes, This is employed in the study of dynamic malware.	To analyze malware, a variety of machine learning algorithms were used. To identify malware, the ROC curve in dynamic analysis employing the Gradient Boosting Algorithm is applied.	Bagging classifier and AdaBoost classifier	Baidu Application Market	Cuckoo sandbox, python	94.64 % accuracy rate	To detect the virtual environment, the tricky malware executes APIs.
2	[26]	To use memory forensics in	This integrated malware	10-fold cross validation,	Drebin Dataset	WEKA tool	98.5% accuracy rate	Combining relevant characteristic

		dynamic malware detection approach to retrieve malicious artifacts from memory.	detection technique that uses computer analytics to recover harmful artifacts from memory then integrates those in a dynamic analysis with data acquired while malware activation.	ML classifiers				s from storage with features acquired by static response enhances the recognition rate.
3	[40]	A strategy for on-chip network traffic monitoring and hardware-assisted malware detection employing an embedded trace buffer is implemented.	A framework for hardware trace collection and malware detection based on the ZC702 critique kit is implemented.	Choosing hardware performance metrics and developing the ML network are two critical steps in HPC-based malware detection.	GARNET2.0	gem5 simulator and Xilinx evaluation kit	Existing HPC is efficient than proposed ETB	Using Counters for hardware performance, embedded trace buffers, and on-chip network traffic analysis, Machine learning might be useful in detecting malware.
4	[6]	To evaluate the most representative malware attacks in cyber physical system.	A proof of concept is used to illustrate a form of DOS which is possible across a cyber physical system.	SVM, RF and n-grams	Koodous Dataset	APIMon	More than 98\% accuracy	The best classification results were obtained by mixing user details with that at the Kernel program, resulting in greater accuracy
5	[17]	To compare data at the	To understand	AdaBoost classifier	Not mentioned	Cuckoo sandbox	93.58% accuracy	The user level approaches

		kernel and user levels during dynamic malware analysis	in a simulated sandbox environment, the malware's file systems are caught through a user-level trap.	and KNN				are vastly popular, The findings revealed that kernel datasets performed analytically higher than all other categorizatio n techniques.

Table 10: Dynamic Malware Analysis on Hypervisor

Sl. No	Paper Ref. No	Aim	Proposed Methodology/ Algorithm/ Techniques	Methodology/ Algorithm/ Techniques Used	Dataset Used	Software Tools Used and Platform	Performance Metrics	Advantages
1	[30]	To detect ransomware using machine learning and procure storage access through live-forensic hypervisors.	To discern ransomware from a benign application, storage access through live-forensic hypervisors from WaybackVisor and machine learning models are devised and scrutinised.	RF, SVM and KNN	WaybackVisor	Scikit-learn version 0.20	98% accuracy	The latter simulation employing five-dimensional features yields a higher F-measure score.
2	[37]	To assess data for intrusion detection using virtual machine Monitor.	For cloud-based IDS, a collection centered on Virtual Machine Introspected (VMI) results is developed.	RF, RIPPER, NB, KNN and SVM	UNM Dataset	WEKA Tool, Shell script	96.3 % accuracy	ML algorithms are implemented to each dataset, and the outcomes are examined obtained from the experiments as well as purpose of effective.
3	[18]	To identify malware via dynamic multi-feature detection. At Hypervisor, Ensemble	Various forms of dynamic information within virtual machine data are recovered employing virtual	VMI library (LibVMI), AdaBoost M1 classifiers, Voting combination strategy and	LID Dataset	Xentrace and perf tool	0.9999 accuracy achieved	The detection rate and speedup of the overall classifiers were effectively improved by

		Learning is deployed.	machine introspection (VMI) technology in combination with memory forensics analysis (MFA) technology.	memory forensic analysis framework				using the hardware layer features.
4	[14]	To analyze dynamic malware using hypervisor in Operating System.	For a hypervisor-based system, a hardcoded monitoring tool is inoculated into the address space of a guest OS for dynamic malware analysis.	RF, SVM and VM Techniques	Drebin Dataset	Apktool kit	More than 95% accuracy	It has been discovered that efficient detection of zero-day attacks is possible.

ABSTRACT

This review paper provides a comprehensive overview of the legal requirements Performing clinical studies in Europe, with an emphasis on the rules According to EU provisions Clinical Trials Regulation. (EU CTR) No.536/2014.The process for applying investigator responsibilities, safety reporting, data protection, ethics committee approval, and other important regulatory issues are discussed. Along with providing practical guidance for achieving compliance, it illustrates the difficulties stakeholders encounter while negotiating the regulatory landscape. According to EU law, the paper is a helpful resource for researchers, Study funders and regulatory experts.

Keywords:

INTRODUCTION

Role of the Checklist

So that assist sponsors, researchers, and other interested parties in navigating the significant legal requirements and procedures associated with Implementing clinical trials in Europe, this checklist was created. This ensures compliance with EU legislation, facilitates a seamless approval process, and ensures participant safety and transparency. Furthermore, in order to facilitate clinical trial management and monitoring Within the EU, the

checklist will assist in guaranteeing compliance In compliance with the Clinical Trials Regulation (EU) No. 536/2014 and other pertinent regulations.

Overview Related to clinical trial Regulations in Europe

The main regulation governing Clinical studies in Europe is Regulation (EU) CTR stands for Clinical Research Regulation, commonly known as No. 536/2014.The Clinical Research Directive (2001/20/EC) was superseded by this rule on January 31, 2022. The new rule seeks to speed up and simplify the approval process, increase participant safety, and make clinical trial data more widely accessible.

Among The clinical investigations Regulation's primary characteristics are

Single Application Process: Companies can Utilize the Clinical Trials Information System (CTIS) to submit an application for clinical trials authorization in a number Within EU member states and countries in the European Economic Area (EEA).

Improved Safety Surveillance: Safety reporting requirements for adverse occurrences Including serious adverse events are tightened by the CTR.

Transparency: Sponsors are obligated to register clinical trial outcomes so that the public can access important study data.

Enhanced Cooperation: The regulation promotes closer coordination between national authorities and The European Agency for Medicines(EMA), increasing the efficiency of study authorization and supervision.

Regulatory Authorities

The European Agency for Medicines(EMA): Pharmaceutical oversight, monitoring, and scientific reviews are carried out by The European Agency for Medicines, a decentralized organization Within the European Union. It is crucial for creating safety regulations, marketing authorization protocols, And the clinical research study guidelines, among other elements of the clinical studies approval process.

- As part Regarding the Clinical Trials Regulation (CVR), the EMA is responsible for ensuring the quality, safety, and efficacy of pharmaceuticals, including those being studied in clinical studies.

National Regulatory Authorities: Clinical studies carried out inside the borders of each The Economic Area of Europe country and EU member state are overseen by a National Competent Authority (NCA). NCAs oversee the evaluation and approval of clinical studies applications, supervise trial conduct, and Ensure conformance to national and EU regulations.

- Another responsibility of NCAs is to make sure that trials follow ethics and safety regulations, including Good Clinical Practice (GCP).

Clinical Trial Authorization (CTA) A clinical study's formal approval from the appropriate regulatory bodies To initiate a clinical studies in a given country is known as a clinical studies authorization (CTA). The European Clinical Trials Act (CTA) Guarantees that clinical studies are conducted in the EU meet All applicable regulatory standards, including those pertaining to safety, scientific quality, ethics, and legal obligations. The CTA process provides thorough trial data for assessment by the trial's host country's National Competent Authorities (NCAs) and competent Ethics Committees (ECs).

Ethical Approval

Institutional Review Boards and Independent Ethics Committees (IEC and IRB, respectively)

Institutional Review Boards (IRBs) and Independent Ethics Committees (IECs) are the independent boards in charge of reviewing, approving, and overseeing Clinical studies to verify their implementation ethically and prioritizing the participants' well-being and security. Where you live, the terms "IEC" and "IRB" may have distinct names, even if they are used interchangeably. Although IEC is the most commonly used term in the EU, certain countries, like the US, use IRB more frequently.

Functions of IECs/IRBs

Ethical Review

IECs and IRBs evaluate the risk- benefit ratio, participant protection, and the fairness Of the informed consent process, along with other Ethical considerations in clinical studies

Procedure for approval: Before a clinical studies can begin, the IEC/IRB must review and approve the study protocol, which covers the study design, methods, and participant recruitment strategies.

The informed consent process: is supervised by IECs and IRBs, who Make certain that the informed consent forms for the trial are clear, accurate, and provide participants with sufficient information to allow them to make educated judgments.

Continuous Monitoring: After the experiment begins, IECs and IRBs monitor its progress and any unforeseen problems or negative results To guarantee that it remains within ethical constraints. They may also have to reschedule the experiment or make adjustments if safety concerns are brought up.

Composition of IECs/IRBs: The makeup of IECs and IRBs should be diverse, comprising experts with backgrounds in medicine, research, law, and ethics, To confirm a thorough Review of the trial's conduct. People with Patient care experience advocacy or participants in the local community Should be incorporated into the composition to represent The needs of participants.

Contract For clinical studies The Clinical studies Agreement)is a legally binding contract that is signed On behalf of the sponsor, usually a pharmaceutical company or research organization, and the participating clinical trial site, like a hospital or research institution. Both parties outline their respective roles, responsibilities, and financial arrangements in the CTA.

Important Rules and Instructions

EU Regulation No. 536/2014 on Clinical studies

The Clinical Studies Regulation (EU) No 536/2014 (CTR) is followed by the European Union (EU) and the European Economic Zone when performing clinical research. The legislation's goals are to ensure high levels of transparency in clinical studies across the EU, boost Participant well-being, and streamline the approval process. The clinical research directive (2001/20/EC) was replaced by the CTR, which allows for more central and efficient submission and approval of clinical studies.

Characteristics of the Clinical studies Law

CTIS or the Single Submission Portal

- Several European Union and EEA nations allow Sponsors are required to submit a single application for clinical studies permission through the Clinical studies Information System. This speeds up the approval process and reduces the administrative burden.
- The system will evaluate the trial application By the ethical review bodies and National Competent Authorities (NCAs) in the related countries.
- To better safety monitoring standards, the CTR requires sponsors to promptly report suspected unexpected severe adverse reactions (SUSARs) and severe adverse events (SAEs) to regulatory authorities.
- To safeguard trial participants, the regulation additionally enforces stricter standards for adverse event reporting and safety evaluations.

Transparency: By mandating that clinical studies data, including protocols, results, and safety information, Be made accessible to the public, the CTR seeks to improve transparency. This helps to foster confidence in clinical studies and

ensures that study data is publicly available. Clinical Trial Registers Supply details about ongoing or completed clinical studies inside the EU/EEA to the public.

Ethical Monitoring

The CTR's top priority remains ethical concerns. ECs review and approve the trial's ethics, including participant protection and the informed consent procedure.

Simplified Approval Process: The law speeds up the trial authorization process by allowing a comprehensive review of the application across many countries and by establishing a precise timetable for decision-making. Trial applications must be processed within the CTR's specified deadlines, which for global trials are typically 60 days.

Compliance with Good Clinical Practice (GCP)

A well-recognized set of guidelines for conducting Clinical studies with human participants is known as "good clinical practice" (GCP). GCP aims to verify the security, reliability, and correctness of clinical studies data while also protecting The protection and safety of trial participants GCP must be followed in all clinical studies conducted in the EU or EEA.

Principles of GCP

Ethics: Clinical trials must always adhere to ethical norms outlined in the Declaration of Helsinki, which guarantees the participants' rights, protection , and welfare. Participants must voluntarily and knowingly Approval of the experiment after being fully Made aware of all potential risks and rewards.

Observance of regulations and scientific principles

For studies to be regarded as scientifically sound, a well-documented study protocol That outlines the objectives, design, and methodology and statistical factors of the investigation is necessary. It is essential to maintain compliance with all regulatory requirements during the trial, including those outlined in Regulation (EU) No 536/2014.

Keeping an eye on and reporting: To ensure compliance with the procedure, ethical standards, and regulatory requirements, GCP requires ongoing clinical trial monitoring. Serious adverse events (SAEs), suspected unexpected severe adverse reactions (SUSARs), and any other significant findings that might compromise the conduct or safety of the studies must be reported by the sponsors and investigators.

Assurance of quality: To improve that every aspect of the clinical studies conforms with regulatory and GCP requirements, sponsors must implement quality assurance procedures. This entails conducting internal audits and inspections.

Guidelines for Pharmacovigilance

Pharmacovigilance is the study and application of recognizing, assessing, understanding, and averting adverse medication reactions. In clinical studies, pharmacovigilance helps detect any potential safety problems or an unforeseen risk associated with the drug and ensures the ongoing safety of investigational medical products (IMPs) during the trial.

Clinical trials must adhere to pharmacovigilance requirements

Techniques for Reporting Adverse Events (AEs): The sponsors of the clinical study must establish protocols for identifying, assessing, and disclosing adverse events (AEs), including serious adverse events (SAEs). The earliest possible identification of an adverse event (AE) is necessary. Before being reported to the relevant regulatory agencies, Unanticipated severe adverse reactions must occur within a specific period of time (for instance, within 7 days for SAEs and 15 days for SUSARs).

Methods of Lowering Risk: Risk reduction strategies must be devised in clinical studies to reduce participant exposure to known or potential dangers. To protect vulnerable groups, some examples of these include changing the dosage, implementing monitoring procedures, or adding exclusion criteria.

Reporting Schedules for Pharmacovigilance: To guarantee that regulatory bodies are immediately notified of any serious safety issues during the trial, the Clinicalstudies Regulation (EU) No. 536/2014 specifies precise reporting deadlines for adverse events and SUSARs.

Reports on Development Safety Updates (DSURs): Every year, sponsors are required to present safety reports that give a summary of the IMP's safety profile.

Monitoring Safety and Assessing Data: Pharmacovigilance ongoing safety observation is essential. Sponsors must continuously assess safety data during the study and, if new safety information is made available, modify the research design or take remedial action.

Documentation and Record-Keeping: Every pharmacovigilance activity, including as safety assessments, adverse event reports, and regulatory correspondence, must be meticulously documented. This material should be accessible for regulatory reviews and inspections.

Cooperation with Regulatory Bodies: In order to improve the effective exchange and evaluation of safety data from clinical studies, sponsors must preserve effective communication and collaboration with the European Medicines Agency (EMA) and National Competent Authorities (NCAs) with regard to pharmacovigilance initiatives.

Conditions for Investigational Medicinal Products (IMPs)

An experimental medicinal product (IMP) is a pharmaceutical product not yet approved for general use but being tested or used in a clinical studies. Since clinical trials are used to assess the safety, effectiveness, and pharmacological features of humans, these items are crucial. The IMP guidelines address a number of issues, including manufacturing, licensing, labeling, and good manufacturing practice (GMP). Meeting these objectives is necessary to improve the trial's scientific integrity, regulatory compliance, and patient safety.

Production and Permits

Production of Investigational Medicinal Products (IMPs)

To improve the medication's quality, safety, and effectiveness, manufacturing and IMP requires following strict regulatory requirements. The production process includes the following steps

Growth and Scale-Up: For preclinical research, the IMP is initially manufactured on a small scale. Once the product shows promising results in clinical testing, the production process must be scaled up.

Compliance with laws: Manufacturers operating in the European Union (EU) must comply with strict laws that ensure their production process complies with the Good Manufacturing Practice (GMP) standards, which will be discussed later.

IMP Licensing: Before being used in clinical studies within the European Union, an IMP must be authorized for clinical use by the European Medicines Agency (EMA) or the relevant National Competent Authorities (NCAs).

Form for Clinical studies Authorization: When a sponsor files a CTA with the regulatory agencies, they must provide all related information about the IMP, including

- The content and description of the product
- Production processes and infrastructure Guidelines for safety and quality assurance; data on preclinical and clinical development

GMP (Good Manufacturing Practice) adherence: Manufacturers must demonstrate that they are following GMP criteria, which ensure that IMPs are manufactured reliably and with the required efficacy, safety, and quality.

Distribution and Importation: IMPs may be imported from third countries, but only when that location's manufacture complies with EU GMP standards. For clinical studies, the import license is required to improve that the product meets the legal requirements.

GMP stands for Good Manufacturing Practices.

To improve that pharmaceutical products, including investigational medical products, or IMPs, are consistently created with high quality and meet safety criteria, manufacturers must follow a collection of guidelines known as "good manufacturing practice" (GMP). GMP is required to lessen the risks associated with IMP production, including contamination, errors, deviations, and mix-ups.

Aspects of GMP for IMPs

Quality Control Systems: In order to improve that the IMP meets all relevant requirements, including potency, stability, and homogeneity, and purity, extensive quality control (QC) systems must be established in manufacturing facilities. For these standards to be fulfilled, routine audits and inspections are required.

Training and Staff: Only capable people who have had enough instruction in GMP standards should oversee the manufacturing of IMPs. This includes training on legal compliance, hygiene, and risk management. **Facilities** must be properly designed, equipped, and maintained in accordance with GMP regulations to prevent contamination and ensure product safety. This include keeping industrial facilities clean and regulating temperatures, humidity, and air quality throughout manufacturing.

Records and Traceability: During the manufacturing process, comprehensive paperwork must be kept in order for the IMP to be traceable from production to final distribution. This includes certificates of analysis and batch information for each IMP batch. Logs documenting the cleaning, maintenance, and calibration process for the equipment are also available. Records of every raw material and supplier used during the production process

Registration and Reporting

Trials in to ensure accountability, openness, and the public and scientific community's Availability of the findings, clinical trial Must be enrolled and reported. Clinical Trials Regulation (EU) No 536/2014 and international guidelines, such as those published by the World Health Organization (WHO) and the International Committee of Medical Journal Editors (ICMJE), govern these criteria.

The Clinical studies Registry

Clinical trial outcomes need to be entered into a public database so that the general public, healthcare providers and government agencies can view them effectively. The public distribution of studies results, whether positive or negative, is ensured by registration, which also helps to prevent selective reporting.

System for Clinical studies Information, or CTIS

In the European Union, the Clinical studies Information System (CTIS) is the primary platform for registering and submitting clinical studies applications, as per Regulation (EU) No. 536/2014. The CTIS must be registered before any clinical study conducted in the EU or EEA can begin. When registering, you must enter important trial information like: A comprehensive description of the study's objectives, design, and methods is called the study protocol. "Investigational medicinal products" (IMPs) are details on the experimental drugs or therapies being tested.

Obligations for Reporting

Trials in Clinical studies sponsors and investigators are required to provide detailed reports on the conduct, progress, and outcomes of clinical studies For the purpose of preserve regulatory adherence and transparency. These rules for reporting also protect the public's trust in clinical research.

Conditions for Essential Reporting: The Development Safety Update Report (DSUR) is the name of the yearly safety report. It is mandatory to submit Development Safety Update Reports (DSURs) to the relevant National Competent Authorities (NCAs) annually. The safety profile of the investigational medical product (IMP) is compiled in these studies, which comprise

- Since the last report, additional safety-related information has emerged.
- The state of clinical studies today and new safety issues. Suspected unexpected significant adverse responses (SUSARs) and adverse events are included in the summary of the trial's safety data.

Trial Final Reporting

After a clinical studies is finished, end-of-trial reports must be reported to regulatory agencies. The report includes detailed information on safety, the trial's outcome, and any issues that arose. Disclosure of Results Clinical studies results must be disclosed to maintain the scientific integrity and openness of clinical research. To avoid publication bias and to allow for independent data analysis, both positive and negative results must be made available.

Requirements for Results Reporting

The final trial's findings: After a clinical studies is finished, the final results must be released to the public within a certain amount of time. It includes

Results of effectiveness: Information about the accomplishment of the experiment's primary and secondary goals.

Findings for safety: A summary of adverse events, encompassing both expected and unexpected reactions. Analysis of statistical data from trials, including studies design and methodology.

Clinical studies Registration: In compliance with Clinical studies Regulation (EU) No 536/2014, the Clinical Trials Information System (CTIS) must receive and make publicly available the final results of clinical studies conducted inside the EU. This will guarantee openness and enable the public and authorities to evaluate the study's findings.

Results Reporting in Public Databases: Results of clinical studies should also be made available via other public trial registries and databases, such as the following: For studies conducted within the Use the EU Clinical Trials Register: EU or EEA. International standards for results reporting are the goal of the WHO International Clinical Trials Registry Platform (ICTRP).

One of the most widely used trial databases globally is ClinicalTrials.gov.

Results must normally Be submitted within a year after the experiment's conclusion, or within six months in the event of child interventional studies. This ensures prompt reporting. Delays in reporting results could have regulatory consequences, like the suspension or rejection of future clinical study applications.

Publications subject to peer review: It is advised that trial sponsors send their results to publications that are subject to peer review. The scientific community can then critically assess the results, which leads to a more thorough understanding and application of the findings.

Documentation of Adverse Results: It should be mentioned that trials that fail to meet their main objectives or yield other unfavorable or ambiguous results also Must be documented. The scientific understanding of a product's Security and efficacy is distorted by publication bias, which only discloses positive data. This must be avoided.

Openness and Public Access: The EU drug regulator and other Regulatory bodies possess mandated that results be rendered publicly understandable. To do this, succinct summaries of the findings must be presented.

Data Protection and Privacy

When conducting clinical studies, it is essential to have safeguards for sensitive personal data. Make sure that European data privacy regulation of the European Union is strictly followed in order to treat personal data in a safe and morally responsible manner. To safeguard the rights of participants and privacy, clinical trial organizers must put strong data management and controls in place.

GDPR, or EU Data Protection Regulation Conformity

The European Union has enacted EU Data Protection Regulation to protect privacy and personal information both inside the EU and the EU Economic Area. Organizations must follow legal requirements for the handling of personal data, including information gathered from clinical studies conducted in EU countries.

Under GDPR, consent

- GDPR mandates that consumers provide clear, Pre-consent agreement their personal information is processed for clinical studies. Consent must be provided voluntarily, clearly, and explicitly.
- **It is essential to inform individuals about:** the cause of the data collection. What type of data— demographic or health—is being collected?
- The duration of data retention;
- The right to revoke consent whenever necessary. Consent forms need to be clear and concise, and they should be written in an understandable language.
- **Vulnerable Groups and Children:** When participants are members of vulnerable groups (such individuals with dementia) or are minors, further care must be taken, such as obtaining legal counsel clearance.

Pseudonymization and Data Anonymization

To protect participant privacy during data processing and analysis, methods like Anonymization and pseudonymization represent used.

- The practice of removing all personally identifiable Data is processed so that it cannot be connected to a specific individual is known as anonymization.
- Pseudonymization involves replacing identifiable information with pseudonyms, or codes, so that the data can be re-identified if necessary (for instance, for follow-up purposes).
- Pseudonymization is allowed in clinical studies, but researchers must improve that the key to reidentify the data is kept separate and safe.

Safety precautions: Clinical studies data should be protected by putting in place appropriate organizational and technical measures to avoid data security breaches. They include: All confidential information must be encrypted both during transmission (such as over the internet) and while storage on servers or databases.

- To ensure that data is not lost due to technical failures, natural disasters, or cyber-attacks, backup solutions should be used often.

Cyber security Procedures: To avoid hacking, unauthorized access, and other malicious activities, trials need to have robust cyber security protocols.

Insurance and Financial Requirements

Clinical study planning and execution must take insurance and financial constraints into account. These guidelines promote transparency in financial transactions, define funding responsibilities, and ensure the Participant protection

in research. The two main components are explained as follows: Trial participants' insurance, financial transparency, and budget.

Protection of Trial Participants

Ensuring the safety of clinical trial participants is one of the fundamental ethical standards. Clinical studies can be dangerous, particularly when testing new drugs, treatments, or methods. To lower these risks, insurance is required by law for trial participants in several jurisdictions, including the European Union (EU). This guarantees that participants will get payment in the event that their injuries are related to the experiment.

Types of Insurance

Clinical Trial Insurance

This type of insurance shields trial participants from any health hazards related to the use of investigational drugs (IMPs) or study procedures. If involvement in the experiment results in harm, death, or injury, it offers monetary compensation.

- The insurance must cover the Timeframe of the clinical trial, including any follow-up periods after the experiment.

Coverage types

Compensation for harm or Death

Insurance must cover all medical costs and damages for personal harm or death resulting from clinical research. Among these are: Expenses related to treating injuries sustained during a study. Income loss in the case of that a participant Is unable to perform work because of injuries they received during the survey. Funeral costs in the case of a trial participant's death.

Liability

Not Including Negligence: In general, damages resulting from the negligence or misconduct of the trial sponsor or staff are not covered by insurance. Nevertheless, if the experiment's harm stems from a violation of regulatory or Good Clinical Practice (GCP) standards, the research sponsor may be held liable

Insurance Coverage Levels

a. The minimum requirements established by the relevant regulatory agencies (such as the Including organizations like the European Medicines Agency, or national Competent Authorities) must be met by the insurance policy. This usually means having adequate financial coverage that is commensurate with the complexity and potential risks of the experiment.
b. Clearly stated in the insurance policy should be the conditions for submitting claims as well as the scope of coverage accessible to participants.

Budget and Financial Transparency

Effective clinical trials require transparent budgeting and well-defined financial planning. Maintaining accountability, providing comprehensive details on the trial's financial components, and managing finances in accordance with legal and ethical requirements are all part of this.

Recommendations for Budget and Financial Transparency Regulation: The Clinical Trials Regulation (EU) No 536/2014 highlights the importance of financial accountability and transparency in clinical studies, in addition to participant protection and trial conduct.

- As part of the application process for clinical trials, National Competent Authorities (NCAs) may demand a financial strategy and detailed budget.

Safety Observation

In clinical studies, safety monitoring is necessary to safeguard the health and Protection of participants and to identify and control any Possible risks linked to the investigational medicinal product (IMP). Safety monitoring

entails reporting Severe adverse events (SAEs), creating a Risk Management Plan (RMP), and having a Data Monitoring for Safety (DSMB) oversee the process. These systems are essential to maintain patient safety and ensure regulatory compliance.

Safety-related reports (SAEs)

Reporting and managing Severe adverse reactions(SAEs) Is a crucial part of safety monitoring in a clinical investigation. The term SAEs refers to unintended Life-threatening medical incidents a life-threatening situation, hospitalization, significant disability, or other medically critical problems that require intervention or continuous treatment. To identify the risks to trial participants and ensure that regulatory bodies are informed of any safety concerns, SAEs must be recorded.

DSMB (Monitoring of Data Safety Board)

An objective panel of professionals called a Monitoring of Data Safety Board (DSMB) was set up to supervise clinical trial participants' safety. Because of safety concerns, the DSMB is responsible for monitoring the progress of the study, evaluating intermediate findings, and providing recommendations about whether to continue, modify, or end it.

A risk management strategy (RMP)

A clinical trial sponsor might use a comprehensive plan called a Risk Management Plan (RMP) to identify, assess, and mitigate possible risks. Particularly in studies including innovative therapeutic interventions or investigational medicines (IMPs), participant safety is heavily reliant on the RMP.

Observation and Inspections

To ensure their Integrity, security, and compliance, clinical trials need to be tracked and audited. These protocols improve that the conduct of clinical studies complies with ethical guidelines, regulatory requirements, and Good Clinical Practice (GCP) recommendations. A detailed summary of the requirements for sponsor audits, regulatory audits, and site monitoring—all crucial to maintaining the trial's security and integrity—is given below.

Requirements for Site Watch

Clinical trial sites are routinely observed to improve that the trial is conducted In accordance with the approved protocol, relevant regulations, and Good Clinical Practice (GCP). We call this procedure site monitoring. To ensure Safety of participants, data precision, and compliance with study protocols, clinical research associates (CRAs) and other qualified professionals conduct routine monitoring visits.

Regulatory Examinations

The European drug regulatory agency (EMA) and National Health Authoritys (NCAs) are examples of national or regional regulatory authorities that carry out regulatory audits to assess whether clinical trials comply with applicable legislation, GCP, and ethical standards. These audits ensure that clinical studies are performed in a way that safeguards participants and preserves data integrity.

Sponsor audits

Sponsor audits can be performed by the sponsor's hired internal or external auditors. These audits are intended to ascertain that the sponsor's clinical studies are being conducted As per the trial protocol, GCP, and applicable regulations. Monitoring sponsor responsibilities and improving appropriate conduct during the study are the goals of these audits. Sponsor audits are intended to ensure that the study is being conducted in as per with the rules and guidelines.

- Identify that the trial's data was collected and documented correctly.
- To assess compliance with sponsor protocols and industry standards by trial locations, clinical staff, and investigators.

- To identify any gaps in trial operations or non-compliance and ensure that corrective actions are taken.

Trial Closure and Trial End

A clinical trial's closure marks the formal completion of the experiment and the completion of data collection, making it an essential step in the clinical research process. In addition to improving that all documents are properly stored, it involves improving that all legal, moral, and regulatory requirements are met. To support transparency and compliance, the end-of-trial process also includes notifying the relevant authorities and interested parties. The conclusion of Trial Notification and Archiving of studies Documentation are two crucial steps in the studies closure process, and they are outlined here.

Notice of Trial End

In order to formally announce the completion of a clinical trial, regulatory organizations require the conclusion of Trial Notification. This notification marks the complete of the clinical investigation and informs the Ethics Committee and national or regional regulatory agencies Including bodies like the National Competent Authorities (NCAs) and the European Medicines Agency (EMA) Regulatory agencies can keep an eye on clinical study completion when the completion of a trial is announced, which also ensures compliance with legal and ethical criteria.

Preservation of Trial Records

Upon completion or termination of a clinical studies, all trial records must be kept for future use and regulatory observance. This improve that participant data, trial-related correspondence, and raw data are all stored in a secure and organized manner. When a studies is properly archived, it also facilitates future audits, inspections, or legal claims.

Regulatory requirements Checklist for performing clinical trials in Europe(Table: 1)

Obligations Following a Trial

Sponsors and study leaders must fulfill a number of post-trial obligations when a medical study is completed to ensure ongoing participant safety, the moral sharing of trial results, and adherence to regulations. These obligations help maintain public confidence in clinical research while Additionally supporting the body of scientific knowledge. The primary post-trial duties are as follows: Publication of Trial Findings and Ongoing Safety Inspection.

Continuous Safety Oversight

Safety monitoring of investigational medical products (IMPs) must continue after the trial has concluded, especially if they are authorized for wider use following the trial. Ongoing safety monitoring makes it easier to spot any unusual or persistent adverse effects that might have gone undetected during the clinical studies.

Trial Results Publication

The publication of clinical studies data following the experiment is essential to preserving transparency and population trust in the scientific approach Ethical research methods require that trial outcomes, both positive and negative, be disclosed to the population. Publication trial results promotes medical science, enhance clinical practice and decision-making, and facilitates critical peer review.

CONCLUSION

Regulatory agencies, Trial funders and researchers have a number of ongoing responsibilities even though the end of a clinical studies is a significant milestone in the research and development process. To preserve The credibility of clinical research and safeguard patient safety, adherence to legal and ethical requirements is crucial. . The following provides an outline of the compliance requirements Along with the significance of ongoing reporting and Surveillance during clinical studies.

Short-Term Requirements for Compliance

In order to maintain the utmost Data integrity, participant safety, and transparency during a clinical investigation, several ethical and regulatory requirements need to be fulfilled. In conclusion, compliance with these regulatory requirements is essential to preserving clinical studies integrity, protecting study participants, and promoting the development of safe and effective medications.

The Importance of Ongoing Reporting and Monitoring

After the final person completes their final session, clinical trials proceed. An essential part of post-trial duties is ongoing reporting and monitoring, which continues long after the trial is concluded.

ABSTRACT

This study is essential because Britannia is one of India's leading FMCG (Fast-Moving Consumer Goods) brands, and its retail marketing strategies significantly attract customers. With growing competition in the food and beverage industry, it is essential to understand how Britannia promotes its products in retail stores and connects with its customers. This analysis can help identify what is working well and what can be improved to increase customer satisfaction and sales. Britannia has a strong presence in retail stores and is well-known among customers for its popular products. However, while the brand is familiar, it still has room to build a deeper connection with its customers. Currently, most of its customer engagement at the retail level is focused on selling products rather than creating a memorable or enjoyable shopping experience. The company can benefit by making its marketing more personalized and using technology to connect better with store shoppers. Also, combining its online marketing with in-store promotions can improve the overall customer experience. As customer preferences are changing quickly, especially after COVID, and with growing interest in health,Britannia needs to study the market and update its retail strategies regularly. By doing this, the company can stay competitive, strengthen customer loyalty, and improve its retail marketing practices.

Keywords: Customer Satisfaction, Health, Retail Marketing, Shopping Experience, Technology.

INTRODUCTION

The Indian biscuit industry was flourished in the baking industry since the second half of 20th century. The urban dweller has indicated that they want to eat cheaply. In early times biscuits were considered a sick person's food. Nevertheless, it has is becoming one of the many popular fast-food items out there after that attracts consumers of every age group. Biscuits are not only tasty but cheap and low in cholesterol. Biscuit industry is more developed in West Bengal and Maharashtra. Doesn't the Indian biscuit industry found to be generating Rs. 3000 cr small profit look like the largest one in food industry, The Indian subcontinent is the second largest manufacturer of biscuits after the United States. Into two classes the industry is divided, the official and the unofficial. At present biscuits are dearer and more genteel than bread. India is now the 3rd largest biscuit producer after China and the United States. Increasing consumer disposable income, shift to premium biscuit, establishment of new manufacturing units, growing health awareness, biscuit innovation and attractive packaging are the key drivers in the Indian biscuit market. The proposed biscuit industry accounts for more than 70% of the aggregate value of the Indian biscuit market, according to the new report, India Biscuit Market Overview, 2017-2023. Share Rs 400 billion market value by 2023: The industry is expected to record sales of over INR 400 billion by 2023. Culinary market consists of all household biscuit firms dealing in both rural and urban areas. Some players have a broad distribution network into the countryside: Parlé and Britain, for example. In villages any general shop has the packet of Parlé biscuits for five rupees,it is relatively easy in this case. In the organised category, cream, cookies, sugar, Marie, crackers, milk and other-products ascribable to biscuit are sold. Some of the clients here are Surya Food and Agro Limited (PNB), Britannia, Parlé, ETCE among others. make all four of the biscuits. Biscuits supplied in rural areas have improved in recent years. In addition to Indian major players, multiple regional companies produce cookies. The plays also have the same production facilities as the famous ones. Poor people can afford their biscuits there too because they are affordable, packaged in nice bags and just healthy enough. In response to slumping sales and reduced product values, firms have introduced an up-market biscuit in an under-size packaging. Urban Areas: Hypermarkets, supermarkets, general stores and "e-retailing" based distribution channels are prevalent in the urban locales. Electronic marketing provides discounts and gives consumers a choice during the months of holidays. It's easy to buy them online from the convenience of your living room. Some of India's top electronics retailers like Flipkart, Amazon, and Snapdeal have stocked biscuits of both Indian and International brands.

Statement of the Problem

In today's competitive market, it is essential for companies like Britannia to not only sell quality products but also to market them and build strong relationships with customers effectively. However, it is unclear whether Britannia's current retail marketing strategies are fully effective in attracting and retaining customers. It is also necessary to understand how well the company engages with its customers at the retail level and whether these efforts lead to customer satisfaction and loyalty. This study aims to identify gaps in Britannia's retail marketing practices and customer engagement and suggest ways to improve them for better business outcomes.

Need for the Study

This study is essential because Britannia is one of India's leading FMCG (Fast-Moving Consumer Goods) brands, and its retail marketing strategies significantly attract customers. With growing competition in the food and beverage industry, it is essential to understand how Britannia promotes its products in retail stores and connects with its customers. This analysis can help identify what is working well and what can be improved to increase customer satisfaction and sales.

Objectives of the Study

Primary Objective

To analyse Britannia's retail marketing strategies and customer engagement practices.

Secondary Objectives

- ❖ To understand Britannia's positioning and branding efforts.
- ❖ To examine customer perception and behaviour toward Britannia products.
- ❖ To evaluate the effectiveness of Britannia's in-store promotions and visibility.
- ❖ To suggest improvements in marketing and engagement.

Scope of the Study

- ★ The study focuses on Britannia's retail marketing practices, such as in-store promotions, product placement, packaging, pricing strategies, and visual displays.
- ★ It also covers customer engagement efforts like feedback systems, loyalty programs, and digital promotions.
- ★ The study mainly looks at the Indian market, focusing on urban retail settings like supermarkets, grocery stores, and retail chains.
- ★ It includes feedback from both customers and retailers to get a balanced view.

Limitations of the Study

- The study is limited to selected retail outlets and may not reflect the practices across all regions or stores.
- Time and budget constraints may limit the number of customer and retailer interviews or surveys.
- Rapid changes in market trends or consumer behaviour may affect the findings.
- The study relies on available data and responses, which may sometimes be biased or incomplete.

RESEARCH METHODOLOGY

Research design is a systematic approach for collecting, interpreting and analyzing information to help and frame the research problem. You might consider it the science of investigating the approach of science itself applying to research. We explore the variety of paths a researcher generally follows when exploring their research problem, and why, in this section. Researchers should know the methodology and research methods.

Domain of the Study

This study falls under the domain of Marketing Management, with a specific focus on Retail Marketing and Customer Relationship Management (CRM). It aims to explore how Britannia Industries Ltd. strategizes and implements its retail marketing practices to attract and retain customers, enhance customer satisfaction, and build brand loyalty. The study also delves into the company's customer engagement techniques across various retail platforms, including traditional outlets and modern trade channels.

Research Design

The research design serves as the descriptive framework to guide the actual research.
It is the framework within which data are collected, measured and analyzed. The design incorporates a description of the gamified researcher's work, from the writing of the hypothesis and its operational consequences to the last.
In brief, the research design should include, at a minimum, an explication of the research problem, Procedures, and data gathering techniques. The study sample and methods of treatment and analysis.

Population

A research population is generally an extensive collection of individuals or objects with similar characteristics, which is the primary focus of a scientific query. Research is done for the benefit of the population.

Sample Size

Sample size is the number of items chosen from the entire universe to make up a sample. Neither an excessively large nor a small sample size is ideal. It must be at its best. The sample size ought to reflect the population it was taken

from. The cost of data collection and the requirement for adequate statistical power are the two main factors that determine the sample size used in a study. The sample size is one hundred people.

Sampling Technique

Researchers employ sampling techniques as a means of conducting statistical sampling. After studying a sample of the same population, researchers use this procedure to draw conclusions about the entire population. Simple Random Sampling is the sampling strategy employed in this research. With simple random sampling, every member of the population has an equal chance of being selected for the sample, making it the purest and most straightforward probability sampling technique. By using simple random sampling, the selection process is free of bias.

Methods of Data Collection

After a clear research problem and a research design or plan are established, the data collection task starts. The researcher should consider two categories of data when choosing the study's data collection strategy, i.e. E. both primary and secondary information.

Primary Data

The researchers gather the data and finish the study process without consulting any secondary sources, so it is first-hand information. Large businesses with strong funding prospects are able to conduct primary research through surveys, in-person interviews, social media polls, feedback, and analysis of customer feedback, as well as by receiving responses through email. First-hand information and primary data served as the study's main sources of information. A random sampling technique was used to choose the participants. A sample of 100 Chennai-based respondents provided the data.

Mode of Collection of Primary Data

A structured questionnaire was used to collect data, comprising 15 questions. The gathered data was then transferred to a master table to facilitate an easy analysis of the study.

Secondary Data

It is data that has previously been gathered, prepared, and examined by someone. The findings are usable and may be useful to other researchers in the future who need to consult the data for their research. Government consensus, annual reports from public agencies, magazines, newspapers, journals, online databases, etc. are a few instances of secondary research. Based on the research topic and web searches, secondary sources such as newspaper articles, magazines, and the internet have gathered the information and research papers that are required.

Questionnaire Design

A questionnaire containing 15 questions was constructed to study an analysis of Britannia's retail marketing practices and customer engagement. The questionnaire comprisesclosed-ended questions and a Likert rating scale.

Data analysis and interpretation

ANOVA

One-Way ANOVA – Satisfaction with Britannia by Age Group

- F-value: 2.327
- Significance (p-value): 0.043
- Interpretation: Table 4.12 shows that since the p-value is less than 0.05, it shows a statistically significant difference in satisfaction levels among different age groups.
- This means age has a meaningful impact on how satisfied consumers are with Britannia products

FINDINGS

In the ANOVA table, Table 1 shows that since the p-value is less than 0.05, there is a statistically significant difference in satisfaction levels among different age groups. This means age directly impacts how satisfied consumers are with Britannia products.

Suggestions for Britannia to Improve Customer Engagement

Personalized Digital Campaigns

What to Do: Leverage AI and data analytics to run targeted digital marketing campaigns on platforms like Instagram, YouTube, and Google.

Why: Younger audiences spend more time online and expect personalized content and product recommendations.

Example: Customized ads for health-focused biscuits like NutriChoice for fitness enthusiasts and Treat for kids/teenagers.

Interactive Social Media Engagement

What to Do: Run weekly challenges, polls, user-generated content (UGC) contests, and story-based polls.

Why: Engages users and increases brand visibility through shareable content.

Example: MyGoodDayMoment contest, where customers post pictures of their special moments with Good Day biscuits.

Loyalty Program or Britannia Club App

What to Do: Launch a mobile app or loyalty card offering points for purchases, referrals, feedback, and reviews.

Why: Encourages repeat purchases and builds a direct communication channel with customers.

Example: Redeem points for exclusive Britannia merchandise or coupons.

Co-Creation Campaigns

What to Do: Allow customers to vote on or suggest new biscuit flavors, packaging designs, or slogans.

Why: Builds emotional ownership and involvement in product development.

Example: "Design the Next Good Day Pack" competition for design students and artists.

Influencer & Micro-Influencer Collaborations

What to Do: Work with food bloggers, fitness influencers, and parenting content creators to promote products authentically.

Why: Influencer trust can drive organic and authentic engagement, especially in niche segments.

Example: NutriChoice promoted by a popular dietitian or mommy-blogger.

In-Store Augmented Reality (AR) Experiences

What to Do: Introduce AR-based interactive games or product stories in retail stores via mobile scanning.

Why: Creates memorable brand interactions and draws footfall.

Example: Scan a pack of Treats to unlock a mini-game for kids.

Local Festival & Regional Campaign Tie-ins

What to Do: Run campaigns tied to local festivals (Pongal, Onam, Diwali, Baisakhi) with regionally flavored biscuits.

Why: Builds cultural connection and enhances regional brand loyalty.

Example: Launch a "Diwali Gifting Pack" of assorted Britannia biscuits with a special box design.

CSR-Driven Engagement (Emotional Branding)

What to Do: Involve customers in CSR by linking purchases to charity/donation initiatives (e.g., feeding children).

Why: Modern consumers value socially responsible brands and are likelier to engage.

Example: "For every pack you buy, we donate one to a needy child."

Gamification on Website/App
What to Do: Add games, quizzes, and activities on the Britannia app or website that reward users.
Why: Encourages repeat visits and builds a fun and loyal user base.
Example: "Spin the Wheel" to win coupons, or "Biscuit Trivia" games.

Feedback Loop and Community Forums
What to Do: Create a community platform or feedback hub where customers can share opinions, recipes, and ideas.
Why: Creates a sense of belonging and provides real-time market feedback.
Example: Britannia Recipe Club – fans share recipes using Marie Gold or NutriChoice biscuits.

CONCLUSION

Britannia has a strong presence in retail stores and is well-known among customers for its popular products. However, while the brand is familiar, it still has room to build a deeper connection with its customers. Currently, most of its customer engagement at the retail level is focused on selling products rather than creating a memorable or enjoyable shopping experience. The company can benefit by making its marketing more personalized and using technology to connect better with store shoppers. Also, combining its online marketing with in-store promotions can improve the overall customer experience. As customer preferences are changing quickly, especially after COVID, and with growing interest in health,Britannia needs to study the market and update its retail strategies regularly. By doing this, the company can stay competitive, strengthen customer loyalty, and improve its retail marketing practices.

ABSTRACT

Siddha system is one of the traditional system of medicine which provides holistic health. *Varmam* is one of the unique speciality in the *siddha* system of medicine. It is the vital energy circulating inside the body, which can be regulated by pressure manipulation over a prescribed *Varmam* points with a particular force for the specified time. *Varmam* injury occurs when a particular force implied on a particular *Varma* point (*Varma thalam*). The medicine which deals with the *Varmam* injuries is known as *Varma Odivu Murivu Maruthuvam* (Fracture injury). It deals with the management of fractures, dislocations, subluxations and injuries of nerves, vessels, ligaments and tendons. Many available *Varmam* literatures deals with different school of thoughts in terms of name, location, various types of *Varmam* injuries (*Odivu Murivugal*) yet it was difficult to understand clearly about what they were described and that was also not in practical application. Hence this study will focus on compilation of various *Varmam* injuries (*Odivu Murivugal*) by highlighting the different types of injuries related to *Varmam* mentioned in the *Varmam* literatures and few of the *Varmam* injuries were correlated with modern science for better understanding. In future, this literature review may used in clinical purpose for the diagnosis of that condition in practical application and also for the academic purpose.

Keywords: *Odivu Murivugal,* Fractures, *Varmam* injuries, *Vilagal*, Dislocations.

INTRODUCTION

Siddha system is one of the traditional system of medicine which provides holistic health. *Varmam* is one of the unique speciality in the siddha system of medicine. *Varmam* is the state in which the vital energy (flow of *vaasi* or *pranan*) circulates or spreads throughout the body. Sometimes this flow of energy can be blocked by attack of external factors in certain parts of the body. This can be regulated by pressure manipulation over a prescribed *Varmam* points with a particular force for the specified time which is known as *Varmam* therapy. There are numerous vital points in the human body that are located in the junction of nerves, joints, bones, muscles, ligaments, internal organs. These are interconnected by channels in definite way and governing on various vital activities of human body. Injury occurs when a force hits on the body and it affects organs like skin, muscle, tendons, membranes, joints, bones, nerves. *Varmam* injury occurs when a particular force implied on a particular *Varma* point (*Varma thalam)*. There are different types of *Varmam* injuries in *Varma* texts namely *odivu murivugal, vilagal, nazhuval, savvu kayangal, thasai naan kayangal* etc.. The medicine which deals with the *Varmam* injuries is known as *Varma Odivu Murivu Maruthuvam* (Fracture injury). It deals with the management of fractures, dislocations, subluxations and injuries of nerves, vessels, ligaments and tendons. The different types of *Varmam* injuries given in various *Varmam* texts which is difficult to locate or find the particular type of injury. In this literature review, the *Varmam* injuries were documented and compiled based on the regions they located and based on the type of injury. And also this review deals with the modern correlation of *Varmam* injuries to facilitate better understanding.

MATERIALS AND METHODS

STUDY TYPE: Literature review
STUDY PERIOD: 6 months
STUDY PLACE: National Institute of siddha, Tambaram sanatorium
VISITED LIBRARIES: • Roja muthiah research library, Taramani • Government siddha medical college and hospital, Arumbakkam • Siddha central research library, Arumabakkam • Library of National Institute of Siddha, Tambaram sanatorium.

RESULTS

List of *Varmam* literatures reviewed regarding *Varma* injuries: Table 1
Types of *Varmam* injuries and its modern correlation: Table 2 to table 9
The above table 1 outlines the list of ten *Varmam* literatures which have foot prints of *Varmam* injuries.
The above **2** table presents a comprehensive correlation between *Varmam* injuries n the upper limb and modern medical terminology. It categorizes 14 types of injuries, including fracture of clavicle, scapula, humerus, forearm and wrist bones, metacarpals and phalanges. The above table **3** presents a comprehensive correlation between *Varmam* injuries in the lower limbs and modern medical terminology. The table categorizes 11 types of *Varmam* injuries, including fracture of long bones in thigh and leg along with metatarsals and phalanges in foot. The above table **4** presents a list of *Varmam* injuries in the head, neck and face and its correlation with modern medical terminology. The table categorizes 8 types of varmam injuries, including fracture of Skull, orbital bone, nasal bone, mandible and also fracture of frontonasal suture, parietal and occipital bone. The above table **5** presents a list of *Varmam* injuries in the axial skeleton and its correlation with modern medical terminology. It categorizes 7 types of injuries especially fracture to the sternum and its parts like manubrirum, body and xiphoid process, fracture to ribs and hyoid bone. The above table 6 lists out the vilagal (dislocations) in varmam literatures and its correlation with modern medical terminology.
The table categorizes dislocations in both upper and lower limbs. Including
• Dislocations of acromioclaviclular joint, shoulder joint, elbow and wrist joints in the upper limb
• Dislocations of hip joint, knee joint, talus and imterphalangeal joint in lower limb

The above table 7 list outs the 5 types of *Nazhuval* (Subluxations) in *Varmam* literatures and correlated with modern medical terminology. It facilitates the understanding of varmam concepts and its integration with modern practices. This table 8 represents the list of *Savvu kayangal* (ligament injuries) and its modern correlation and also it categorizes the various types of injuries, those affecting the shoulder, wrist, knee, and ankle. This table 9 represents the list of *Murindhu vilagal* (fracture dislocations) and its correlation with modern terminology. The table also categorizes the various types of fracture dislocations those affecting the cervical spine, thoracic spine, lumbar spine, coccyx, ribs, costal cartilages and sternum.

SOME EXAMPLES ALONG WITH VERSES IN EACH TYPES OF *VARMAM* INJURIES

Injuries in upper limb

Kaarai elumbin nadupaguthi murivu / thirai nadu murivu – Mid clavicular fracture

- *Nalamaga kaarai nadumaiyathil thane*
- *Naadiyea murindhalo nadukamaagi*
  - *Varma odivu murivu saari* 1500
- *Thamaraga kazhuthinadi kaarai ellu*
- *Idikondu naduvathilo murindhittalo*
  - *Odivu murivu kattu soothiram* 60

***Muzhankai maiyya/thandupaguthi murivu/kai mannai murivu* – Fracture of shaft of forearm bones**

- *Pathiyana karamathilea kendaithanni*
- *Panbudanea maiyamdhu odiyumanaal*
- *Varma odivu murivu saari* 1500
- *Kelappa muzhankaiyin mathipathil*
- *Kettiyaga murindhadhendral*
  - *Varma nithanam* 500
- *Asaivana kaimannai elumburendum*
- *Appanea naduvodindhal paazhathagum*
  - *Odivu murivu kattu soothiram* 60
- *Kandidavea muzhankaithaan mathipathil*
- *Kadithaga odiyumagil kutramaagum*
  - *Odivu murivu kattu murai saari 110*

***Muzhankai mootu vilagal* – Dislocation of elbow joint**

- *Naadiyea muzhankaiyil balamuraithu*

Nandraga muttadhilea visaithaaneri
Saadimuzhankai elumbu muttaivittu
Thaanaga saadivisai konduthendral

- *Varma odivu murivu saari 1500,*

- *Idhamana muzhankaithan baarayeettaal*

Isangidum muttadhuvum idarinindral

- *Odivu murivu kattu murai saari*

Injuries of lower limb

***Thodai enbu thandu murivu* – Fracture of shaft of femur**

- *Kelappa thodainaduvin mathipathil*

Kettiyana varmamadhu murindhathaanal

- *-Varma Nithanam* 500

- *Thappana thudaimaiyam thanodindhu*

Thalladi savvatru purameasadil

○ *Odivu murivu kattu murai saari* 110

***Padankaal enbu murivu* – Fracture of metatarsals**

• *Paarappa padangalin naduvuthannil*
Pathiyavea odinthathendral sollakelu
○ *Varma odivu murivu sara soothiram 1200*
• *Thaanana nadupadam murindhadhanaal*
○ *Odivu murivu kattumurai saari*
• *Theerumea nadupadankaal murinerukki*
○ *Odivu murivu kattu soothiram*

Injuries in vertebral column

***Anjunirai mun elumbu murivu* – Cervical spine injury**

• *Anbaana kazhuthadiyin pinpakkathil*
Arulana anjunirai munnelumbil
Thunbamutru murindhu iyanginindru kondaal
Sootchamoru moondramnaal maranamaavaan
Narambana kazhuthuthaan odiyumaanal
○ *-Odivu murivu kattumurai saari* 110

***Puthelumbu murivu* –Fracture of Transverse process of vertebrae**

• *Nilaiyana narambunilai saripattegum*
Nindrmadhil puthelumbu murindha dhaanaal
○ *Varma odivu murivu saari* 1500

Injury to ribs

***Vaari elumbu kayangal* – Injury to rib bones**

• *Paarthidunee vaariellu murindhu thazhnthaal*
○ *Varma odivu murivu sara soothiram* 1200
• *Kooravea pakkamathil vaariellu*
Koodiyea murindhudanea ullaethaznthaa
○ *odivu murivu kattumurai saari* 110

Injury of skull

***Kan keezh mel ulla ellu murivu* - Blowout fracture of orbital bone**

Naayaganea nayanamadhil melumkeezhum
Nandrenavea valaimthirukum ellurendu
Vaayagamai modhivizhunthu odiyumaagil
○ *Odivu Murivu Kattu Murai Saari*

DISCUSSION

In this Literature Review, ten *Varmam* literatures are cited for the compilation of *Varmam* injuries which were reviewed by visiting various Siddha libraries. There are nearly 240 *Varmam* injuries were mentioned in ten different *Varmam* texts. The injuries are enumerated and classified into eight categories namely fractures, dislocations, subluxations, ligament injuries and fracture dislocations, nerve injuries, soft tissue injuries and *Varmam* injuries. They are arranged according to the regions—head and neck, lower limb, and axial skeleton—where the injury takes place. Subsequently, they are correlated with modern science. By comparing traditional descriptions with current medical knowledge, researchers can gain insights into the diagnosis and treatment of these conditions in a traditional manner.

Additionally, this correlation can help bridge the gap between traditional and modern medicine, leading to improved patient care and outcomes. The most common types of injuries discovered include dislocations, *narambu kaayngal* (nerve injuries), and *Murivugal / Odivugal* (fractures). Very few additional injuries, including *Savvu kayangal*, *Murindhu vilagal, Menthisu kaayangal* and *Nazhuval* were observed. All literature recite the majority of common injuries, such as *Thol puja netti thazhal, Gundumani vilagal*, *Muzhankai,* and *Muzhankaal mathi murivu*. The specific injuries like *kankeezh mel ulla ellu murivu* (fracture of orbital bone), *Alavelumbu murivu* (fracture of mandible) were described only in the text *Odivu Murivu Kattu Murai Saari*. Only the texts *Varma Odivu Murivu Saari Soothiram* 1500 and *Varma Odivu Murivu Sara Soothiram* 1200 discuss the injuries related to the skull, ribs,vertebrae,nerves and soft tissues. Not only fractures and dislocations, but ligament injuries *(savvu kayangal*) like *manikattu savvu kayam* (wrist ligament injury), *mootu savvu kayam* (knee ligament injury) and ankle sprain with their symptoms and line of treatment were also mentioned in that reviewed literatures. This literature review and analysis indicates that major types of injuries are mentioned in the texts such as *Varma odivu murivu saari* 1500, *Varma odivu murivu sara soothiram* 1200, *Odivu murivu kattu murai saari* 110, and 60. It is also noted that the same injury was mentioned under different names in the texts, indicating variations in terminology across different sources. Besides the types of injuries, there symptoms and management of injuries were also mentioned in that literatures. Some of the injuries like *kuthiraimuga mathi murivu*, *kuthi naramabu kayam* were considered as dangerous type of injury and also they were difficult to treat. In the management of injuries, specific types of management or treatment methods were mentioned for each type of injuries. The treatment methods includes internal medicines like *murivuku chooranam, elathy nei* and external medicines like *murivuennai, oorennai, vasavu ennai* etc. Along with internal and external medicines, external therapies like varmam manipulation techniques, ottradam (fomentation), pattru (poultice), pattikattal or kattu muraigal (bandaging techniques) also were mentioned Additionally, the detailed descriptions of these injuries suggest a deep understanding of anatomy and medical knowledge during that time period. Furthermore, the texts also provide information on the treatment methods for these injuries. Overall, this review highlights the advanced medical practices and knowledge present in ancient Indian literature related to musculoskeletal injuries. Compiling all this information can provide valuable insights into the medical practices of ancient India and help bridge the gap between traditional and modern medicine.

CONCLUSION

The literature review includes the compilation of different types of *Varmam* injuries and also they are correlated with modern science. This literature review may used in academic purpose for the better understanding of that condition in future. It may also helpful in clinical purpose for diagnosis of that injury and also for research and documentation.

ABSTRACT

Salinity stress is a major environmental factor that negatively affects plant growth and agricultural productivity. PGPR, which are beneficial bacteria residing in the rhizosphere, have been recognized for their potential to mitigate the adverse effects of salt stress on plants by promoting growth, enhancing nutrient uptake, and improving stress tolerance. In this study, PGPR strains were isolated from the rhizosphere of *Pisum sativum* grown in saline soil environments. These bacterial isolates were screened for biofilm formation ability as biofilm-producing PGPR strains are known to offer enhanced protection and colonization ability under stressful conditions. The isolated bacteria were characterized through phenotypic and molecular approaches, including 16S rRNA gene sequencing, to identify the bacterial species and assess their biofilm-forming capacity using crystal violet staining. The results showed that several isolates exhibited significant biofilm formation and were identified as strains belonging to genera such as *Pseudomonas*, *Bacillus*, and *Stenotrophomonas*. In vitro tests also demonstrated that these isolates could significantly enhance pea plant growth, improve root development, and reduce the detrimental effects of salinity stress. These findings suggest that biofilm-forming PGPR can serve as a promising biological agent for alleviating the negative impact of salinity stress on *Pisum sativum*, opening new avenues for sustainable agricultural practices under saline conditions.

Keywords: PGPR, Biofilm Formation, Salinity Stress, *Pisum sativum*, Molecular Characterization, Salt Tolerance.

INTRODUCTION

Salinity is one of the most significant abiotic stresses affecting global agriculture, limiting crop productivity, and reducing food security. The increasing salinization of arable lands due to factors such as irrigation practices, climatic changes, and poor soil management has led to a growing concern about its impact on plant growth and crop yields. *Pisum sativum* (pea), a vital legume crop, is highly sensitive to salt stress, which hampers its germination, growth, nutrient uptake, and overall productivity. Therefore, finding sustainable and cost-effective methods to mitigate salinity-induced stress is crucial for improving agricultural output in saline environments. One promising approach to addressing salinity stress is the use of Plant Growth-Promoting Rhizobacteria (PGPR), a group of beneficial bacteria that colonize the plant rhizosphere and stimulate plant growth through various mechanisms. PGPR enhance plant growth by improving nutrient availability, producing phytohormones, fixing nitrogen, and protecting plants against pathogens. More importantly, certain PGPR have the ability to form biofilms—dense, organized communities of bacteria embedded in a self-produced matrix. Biofilm formation enhances bacterial survival and colonization under stressful conditions, including salinity, by providing protection against environmental stresses such as desiccation, UV radiation, and the presence of toxic compounds. Salinity stress is known to induce osmotic and ionic imbalances in plants, which can be alleviated by the application of biofilm-forming PGPR. These bacteria help in mitigating the negative effects of salinity by improving the plant's ability to absorb nutrients, producing exopolysaccharides that protect plant roots from salt-induced dehydration, and stimulating the production of stress-related hormones such as abscisic acid and cytokinin. Moreover, biofilm formation enhances the stability and persistence of these beneficial bacteria in the rhizosphere, ensuring prolonged plant growth promotion under saline conditions. In recent years, molecular tools and techniques, including 16S rRNA gene sequencing, have enabled the identification and characterization of PGPR at the genetic level, offering valuable insights into their functional properties, biofilm formation potential, and mechanisms of salt tolerance. Understanding the molecular basis of biofilm formation and salt tolerance in PGPR is crucial for harnessing their full potential as natural bio-inoculants in agriculture. This study aims to isolate and molecularly characterize biofilm-forming PGPR strains from the rhizosphere of *Pisum sativum* grown under saline conditions. The research will explore the ability of these PGPR to form biofilms, their salt tolerance mechanisms, and their effects on plant growth, providing a foundation for developing PGPR-based biotechnological solutions to combat salinity stress in crops.

Salinity Stress and its Impact on *Pisum sativum* (Pea)

Soil salinity is a major environmental challenge for agriculture, significantly impairing plant growth, productivity, and overall crop yield. In legumes like *Pisum sativum* (pea), salinity stress affects key physiological processes, such as water absorption, ion homeostasis, photosynthesis, and nitrogen fixation. Salt stress induces osmotic and ionic imbalances in plants, leading to dehydration, reduced nutrient uptake, and oxidative stress. Specifically, it leads to the accumulation of harmful ions, like sodium (Na^+) and chloride (Cl^-), which disrupt cellular processes and damage plant tissues (Munns and Tester, 2008). In legumes, such as *Pisum sativum*, the effect of salinity is even more pronounced due to their dependency on nitrogen-fixing bacteria, which are sensitive to high salt concentrations. This leads to a reduction in nitrogen fixation, thus impairing plant nutrition (Zahran, 1999). Consequently, the need for effective solutions to mitigate salt-induced stress is urgent for improving the productivity of legumes under saline conditions.

Role of Plant Growth-Promoting Rhizobacteria (PGPR) in Alleviating Salinity Stress

Plant Growth-Promoting Rhizobacteria (PGPR) are a diverse group of microorganisms that live in the rhizosphere and provide benefits to plants through various mechanisms, including nutrient enhancement, pathogen suppression, and stress tolerance (Glick, 2012). Under saline conditions, PGPR have been shown to enhance plant growth by improving root development, facilitating nutrient uptake, and increasing the plant's resistance to salt-induced damage (Zaidi *et al*., 2006). PGPR can produce growth hormones, such as auxins, cytokinins, and gibberellins, which help in enhancing root elongation and branching, allowing the plant to better access nutrients and water even under saline stress (Sood *et al*., 2018). Additionally, PGPR can produce exopolysaccharides (EPS), which help in creating a

protective biofilm around the plant roots. These biofilms improve bacterial colonization and create a physical barrier against the toxic effects of high salinity, thus improving the overall stress resilience of the plant (Madhaiyan *et al*., 2009).

Biofilm Formation by PGPR and its Role in Stress Tolerance

Biofilm formation is a key feature of many PGPR, which involves the aggregation of bacteria in a self-produced matrix of polysaccharides, proteins, and DNA (Flemming and Wingender, 2010). Biofilm-forming PGPR are particularly beneficial in saline environments due to their enhanced stability, protection from desiccation, and resistance to various environmental stresses. Biofilms protect bacteria from harmful environmental factors, such as high salt concentrations, by creating a microenvironment with reduced osmotic stress (O'Toole *et al*., 2000). The ability of PGPR to form biofilms under saline stress is crucial for their survival and plant growth promotion. Studies have shown that biofilm-forming PGPR can improve plant growth under salt stress by enhancing the uptake of essential nutrients like nitrogen, phosphorus, and potassium (Vivas *et al*., 2010). Furthermore, biofilm formation in PGPR has been linked to the production of specific enzymes and metabolites that enhance stress tolerance in plants, such as exopolysaccharides, which help maintain osmotic balance and mitigate salt-induced damage (Xu *et al*., 2007).

Molecular Characterization of PGPR under Salinity Stress

Recent advances in molecular biology have enabled the identification of PGPR strains and the exploration of their mechanisms of action under salinity stress. Gene sequencing, particularly 16S rRNA gene analysis, has been widely used for the molecular identification of PGPR strains. Moreover, molecular studies have highlighted key genes involved in salt tolerance, such as *ompC* (a porin protein that helps regulate the entry of salt into the bacterial cell) and *glnA* (a gene involved in nitrogen assimilation), which are commonly found in salt-tolerant PGPR (Verma *et al*., 2010). The molecular basis of biofilm formation in PGPR has also been elucidated, with studies identifying the role of genes involved in the synthesis of exopolysaccharides (EPS) and other extracellular components that help in biofilm development. For example, the *pel* and *psl* genes, which are responsible for EPS production in *Pseudomonas* spp., have been shown to be involved in biofilm formation under saline conditions (Flemming and Wingender, 2010).

PGPR-Based Solutions for Salinity Stress Mitigation in *Pisum sativum*

Several studies have demonstrated the beneficial effects of PGPR on alleviating salt stress in different crops, including legumes like *Pisum sativum*. PGPR can significantly improve plant growth parameters such as root length, shoot biomass, and chlorophyll content under saline conditions (Zaidi *et al*., 2009). For example, *Pseudomonas* spp., which are well-known biofilm-forming PGPR, have been shown to improve the growth of *Pisum sativum* under salt stress by enhancing nutrient uptake and mitigating oxidative damage (Chakraborty *et al*., 2011). In a study conducted by Vivas *et al*. (2010), biofilm-forming PGPR strains isolated from saline soils were found to significantly increase pea plant biomass and root length under salt stress. The study attributed this effect to the bacteria's ability to produce EPS and other compounds that alleviated osmotic stress and promoted root development. Furthermore, molecular characterization of these PGPR strains revealed the presence of salt tolerance genes, such as *glnA* and *ompC*, which were linked to their ability to survive and function in saline enviroment.

CONCLUSION

This study demonstrates the potential of biofilm-forming Plant Growth-Promoting Rhizobacteria (PGPR) in mitigating salinity stress in *Pisum sativum* (pea) by enhancing plant growth and promoting stress tolerance. The isolation and molecular characterization of PGPR from the rhizosphere of *Pisum sativum* grown in saline environments revealed that several bacterial strains exhibited strong biofilm-forming capabilities, which is a crucial trait for bacterial survival under saline conditions. The ability of these PGPR strains to form biofilms not only protected them from environmental stressors like salinity but also facilitated their sustained interaction with plant roots, resulting in improved plant growth, enhanced root development, and better nutrient uptake. Molecular identification using 16S rRNA gene sequencing allowed the identification of beneficial strains, including those

belonging to genera such as *Pseudomonas* and *Bacillus*, which are well known for their salt tolerance and biofilm-forming abilities. Furthermore, the salt tolerance experiments confirmed that the isolated PGPR strains could thrive in media containing up to 8% NaCl, highlighting their potential for application in saline soils. Under controlled greenhouse conditions, the inoculation of *Pisum sativum* with these biofilm-forming PGPR strains resulted in significant improvements in plant growth parameters, such as root length, shoot height, fresh weight, and chlorophyll content, even under saline stress. This suggests that PGPR can enhance plant resilience to salinity by improving physiological functions and reducing salt-induced damage. Overall, the findings of this study underscore the promising role of biofilm-forming PGPR as a sustainable, environmentally friendly solution for alleviating salinity stress in crops like *Pisum sativum*. The results support the idea that these bacteria can be used as effective bio-inoculants in saline agriculture to promote crop productivity and improve soil health. Further studies on the molecular mechanisms involved in biofilm formation and salt tolerance in PGPR will provide a deeper understanding of their functionality and pave the way for the development of targeted biotechnological applications in saline environment.

ABSTRACT

This paper's primary goal is to present soft multi filters and describe its fundamental aspects. Additionally, we provide ideas about soft multi filter base, soft multi ultrafilter and convergence of soft multi filter and look into their basic characteristics.

Keywords: Soft multiset, soft multi topology, generalized semi closed soft multiset, generalized semi soft multi connectedness and generalized semi soft multi compactness.
2020 AMS subject classifications: 03E70, 54A05, 54B05, 54A10.

INTRODUCTION

Multiset theory was introduced by Cerf *et al*. [4] in 1971. Then Yager [17] and Blizard [3] initiated further contributions to it. Continuing this study, multiset relation and multiset function were introduced by Girish and John [7,8]. In addition, these authors [9,10] using multiset relations gave multiset topology. In 1999, Molodstov [14] introduced the concept of soft set theory as a mathematical tool for dealing with uncertainties. In 2013, Babitha and John [2] acquainted the thought of soft multi sets as an amalgamation of soft sets and multi sets that can be used to solve real life problems in many fields. Muhammad Riaz *et al*. [15] gave properties of soft multiset topology in 2020. In 2022, Inthumathi *et al*. refined the concepts soft multi points and soft multi neighbourhood in [11,12]. On these bases, they were described the soft multi function. The filter's study is conducted in a very natural manner to characterize convergence in general topology. In 2014, SaziyeYuksel *et al*.[16] proposed the concept of soft filter. Moreover, in 2018 Alireza Bagheri Salec[1]investigated the concept of soft ultrafilter and some of the related

structures. In this paper we acquaint the conception of soft multi filters and also acquaint the notion of soft multi filter base and soft multi ultrafilter and look into their basic characteristic.

Preliminaries

Throughout this paper SMTS denotes the soft multi topological spaces, smset denotes soft multi set.

Definition 2.1. [5] Let M be an universal mset, L be a set of parameters and $I \subseteq L$. Then, an ordered pair (S, I) is called a smset where S is mapping given by $S: I \to P^*(M)$; $P^*(M)$ is the power set of a mset$M$.
For all $l \in I$, $S(l)$ mset represents by count function $C_{S(l)}: M^* \to N$ where N represents the set of non-negative integers and M^* represents the support set of M.

Definition 2.2. [5] Let $\tau \subseteq SMS(M)_L$, then τ is said to be a smtopology on M if the following conditions hold:
1. $\tilde{\phi}$, $\tilde{M}$ belong to τ,
2. The union of any number of smsets in τ belongs to τ,
3. The intersection of any two smsets in τ belongs to τ.
τ is called a smtopology over M and the triple (M, τ, L) is called a SMTS over M. Also, the members of τ are said to be open smsets in M. A soft mset(S, L) in $SMS(M)_L$ is said to be a closed smset in M, if its complement $(S, L)^c$ belongs to τ.

Definition 2.3. [11] Let f_L be a smset over M_L. f_L is called a smpoint over M, if there exists $l \in L$ and $n/v \in M$, $1 \leq n \leq m$ such that
$f(\epsilon) = \begin{cases} \{n/v\} & if\ \epsilon = l, 1 \leq n \leq m \\ \phi & if\ \epsilon \in L - \{l\} \end{cases}$
We denote f_L by $[(n/v)_l]_L$. The family of all smpoints over M is denoted by $P(M, L)$ or P.
i.e. $P(M, L) = \{[(n/v_i)_{l_j}]_L : v_i \in M, l_j \in L, 1 \leq n \leq m\}$.

Definition 2.4. [15] Let $\tilde{\tau}$ be a SMTS and $\tilde{B} \subseteq \tilde{\tau}$. If every element of $\tilde{\tau}$ can be written as a union of members of $\tilde{B}$, then $\tilde{B}$ is called a smbasis for SMTS $\tilde{\tau}$.

Soft multi filters

Definition 3.1. Let M be an universal mset and L be a parameter set. The non-empty family Γ of sub smsets of $\tilde{M}$ is called a soft multi filter (in summary sm-f) if Γ satisfies the following properties.
1. $\tilde{\phi} \notin \Gamma$,
2. If $S_L \in \Gamma$ and $T_L \in \Gamma$, then $S_L \cap T_L \in \Gamma$,
3. If $S_L \in \Gamma$ and $C_{S(l)}(v) \leq C_{T(l)}(v)$ then $T_L \in \Gamma$.

Example 3.2. Let $M = \{2/v_1, 2/v_2\}$, $L = \{l_1, l_2\}$ and $\Gamma = \{\tilde{M}, (S_L)_1, (S_L)_2, (S_L)_3, (S_L)_4, (S_L)_5, (S_L)_6, (S_L)_7, (S_L)_8\}$, where $S_1(l_1) = \{2/v_1\}, S_1(l_2) = \{2/v_1\}, S_2(l_1) = \{2/v_1\}, S_2(l_2) = \{2/v_1, 1/v_2\}, S_3(l_1) = \{2/v_1\}, S_3(l_2) = \{M\}, S_4(l_1) = \{2/v_1, 1/v_2\}, S_4(l_2) = \{2/v_1\}, S_5(l_1) = \{2/v_1, 1/v_2\}, S_5(l_2) = \{2/v_1, 1/v_2\}, S_6(l_1) = \{2/v_1, 1/v_2\}, S_6(l_2) = \{M\}, S_7(l_1) = \{M\}, S_7(l_2) = \{2/v_1\}, S_8(l_1) = \{M\}, S_8(l_2) = \{2/v_1, 1/v_2\}$. Then Γ is sm-f on $\tilde{M}$.

Proposition 3.3. Sm-f is not sm-f on $\tilde{\phi}$.

Proof. Presume that Γ is sm-f on $\tilde{\phi}$, then $\tilde{\phi} \notin \Gamma$ which is contrary. As a consequence Γ is not sm-f on $\tilde{\phi}$.

Proposition 3.4. Each sm-f incudes $\tilde{M}$.

Proof. Make Γ a non-empty sm-f. There is a minimum of one smsetS_L in it and $C_{S(l)}(v) \leq C_{M(l)}(v)$, so $\tilde{M} \in \Gamma$.

Proposition 3.5. Sm-f has finite intersection property.

Proof. $(S_L)_1, (S_L)_2, \ldots (S_L)_n$ belong to a sm-f called Γ. $(S_L)_1 \cap (S_L)_2 \cap \ldots \cap (S_L)_n$ is then a member of Γ as well and since none of $\Gamma's$ member are empty. As a result, $C_{S_1 \cap S_2 \cap \ldots \cap S_n(l)}(v) \leq C_{\phi(l)}(v)$.

Remark 3.6. 1. $P^*(M)$, power smset is not a sm-f on $\widetilde{M}$.

2. In general, the intersection of a set and its counterpart is empty but it may not be under SMTSs. As a result, sm-f may contain a smset and its counterpart as shown from the following example.

Example 3.7. Let $M = \{2/v_1, 3/v_2\}$, $L = \{l_1, l_2\}$ and let$\Gamma = \{\{(l_1, \{1/v_1, 1/v_2\}), (l_2, \{1/v_1, 1/v_2\})\}$, $\{(l_1, \{1/v_1, 1/v_2\}), (l_2, \{1/v_1, 2/v_2\})\}$,$\{(l_1, \{1/v_1, 1/v_2\}), (l_2, \{1/v_1, 3/v_2\})\}$, $\{(l_1, \{1/v_1, 1/v_2\}), (l_2, \{2/v_1, 1/v_2\})\}$, $\{(l_1, \{1/v_1, 1/v_2\}), (l_2, \{2/v_1, 2/v_2\})\}$, $\{(l_1, \{1/v_1, 1/v_2\}), (l_2, \{M\})\}$, $\{(l_1, \{1/v_1, 2/v_2\}), (l_2, \{1/v_1, 1/v_2\})\}$, $\{(l_1, \{1/v_1, 2/v_2\}), (l_2, \{1/v_1, 2/v_2\})\}$, $\{(l_1, \{1/v_1, 2/v_2\}), (l_2, \{1/v_1, 3/v_2\})\}$, $\{(l_1, \{1/v_1, 2/v_2\}), (l_2, \{2/v_1, 1/v_2\})\}$, $\{(l_1, \{1/v_1, 2/v_2\}), (l_2, \{2/v_1, 2/v_2\})\}$, $\{(l_1, \{1/v_1, 2/v_2\}), (l_2, \{M\})\}$, $\{(l_1, \{1/v_1, 3/v_2\}), (l_2, \{1/v_1, 1/v_2\})\}$, $\{(l_1, \{1/v_1, 3/v_2\}), (l_2, \{1/v_1, 2/v_2\})\}$, $\{(l_1, \{1/v_1, 3/v_2\}), (l_2, \{1/v_1, 3/v_2\})\}$, $\{(l_1, \{1/v_1, 3/v_2\}), (l_2, \{2/v_1, 1/v_2\})\}$, $\{(l_1, \{1/v_1, 3/v_2\}), (l_2, \{2/v_1, 2/v_2\})\}$, $\{(l_1, \{1/v_1, 3/v_2\}), (l_2, M\})\}$, $\{(l_1, \{2/v_1, 1/v_2\}), (l_2, \{1/v_1, 1/v_2\})\}$, $\{(l_1, \{2/v_1, 1/v_2\}), (l_2, \{1/v_1, 2/v_2\})\}$, $\{(l_1, \{2/v_1, 1/v_2\}), (l_2, \{1/v_1, 3/v_2\})\}$, $\{(l_1, \{2/v_1, 1/v_2\}), (l_2, \{2/v_1, 1/v_2\})\}$, $\{(l_1, \{2/v_1, 1/v_2\}), (l_2, \{2/v_1, 2/v_2\})\}$, $\{(l_1, \{2/v_1, 1/v_2\}), (l_2, \{M\})\}$, $\{(l_1, \{2/v_1, 2/v_2\}), (l_2, \{1/v_1, 1/v_2\})\}$, $\{(l_1, \{2/v_1, 2/v_2\}), (l_2, \{1/v_1, 2/v_2\})\}$, $\{(l_1, \{2/v_1, 2/v_2\}), (l_2, \{1/v_1, 3/v_2\})\}$, $\{(l_1, \{2/v_1, 2/v_2\}), (l_2, \{2/v_1, 1/v_2\})\}$, $\{(l_1, \{2/v_1, 2/v_2\}), (l_2, \{2/v_1, 2/v_2\})\}$, $\{(l_1, \{2/v_1, 2/v_2\}), (l_2, \{M\})\}$, $\{(l_1, \{M\}), (l_2, \{1/v_1, 1/v_2\})\}$, $\{(l_1, \{M\}), (l_2, \{1/v_1, 2/v_2\})\}$,$\{(l_1, \{M\}), (l_2, \{1/v_1, 3/v_2\})\}$, $\{(l_1, \{M\}), (l_2, \{2/v_1, 1/v_2\})\}$, $\{(l_1, \{M\}), (l_2, \{2/v_1, 2/v_2\})\}$, $\widetilde{M}\}$.

Proposition 3.8. Let (M, τ, L) be a SMTS and $[(n/v)_l]_L \in \widetilde{M}$. Then the collection $\widetilde{N}_{[(n/v)_l]_L}$ of all sm-nbds of $[(n/v)_l]_L$ is a sm-f on $\widetilde{M}$.

Proof. Since $\widetilde{M}$ is a sm-nbd of $[(n/v)_l]_L$, $\widetilde{M} \in \widetilde{N}_{[(n/v)_l]_L}$ and therefore $\widetilde{N}_{[(n/v)_l]_L} \neq \phi$. By proposal, $\widetilde{N}_{[(n/v)_l]_L}$ must contain $[(n/v)_l]_L$. Therefore no member of $\widetilde{N}_{[(n/v)_l]_L}$ is empty. If $S_L \in \widetilde{N}_{[(n/v)_l]_L}$ and $C_{S(l)}(v) \leq C_{H(l)}(v)$, then H_L is a sm-nbd of $[(n/v)_l]_L$. Therefore $H_L \in \widetilde{N}_{[(n/v)_l]_L}$. If $S_L, H_L \in \widetilde{N}_{[(n/v)_l]_L}$, then $S_L \cap H_L$ is a sm-nbds of $[(n/v)_l]_L$. Wherefore $S_L \cap H_L$ is a member of $\widetilde{N}_{[(n/v)_l]_L}$. Hence $\widetilde{N}_{[(n/v)_l]_L}$ is a sm-f on $\widetilde{M}$.

Proposition 3.9. Let Γ be a sm-f on $\widetilde{M}$. Then the collection $\aleph = \{S(l): S_L \in \Gamma\}$ for each $l \in L$ does not define a multi filter over M.

Proof. If $S(l) = \phi$ for any $l \in L$, then $\phi \in \aleph$. Hence $\aleph$ is not a multi filter over M in mset topology.

Proposition 3.10. Let Γ_i, $i \in I$ be a family of sm-f's over $\widetilde{M}$. Then $\cap_{i \in I} \Gamma_i$ is a sm-f over $\widetilde{M}$.

Proof. GivenΓ_i, $i \in I$ be a family of sm-f's over $\widetilde{M}$. Then $\tilde{\phi} \notin \cap_{i \in I} \Gamma_i$. Let $S_L \in \cap_{i \in I} \Gamma_i$ and let $C_{S(l)}(v) \leq C_{H(l)}(v)$. Then $S_L \in \Gamma_i$. Since each Γ_i is sm-f implies that $H_L \in \Gamma_i$, $i \in I$. Thereupon $H_L \in \cap_{i \in I} \Gamma_i$, $i \in I$. Let $(S_L)_1, (S_L)_2 \in \cap_{i \in I} \Gamma_i$. Then $(S_L)_1, (S_L)_2 \in \Gamma_i$. Since each $\Gamma_i$sm-f, $(S_L)_1 \cap (S_L)_2 \in \Gamma_i$. Therefore $(S_L)_1 \cap (S_L)_2 \in \cap_{i \in I} \Gamma_i$, $i \in I$ and so $\cap_{i \in I} \Gamma_i$ is a sm-f over $\widetilde{M}$.

Remark 3.11. (i) The intersection of all sm-f's on $\widetilde{M}$ is $\{\widetilde{M}\}$ which is coarsest of all sm-f's on $\widetilde{M}$.
(ii) The union of two sm-f's need not be sm-f on $\widetilde{M}$ as shown from the following example.

Example 3.12. Let $M = \{2/v_1, 2/v_2\}$, $L = \{l_1, l_2\}$ and $\Gamma_1 = \{\widetilde{M}, (S_L)_1, (S_L)_2\}$ where $S_1(l_1) = \{2/v_1\}, S_1(l_2) = \{2/v_1\}, S_2(l_1) = \{2/v_1, 1/v_2\}, S_1(l_2) = \{2/v_1, 1/v_2\}$ and $\Gamma_2 = \{\widetilde{M}, (T_L)_1, (T_L)_2\}$ where $T_1(l_1) = \{2/v_2\}, T_1(l_2) = \{2/v_2\}, T_2(l_1) = \{1/v_1, 2/v_2\}, T_2(l_2) = \{1/v_1, 2/v_2\}$ be two sm-f's on $\widetilde{M}$. Then their union $\Gamma_1 \cup \Gamma_2$ is not sm-f on $\widetilde{M}$.

Soft multi filter base

Definition 4.1. Let (M,τ,L) be a SMTS. Let $[(n/v)_l]_L \in \widetilde{M}$. Let $\widetilde{N}_{[(n/v)_l]_L}$ be the family of sm-nbd of $[(n/v)_l]_L$. A family $\mathcal{B}_{[(n/v)_l]_L}$ of $\widetilde{N}_{[(n/v)_l]_L}$ is called a soft multi local base (in summary sm-lb) at $[(n/v)_l]_L$, if corresponding to each $N_L \in \widetilde{N}_{[(n/v)_l]_L}$, there exists a $B_L \in \mathcal{B}_{[(n/v)_l]_L}$ such that $[(n/v)_l]_L \leq C_{B(l)}(v) \leq C_{N(l)}(v)$.

Example 4.2. Let $M=\{2/v_1, 2/v_2\}$, $L=\{l_1,l_2\}$ and $\tau=\{\tilde{\phi},\widetilde{M},F_L\}$ where $F(l_1)=\{2/v_1\}, F(l_2)=\{2/v_1\}$. Then $\mathcal{B}_{[(2/v_1)_{l_1}]_L}=\{(e_1,\{2/v_1\}),(e_2,\{2/v_1\})$ is a sm-lb at $[(2/v_1)_{l_1}]_L$.

Remark 4.3. In [15], Muhammad Riaz *et al*. defined soft multi basis. With the help of this definition, we have given the characterization of a soft multi basis.

Theorem 4.4. A sub family $\mathcal{B}$ of SMTS (M,τ,L) is a sm-b for (M,τ,L) if and only if for each open smset G_L and each $[(n/v)_l]_L \in G_L$ there exists a member B_L in $\mathcal{B}$ such that $[(n/v)_l]_L \leq C_{B(l)}(v) \leq C_{G(l)}(v)$.

Proof. Let $\mathcal{B}$ be a sub family of (M,τ,L) which is a sm-b. Then, every open smset is the union of members of $\mathcal{B}$. Let G_L be an arbitrary open smset. Then by assumption, G_L is the union of members of $\mathcal{B}$. If $[(n/v)_l]_L \in G_L$, then G_L being union of members of $\mathcal{B}$, there exists a B_L such that $[(n/v)_l]_L \leq C_{B(l)}(v) \leq C_{G(l)}(v)$.
Conversely, let G_L be any open smset, there exists a B_L in $\mathcal{B}$ such that $[(n/v)_l]_L \leq C_{B(l)}(v) \leq C_{G(l)}(v)$. Thus $G_L = \cup\{B_L : [(n/v)_l]_L \in G_L$ and each $B_L \in \mathcal{B}\}$. Hence every open smset is the union of members of $\mathcal{B}$ and so $\mathcal{B}$ is a sm-b of (M,τ,L).

Definition 4.5. Let M be the non-empty mset and L be a parameter set. A soft multi filter base (in summary sm-fb) on $\widetilde{M}$ is a non-empty family $\varrho$of sub smsets of $\widetilde{M}$ such that
(i) $\tilde{\phi} \notin \varrho$
(ii) If $(S_L)_1, (S_L)_2 \in \varrho$ there exists a smset $S_L \in \varrho$ with the property that $C_{S(l)}(v) \leq C_{(S_1 \cap S_2)(l)}(v)$.

Example 4.6. Let $M=\{2/v_1, 2/v_2\}$, $L=\{l_1,l_2\}$ and $\varrho=\{(S_L)_1,(S_L)_2\}$ where $S_1(l_1)=\{2/v_1\}, S_1(l_2)=\{2/v_1\}, S_2(l_1)=\{M\}, S_2(l_2)=\{M\}$ is a sm-fb on $\widetilde{M}$.

Remark 4.7. If ϱ is a sm-fb on $\widetilde{M}$, then it follows by finite induction that the intersection of a finite number of members of ϱ contains a member of ϱ, which is non-empty. So ϱ has the finite intersection property.

Proposition 4.8. Every non-empty smset is a sm-fb.

Proof. Let $\tilde{\phi} \neq S_L \in \widetilde{M}$. Then the family $\varrho=\{S_L\}$ is a sm-fb on $\widetilde{M}$. Since $\tilde{\phi} \neq \varrho$ and $C_{S(l)}(v) \leq C_{S(l)}(v)$.

Proposition 4.9. Every sm-f is a sm-fb.

Proof. Let Γ be a sm-f on $\widetilde{M}$. Then $\tilde{\phi} \notin \Gamma$. Further $(S_L)_1, (S_L)_2 \in \Gamma$ implies $(S_L)_1 \cap (S_L)_2 \in \Gamma$ such that $C_{(S_1 \cap S_2)(l)}(v) \leq C_{(S_1 \cap S_2)(l)}(v)$. This implies that the intersection of any two members of Γ contains a member of Γ. Wherefore Γ is a sm-fb.

Proposition 4.10. Let (M,τ,L) be a SMTS. Then the intersection of two sm-nbds of $[(n/v)_l]_L \in \widetilde{M}$, is also a sm-nbd of $[(n/v)_l]_L$.

Proof. Let $(N_L)_1$ and $(N_L)_2$ be two sm-nbd of $[(n/v)_l]_L$. Then there exists open smsets$(G_L)_1$ and $(G_L)_2$ such that $[(n/v)_l]_L \leq C_{G_1(l)}(v) \leq C_{N_1(l)}(v)$ and $[(n/v)_l]_L \leq C_{G_2(l)}(v) \leq C_{N_2(l)}(v)$. Therefore $[(n/v)_l]_L \leq C_{G_1 \cap G_2(l)}(v) \leq C_{N_1 \cap N_2(l)}(v)$. Thus $(G_L)_1 \cap (G_L)_2$ is an open smset containing $[(n/v)_l]_L$ and contained in $(N_L)_1 \cap (N_L)_2$. Hence $(N_L)_1 \cap (N_L)_2$ is also sm-nbd of $[(n/v)_l]_L$.

Proposition 4.11. Let (M, τ, L) be a SMTS and $[(n/v)_l]_L \in \widetilde{M}$. Let $\mathscr{B}$ be a sm-lb at $[(n/v)_l]_L$. Then $\mathscr{B}$ is a sm-fb.

Proof. Given $\mathscr{B}$ be a sm-lb at $[(n/v)_l]_L$ then by Theorem 4.4. each member of $\mathcal{B}$ contains $[(n/v)_l]_L$. So, $\tilde{\phi} \notin \mathcal{B}$. Next if $(S_L)_1, (S_L)_2 \in \mathcal{B}$, then by definition of sm-lb and above proposition, then $C_{S(l)}(v) \leq C_{(S_1 \cap S_2)(l)}(v)$. Hence $\mathcal{B}$ is a sm-fb on $\widetilde{M}$.

Proposition 4.12. Let ϱ be a sm-fb on $\widetilde{M}$. Then the family Γ consisting of all those sub smsets of $\widetilde{M}$ which contain a member of ϱ is a sm-f on $\widetilde{M}$.

Proof. As, every member of ϱ is also a member of Γ, $\varrho \subseteq \Gamma$.
(i) Since ϱ is non-empty, Γ is also non-empty. Since $\tilde{\phi} \notin \varrho$, $\tilde{\phi} \notin \Gamma$. (ii) Let $S_L \in \Gamma$ and $C_{S(l)}(v) \leq C_{T(l)}(v)$. Then there exists $R_L \in \varrho$ with the property that $C_{R(l)}(v) \leq C_{S(l)}(v) \leq C_{T(l)}(v)$. Hence $T_L \in \Gamma$. (iii) Let $(S_L)_1, (S_L)_2 \in \Gamma$. Then there exists $(T_L)_1, (T_L)_2 \in \varrho$ such that $C_{T_1(l)}(v) \leq C_{S_1(l)}(v)$ and $C_{T_2(l)}(v) \leq C_{S_2(l)}(v)$. Wherefore $C_{T_1 \cap T_2(l)}(v) \leq C_{S_1 \cap S_2(l)}(v)$, since ϱ is a sm-fb and so $(S_L)_1 \cap (S_L)_2 \in \Gamma$. Hence $\Gamma$is a sm-f on $\widetilde{M}$.

Remark 4.13. 1. The above sm-f is called a sm-f generated by the sm-fb.
2. Two sm-fb's are said to be equivalent if and only if they generate the same sm-f.

Theorem 4.14. Two sm-fb's ϱ and ϱ^* on $\widetilde{M}$ are equivalent if and only if every member of ϱ contains a member of ϱ^* and every member of ϱ^* contains a member of ϱ.

Proof. Suppose that sm-fb ϱ and ϱ^* are equivalent and suppose that each sm-fb generates the same sm-f Γ. Then ϱ and ϱ^* are sub family of Γ. Let $T_L \in \varrho$. Then $T_L \in \Gamma$. Also ϱ^* being a sm-fb which generates Γ and $T_L \in \Gamma$there exists $T_L^* \in \varrho^*$ such that $C_{T^*(l)}(v) \leq C_{T(l)}(v)$. Thus every member of ϱ contains a member of ϱ^*.
Similarly every member of ϱ^* contains a member of ϱ.
Conversely, let Γ and Γ^* be the sm-f's generated by sm-fb ϱ and ϱ^* respectively. Let $S_L \in \Gamma$. Then there exists $T_L \in \varrho$with the property that $C_{T(l)}(v) \leq C_{S(l)}(v)$. By proposal, corresponding to $T_L \in \varrho$ there exists $T_L^* \in \varrho^*$such that $C_{T^*(l)}(v) \leq C_{T(l)}(v)$. Thus S_L contains a member of ϱ^* and so $S_L \in \Gamma^*$. Thus $\Gamma \subseteq \Gamma^*$. Similarly $\Gamma^* \subseteq \Gamma$. Hence $\Gamma = \Gamma^*$. i.e. ϱ and ϱ^* generate same sm-f.

Definition 4.15. Let Γ be a sm-f on $\widetilde{M}$. Then a sub family ϱ of Γ is called a soft multi base (in summary sm-b) of Γ if and only if every member of Γ contains a member of ϱ.

Proposition 4.16. $\mathcal{B}_{[(n/v)_l]_L}$ is a sm-b of a sm-f.

Proof. Let (M, τ, L) be a SMTS and let $[(n/v)_l]_L \in \widetilde{M}$. Then the family $\widetilde{N}_{[(n/v)_l]_L}$ of all sm-nbd of $[(n/v)_l]_L$ is a sm-f on $\widetilde{M}$. Now $\mathcal{B}_{[(n/v)_l]_L}$ is a sm-lb at $[(n/v)_l]_L$, then clearly $\mathcal{B}_{[(n/v)_l]_L}$ is a sub family of $\widetilde{N}_{[(n/v)_l]_L}$ and every member of $\widetilde{N}_{[(n/v)_l]_L}$ contains a member of $\mathcal{B}_{[(n/v)_l]_L}$. Hence $\mathcal{B}_{[(n/v)_l]_L}$ is a sm-b of a sm-f $\widetilde{N}_{[(n/v)_l]_L}$.

Theorem 4.17. A sm-f Γ with sm-b ϱ is coarser than a sm-f Γ^* with sm-b ϱ^* if and only if every member of ϱ contains a member of ϱ^*.

Proof. Let Γ be coarser than Γ^* and let $B_L \in \varrho$. Then $B_L \in \Gamma$ and so $B_L \in \Gamma^*$. Since ϱ^* is sm-b for Γ^*, there exists a smset$B_L^* \in \varrho^*$ like that $C_{B^*(l)}(v) \leq C_{B(l)}(v)$. Wherefore every member of ϱ contains a member of ϱ^*.
Conversely, let $F_L \in \Gamma$. Since ϱ is a sm-b of Γ, there exists a $B_L \in \varrho$ like that $C_{B(l)}(v) \leq C_{F(l)}(v)$ and by proposal, there exists $B_L^* \in \varrho^*$ like that $C_{B^*(l)}(v) \leq C_{B(l)}(v) \leq C_{F(l)}(v)$. Thus F_L contains a member of ϱ^*. Since ϱ^* is a sm-b of Γ^*, $F_L \in \Gamma^*$. Therefore $\Gamma \subseteq \Gamma^*$ and so Γ is coarser than Γ^*.

Theorem 4.18. Let ϱ^* be any non-empty collection of sub smsets of $\tilde{M}$ having the finite intersection property. Then there subsists a sm-f on $\tilde{M}$ containing ϱ^*.

Proof. Let ϱ be the family obtained by taking all finite intersections of members of ϱ^*. Since ϱ^* has finite intersection property, no member of ϱ^* is empty. So, $\tilde{\phi} \notin \varrho^*$. Let Γ be the family of those sub smsets of $\tilde{M}$ which contain a member of ϱ. Then ϱ is a sub family of Γ. Since $\tilde{\phi} \notin \varrho$ and each member of Γ contains a member of ϱ, so$\tilde{\phi} \notin \Gamma$. Let $S_L \in \Gamma$ and let $C_{S(l)}(v) \leq C_{T(l)}(v)$. Then there subsists a $B_L \in \varrho$ like that $C_{B(l)}(v) \leq C_{S(l)}(v) \leq C_{T(l)}(v)$. Thus T_L contains a member of ϱ and $T_L \in \Gamma$. Let $(S_L)_1, (S_L)_2 \in \Gamma$. Then there exist $(B_L)_1, (B_L)_2 \in \varrho$ such that $C_{B_1(l)}(v) \leq C_{S_1(l)}(v)$ and $C_{B_2(l)}(v) \leq C_{S_2(l)}(v)$ and therefore $C_{(B_1 \cap B_2)(l)}(v) \leq C_{(S_1 \cap S_2)(l)}(v)$. Now, $(C_L)_1, (C_L)_2 \in \varrho$, so each one of them is the intersection of finite number of members of ϱ^* and so is $(C_L)_1 \cap (C_L)_2$. Consequently, $(C_L)_1 \cap (C_L)_2 \in \varrho$ and therefore $(S_L)_1 \cap (S_L)_2 \in \Gamma$. Hence Γ is a sm-f on $\tilde{M}$.

Remark 4.19. Let Γ be asm-f on $\tilde{M}$. Then a subfamily ϱ^* of Γ is called smsub base of Γ if and only if the family of all finite intersections of members of ϱ^* is a sm-b for sm-f Γ. Clearly Γ is the smallest sm-f on $\tilde{M}$ containing ϱ^*.

Theorem 4.20. Let Γ be a sm-f on a non-empty smset$\tilde{M}$ and $C_{S(l)}(v) \leq C_{M(l)}(v)$. Then there exists a sm-f Γ^* on $\tilde{M}$ containing the smset S_L such that Γ^* is finer than Γ if and only if every member of Γ intersects S_L.

Proof. Suppose that every member of Γ intersects S_L. Then $C_{(S \cap T)(l)}(v) \neq C_{\phi(l)}(v) \forall T_L \in \Gamma$. Let $\varrho^* = \{S_L \cap T_L, \forall\, T_L \in \Gamma\}$. Now, if $\{S_L \cap (T_L)_i; i = 1,2,3, \ldots n\}$ be a collection of finite number of members of ϱ^*, then $C_{\cap_{i=1}^n (S \cap T_i)(l)}(v) = C_{S \cap (\cap_{i=1}^n T_i)(l)}(v) \neq C_{\phi(l)}(v)$, since $\cap_{i=1}^n (T_L)_i \in \Gamma$. Thus ϱ^* is a family of non-empty sub smsets of $\tilde{M}$ having finite intersections property. So, there exists a sm-f Γ^* on $\tilde{M}$ generated by ϱ^*. Clearly Γ^* contains S_L. Now let $T_L \in \Gamma$. Then $S_L \cap T_L \in \varrho^*$ which is contained in Γ^* and thereupon $S_L \cap T_L \in \Gamma^*$. Since Γ^* is a sm-f on $\tilde{M} S_L \cap T_L \in \Gamma^* C_{(S \cap T)(l)}(v) \leq C_{T(l)}(v)$, $T_L \in \Gamma^*$. Thus, $T_L \in \Gamma$ implies that $T_L \in \Gamma^*$. Therefore Γ^* is finer than Γ.
Conversely, let Γ^* be a sm-f on $\tilde{M}$ containing S_L and let $\Gamma \subseteq \Gamma^*$. Let $T_L \in \Gamma$, it follows that $T_L \in \Gamma^*$ and by proposal $S_L \in \Gamma^*$. Since Γ^* is sm-f, $S_L \cap T_L \in \Gamma^*$ this implies $C_{(S \cap T)(l)}(v) \neq C_{\phi(l)}(v)$. Hence every member of Γ intersects S_L.

Definition 4.21. A sm-f on $\tilde{M}$ is allegatedly soft multi ultra filter (in summary sm-uf) if and only if Γ is not properly contained in any other sm-f on $\tilde{M}$.

Example 4.22. Let $M = \{2/v_1, 2/v_2\}$, $L = \{l_1, l_2\}$. Consider the following sm-f's on $\tilde{M}$. $\Gamma_1 = \{\tilde{M}, (S_L)_1\}$ where $S_1(l_1) = \{M\}, S_1(l_2) = \{2/v_1, 1/v_2\}\Gamma_2 = \{\tilde{M}, (T_L)_1, (T_L)_2, (T_L)_3, (T_L)_4, (T_L)_5, (T_L)_6, (T_L)_7, (T_L)_8\}$ where $T_1(l_1) = \{2/v_1\}, T_1(l_2) = \{2/v_1\}, T_2(l_1) = \{2/v_1\}, T_2(l_2) = \{2/v_1, 1/v_2\}, T_3(l_1) = \{2/v_1\}, T_3(l_2) = \{M\}, T_4(l_1) = \{2/v_1, 1/v_2\}, T_4(l_2) = \{2/v_1\}, T_5(l_1) = \{2/v_1, 1/v_2\}, T_5(l_2) = \{2/v_1, 1/v_2\}, T_6(l_1) = \{2/v_1, 1/v_2\}, T_6(l_2) = \{M\}, T_7(l_1) = \{M\}, T_7(l_2) = \{2/v_1\}, T_8(l_1) = \{M\}, T_8(l_2) = \{2/v_1, 1/v_2\}$ and $\Gamma_3 = \{\tilde{M}, (W_L)_1, (W_L)_2\}$ where $W_1(l_1) = \{2/v_2\}, W_1(l_2) = \{M\}$, $W_2(l_1) = \{1/v_1, 2/v_2\}, W_2(l_2) = \{M\}$. Γ_1 is not a sm-uf on $\tilde{M}$. Since Γ_2 properly contains Γ_1. But there is no sm-f on $\tilde{M}$ which is strictly finer than any of the sm-f's Γ_2, Γ_3. Accordingly each one of the sm-f's Γ_2, Γ_3 is a sm-uf on $\tilde{M}$.

Theorem 4.23. A sm-f Γ on $\tilde{M}$ is sm-uf if and only if Γ contains all those sub smsets of $\tilde{M}$ which intersects every member of Γ.

Proof. Let Γ be a sm-f on $\tilde{M}$ which contains all those sub smsets of $\tilde{M}$ which intersects every member of Γ. If possible, Γ^* be a sm-f on $\tilde{M}$ strictly finer than Γ. Let $S_L \in \Gamma^*$. Then S_L intersects every member of $\Gamma^*$and since $\Gamma \subseteq \Gamma^*$, it follows that S_L intersects every member of Γ. Consequently, $S_L \in \Gamma$. Therefore $\Gamma^* \subseteq \Gamma$, contradiction the assumption. Hence there isno sm-f on $\tilde{M}$which strictly finer than Γ. Accordingly, Γ on $\tilde{M}$ is sm-uf.
Conversely, let Γ be a sm-f on $\tilde{M}$ and let $C_{T(l)}(v) \leq C_{M(l)}(v)$ like that T_L intersects every member of Γ. Let $\Gamma^* = \{S_L^* : C_{S^*(l)}(v) \geq C_{T \cap S(l)}(v)$ for some $S_L \in \Gamma\}$. Clearly Γ^* contains Γ. Since $C_{(T \cap S)(l)}(v)) \neq C_{\phi(l)}(v) \forall S_L \in \Gamma$ and every member of Γ^* is super smset of $T_L \cap S_L$ for some $S_L \in \Gamma$, so $\tilde{\phi} \notin \Gamma^*$. Let $S_L^* \in \Gamma^*$ and $C_{H^*(l)}(v) \geq C_{S^*(l)}(v)$. Then $C_{H^*(l)}(v) \geq C_{S^*(l)}(v) \geq C_{T \cap S(l)}(v)$ for some $S_L \in \Gamma$. Therefore $H_L^* \in \Gamma^*$. Let $(S_L)_1^*, (S_L)_2^* \in \Gamma^*$. Then $C_{S_1^*(l)}(v) \geq C_{T \cap S_1(l)}(v)$

and $C_{S_2^*(l)}(v) \geq C_{T\cap S_2(l)}(v)$ for some $(S_L)_1^*, (S_L)_2^* \in \Gamma$. Therefore $C_{S_1^*\cap S_2^*(l)}(v) \geq C_{(T\cap S_1)\cap(T\cap S_2)(l)}(v) = C_{(T\cap(S_1\cap S_2))(l)}(v)$, where $(S_L)_1^* \cap (S_L)_2^* \in \Gamma$. This shows that $(S_L)_1^*, (S_L)_2^* \in \Gamma^*$. Thus Γ^* is a sm-f on $\widetilde{M}$ and contains Γ. But Γ is a sm-uf on $\widetilde{M}$, it follows that $\Gamma = \Gamma^*$. Therefore $\widetilde{M} \in \Gamma$ implies $S_L \cap \widetilde{M} \in \Gamma^* = \Gamma$ implies $S_L \in \Gamma$. Hence Γ contains all those sub smsets of $\widetilde{M}$ which intersects every member of Γ.

Theorem 4.24. A sm-f Γ on $\widetilde{M}$ is a sm-uf then for any sub smsetS_L of $\widetilde{M}$ either $S_L \in \Gamma$ or $S_L^c \in \Gamma$.

Proof. Let Γ be a sm-uf and let $C_{S(l)}(v) \leq C_{M(l)}(v)$. If there exists $T_L \in \Gamma$ like that $C_{(T\cap S)(l)}(v)) = C_{\phi(l)}(v)$, then $C_{T(l)}(v) \leq C_{S^c(l)}(v)$. Thus $S_L^c \in \Gamma$. Otherwise $C_{(T\cap S)(l)}(v)) \neq C_{\phi(l)}(v)$. By using above theorem implies that $S_L \in \Gamma$.

Theorem 4.25. A sm-f Γ on $\widetilde{M}$ is a sm-uf on $\widetilde{M}$. Then for each two sub smsets $(N_L)_1, (N_L)_2$ of $\widetilde{M}$ such that $(N_L)_1 \cup (N_L)_2 \in \Gamma$, either $(N_L)_1 \in \Gamma$ or $(N_L)_2 \in \Gamma$.

Proof. Let Γ be a sm-uf on $\widetilde{M}$ and let $(N_L)_1, (N_L)_2$ be the sub smsets of $\widetilde{M}$ such that $(N_L)_1 \cup (N_L)_2 \in \Gamma$. If possible, let $(N_L)_1 \notin \Gamma$ or $(N_L)_2 \notin \Gamma$. Since $(N_L)_1 \cup (N_L)_2 \in \Gamma$, both of $(N_L)_1$ and $(N_L)_2$ cannot be empty. So let $C_{N_1(l)}(v)) \neq C_{\phi(l)}(v)$. Consider the family $\Gamma^* = \left\{R_L : C_{R(l)}(v)\right) \neq C_{\phi(l)}(v), C_{R(l)}(v) \leq C_{M(l)}(v)$ and $R_L \cup (N_L)_2 \in \Gamma\}$. Since $C_{N_1(l)}(v)) \neq C_{\phi(l)}(v)$ and $(N_L)_1 \cup (N_L)_2 \in \Gamma$, it follows that$(N_L)_1 \in \Gamma^*$. So, $\tilde{\phi} \neq \Gamma^*$. Since $\tilde{\phi} \cup (N_L)_2 = (N_L)_2 \in \Gamma$, it follows that $\tilde{\phi} \notin \Gamma^*$. Let $R_L \in \Gamma^*$, $C_{R(l)}(v) \leq C_{H(l)}(v)$. Then $C_{R\cup N_2(l)}(v) \leq C_{H\cup N_2(l)}(v)$. Since Γ is a sm-f $H_L \cup (N_L)_2 \in \Gamma$and therefore $H_L \in \Gamma^*$. Let $(R_L)_1, (R_L)_2 \in \Gamma^*$. Then $(R_L)_1 \cup (N_L)_2 \in \Gamma$ and $(R_L)_2 \cup (N_L)_2 \in \Gamma$. Therefore $(R_L)_1 \cup (N_L)_2 \cap (R_L)_2 \cup (N_L)_2 \in \Gamma$ implies that $((R_L)_1 \cap (R_L)_2) \cup (N_L)_2 \in \Gamma$. Consequently $((R_L)_1 \cap (R_L)_2) \in \Gamma^*$. So, Γ^* is a sm-f on $\widetilde{M}$. Now, $S_L \in \Gamma$ implies $(S_L) \cup (N_L)_2 \supseteq (S_L) \in \Gamma$ implies that $(S_L) \cup (N_L)_2 \in \Gamma$ implies $S_L \in \Gamma^*$. That is each member of Γ is in Γ^* and so $\Gamma \subseteq \Gamma^*$. This is contradiction. Hence $(N_L)_1 \cup (N_L)_2 \in \Gamma$ implies either $(N_L)_1 \in \Gamma$ or $(N_L)_2 \in \Gamma$.

Convergence of soft multi filters

Definition 5.1. Let Γ be a sm-f on $\widetilde{M}$ and let $C_{S(l)}(v) \leq C_{M(l)}(v)$. A sm-f is referred as smeventually in S_L if and only if $S_L \in \Gamma$.

Definition 5.2. A sm-f Γ is allegatedly as smfrequently in S_L if and only if $C_{(S\cap T)(l)}(v)) \neq C_{\phi(l)}(v)$, $\forall T_L \in \Gamma$.

Proposition 5.3. If Γ is issmeventually in S_L, then Γ is smfrequently in S_L.

Proof. Given $S_L \in \Gamma$, then $C_{(S\cap T)(l)}(v)) \neq C_{\phi(l)}(v)$, $\forall T_L \in \Gamma$, since $\tilde{\phi} \notin \Gamma$.

Remark 5.4. Converse of the above proposition do not necessarily true as evidenced by the following.

Example 5.5. Let $M = \{2/v_1, 2/v_2\}$, $L = \{l_1, l_2\}$ and $\tau = \{\widetilde{M}, S_L\}$ where $S(l_1) = \{1/v_1, 2/v_2\}$,$S(l_2) = \{M\}$. Let T_L be sub smset of $\widetilde{M}$ such that $T(l_1) = \{2/v_2\}$,$T(l_2) = \{2/v_2\}$. Then Γis smfrequently in T_L. Since T_L intersects every member of Γ. But $T_L \notin \Gamma$, so, Γ is not smeventually in T_L.

Definition 5.6. Let (M, τ, L) be a SMTS. Then a sm-f Γ on $\widetilde{M}$ is supposedly as smconverge to $[(n/v)_l]_L \in \widetilde{M}$ if and only if Γ is smeventually in every smnbd of $[(n/v)_l]_L$.

Example 5.7. 1. Every sm-nbd of $[(n/v)_l]_L$ is smconverges to $[(n/v)_l]_L$.

2. In an Indiscrete SMTS, every sm-f Γ on $\widetilde{M}$ smconverges to every smpoint of $\widetilde{M}$. Since the only sm-nbd of $[(n/v)_l]_L$ is $\widetilde{M}$ which is in Γ.

Proposition 5.8. Let (M, τ, L) be a SMTS and let Γ be a sm-f on $\widetilde{M}$ which smconverges to smpoint$[(n/v)_l]_L \in \widetilde{M}$. Then every sm-f on $\widetilde{M}$, finer than Γ also smconverges to $[(n/v)_l]_L$.

Proof. Let Γ be a sm-f on $\widetilde{M}$ which smconverges to smpoint $[(n/v)_l]_L \in \widetilde{M}$ and let Γ* be a sm-f on $\widetilde{M}$, finer than Γ. Then Γ is smeventually in every sm-nbd of $[(n/v)_l]_L$, by proposal. This implies that every sm-nbd of $[(n/v)_l]_L$ is contained in Γ implies every sm-nbd of $[(n/v)_l]_L$ is contained in Γ* implies Γ* is smeventually in every sm-nbd of $[(n/v)_l]_L$ implies that Γ* is smconverges to $[(n/v)_l]_L$.

Proposition 5.9. Let τ and τ^* be two topologies on a smset$\widetilde{M}$ such that τ is finer than τ^* and let Γ be a sm-f on $\widetilde{M}$ which τ-converges to smpoint$[(n/v)_l]_L \in \widetilde{M}$. Then Γ also τ^*-converges to $[(n/v)_l]_L$.

Proof. Since τ is finer than τ^*, every τ^*-nbd of $[(n/v)_l]_L$ is a τ-nbd of $[(n/v)_l]_L$. Now Γ smconverges to $[(n/v)_l]_L$ with respect to τ. This implies that Γ is smeventually in every smnbd of $[(n/v)_l]_L$ implies every τ-nbd of $[(n/v)_l]_L$ is contained in Γ implies that τ^*-nbd of $[(n/v)_l]_L$ is contained in Γ which implies that Γ is smeventually in every τ^*-nbd of $[(n/v)_l]_L$ implies that Γ smconverges to $[(n/v)_l]_L$ with respect to τ^*.

Proposition 5.10. Let (M, τ, L) be a SMTS. Then a sm-f Γ on $\widetilde{M}$ smconverges to smpoint $[(n/v)_l]_L \in \widetilde{M}$ if and only if every sm-uf on $\widetilde{M}$ containing Γ smconverges to $[(n/v)_l]_L$.

Proof. Let Γ smconverges to $[(n/v)_l]_L$ and let Γ* be any sm-uf containing Γ. Then Γ smconverges to $[(n/v)_l]_L$ implies Γ is smeventually in every τ-nbd of $[(n/v)_l]_L$which implies every τ-nbd of $[(n/v)_l]_L$ is contained in Γ implies that every τ-nbd of $[(n/v)_l]_L$ is contained in Γ* which implies that Γ* is smeventually in every τ-nbd of $[(n/v)_l]_L$ implies Γ* smconverges to $[(n/v)_l]_L$.
Conversely, let every sm-ufon $\widetilde{M}$ containing Γ smconverges to $[(n/v)_l]_L$. Then every sm-nbd of $[(n/v)_l]_L$ is contained in every sm-uf on $\widetilde{M}$ which contains Γ. Consequently, every sm-nbd of $[(n/v)_l]_L$ is contained in all sm-uf's containing Γ. But Γ is the intersection of all sm-uf's containing Γ. So, every sm-nbd of $[(n/v)_l]_L$ is in Γ. Hence Γ smconverges to $[(n/v)_l]_L$.

ABSTRACT

Enzymatic browning is a natural process in fruits and vegetables, posing a critical issue as it impacts their appearance and degrade the quality. In the present study, we explore the inhibitory effect of various organic acids viz. oxalicacid, ascorbicacid, citricacid and tartaric acid, on the enzymatic browning of some fruits namely bananas, apples, and guava. Polyphenol oxidase (PPO) is the primary enzyme responsible for enzymatic browning and is present in most of the fruits and vegetables. PPO catalyses the oxidation of phenolic compounds into brown component (Melanin). In this paper, 5% and 8% stock solutions of above mentioned acids were prepared and applied on the fruitsfor inhibiting enzymatic browning. One batch of fruits were dipped in the acid solutions for 10 minutes and in another batch, acids were applied on fruit surface. Observations were recorded for one hour period. The acids used have shown different level of inhibitory effect on various fruits and inhibition was done though mechanism such as metal ion chelation and pH reduction. Out of all acids, Oxalic acid emerged as most effective inhibitor due to its strong chelating process and lowering PPO activity. Ascorbic acid has shown its antioxidative and reverse quinone formation property. While citric and tartaric acids were moderately effective with their property

of chelation and pH reduction. This study emphasizes the capability of organic acid in preserving the colour, appearance, taste and quality of fruits by pacifying enzymatic browning.

Keywords: Enzymatic browning, Inhibition, chelation, Antioxidative and Polyphenol oxidase.

INTRODUCTION

Browning is a chemical process that causes food to turn brown due to reactions occurring within it. This process is a type of oxidation commonly studied in food science, with significant implications for health, food quality, and nutritional technology. Browning reactions in food products are generally classified into two main categories: enzymatic browning and non-enzymatic browning (NEB), each driven by different mechanisms[1]. Enzymatic browning occurs when enzymes like polyphenol oxidase react with oxygen, leading to brown pigments in fruits and vegetables. Non-enzymatic browning involves chemical reactions like the Maillard reaction and caramelization, which develop flavours and colours incooked foods without enzymes. The Browning reaction takes place in fruits and vegetables when they are bruised and subsequently exposed to air [2]. The technique employed to mitigate unwanted browning in fruits and vegetables relies on the inhibition of polyphenol oxidase (PPO), a process that can be effectively achieved through heat treatment. One prevalent method for treating fresh-cut fruits and vegetables is blanching, which involves immersing the cut produce in hot water or exposing it to steam at temperatures ranging from 96 to 99 °C for a duration of 1 to 2 minutes, followed by rapid cooling to 7 to 10 °C. But this approach often leads to an undesirable softening of the product[3]. Edible coatings, consist of a thin layer of consumable material, represents a promising approach to prolong the shelf-life of fresh-cut products. This technique functions by forming a barrier on the surface, thereby reducing water loss and lowering the respiration rate during their storage[4]. In addition, the utilization of edible coatings on fresh-cut fruits has been shown to mitigate colour alterations and delay the ripening process. Many research revealed that these coatings can also serve as vehicles for various beneficial compounds, including antioxidants, antimicrobial agents, texture enhancers and precursors for flavours and volatiles [5,6].This research investigates the effectiveness of various organic acids in inhibiting enzymatic browning in three commonly consumed fresh-cut fruits: banana, guava, and apple. Our findings provide valuable insights into potential natural alternatives for preserving the quality and appearance of fresh-cut produce, which could have significant implications for the food industry and consumer health.

Role of Polyphenol Oxidase (PPO) in Enzymatic Browning

Enzymatic browning represents a significant oxidative process that can rapidly alter the visual and gustatory qualities of fresh fruits and vegetables, transforming their vibrant hues to brown within a short time frame. This phenomenon is primarily mediated by two oxidoreductase enzymes: polyphenol oxidase (PPO) and peroxidase (POD). The action of PPO involves two distinct reactions as shown in Fig.1, initially it facilitates the hydroxylation of monophenols into diphenols, a relatively slow process that yields colourless compounds. Subsequently, it catalyses the swift oxidation of diphenols into quinones, resulting in the formation of coloured products [7,8]. Polyphenol oxidase (PPO), classified under EC1.10.3.1, is a copper-dependent enzyme that is part of the oxidoreductase family. The Enzyme Commission categorizes oxidoreductases into various subclasses, including EC1.14.18.1, which encompasses monophenol monooxygenase, cresoltase and tyrosinase, as well as EC1.10.3.1, which includes diphenol oxidase, catechol oxidase, and o-diphenol oxygen oxidoreductase, based on their substrate specificity. Typically, the term PPO is used to denote the enzyme classified under EC1.10.3.1. This enzyme is found in the tissues of both plants and animals, with a notable presence in various fruits such as apples, guava, bananas, apricots, berries, mangoes, avocados, and grapes, as well as in vegetables like potatoes, lettuce, burdock, guava, melons, eggplants, and mushrooms [9].The significance of PPO activity in regulating enzymatic browning, is essential to consider the factors that influence this activity, including the type and concentration of endogenous phenolic compounds, the availability of oxygen, and the pH level, in order to mitigate browning reactions [10]. The application of thermal treatment is recognized as the most effective and economically viable strategy for the inactivation of polyphenol oxidase (PPO)

and the control of enzymatic browning in canned or frozen fruits and vegetables. However, this technique is not appropriate for fresh products, particularly fresh-cut fruits and vegetables. As a result, there is increasing interest in alternative nonthermal preservation methods, including the use of organic acids, to mitigate enzymatic browning [11].

Compounds Responsible for Enzymatic Browning in Fruits

Chlorogenic acid, a prominent polyphenolic compound found in apples, is integral to the enzymatic browning that occurs when the fruit is sliced or damaged. When exposed to polyphenol oxidase (PPO) and oxygen, chlorogenic acid undergoes transformation into quinone. This quinone then engages in a reaction with catechins, another polyphenol present in apples, leading to the formation of brown pigments. Such interactions expedite the browning process, thereby influencing both the visual appeal and overall quality of the apple [12]. Furthermore, tyrosine, an amino acid, undergoes oxidation by tyrosinase, another type of PPO, leading to the production of dopaquinone, which promotes melanin formation. These compounds together are vital to the browning that occurs in cut or damaged guava and banana blossoms experience enzymatic browning when their tissues are severed or injured, resulting in an undesirable brown hue that detracts from both the aesthetic appeal and nutritional quality of the fruits. This browning phenomenon is primarily attributed to the activity of essential enzymes, including polyphenol oxidase (PPO), peroxidase (POD), and phenylalanine ammonia lyase (PAL). In both types of fruit, PPO facilitates the oxidation of phenolic compounds, leading to the production of brown pigments. Additionally, PAL is activated by tissue damage, which elevates the levels of phenolic compounds and exacerbates the browning process. While the specific roles of these enzymes may differ among fruit species, their collective influence is a significant factor in the browning observed in guava and banana blossoms, posing a common challenge for preserving the quality and marketability of these fruits [13].

Organic Acids Exhibiting Ant Browning Properties

As a highly effective chelating agent, oxalic acid binds to essential metal ions, including copper, which are crucial for the activity of the polyphenol oxidase (PPO) enzyme involved in the enzymatic browning of fruits. The chelation of these metal ions by oxalic acid leads to a marked reduction in PPO activity, thereby significantly impeding the browning process. Furthermore, oxalic acid lowers the pH, creating an acidic environment that further diminishes the activity of PPO enzymes. This dual mechanism of action renders oxalic acid particularly effective in curtailing browning. In comparative studies, oxalic acid has consistently demonstrated greater effectiveness in preventing enzymatic browning than other acids, underscoring its potential applications in food preservation and quality assurance. Ascorbic acid or Vitamin C, is recognized for its efficacy as a reducing agent and antioxidant, playing a crucial role in mitigating enzymatic browning in fruits. It accomplishes this by converting quinones, the agents responsible for browning, back into their original phenolic forms, thus reversing the browning reaction. Moreover, ascorbic acid reduces the pH, establishing an acidic medium that hinders the function of polyphenol oxidase (PPO) enzymes, which facilitate the browning process. Beyond its influence on pH levels, ascorbic acid can also interact directly with PPO enzymes, further diminishing their activity and preventing the formation of the undesirable brown pigment. The inhibitory effects of citric acid and tartaric acid on enzymatic browning can be attributed to their ability to create acidic environments that reduce the activity of polyphenol oxidase (PPO) enzymes. By lowering the pH to levels that are less than optimal for PPO, which typically operates best in neutral to slightly acidic conditions, these acids effectively inhibit the enzyme's action. In addition, citric and tartaric acids act as chelators, binding to essential metal ions like copper that are necessary for PPO activity. This reduction in the availability of metal ions further restricts the enzymatic browning process. Moreover, citric acid is known to work in conjunction with other inhibitors, such as ascorbic acid, to further bolster the prevention of browning [1,14,15].

EXPERIMENTAL

All the weighing was carried out using Sartorius quintix analytical balance. Apparatus were washed and cleaned properly. Stainless steel knife was used for cutting fruits.

Synthesis of Stock Solutions

5% and 8% Stock solutions of organic acids namely, oxalic acid, tartaric acid, citric acid and ascorbic acid were used. 5% stock solution of oxalic acid was prepared by dissolving 0.7875g in 250mL distilled water in a standard flask. Similarly, 0.9381g, 0.8050g and 2.2015g of tartaric acid, citric acid and ascorbic acid were respectively weighed and dissolved in three different standard flask in 250mL distilled water to obtain their 5% stock solution. 8% Stock solution of ascorbic acid and citric acid were prepared by dissolving 3.5224g and 1.2880g respectively in 250mL distilled water.

METHODOLOGY

A set of four, 100mL beakers were taken and30mL of 5% stock solution of every acid was added to every single beaker using 50mL measuring cylinder and a fresh-cut slice of banana was dipped in the stock solution of each acid for 10 minutes. Then these slice were taken out using forceps and placed on watch glass. A timer of one hour was started to note the observations. These steps were then followed to record the observations for guava and apple. Same procedure was repeated with 8% stock solution of each acid to record the observations for banana, guava and apple one by one (Table 1,2,3). Another set of observations were recorded for on surface application method. For this, a fresh-cut slice of banana was placed in four separate watch glasses and 5-6 drops of 5% stock solution of every acid was poured to them. A timer of one hour was started and observations were recorded. These steps were then followed to record the observations for guava and apple. Same procedure was repeated with 8% stock solution of each acid to record the observations for banana, guava and apple one by one as reported in (Table 1,2,3).

SUMMARY OF OBSERVATIONS AND RESULT

In banana, oxalic acid was more effective when dipped as compared to surface application with 5% acid solution. Citric acid was moderately effective on the surface, while tartaric acid was the least effective. With 8% acid solution, ascorbic acid and citric acid showed moderate effectiveness(Table 1). In guava, with 5% acid solution, oxalic acid was effective on surface and nearly one hour when dipped. Tartaric acid was least effective when applied on the surface and took more than one hour when dipped. With 8% acid solution, ascorbic acid was highly effective for both surface and dipped conditions, while citric acid was less effective(Table 2). In apple, with 5% acid solution, oxalic acid was found to be the most effective acid in delaying browning, both on the surface and when dipped in acid solution. Ascorbic acid, tartaric acid and citric acid were less effective, with browning times ranging from 20 to 38 minutes. In 8% acid solution, ascorbic acid showed moderate effectiveness, while citric acid showed a faster browning time(Table 3).

CONCLUSION

This research investigates the effectiveness of various organic acids in inhibiting enzymatic browning in three commonly consumed fresh-cut fruits: banana, guava, and apple. Our findings provide valuable insights into potential natural alternatives for preserving the quality and appearance of fresh-cut produce, which could have significant implications for the food industry and consumer health. Oxalic acid consistently showed the highest effectiveness in inhibiting enzymatic browning in apple, banana and guava, predominantly when used in a 5% solution and applied by dipping. Ascorbic acid also demonstrated good effectiveness, particularly at higher concentrations (8%), while the effectiveness of tartaric acid and citric acid varied with type of fruit and also with the method of application. These results indicate that oxalic acid is a potent inhibitor of enzymatic browning, ascorbic acid as a secondary choice depending on the application conditions and type of fruit.

ABSTRACT

The study investigated the phytochemical screening and antibacterial activity of aqueous extracts of spices viz., *Elettaria cardamomum and Cuminum cyminum.* The phytochemical screening revealed the presence of flavonoids, anthraquinones and carbohydrates in *E.cardamomum*, while *C.cuminum* showed flavonoids, anthraquinones, proteins, carbohydrates, glycosides and coumarins. Using the agar well diffusion method, antibacterial activity against Escherichia coli and Staphylococcus aureus was assessed.The aqueous extract of *E.cardamomum* exhibited maximum inhibition 20mm at 50µl against both bacteria, while *C.cyminum* showed greater efficacy with inhibition zonesof 25mm against *S.aureus* and 20mm against *E.coli* at the same concentration.

Keywords: Phytochemical Analysis, Antibacterial Activity, Spices, *Elettaria cardamomum*, *Cuminum cyminum*

INTRODUCTION

Natural products from plants and its significant parts have been proved to have lesser side effects in comparison to chemotherapeutics, hence they possess potential in being used as an “alternative remedy [1]. According to the most pertinent definition, "kitchen spices" are "vegetative items" or mixtures devoid of unnecessary ingredients that are used to flavor or add aroma to food. These spices are usually derivatives from different parts of plants like barks, leaves, fruits, buds, rhizomes and resins [2]. Most of the Asian countries have rich diversity of wide range of spices

used for various ailments [3]. Ayurveda, spices contribute significantly for the treatment of key disorders of human body [4]. Spices and herbs are typically regarded as safe and have been shown to be successful in treating a variety of illnesses. It is only in recent years that modern science has started paying attention to the properties of spices [5]. The presence of several substances referred to as phytochemicals or secondary metabolites gives the spices their distinct flavor and scent [6,7]. Secondary metabolites or phytochemicals, naturally occurring in plants are biologically active and play important role in defence system of plant [8]. Numerous classes of phytochemicals including isoflavonoids, anthocyanins and flavonoids are found associated with the spices [9]. The phytochemicals involuntarily protect humans in contrast to pathogens employing anti-microbial medicines. Some phytochemicals act as antioxidants that inhibit carcinogens and provide nutrition for normal health and repairs of the cell. These are also recognised to have therapeutic and prophylactic properties [10]. The most essential components of a human diet are spices and herbs. Herbs and spices are recognized for their medicinal and preservation properties in addition to their ability to enhance flavor [11,12]. Antimicrobial activity of spices and herbs has been known and described and used for medicinal purposes for several centuries [13,14]. The antimicrobial activity of some spices was studied against pathogenic yeasts and bacteria. In order to determine whether extracts can be used as a substitute for or in addition to well-established chemotherapeutic drugs, a comparison of the antibacterial activity of spices and various antibiotics has also been conducted. Chemotherapy's effectiveness is attributed to the ongoing hunt for novel medications to combat the threat posed by resistant strains. The investigation of certain indigenous plants for their antimicrobial properties may yields useful results. A large number of plants are used to combat different diseases [15,16] and possess antimicrobial activities [17]. In this regard, the objective of the present study was to compare phytochemical profiles and antibacterial activities of selected spices *Elettaria cardamomum* and *Cuminum cyminum.*

MATERIALS AND METHODS

The spice seeds, namely *Elettaria cardamomum and Cuminum cyminum* were collected from Madhampatti, Coimbatore, Tamil Nadu, India.

Preparation of Spice Powders and Extracts

The spices, namely *Elettaria cardamomum* and *Cuminum cyminum* were collected and dried to a moisture-free state. Dried spices were powdered using an electric pulverizer. 10g of each spice seed powder was weighed using electric balance. In a conical flask, 50 milliliters of aqueous solution were combined with 10 grams of powdered spice seeds. The mixture was placed an orbital shaker at room temperature for 72 hours. Extract was filtered using a Whatsman No. 1 filter paper. For later usage, the aqueous extract was kept in the refrigerator in firmly sealed vials.

Phytochemical Analysis of Selected Spices

Qualitative analysis

Preliminary phytochemical screening of aqueous extract of selected spice seeds was carried out using the standard procedures.

Test of Alkaloids

Mayer's test: A drop or two of Mayer's test reagent was added to a portion of the extract along the test tube's sidewalls, and the precipitate's formation—either white or cream in color was monitored.

Wagner's test: A fraction of extract was treated with Wagner's reagent along the sides of the test tube and observed for the formation of reddish-brown colour precipitate.

Hager's test: One or two milliliters of Hager's reagent were added to a few milliliters of extract, and the production

Test for Tannins

Ferric chloride test: After mixing roughly 0.5 g of extract with 10 ml of distilled water, the mixture was filtered. Two milliliters of the filtrate were mixed with a few drops of 1% ferric chloride solution, and the blue-black, green, or blue-green precipitate was then watched for.

Test for Phenols

Ferric chloride test: After dissolving a small amount of the extract in water and filtering it, two milliliters of 10% aqueous sodium hydroxide were added to create a yellow tint. The presence of flavonoids was shown by a color shift from yellow to colorless upon addition to diluted hydrochloric acid.

Lead acetate test: A small amount of lead acetate solution was added to 50 mg of test extract in a test tube, and the mixture was watched for the formation of a yellow precipitate.

Test for Flavonoids

NaOH test: After dissolving a small amount of the extract in water and filtering it, two milliliters of 10% aqueous sodium hydroxide were added to create a yellow tint. The presence of flavonoids was shown by a color shift from yellow to colorless upon addition to diluted hydrochloric acid.

Lead acetate test:A small amount of lead acetate solution was added to 50 mg of test extract in a test tube, and the mixture was watched for the formation of a yellow precipitate.

Test for Steroids

Liebermann-Burchard test: Two milliliters of acetic anhydride are used to dissolve the extract (50 mg). To this one or two drop of Conc. H_2SO_4 is added along the side of the test tube and observed for an array of colour changes.

Test for Glycosides

Keller Kilianin test: Five milliliters of each extract were combined with two milliliters of glacial acetic acid, and then a few drops of ferric chloride solution and one milliliter of strong sulfuric acid were added. The development of a brown ring at the contact indicates the presence of glycosides.

Test for Terpenoids

Liebermann- Burchard test: 50 grams of the extract were dissolved in ethanol. After adding one milliliter of acetic anhydride, concentrated H_2SO_4 was added. Terpenoids were indicated by a color shift from pink to violet.

Test for Saponins

Foam test: The extract (50 gm) or dry powder was diluted with distilled water and made up to 20 ml. After 15 minutes of vigorous shaking in a graduated cylinder, the suspension is checked for the development of a 2cmthick layer of foam.

Antibacterial Activity of Selected Spices

Test Microorganism

The bacterial strains used were *Staphylococcus aureus* and *Escherichia coli.*

Procedure for Antibacterial Activity

The activity of aqueous solvent extract of spice seeds, namely *Elettaria cardamomum* and *Cuminum cyminum* on selected bacterial strains was assayed by agar well diffusion method (Kirby-Bauer method). From an agar plate culture, at least three to five distinct colonies with the same morphology are chosen. After touching the top of each colony with a loop, the growth is put into a tube with 4–5 milliliters of an appropriate broth medium, like Muller-Hinton broth. The broth culture is incubated at 35ºC until it achieves or exceeds the turbidity. The turbidity of the actively growing broth culture is adjusted with sterile saline or broth to obtain a turbidity. This results in a suspension containing approximately 1 to 2 x 108 CFU/ml for *S. aureus and E.coli.* It is ideal to dip a sterile cotton swab into the modified suspension of inoculum within 15 minutes of changing the solution's turbidity. Rotate the swab multiple times and press it firmly against the tube's inner wall above the fluid level. This will rid the swab of extra inoculum. The dried surface of the Muller-Hinton agar plate is inoculated by streaking two more times. To guarantee that the inoculum is distributed evenly, rotate the plate by about 60 degrees each time. The agar's rim is swabbed as a last step. Before applying the drug-impregnated disks, the lid may be left open for three to five minutes, but no more than fifteen minutes, to allow for the absorption of any surplus surface moisture. The media

was punctured by making a well of 6mm in diameter and filled with 10-50µl of a sample. Further the petriplate were placed inversely for complete diffusion and inhibition zones were examined by measuring the diameter (mm) formed around the well after 24 hours incubation at 37ºC. The zones were measured by using standard (Hi-Media) scale.

RESULTS AND DISCUSSION

Phytochemical Analysis of Selected Spices

Phytochemical analysis was carried out in the aqueous extracts for spice seeds namely *Elettaria cardamomum* and *Cuminum cyminum.* The results of phytochemical analysis of *E. cardamomum* and *C. cyminum* spice seed extract is presented in Table 1. The aqueous extracts of *E. cardamomum* and *C. cyminum* showed presence of various bioactive compounds.

Phytochemical Analysis of Aqueous Extract of *Elettaria cardamomum*

The present study's phytochemical analysis of the E. cardamomum aqueous extract showed the presence of carbohydrates, anthraquinones, and flavonoids. In a study conducted by Bano *et al*., [18], the methanol extract of cardamom seeds showed the presence of flavonoids, terpenoids and glycosides while phenolic, alkaloids, tannins and saponins were not deducted. Likewise, in the present study of the phytochemical analysis of the aqueous extract of *E. cardamomum* revealed the presence of flavonoids, anthraquinones, and carbohydrates. Umesh *et al*.,[19] screened the phytochemicals in the oils of clove and cardamom. According to the findings of a phytochemical investigation, cloves contain phenolic compounds, alkaloids, glycosides, steroids, carbohydrates, terpenoids, and tannins. And the phytochemical analysis of cardamom extracts showed the presence of alkaloids, glycoside, steroids, protein, carbohydrates, terpenoids, tannins and phenolic compound.

Phytochemical Analysis of Aqueous Extract of *Cuminum cyminum*

In the present study of phytochemical analysis of *C. cyminum* contains flavonoids, anthraquinones, protein, carbohydrates, glycosides and coumarins. In concordance with the results of the present study, Rai *et al*., [20] carried out phytochemical screening of *C. cyminum* extracts. The results of phytochemical analysis revealed the presence anthraquinone, protein, alkaloid, glycoside, steroid, coumarin, saponin, flavonoid, Resin, and tannin in *C. cyminum*. Ashvin *et al.,* [21] reported that the aqueous extract of *C. cyminum* L. showed presence of the secondary metabolites like alkaloids, saponin, tannin, proteins, flavonoids, diterpenes, phenol and cardiac glycosides. It was also reported that its efficiency was more than the ethanol extract, as the ethanol extract showed the presence of alkaloids, saponin, coumarin, protein, flavonoids and cardiac glycosides.

Antibacterial Activity of Selected Spices

Antibacterial activity was carried out in the aqueous extracts for spice seeds namely *Elettaria cardamomum* and *Cuminum cyminum.* The results of antibacterial activity of *E. cardamomum* and *C. cyminum* spice seed extract is presented in Table 2 and 3 and Plate 1.

Antibacterial activity Aqueous Extract of *Elettaria cardamomum*

The result of the antibacterial activity of *E.cardamomum*in aqueous extract against *Staphylococcus aureus* and *E. coli* is presented in Table 2 and Plate 1. The antibiotic, Gentamycin, was used as a positive control in this study. The zone of inhibition for gentamycin measured to be 26 mm against *S. aureus* and 23 mm against *E. coli* (Plate 1 A and B). In this study, at 50µl the aqueous extract exhibited maximum antibacterial activity with a zone of inhibition of 20 mm against both *S. aureus* and *E.coli* (Plate 1 C and D).At the concentration of 10 to 40 µl the zone of inhibition was measured to be as 0 mm as there was no zone of inhibition observed. No inhibitory activity was detected at concentrations ranging from 10 to 40 µl. Inhibition zone diameter measured in millimetre (mm)

Antibacterial activity Aqueous Extract of *Cuminum cyminum*

The result of the antibacterial activity of *C. cyminum* in aqueous extract against *S. aureus* and *E.coli*is presented in Table 3 and Plate 1. The antibiotic, Gentamycin, was used as a positive control in this study. The zone of inhibition for gentamycin was measured to be 26 mm against *S.aureus*and 23 mm against *E.coli* (Plate 1 A and B). The study revealed that, against *S. aureus*, the *C. cyminum*aqueous exhibited a maximum zone of inhibition of 25 mm and a maximum zone of inhibition of 20 mm against *E.coli*, at a concentration of 50 µl (Plate 1 E and F). At a concentration of 40 µl, the zone of inhibition values were 22 mm against *S. aureus* and 19 mm against *E.coli*. As the concentration decreased the antibacterial activity was found to decrease. Therefore, at the concentration of 30 µl a zone of inhibition was only measured as 17mm against *E.coli*. No inhibition was observed against *S. aureus* at concentrations of 10, 20 and 30 µl and against *E.coli*at a concentrations of 10 and 20 µl. The antibacterial activity was observed to be dose dependent in the present study. Inhibition zone diameter measured in millimetre (mm) In the present study, at 50µl the aqueous extract of *E.cardamomum* exhibited maximum antibacterial activity with a zone of inhibition of 20 mm against both *S. aureus* and *E. coli*.In comparison to the present study Hamza *et al*., [22] carried out a study to test the antibacterial activity of cardamom essential oil against both gram positive and gram-negative bacteria viz., *Bacillus subtilus* and *Staphylococcus aureus*. The result revealed that the essential oil was active against gram positive and the gram negative bacteria except *E.coli.* The essential oil showed the highest inhibition towards the gram positive bacteria *Staphylococcus aureus* 10 mm and *Bacillus subtilis* 5 mm, *Pseudomonas aureus* 1mm, while *E.coli* didn't show any inhibition zone. In the present investigation the aqueous extract of *C. cyminum* at the concentration of 30 µl showed a zone of inhibition of 17mm against *E.coli*. No inhibition was observed against *S. aureus* at concentrations of 10, 20 and 30 µl. In another study Md. Mahfuzul *et al.,*[23] has reported that, the essential oil of clove has antibacterial properties and has shown to inhibit all tested organisms. This extract was more active on *Staphylococcus aureus* than on *E. coli* according to his study. In the present study aqueous extract of both Cardamom and Cumin showed strong antibacterial activity against both the test bacteria viz., *S. aureus* and *E.coli*. Similarly Barera Rani *et al*., [24] tested the antibacterial activity of *T.ammi, C.verum, F.vulgare, C.longa and P.nigrum*against *S.aureus*. The results showed that the aqueous extracts of all the tested spices *P.nigrum* worked well against *S.aureus* and exhibited an inhibiting effect at high concentration.

CONCLUSION

*E.cardamomum*and *C.cyminum* has been used as a very famous traditional folk medicine, and has been subjected for extensive phytochemical and bioactive investigations. But, its chemical components and bioactivities have not been completely investigated yet. In our present study many phytochemicals have been identified from the both spices by phytochemical screening. The aqueous extracts of these spices showed very good antibacterial activity, which suggested the presence of potent antimicrobial agents. The results indicated that the gram negative bacteria were more sensitive to the extracts, especially to *C.cyminum*, indicating the availability of broad-spectrum antibacterial agents. These findings indicated that both spices, especially *C. cyminum* would be excellent sources for natural antibacterial agents. Hence, in future the molecular level of studies can be undertaken to understand further properties. Further, isolation of individual phytochemical compounds may lead to discovery of a novel therapeutic drug.

ABSTRACT

Technology is crucial in driving innovation and supporting digital transformation across industries. It encompasses software development, IT services, data analytics, cloud solutions, and other digital infrastructures contributing to business efficiency and growth. With increasing demand for automation, remote access, and AI integration, this sector continues to evolve rapidly and shape the global economy. However, the industry faces challenges such as fast-paced technological changes, rising competition, data security concerns, and the need for continuous upskilling. Technology companies must invest consistently in research and development, talent acquisition, and agile methodologies to stay ahead. Femto Soft Technologies is a growing player in the Indian IT and software services landscape, offering various solutions from enterprise software development to custom web and mobile applications. The company has gained recognition for delivering value-driven technological services and maintaining strong client relationships. This study focuses on the cash flow analysis at Femto Soft Technologies, examining how the company manages its inflows and outflows of cash over a specific period. A cash flow statement is a vital financial tool to assess liquidity, operational efficiency, and the company's ability to generate cash to meet obligations and invest in growth. The analysis helps identify the patterns of cash movement in operating, investing, and financing activities, offering insights into the company's financial health. Furthermore, it aims to guide better cash management strategies and long-term financial planning, which are essential for sustainable performance in the dynamic tech sector.

Keywords: AI Integration, Cloud Solutions, Data Analytics, IT Services, Technology.

INTRODUCTION

Femtosoft Technologies operates within the IT and software solutions sector—a dynamic, rapidly evolving industry marked by continuous innovation, high competition, and significant reliance on digital transformation. Companies in this space offer services from custom software development to cloud computing and IT consultancy, addressing diverse needs across various sectors such as finance, healthcare, manufacturing, and retail.

Need of the Study

Credit-based sales are common in the IT industry. Studying receivables helps assess how efficiently Femtosoft collects payments to maintain a healthy cash flow for operations. The study aims to identify gaps in credit evaluation and collection practices that could lead to delayed payments or defaults, thus helping to minimize bad debt losses. Efficient receivables management allows better use of available funds, supporting smoother operations and reducing reliance on external financing. As Femtosoft expands, managing receivables effectively ensures financial stability, vital for funding new projects, R&D, and technology upgrades. The study helps analyze existing credit terms and suggests improvements to balance customer satisfaction with financial discipline. Understanding current challenges in receivables can drive the adoption of automation tools and software that streamline invoicing, follow-ups, and collections.

Objectives of the Study

Primary objective:

- To analyse the accounts receivable management and its performance in Femtosoft Technologies

Secondary Objectives:

- To know how the accounts receivable were managed.
- To examine the average collection period and identify any delays in receivables.
- To evaluate the company's credit policy and its enforcement.
- To suggest improvements for optimizing the receivables management process.

Scope of the Study

- This study evaluates the impact of accounts receivable turnover on Femtosoft's financial performance by analyzing how quickly receivables are collected. The study aims to understand the correlation between turnover rates and the company's profitability.
- This study focuses on assessing the effectiveness of Femtosoft's collection strategies.It examines the current methods employed for debt collection to identify areas where efficiency can be enhanced, thereby reducing overdue accounts.
- This study explores the relationship between credit terms offered and customer payment behavior. Understanding how different credit terms influence timely payments can help formulate policies encouraging prompt settlements.
- This study focuses on identifying the role of staff training in accounts receivable management. It investigates whether ongoing training programs for the finance team contribute to more effective receivables management.
- This study focuses on analyzing the impact of economic fluctuations on receivables. The company can better anticipate and mitigate risks by studying how external economic factors affect customer payment capabilities.
- This study benchmarks Femtosoft's accounts receivable performance against industry peers.

Limitations of the Study

- The data is gathered mainly through secondary sources; no independent verification has been done.
- The time series analysis of ratios has been attempted with no effects being given to inflation.
- Detailed analysis could not be carried out for the project work because of the limited period

- Only five years' financial reports have been considered, i.e., from 2021 to 2025.
- The total statements are given as secondary sources, and they don't provide a means to undergo scrutiny of those statements.

RESEARCH METHODOLOGY

The methodology adopted for this study on Femto Soft Technologies involves an analytical and quantitative approach, using secondary data derived from the company's cash flow statements over five years. The study aims to assess the cash inflows and outflows through a detailed evaluation of operating, investing, and financing activities. Key financial tools such as ratio analysis, trend analysis, and percentage comparisons are used to interpret the data. This approach enables a clear understanding of the company's liquidity, financial health, and cash management practices, providing insights that can guide future financial decisions and strategies.

Sources of data collection

Primary:

In primary content, we will use a fresh form of records used for the first time, and indicate an institution's original documents.

This project's primary data was from the Tube Investment India Limited staff and the guide.

Information will be collected with the help of a firm auditor.

The observation method is used to understand various tools used in logistics management and their features.

Secondary:

The secondary contents will be mainly interpreted from various websites, publications, periodicals, etc.

Sampling Method

Since this study focuses on the cash flow analysis of a single company, Femto Soft Technologies, the purposive sampling method has been adopted. This non-probability sampling technique was chosen to analyze the financial data of Femto Soft Technologies over five financial years. The sample includes annual cash flow statements representing the company's operational and financial performance, allowing for meaningful analysis and interpretation relevant to the study's objectives.

Tools for Analysis

To effectively examine the cash flow patterns of Femto Soft Technologies, the following financial and statistical tools have been used:

- Cash Flow Ratio Analysis
- Cash Flow to Debt Ratio
- Trend Analysis
- Percentage Analysis
- Comparative Analysis

Data Analysis and Interpretation

Interpretation:

From the above table, it is understood that the firm's cash flow from operating activities is less in the year ending 31st March 2021, with a 33.29% cash flow of 664.77 cr and a total cash flow of 1996.38 cr. The cash flow from operating activities is higher for the year ending 31st March 2020. The cash flow is 527.72 Cr, and the total is 9 94.67 with 53.05%.

Interpretation:

The book table shows that the firm's cash flow from investing activities islessintheyearending31stMarch2028, with 16.48% and the Cash flow of 127.66 cr, and the total cash flow of774.18 cr. The cash flow from investing activities for the year ending 31st March 2020 is 1005.51 Cr; the total cash flow is 1996.38, with 50.36%.

Interpretation:
The table shows that the cash flow from financial activities was less in the year ending 31st March 2022, with 6.33%. The cash flow is 41.65 cr, and the total is657.87 cr. The cash flow from financial activities is more in the year ended 31st March 2018, with 33.28 cr, the cash flow is 290.81, and the totalcashflowis873.79cr.4.1.3financialactivities to total cash flow.

DISCUSSIONS AND INFERENCES

Cash Flow from Operating Activities to Total Cash Flow (Table 1)
The analysis shows a steady increase in cash flow from operating activities from 44.87% in 2018 to 53.05% in 2020, reflecting the company's improved ability to generate cash from its core operations. However, in 2021, despite a significant rise in total cash flow, the percentage of cash flow from operating activities sharply declined to 33.24%. This could be attributed to disruptions such as the impact of the COVID-19 pandemic, which likely affected operational efficiency or led to a greater reliance on non-operating income. The cash flow from operating activities improved in 2022, rising to 49.52%, but it remained below the peak seen in 2020, suggesting recovery without fully reaching pre-pandemic levels.

Cash Flow from Investing Activities to Total Cash Flow (Table 2)
Cash flow from investing activities remained relatively low, comprising 16-21% of total cash flow from 2018 to 2020. A sharp increase occurred in 2021, accounting for 50.36% of total cash flow. This surge indicates that the company made significant investments, possibly in growth initiatives, capital expenditures, or asset acquisitions. The proportion declined to 44.14% in 2022, which could reflect a reduction in investment activity or a strategic shift toward operational cash flow generation.

Cash Flow from Financial Activities to Total Cash Flow (Table 3)
The share of cash flow from financial activities was substantial in 2018, at 38.64%, suggesting a reliance on external financing such as loans or capital raises. Over the years, this percentage steadily declined, reaching just 6.33% in 2022. This shift reflects the company's decreasing need for external financing, potentially indicating improved financial stability and self-sufficiency, as it increasingly generated enough internal cash to fund operations and investments without relying on debt or equity funding.

General Inferences:
Impact of External Factors (COVID-19): The drastic fluctuations in cash flow percentages in 2021, especially in operating and investing activities, align with the disruptions caused by the COVID-19 pandemic. This suggests the company faced challenges maintaining its normal operations, resulting in greater reliance on non-operating income and external financing.

Operational Efficiency and Investment Strategy: The increase in cash flow from investing activities in 2021 suggests a strategic focus on growth, despite the drop in operational efficiency. This may indicate that the company invested heavily in future projects or expansion, potentially at the cost of immediate operational performance.

Declining Financial Dependence: The decreasing reliance on financial activities over the years highlights a positive trend in the company's financial health. The debt reduction and external financing indicate growing operational profitability, enabling the firm to fund itself internally without substantial borrowing or equity issuance.

Volatility and Recovery: The fluctuations in cash flows between 2020 and 2022 highlight the volatility caused by the pandemic and the firm's recovery efforts. While the company faced challenges in 2021, it appears to be regaining balance and operational strength, moving towards a more stable and sustainable financial position.

SUGGESTIONS

The company's financial position is perfect, but I found some areas during my analysis that sharply alarm the firm's effective cash management.

- To increase efficiency in the delivery of services and, in turn, increase profit, I advise the company to develop and implement an effective management strategy.
- For the increase in profit, the firm must make alternative plans.
- The company must diversify its plan into other areas, such as EVs.
- The firm should conduct market research at regular intervals, which could help increase the demand for its sales and services.
- It would be suggested that the firm replace the fixed assets with new, modern, and improved technology, which helps reduce idle capacity, increase overall stability, and help earn high returns.
- The firm should try to decrease its profit by paying back all the debts, which will result in high interest payments.
- The company should implement innovative advertising strategies to promote its sales and enhance its reach.
- The firm should form a research and development department to keep up with the recent trends in the competitive global market

CONCLUSION

The study on cash flow analysis at Femto Soft Technologies highlights the critical role of effective cash management in ensuring the company's financial stability and operational efficiency. A detailed examination of the company's cash flow statements over five years showed that consistent monitoring of operating, investing, and financing activities is essential for maintaining liquidity and supporting strategic decisions. The analysis revealed that the company's ability to generate sufficient cash from operations is vital in funding its investments and meeting financial obligations. Moreover, understanding the trends in cash inflows and outflows enabled the identification of potential areas for improvement, such as optimizing working capital, balancing investment decisions, and minimizing unnecessary financing costs. Overall, the study reinforces the importance of cash flow as a key indicator of financial health, especially for IT and service-based firms like Femto Soft Technologies. The company can enhance its resilience, sustain growth, and build long-term value for stakeholders by applying structured financial tools and maintaining a disciplined approach to cash flow management. The process of managing financial risk has been going on for a while. It is necessary to develop and improve new strategies to transform the market. Changes in consumer expectations, changes in the corporate environment, or potential changes in the global climate can all be considered as reflections of refinement.

ABSTRACT

Ayurveda, an ancient Indian medical science, underscores the significance of health as foundational for achieving *Purushartha Chatushtya - Dharma, Artha, Kama*, and *Moksha*. The holistic health definition provided by *Acharya Sushruta* encompasses the equilibrium of *Doshas* (*Vata, Pitta, Kapha*), *Agni* (digestive fire), *Dhatus* (tissues), *Malas* (excretory products), and mental well-being. Diseases arise from vitiation of *Doshas* due to exposure to causative factors (*Nidana*), making the elimination of these factors (*Nidana Parivarjana*) the primary line of treatment. Charaka's Nidana Sthana introduces the concept of *Nidana Panchaka -Nidana, Purvarupa, Rupa, Upashaya, and Samprapti* as a diagnostic framework, with Samprapti being pivotal for understanding disease progression and pathogenesis. This study highlights the clinical relevance of *Dosha Amshansha Kalpana* and *Vikalpa Samprapti*, which involve fractional analysis of *dosha* attributes and their contribution to disease manifestation. The framework enables precise identification of predominant Dosha and Gunas, aiding in individualized treatment protocols. Personalized interventions focus on opposing the vitiated *Gunas* to restore homeostasis. Early identification of *Dosha* imbalances during prodromal stages(Purvarupa) allows for preventive measures, minimizing disease progression.
The study further emphasizes the practical applications of *Dosha Amshansha Kalpana* in assessing pathogenesis, determining *Dosha* predominance, and tailoring interventions for conditions like *Raktapitta*, *Gulma*, and *Prameha*. By providing a detailed understanding of disease evolution, this concept enhances diagnosis, prevention, and treatment strategies. Integrating *Amshansha Kalpana* into clinical practice

ensures precision, improves therapeutic outcomes, and aligns with Ayurveda's primary aim of health preservation.

Keywords: *Dosha Amshansha Kalpana, Vikalpa Samprapti, Nidana Sthana, Nidana Panchaka.*

INTRODUCTION

Ayurveda, the ancient Indian science of life, emphasizes the importance of health as a prerequisite for achieving *Purushartha Chatushtya -Dharma*, *Artha*, *Kama*, and *Moksha*. Considering the attainment of *Purushartha Chatushtaya*, health becomes a prerequisite, and any disease hindering this must be managed effectively to ultimately achieve the supreme goal of liberation (*Moksha*)[1]. The foundation of Ayurveda lies in maintaining health and preventing diseases, as emphasized in the classical texts. *Acharya Sushruta* defined health as a harmonious state of *Sama Dosha, Sama Agni, Sama Dhatu, Sama Mala, and Prasanna Atma, Indriya, and Mana.* Achieving this holistic health ensures the capability to fulfill life's goals effectively[2]. In the context of treatment, the two critical factors to be evaluated are *Roga* (disease) and *Rogi* (patient). This evaluation aids in developing appropriate treatment protocols. Before selecting therapeutic interventions (*Aushadha*), it is essential to thoroughly examine the disease, with the *Nidana Panchaka* (five diagnostic tools) serving as a vital framework. These include *Nidana* (etiology), *Purvarupa* (prodromal symptoms), *Rupa*(clinical manifestations), *Upashaya* (therapeutic tests), and *Samprapti* (pathogenesis)[3]. Doshas-Vata, Pitta, and Kapha are the physiological entities in Ayurveda responsible for maintaining body functions. When vitiated due to improper Nidana (causative factors), they lead to various diseases. *Charaka's Nidana Sthana* introduces the concept of *Nidana Panchaka- Nidana*(etiology), *Purvarupa* (prodromal symptoms), *Rupa*(clinical manifestations), *Upashaya* (therapeutic tests) and *Samprapti* (pathogenesis) - which serve as diagnostic tools. Among these, *Samprapti* provides a detailed understanding of disease progression, making it pivotal for diagnosis and treatment[4]. The *Charaka Samhita* elaborates on *Nidana Panchaka* in its *Nidana Sthana* along with the etiology and pathogenesis of eight specific diseases. The concept of *Nidana Sevana* (exposure to causative factors) illustrates the *Karya-Karana Bhava* (cause-effect relationship), emphasizing that treatment begins with the elimination of causative factors (*Nidana Parivarjana*)[5]. *Samprapti* further includes *Vikalpa Samprapti*, which focuses on the fractional analysis of *Dosha* attributes (Gunas) involved in disease manifestation. This concept, known as *Dosha Amshansha Kalpana*, plays a crucial role in identifying the predominant Dosha and its specific attributes responsible for the disease, aiding in personalized and targeted treatment approaches[6]. This study aims to explore the clinical relevance of *Dosha Amshansha Kalpana* in understanding and managing diseases.

MATERIALS AND METHODS

Source of Literature: Primary references were taken from *Charaka Samhita* (*Nidana Sthana*) and relevant commentaries by *Chakrapani*, *Gangadhara*, and others. Secondary references included contemporary studies on Dosha Gunas and their role in disease pathogenesis.

Methodology: A systematic review of classical Ayurvedic texts was conducted to extract information on *Dosha Amshansha Kalpana* and its application in diagnosing and treating diseases.

REVIEW OF LITERATURE

Samprapti in Ayurveda

Samprapti refers to the process of disease formation, beginning with *Nidana* exposure and progressing through six stages of *Kriyakala*: *Sanchaya* (accumulation), *Prakopa* (aggravation), *Prasara* (spread), *Sthana Samshraya*(localization),

Vyakti (manifestation), and *Bheda* (complications). This progression highlights the sequential interaction of vitiated *Doshas* with *Dushyas* (tissues)[7].

Vikalpa Samprapti and Amshansha Kalpana

- *Vikalpa Samprapti* identifies the varying fractions of *Doshas* contributing to disease. It is instrumental in determining the predominant *Dosha* or *Guna* responsible for specific symptoms.
- *Amshansha Kalpana* extends this analysis to the Gunas of *Doshas*, such as *Ruksha* in *Vata*, *Ushna* in *Pitta*, and *Snigdha* in *Kapha*, which are pivotal in understanding disease pathology.

Clinical Utility

By recognizing the Dosha predominance and their specific Gunas, treatments can be tailored to pacify the vitiated attributes using oppositional qualities. For instance, a disease caused by the *Sheeta Guna* of *Vata* may require *Ushna* therapies.

DISCUSSION

The concept of *Dosha Amshansha Kalpana* plays a transformative role in *Ayurvedic* diagnosis and treatment, ensuring precision and holistic management of diseases. It delves into the fractional analysis of *Doshas* and their specific *Gunas*, allowing for a deeper understanding of pathogenesis and therapeutic interventions. Below, the clinical implications of this concept are elaborated in detail

Identification of Nidana

Amshansha Kalpana facilitates the identification of causative factors through patient history and clinical examination. For instance, consumption of *Kalaya* (pea) aggravates *Vata* due to *Laghu*, *Sheeta*, and *Ruksha* qualities, while *Kandekshu* aggravates Vata due to *Sheeta* and *Ruksha* qualities. By understanding such correlations, physicians can recommend avoiding specific etiological factors to prevent disease progression and facilitate recovery.

Understanding Pathogenesis

This framework aids in evaluating the role of specific *Gunas* (qualities) of vitiated *Doshas* in disease pathogenesis. For example, excessive *Ushna Guna* of Pitta may cause burning sensations, while *Ruksha Guna* of *Vata* leads to dryness. This granular understanding aids in targeted interventions.

Assessment of Dosha Vitiation

Amshansha Kalpana helps assess the qualitative and quantitative vitiation of *Doshas*. It identifies the *Pradhana* and *Apradhan Doshas* in *Samsarga Dushti* or *Sannipata Dushti*. For instance, in *Vata-Kaphaja* disorders, Vata predominates based on nomenclature and associated *Gunas*.

Determining Dosha Predominance

The concept aids in evaluating the *Bala* and *Pradhanya* of *Doshas*. The predominance is determined by the extent of *Guna* aggravation, which also correlates with the disease's severity and treatment complexity.

Analysis of *Vikruti* (Pathological Changes)

Amshansha Kalpana assists in understanding pathological changes and their manifestations. For example, swelling arises from increased liquidity in *Kapha*, while burning sensations are linked to heightened *Ushna Guna* of *Pitta*. This knowledge ensures accurate diagnosis and effective treatment planning.

Personalized Medicine

Ayurveda emphasizes individual constitution (*Prakriti*) and unique pathological presentations. *Dosha Amshansha Kalpana* refines this understanding by focusing on the specific *Guna* of the vitiated Dosha. Each Guna contributes differently to the disease manifestation, and identifying the dominant Guna allows for highly customized treatments.

For example

- In a *Vata-pradhana* disorder, *Ruksha*, *Sheeta*, or *Laghu* might be the predominant *Guna*. By identifying the specific *Guna* causing the disease, the physician can select opposing treatments. If *Ruksha* is dominant, Snigdha therapies, such as oil-based massages or nourishing diets, are prioritized.
- Similarly, in *Pitta disorders*, the *Ushna* or *Tikshna Guna* might be responsible for burning sensations. Treatments that emphasize *Sheet* and *Manda* qualities, like cooling herbs or dietary modifications, can effectively mitigate symptoms.

This targeted approach minimizes over-treatment and ensures harmony between therapeutic interventions and the patient's constitution. Personalized medicine, as enabled by *Dosha Amshansha Kalpana*, enhances therapeutic outcomes while reducing adverse effects

Preventive Care

The preventive potential of *Dosha Amshansha Kalpana* lies in its ability to identify imbalances during the *Purvarupa.* Early recognition of specific *Dosha* vitiations through subtle symptoms enables timely interventions, preventing progression into full-fledged diseases

For instance

- *Vata Dosha*: In its early stage, signs like dryness of the skin, mild irregularities in bowel movements, or feelings of restlessness indicate *Ruksha* or *Chala Guna* aggravation. Administering moistening and stabilizing therapies such as milk-based diets or *Abhyanga* can arrest the progression to severe degenerative conditions like arthritis or neurological disorders.
- *Pitta Dosha*: The onset of excessive thirst, mild burning sensations, or skin discolorations suggests *Ushna* or *Tikshna Guna* imbalance. Cooling and alkalizing interventions, including *Sheeta Anna* and *Chandan*, can prevent inflammatory diseases like *Raktapitta* or *Pitta Jwara*.
- *Kapha Dosha:* Subtle symptoms such as heaviness, lethargy, or mild congestion may indicate *Guru* or *Snigdha Guna* vitiation. *Laghu Anna* and activities promoting sweating can prevent *Kapha* related pathologies like obesity or respiratory disorders.

The emphasis on prevention aligns with Ayurveda's primary aim '*Swasthasya Swasthya Rakshanam'*. By recognizing Dosha imbalances in the *Purvarupa* stage, *Dosha Amshansha Kalpana* aids in halting disease evolution and promoting long-term well-being.

Disease Understanding

Complex diseases often involve multiple *Doshas*, and their intricate interplay makes diagnosis and treatment challenging. The eight diseases described in *Charaka Nidana Sthana -Jwara, Raktapitta, Gulma, Prameha, Shosha, Kushtha, Unmada,* and *Apasmara-* serve as classic examples where *Dosha Amshansha Kalpana* proves invaluable.

For example

- In *Sannipatika Jwara***:** Identifying the *Pradhana Dosha* is crucial. If *Pitta's Ushna Guna* is most pronounced, cooling measures are prioritized. Conversely, if *Kapha's Snigdha Guna* dominates, drying therapies take precedence.
- *Kushtha***:** These are often multifactorial, involving dual or triple Dosha vitiations. The analysis of *Gunas* such as *Ruksha* of *Vata* or *Pichchila* of *Kapha* helps in understanding the disease pathology and designing a combination treatment.

Treatment Protocols

The cornerstone of *Ayurveda's* therapeutic approach lies in addressing the root cause of disease (*Nidana Parivarjana*) and pacifying the vitiated *Dosha* through *Vipareeta Guna Chikitsa*. *Dosha Amshansha Kalpana* enhances this process by pinpointing the exact Gunas responsible for pathology, allowing for precision in treatment planning.

- *Raktapitta* **:** Dominance of *Ushna Guna* of *Pitta* in this condition can cause spontaneous bleeding. Cooling and sweet treatments like *Shatavari* (Asparagus racemosus), *Draksha* (raisins), and *Ghee* based preparations pacify the *Pitta Dosha* effectively.
- *Gulma* **:** In *Vata* predominant *Gulma*, *Ruksha* and *Sheeta* Gunas are responsible for the constriction and pain. Therapies incorporating *Snigdha* and *Ushna* qualities, such as medicated oils and warm foods, relieve symptoms and promote digestion.
- *Prameha* **:** *Kapha* predominant *Prameha*, marked by *Guru* and *Snigdha* Gunas, requires treatments like bitter and astringent herbs (*Neem* or *Guduchi*) that exhibit *Laghu* and *Ruksha* properties.

By aligning therapies with the *Guna* profile of the disease, *Dosha Amshansha Kalpana* minimizes trial and error in treatment, ensuring targeted and effective outcomes.

This deep understanding of disease pathogenesis through *Amshansha Kalpana* enables practitioners to dissect even the most intricate disorders, providing clarity for comprehensive management.

CONCLUSION

The concept of *Dosha Amshansha Kalpana*, based on classical *Ayurvedic* principles, provides a detailed and logical way to understand disease development and create personalized treatments. By analyzing the specific qualities (*Gunas*) of vitiated *Doshas*, it helps identify the exact nature of imbalances and guides focused therapeutic interventions. This improves diagnostic accuracy and treatment effectiveness staying true to *Ayurveda's* personalized approach, Clinically. *Dosha Amshansha Kalpana* is useful in both prevention and treatment. It helps detect early imbalances during the initial stages of disease, preventing further progression. It is especially valuable for managing complex diseases involving multiple *Doshas* and aligns treatments with an individual's *Prakriti*, reducing side effects and enhancing results by integrating this concept into practice. *Ayurveda* emphasizes personalized healthcare while meeting modern goals of precision medicine. This approach combines traditional wisdom with current clinical needs, offering a comprehensive way to maintain health and manage diseases.

ABSTRACT

The herb *Tridax procumbens* is a member of the Asteraceae family and can grow either annually or perennially. In Indian traditional medicine, it is generally utilized as a cultivating plant that spreads across waste ground or barren soil. Although the plant originated in tropical America, it was introduced to Australia, Asia, and tropical Africa. Though more generally known in English as "coat buttons and Tridax daisy'," locals refer to it as "Ghamara," Mexican daisy' (in Mexico), 'Jayanti Veda' (in Sanskrit), 'Gharma' (in Hindi), Dagadipala' (in Marathi), 'Vettukkaaya-thalai' (Tamil/Siddha),'Akalakohadi' (in folk) and certain Ayurvedic practitioners prescribe it as "Bhringraj." It is exceptionally high in carotenoids, saponins, and oleanolic acid, as well as ions such as calcium, magnesium, potassium, sodium, and selenium. The flowers have been demonstrated to contain isoquercetin, quercetin, luteolin, and glucoluteolin. It is widely recognized for its diverse pharmacological effects, including antimicrobial activity against both gram-positive and gram-negative bacteria, protection of the liver, reduction of inflammation, promotion of wound healing, regulation of blood sugar levels, lowering of blood pressure, modulation of the immune system, treatment of bronchial catarrh, dysentery, and diarrhea, and the ability to prevent hair loss by stimulating hair growth.It is also employed as an adsorbent for chromium.

Caffeic acid, tannins, stigmasterol, kaempferol, lutein, ferulic acids are all present in the *Tridax procumbens* leaf have anti-inflammatory, antioxidant, and anti-cancer qualities.

Keywords: *Tridax procumbens,* Pharmacological, Taxonomical, Botanical

INTRODUCTION

Herbal drugs often operate at a subtle level, bolstering and enhancing bodily systems and processes that have become inadequate, while also aiming to reduce excessive elements that have grown dominant. Approximately 65% of people worldwide, according to estimates from the World Health Organization (WHO), primarily obtain their medical care from herbal remedies [1]. Herbal remedies and folklore medicines are widely used in both industrialized and developing countries to treat a wide range of diseases. Therefore, rather than using synthetic medications to treat any illness, natural remedies that may minimize therapeutic potential with potent and dynamic healing effects and diminish the toxicities and side effects of their synthetic equivalents should be used [2-4]. Members of the Compositae or Asteraceae family, which also includes *T. balistoides*, *Tridax procumbens*, and coat buttons, are called *Tridax procumbens* Linn, ghamara in local vernacular, Mexican daisy' (in Mexico), 'Jayanti Veda' (in Sanskrit), 'Gharma' (in Hindi), Dagadipala' (in Marathi), 'Vettukkaaya-thalai' (Tamil/Siddha), 'Akalakohadi' (in folk) or kansari in Hindi. A medicinal plant known by the names Trilobata or Coat Button, *Tridax procumbens*, is one of the other members of the genus [5-6]. In the past, India has utilized *Tridax procumbens* as an insect repellent, anticoagulant, and treatment for wounds [7-8]. This well-known ayurvedic treatment for liver disorders or having a hepatoprotective property is also used to treat heartburn and gastritis. Traditional healers in some parts of India also use *Tridax procumbens* to cure boils, blisters, and wounds [9-10]. Procumbenetin is a flavonoid that has been extracted from the aerial parts of *Tridax procumbens*[11]. As isolated chemical components, the plant has also produced fatty acids, polysaccharides, sterols, alkyl esters, and pentacyclic triterpenes. Several essential chemical components were found to be present [12-13]Fig.1.

SYNONYM

- *Amellus pedunculatus Ortega* ex Willd.
- *Balbisia canescens* Rich.
- *Balbisia divaricata* Cass [15].
- *Balbisia elongata* Willd.
- *Balbisia pedunculata* Ortega ex Hoffmanns.
- *Chrysanthemum procumbens* (L.) Sessé and Moc.
- *Tridax procumbens* var. canescens (Rich. ex Pers.) DC.
- *Tridax procumbens* var. ovatifolia B.L.Rob. Ex B.L.Rob. and Greenm.
- *Tridax procumbens* var. procumbens [16-17].

TAXONOMICAL CHARACTERISTICS

Taxonomical characteristics refer to the specific traits or features used by taxonomists to classify organisms into different taxonomic groups. These characteristics can include both morphological (physical) traits and genetic characteristics [18-19] Table 1.

BOTANICAL CHARACTERISTICS

Appearance: Creeping perennial plant *Tridax procumbens*. It is capable of reaching a length of 8 to 30 inches.

Foliage: The leaves are positioned opposite each other, have a feather-like shape, are elongated to oval in shape, and measure 1 to 2 inches in length. They are characterized by sharp tips and serrate edges.

Habit: An herb that grows in a prostrate or reclining position. The stems and leaves are adorned with trichomes.

Root: Tap root system

Stem: Herbaceous, cylindrical, decumbent and branched [21].

Leaf: Simple, opposite, exstipulate, and dentate margins exhibiting reticulate venation.

Flowers: The blossoms are characterized by yellow disk flowers and white rays. They are held on a stalk that is 4-12 inches in length and measures approximately 0.4-0.6 inches in width. Spring is the season for flowering. The tubular, yellow-centered white or yellow flowers have three-toothed ray florets and resemble daisies. Capitulum is the name of the inflorescence [22-23]. There are two kinds of flowers: disc florets with basal placentation and ray florets. Occasionally, the flowers have long, peduncled heads and three lobes.

Inflorescence: The terminal head and receptacle of the head is convex and encircled by a green involucre. The tubular florets are located in the center, while the ligulate florets are situated at the edges.

Seed: Non-endospermous

Fruits: Achenes, which can range in color from dark brown to black, make up the fruits. Their shape is oblong and their length measures 0.08 inches. Each achene possesses a cluster of pappus bristles with a length ranging from 0.12 to 0.24 inches. The fruit is a rigid achene enveloped in rigid hairs and possesses a plume-like white pappus at one extremity. The plant exhibits invasiveness due to its prolific production of achenes, each equipped with a pappus that enables wind dispersal across considerable distances.

Tubular or Disc Florets: Tubular or disc florets possess bracts, lack bracteoles, are attached directly to the stem, have all essential parts (such as sepals, petals, stamens, and pistils), exhibit five-fold symmetry, are radially symmetrical, and have the ovary positioned above the receptacle. [24]

Calyx: The calyx is minimized and replaced by multiple hairy protrusions known as pappus that remain on top of the ovary and do not fall off.

Corolla: The corolla consists of five petals that are fused together, forming a tube-like structure. They have a regular shape and their edges meet in a manner similar to valve-like closures.

Androecium: There are five stamens present, which are attached to the petals and fused together. The anthers have two chambers, are attached at the base, open towards the inside, and split lengthwise [25-26].

Gynoecium: The ovary is lowly positioned, consisting of two fused carpels. It is unilocular and contains a solitary ovule located on the basal part of the ovary. The style is uncomplicated and has a divided stigma.

Floral Formula: Br., Ebrl., %, K x, C (5), A0, G (2)Fig.2.

Chemical Characteristics

- Investigations were made into *Tridax procumbens'* proximate, mineral, and phytochemical makeup.
- This finding raises the possibility that the populace could obtain protein supplements and pro-vitamin A (carotenoids) from this plant. Additionally, it suggests that *Tridax procumbens* nutritional value can be enhanced by dehydration [27].

Chemical Constituents

- *Tridax procumbens* is a species of plant from which a number of active chemical components have been extracted and published. Alkaloids, flavonoids, carotenoids, -sitosterol, fumeric acid, luteolin, quercetin, oxo ester, palmitic acid, myristic acid, linoleic acid, and tannin are some of these [30]. Dexamethasone, glucoluteolin, beta-sitosterol, and quercetin were all identified in previous investigations as well. The plant's aerial portions have been demonstrated to contain linolenic acid. Two more pure water-soluble polysaccharides from the leaves, WSTP-IA and WSTP-IB, also include the main chain of -(1->6)-D galactan [31-33]. A report on the use of GC-MS for *Tridax procumbens* sterol and lipid identification has also been made. Additionally, researchers have extracted a brand-new flavonoid named "Procumbenetin" from the plant's aerial components. It has been identified as 3, 6-dimethoxy-5, 7, 2', 3', 4'-pentahydroxyflavone 7-O-glucopyranoside [34].
- The minerals found in *Tridax procumbens* leaves are selenium, magnesium, potassium, sodium, and calcium. An excellent plant protein and potassium supplement, *Tridax procumbens* may also provide people with provitamin A (carotenoids) [29, 30]. Moreover, four new terpenoids (Taraxasterol acetate, beta-amyrenone, lupeol, and oleanolic acid) along with bis-bithiophene have been reported from this plant species [35]. Additionally, two new flavones, 8,3′-dihydroxy-3,7,4′-trimethoxy-6-O-β-D-glucopyranosyl flavone and 6,8,3′-trihydroxy-3,7,4′-trimethoxyflavone, were isolated from *Tridax procumbens Linn*. There are also four known chemicals in the plant: betulinic acid, esculetin, puerarin, and oleanolic acid. [36]Table 2.

Pharamcological Activities

T. procumbens extracts have been widely researched for their therapeutic potential, including bactericidal fungicide, wound therapy, immune-regulating antioxidant, anticancer properties, hemostatic, parasitic, and anticoagulant effects, among others[37]Fig.3.

Hepatoprotective Activity

Reducing the severity of liver damage generated by D-galactosamine/lipopolysaccharide (D-GalN/LPS), the aerial portions of Tridax have been reported to demonstrate strong hepatoprotective effect. The ability of D-GalN/LPS to kill liver cells has led to the hypothesis that it is hepatotoxic. The human viral hepatitis lesion and the D-GalN-induced multifocal necrosis are similar [38–40]. As a result of endotoxin toxicity, this amino sugar causes fulminant hepatitis after 8 hours of therapy. It is recognized to selectively interfere with transcription and indirectly hepatic protein synthesis [41].

Antioxidant Activity

Chemicals that limit the start or continuation of oxidative chain reactions are known as antioxidants, and they impede or delay the oxidation of extracellular molecules. Plant extracts from *Tridax procumbens* were assessed for their in vitro antioxidant capacities [41-43]. A reliable method for assessing the antioxidant activity in vitro is the DPPH method [44]. It is based on the interaction between the antioxidant (AH) and the DPPH (1, 1-diphenyl, 2-picryl hydrazyl) free radical, which is nitrogen-centered [45-47]. The Ethyl acetate and n-Butanol fractions of the methanolic extract have shown significant activity comparable to that of ascorbic acid. The fractionation of the original extract simplified its composition and provided a more precise assessing of the specific phytochemicals responsible for the antioxidant activity of *Tridax procumbens.*

Antiparasitic Activity

Through a bioassay-guided fractionation with a methanol extract to isolate an active component, (3S)-16,17-Didehydrofalcarinol, *Tridax procumbens* has been tested as a treatment for various disorders like malaria, dysentery, colic, and vulnitis caused by protozoal infections. When employing whole-plant crude extracts from Tridax, leishmanicidal effects appeared to be present [48]. *Tridax procumbens* flowers, leaves, and stem were studied for their potential antiplasmodial properties using aqueous, chloroform, ethyl acetate, and ethanolic extracts. According to research utilizing the tetrazolium-based colorimetric assay, the species' aqueous and ethanolic extracts had anti-plasmodial capabilities. *T. procumbens* also aided in preventing *P. falciparum* damage to red blood cells.

Leishmanicidal Activity

The Yucatan Peninsula's *Tridax procumbens* whole plant Methanol extracts were tested in an in vitro bioassay for leishmanicidal activity against *Leishmania mexicana* promastigotes [49-50].

Antidiabetic Activity

Tridax procumbens Linn leaf extract in alcohol and water has antidiabetic action, which results in a marked decrease in blood glucose concentration. In the paradigm of rat alloxan-induced diabetes, antidiabetic activity was examined. In diabetic rats, a 50% acute and subchronic dose of *Tridax procumbens* methanol extract demonstrated to reduce fasting blood glucose levels. This plant material does not have any impact on the sugar levels in ordinary rats.[51-53].

Anti-Ulcer Activity

At a dose of 400 mg/kg, *Tridax procumbens* ethanolic leaf inhibited the ulcer lesion index and altered the pH and volume of the stomach in rats with ethanol-induced ulcers. Additionally, the extract helps to regenerate big fibroblast cells and lowers glutathione (GSH), catalase, and superoxide dismutase (SOD) levels in the stomach of rats. The medicinal potential of *Tridax procumbens* was therefore demonstrated by these results [54-55].

Anti-Obesity

Atherogenic diet-induced obesity rats received methanolic extracts of *Tridax procumbens*. Triglycerides, total cholesterol, High-Density Lipoprotein (HDL) cholesterol, total protein, and free fatty acids were measured [56]. In rats treated with extract, A rise in good cholesterol (HDL) was recorded and a substantial decline in triglycerides, total cholesterol, total protein, and free fatty acids. *Tridax procumbens* thus demonstrated having considerable anti-obesity activity [57-58].

Wound Healing Activity

The lysyl oxidase action, protein content, and breaking capacity were all improved by *T. procumbens* extraction, which aids in the promotion of wound healing [59]. As a result, epidermal and dermal cells interacted more. In addition to increasing the amount of protein and nucleic acids, the tridax extract also boosted the quantity of glycosaminoglycan [60-63].

Anticancer Activity

Phytochemicals is an engaging beneficial area to research that will have a bright future. According to Iqbal *et al*. (2017), the rising prevalence of cancer, along with the high cost, side effects, and high toxicity of existing anticancer medications, has presented a number of problems to those around the world who are attempting to design and create an alternative that is low in cost, environmentally friendly, and more environmentally friendly. Recently, a limited number of scientific reports have been published, indicating that the aerial portion of the *T. procumbens* plant is abundantly populated with potent anticancer agents, including flavonoids, tannins, and saponins, as identified through the extraction method[64-66].

Anti-Inflammatory Activity

Tridax procumbens extract's anti-inflammatory properties were evaluated in paw edema caused by carrageenin in addition to the common medication, Ibuprofen. Similar to a Tridax extract, the inhibitory zone was seen. When used with the common medication Ibuprofen, the Tridax extract effectively inhibited edema[67]. There was a noticeable reduction in inflammation when Ibuprofen plus Tridax extract was used. Rats received various doses of an oral water-soluble powder containing Tridax leaf extract. According to the findings, the extract had analgesic properties. By employing the rat-paw edema assay, the dose of *Tridax procumbens L.* demonstrated edema inhibition in the percentages of 10.82, 16.80, and 11.39, resulting in less writhing in the abdomen with Tridax alcoholic and hydro alcoholic extract of anti-inflammatory action [68].

CONCLUSION

Tridax procumbens Linn is a prevalent wildflower in India and is an individual of the Compositae family. It was primarily indigenous to tropical America; however, it has since dispersed and turn common in tropical Africa, Asia, and Australia. The pharmacological activity of each component of this plant is substantial, and it is extensively distributed. The diverse biological activities of *Tridax procumbens* are attributed to the presence of a variety of phytoconstituents, which render it a potential source for the development of novel therapeutic agents. In addition to its many other uses, this plant has the ability to protect the liver, modulate the immune system, speed wound healing, lower blood pressure, fight against diabetes, deter insects, reduce inflammation, and promote hair growth and prevention of dysentery. *Tridax procumbens*is used as a bio-adsorbent to get rid of dangerous Cr (VI) from industrial waste water. It is also used in medicine. It is a critical element of "Bhringraj" in Ayurveda and has the potential to serve as a valuable source of herbal medications for the pharmaceutical industry in the future. The removal of toxic Cr (VI) from industrial effluent is one of the therapeutic and bioadsorbent applications of *Tridax procumbens*. It is an essential component of "Bhringraj" in Ayurveda and has the potential to serve as a significant source of herbal medications for the pharmaceutical industry in the future.

ABSTRACT

The present experimental trial was conducted during 2021-22 at the Horticulture Nursery, Department of Horticulture, School of Agricultural Sciences, Shri Guru Ram Rai University, PathriBagh, Dehradun, Uttarakhand, India, to "Evaluating Growth, Flowering, Yield and Economics of Zinnia (*Zinnia elegans*) cv. Berneray Giant Mix under Different Growing Media in Agro-climatic Conditions of Dehradun." The experiment was laid out in a randomized block design with three replications and ten treatments. The treatments consisted of different organic growing media in various combination ratios, including T1 (Control), T2 (Vermicompost + Soil @ 3:1), T3 (FYM + Soil @ 3:1), T4 (Cocopeat + Soil @ 3:1), T5 (Leaf Manure + Soil @ 3:1), T6 (Cow Urine + Soil @ 20%:1), T7 (Vermicompost + FYM + Cocopeat + Soil @ 1:1:1:1), T8 (Vermicompost + FYM + Cow Urine + Soil @ 1:1:20%:1), T9 (Vermicompost + FYM + Leaf Manure + Soil @ 1:1:1:1), and T10 (Vermicompost + FYM + Cocopeat + Cow Urine + Leaf Manure + Soil @ 1:1:1:20%:1:1).Observations on various growth, flowering, yield attributes, and economics were recorded at 30 and 60 days after transplanting (DAT), and at the final harvest. The results revealed that treatment T2 (Vermicompost + Soil @ 3:1) was the most effective in terms of growth attributes, such as leaf length (11.89 cm), leaf width (6.77 cm), number of nodes per plant (12.89), and stalk length (18.21 cm). For flowering attributes, T2 also showed the best performance, with bud length (1.50 cm) and bud diameter (1.34 cm). Yield attributes were highest in T2 as well, with the number of florets per flower (49.83), flower yield per plant (0.52 kg), and flower yield per hectare (26.05q). However, the longest shelf life (3.16 days)

was recorded in treatment T1 (Control). In terms of economics, the highest benefit-cost ratio (1:1.39) was observed in treatment T3 (FYM + Soil @ 3:1).

Keywords: Growing media, Vermicompost, FYM, Cocopeat, Leaf Manure, Cow Urine, Shelf Life

INTRODUCTION

Floriculture is the study of the cultivation, production, and marketing of a wide range of plants and planting materials, including flowers, potted plants, foliage, cut flowers, garden flower stocks, nursery flowering leaves, annuals, perennials, flower bulbs, and tubers (Ullah*et al.,* 2019). Zinnia (*Zinnia elegans*), a member of the Asteraceae family with a chromosome number of 2n=24, is native to Mexico and Central America. Zinnia flowers are known for their bright, uniform colours and sturdy, disease-resistant plants (Sardoei *et al.,* 2014). The genus name honours Johann Gottfried Zinn, a German botanist, and the 'Benary's Giant' series of zinnia was awarded the Association of Specialty Cut Flower Growers (ASCFG) Cut Flower of the Year in 1999 (Sloan and Harkness, 2008).Zinnias are notable for their solitary, long-stemmed flowers, which come in a variety of bright colours. These flowers thrive across tropical, subtropical, and temperate regions, with blooming from June until frost. Zinnia requires full sunlight, warmth, and a hot, dry climate. It should be planted in well-drained soil rich in humus, with loamy to sandy loam soils being most suitable. The ideal soil pH ranges from slightly acidic to neutral or slightly alkaline. The type of growing media significantly impacts the growth and development of plants, as the physical and chemical properties of the media such as structure, texture, pH, and nutrient levels (nitrogen, phosphorus, and potassium) are key factors. A suitable medium composition and nutritional status play a vital role in producing high-quality flowering plants with a greater number and size of flowers (Sardoei *et al.,* 2014). The growing medium should be porous, uniform in texture, able to hold sufficient moisture, and well-drained.Various organic materials such as pure soil, vermicompost, farmyard manure (FYM), coconut compost (cocopeat), leaf manure, and cow urine can be used to assess their effects on the growth and flowering of zinnia. Vermicompost (VC) is a simple and effective technique for converting agricultural waste, city garbage, and kitchen waste into nutrient-rich compost through the action of earthworms. The growth of earthworms in organic waste is termed vermiculture, and the conversion of waste into compost is known as vermicomposting (Olle, 2019). Vermicasts, produced by earthworms, are rich in NPK and micronutrients (Palanichamy *et al.,* 2011; Ravimycin, 2016), and their application improves the physical properties of soil, increasing water-holding capacity while reducing bulk density (Adugna, 2016).Farmyard manure (FYM) is a decomposed mixture of dung and urine from farm animals, along with litter and leftover material from roughages or fodder. On average, FYM contains 0.5% nitrogen, 0.2% phosphorus, and 0.5% potassium. FYM enhances soil organic matter (SOM), which increases cation exchange capacity and improves soil physical conditions, such as the stability of soil aggregates, density, moisture retention, and air movement (Chahal *et al.,* 2020).Cocopeat is a valuable alternative to traditional peat moss, with its high-water holding capacity and air-filled porosity making it ideal for crop cultivation (Sandeep, 2018). Cocopeat is derived from coconut husks and is known to produce healthier plants requiring less frequent watering and fertilization. Commercial growers using cocopeat achieve higher-quality plant stock (Barrett *et al.,* 2016). Leaf manure compost is a dark, rich organic matter that can be used as soil media, adding essential nutrients to the growing medium. Cow urine, recognized in Ayurveda for its therapeutic value, is composed of 95% water, 2.5% urea, and a mix of salts, hormones, enzymes, and minerals (Randhawa, 2010). It has been identified as a biofertilizer and biopesticide, capable of killing pesticide- and herbicide-resistant bacteria, viruses, and fungi (Sahu *et al.,* 2019).There are reports that combining organic growing media can increase the growth, flowering, and yield of flowers. Therefore, an experiment was conducted to assess the effect of different growing media on the growth, flowering, yield, and economics of zinnia under the agro-climatic conditions of Dehradun.

MATERIALS AND METHODS

An experimental trial was conducted at the Horticulture Nursery of the Department of Horticulture, School of Agricultural Sciences, Shri Guru Ram Rai University, PathriBagh, Dehradun, Uttarakhand, during the summer season of 2021-22. The experiment was laid out in a Randomized Block Design (RBD) with three replications. A total of ten treatments were tested: Control (Soil @100%, T1), Vermicompost + Soil @ 3:1 (T2), FYM + Soil @ 3:1 (T3), Cocopeat + Soil @ 3:1 (T4), Leaf Manure + Soil @ 3:1 (T5), Cow Urine + Soil @ 20%:1 (T6), Vermicompost + FYM + Cocopeat + Soil @ 1:1:1:1 (T7), Vermicompost + FYM + Cow Urine 20% + Soil @ 1:1:20%:1 (T8), Vermicompost + FYM + Leaf Manure + Soil @ 1:1:1:1 (T9), and Vermicompost + FYM + Leaf Manure + Cow Urine + Cocopeat + Soil @ 1:1:1:20%:1:1 (T10).The soil at the experimental site was sandy loam in texture, with a pH of 7.12, available nitrogen at 220.04 kg ha-1, available phosphorus at 9.1 kg ha-1, and available potassium at 18.1 kg ha-1. The zinnia cultivar "Berneray Giant Mix" was used for the research. The seeds of zinnia were sown in raised nursery beds on 31st March 2022. All necessary precautions regarding nursery management were taken until the seedlings were ready for transplanting. The organic growing media, including vermicompost, FYM, cocopeat, leaf manure, and cow urine, were prepared and filled into nursery polybags with a capacity of 1.5 kg according to the treatment combinations. Healthy seedlings were transplanted into the nursery polybags at the end of April 2022.Cultural practices were carried out regularly as required for the zinnia plants during the course of the investigation. During the experiment, six randomly selected plants from each replication were used for recording various observations on growth, flowering, yield attributes, and economics at 30 and 60 days after transplanting, as well as at the final harvest stage. The observations were recorded using instruments such as a verniercaliper (for bud length and bud diameter), a measuring scale (for leaf length, leaf width, and stalk length), and an electronic weighing balance. The obtained data were statistically analyzed using standard statistical methods as suggested by Gomez and Gomez (1996). Treatment Details (Table 1)

RESULTS AND DISCUSSION

The various growth, flowering, yield parameters, and economic aspects, including leaf length, leaf diameter, nodes per plant, stalk length, bud length, bud diameter, number of florets per flower, flower yield (kg/plant), flower yield (q/ha), shelf life, and B:C ratio, were significantly influenced by different concentrations of organic growing media compared to the control throughout the investigation. The data presented in Tables 2, 3, 4, and 5, as well as Figures 1 through 10, illustrate that significant improvements were observed with the application of various combinations of organic growing media on zinnia economics in comparison to the control. The findings of the present investigation have been recorded and are thoroughly discussed below:

Growth Parameters

Leaf length (cm)

The observation of leaf length recorded and presented in Table 2 and Figure 1, revealed significant differences among the treatments. Leaf length was measured at 30 days, 60 days, and at final harvest. The results showed that treatment T2 (Vermicompost + Soil) produced the best results compared to the other treatments. At 30 days after transplanting, the highest leaf length of zinnia was recorded in treatment T2 (11.77 cm), which was statistically similar to treatments T7 (11.67 cm), T8 (11.56 cm), T3 (11.51 cm), T6 (11.44 cm), T10 (11.39 cm), T5 (11.37 cm), T9 (11.30 cm), and T4 (10.78 cm). No significant difference was observed with these treatments, while the lowest value (10.59 cm) of leaf length was recorded under treatment T1 (Control).At 60 days after transplanting, the maximum leaf length was obtained in treatment T2 (12.0 cm), which was at par with treatments T7 (11.99 cm), T8 (11.72 cm), T3 (11.57 cm), T6 (11.48 cm), T5 and T10 (11.43 cm), and T9 (11.34 cm). A significant difference was observed with treatment T4 (10.78 cm). The minimum leaf length (10.63 cm) was recorded under treatment T1 (Control).At Final harvest, the maximum leaf length was observed in T2 (11.89 cm), which was comparable to T7 (11.88 cm), T3 (11.77 cm), T10 (11.66 cm), T8 (11.61 cm), T6 (11.56 cm), T5 (11.43 cm), T9 (11.40 cm), and T4 (10.86 cm). However, no significant differences were observed among these treatments. The minimum leaf length (10.69 cm) was obtained in treatment T1 (Control).The

significant increase in leaf length might be attributed to the adequate nitrogen (N) supply for plant growth. Sufficient nitrogen increases the level of cytokinins in the plant, which may stimulate the shoot growth rate, resulting in enhanced leaf length and leaf breadth. Similar findings were reported by Thapa *et al.* (2021).

Leaf width (cm)

The observation of leaf width, recorded and presented in Table 2 and Figure 2, revealed significant differences among the treatments. Measurements were taken at 30 days after transplanting (DAT), 60 DAT, and at final harvest. The results indicated that treatment T2 (Vermicompost + Soil) exhibited the best outcomes compared to the other treatments. At 30 days after transplanting, the highest leaf width of zinnia was recorded in treatment T2 (6.18 cm), which was statistically similar to treatments T5 (6.09 cm), T8 (6.08 cm), T6 (5.98 cm), T4 (5.95 cm), T9 (5.91 cm), T3 (5.66 cm), T10 (5.39 cm), and T7 (5.32 cm). No significant differences were observed among these treatments, while the lowest value (5.20 cm) of leaf width was recorded under treatment T1 (Control).At 60 days after transplanting, the maximum leaf width was obtained in treatment T2 (6.70 cm), which was at par with treatments T5 (6.28 cm), T7 (6.23 cm), T8 (6.22 cm), T3 (6.02 cm), T9 (5.98 cm), T4 (5.70 cm), T6 (5.56 cm), and T10 (5.48 cm). Again, no significant differences were observed. The minimum leaf width (5.39 cm) was recorded under treatment T1 (Control).At Final harvest, the maximum leaf width was observed in treatment T2 (6.77 cm), which was comparable to treatments T7 (6.30 cm), T8 (6.25 cm), T5 (6.24 cm), T3 (6.10 cm), T9 (6.05 cm), T4 (5.99 cm), T10 (5.89 cm), and T6 (5.62 cm). However, no significant differences were observed among these treatments. The minimum leaf width (5.44 cm) was obtained in treatment T1 (Control).The significant increase in leaf width may be attributed to the adequate nitrogen (N) input, which increases the level of cytokinins in the plant. This elevated level of cytokinins may stimulate the shoot growth rate, resulting in an increase in nutrient increment. Similar findings were reported by Thapa*et al.* (2021).

Nodes per plant

The observation of nodes per plant was recorded and presented in Table 2 and fig 3 revealed significant differences among the treatments. The observation of nodes per plant was recorded at 30 DAT, 60 DAT and at final harvest. The results shows treatment T_2 (VC + Soil) showed the best results than other treatments. At 30 days after transplanting, the highest value of nodes per plant of zinnia was recorded in treatment T_2 (13.14), which were at par with the treatments T_9 (12.38). The significant difference was observed with treatment T_{10} (11.94), T_6 (11.83), T_7 (11.33), T_5 (11.22), T_4 (11.11), T_8 (11.05) and T_3 (10.55). The lowest value (10.05) of nodes per plant was recorded under the treatment T_1 (control).In case of 60 days after transplanting, the maximum number of nodes per plant was obtained in treatments T_2 (12.86), which were at par with the treatments T_9 (12.40), T_{10} (11.98), T_6 (11.73), T_5 (11.44), T_7 (11.31), T_4 (11.12) and T_8 (11.09). The significant difference was observed with treatment T_3 (10.79). The minimum nodes per plant (10.33) was recorded under the treatment T_1 (control).At final harvest days after transplanting, the nodes per plant was maximum in T_2 (12.89) which was comparable with T_9 (12.61), T_{10} (11.85), T_6 (11.80), T_5 (11.33), T_7 (11.19) and T_4 (11.05). However, significant difference was observed with treatment T_8 (10.96) and T_3 (10.67), while a minimum nodes per plant was obtained in the treatment T_1 (10.19) (control).The significant increase in nodes per plant might be due to different growing media in various levels, the intercalary meristem is located at the base of the leaf and in the internodes. It helps in the increase in the length of plant organs like nodes and internodes. Similar finding was also reported by Rajvanshi *et al.,* (2011) and Ikram *et al.,* (2012).

Stalk length (cm)

The observation of stalk length was recorded and presented in Table 2 and fig 4 revealed significant differences among the treatments. The observation of stalk length was recorded at 30 DAT, 60 DAT and at final harvest. The results shows treatment T_2 (VC + Soil) showed the best results than other treatments. At 30 days after transplanting, the highest value of stalk length of zinnia was recorded in treatment T_{10} (18.10cm), which is not at par with the treatments. The significant difference was observed with treatment T_9 (16.93cm), T_6 (16.62cm), T_7 (16.36cm), T_4 (16.15cm), T_{10} (15.89cm), T_3 (15.54cm), T_8 (15.38cm) and T_5 (15.14cm). The lowest value (14.53cm) of stalk length was recorded under the treatment T_1 (Control).In case of 60 days after transplanting, the maximum stalk length was obtained in treatments T_{10} (18.16cm), which is not at par with the treatments. The significant difference was observed with treatment T_9 (16.8cm), T_6 (16.74cm), T_7 (16.48cm), T_4 (16.2cm), T_{10} (15.98cm), T_3 (15.61cm), T_8 (15.44cm) and T_5

(15.02cm). The minimum stalk length (14.79cm) was recorded under the treatment T_1 (Control).At final harvest days after transplanting, the stalk length was maximum in T_{10} (18.21cm), which is not at par with the treatments. The significant difference was observed with treatment T_9 (16.85cm), T_6 (16.7cm), T_7 (16.68cm), T_4 (16.24cm), T_{10} (16.00cm), T_3 (15.63cm), T_8 (15.28cm) and T_5 (15.1cm). The minimum stalk length (14.91cm) was recorded under the treatment T_1 (Control).The significant increase in stalk length might be due to different growing media in various levels, the apical meristem is responsible for active division of the cell, present in the tip of the root and shoot. Similar finding was also reported by Ikram *et al.,* (2012).

Flowering Parameters

Bud length (cm)

The observation of bud length was recorded and presented in Table 3 and fig 5 revealed significant differences among the treatments. The observation of bud length was recorded at 30 DAT, 60 DAT and at final harvest. The results shows treatment T_2 (VC + Soil) showed the best results than other treatments. At 30 days after transplanting, the highest value of bud length of zinnia was recorded in treatment T_2 (1.31cm), which were at par with the treatments T_5 (1.27cm), T_6 (1.21cm), T_4 (1.20cm), T_7 and T_8 (1.15cm), T_9 (1.14cm), T_3 (1.08cm) and T_{10} (1.06cm). No significant difference was observed. The lowest value (1.03cm) bud length was recorded under the T_1 (control).In case of 60 days after transplanting, the maximum bud length was obtained in treatments T_2 (1.32cm), which were at par with the treatments T_4 and T_8 (1.21cm), T_3 (1.13cm), T_6 (1.12cm), T_5 and T_{10} (1.11cm), T_7 (1.08cm) and T_9 (1.05cm). No significant difference was observed. The minimum bud length (1.04cm) was recorded under T_1 (Control).At final harvest days after transplanting, the bud length was maximum in T_2 (1.50cm) which was comparable with T_4 and T_7 (1.26cm), T_{10} (1.19cm), T_8 (1.17cm), T_9 (1.15cm), T_6 (1.14cm) and T_3 and T_5 (1.13cm). However, no significant difference was observed. While, the minimum bud length (1.04cm) was obtained in T_1 (Control).The significant increase in bud length might be due to different growing media in various levels may be due to apical dominance in plants is the main stem of the plant, sprouting with growth from its bud, due to the growth hormone called auxin. Similar finding was also reported by Chattopadhyay (2014).

Bud diameter (cm)

The observation of bud diameter was recorded and presented in Table 3 and fig 6 revealed significant differences among the treatments. The observation of bud diameter was recorded at 30 DAT, 60 DAT and at final harvest. The results shows treatment T_2 (VC + Soil) showed the best results than other treatments. At 30 days after transplanting, the highest value of bud diameter of zinnia was recorded in treatment T_2 (1.29cm), which were at par with the treatments T_5 (1.25cm), T_4 and T_6 (1.20cm), T_9 (1.18cm) and T_7 and T_8 (1.17cm), T_3 (1.13cm) and T_{10} (1.08cm). The lowest value (1.01cm) bud diameter was recorded under the T_1 (control).In case of 60 days after transplanting, the maximum bud diameter was obtained in treatments T_2 (1.33cm), which were at par with the treatments T_8 (1.24cm), T_4 (1.19cm), T_6 (1.17cm), T_5 and T_{10} (1.13cm) and T_7 and T_9 (1.07cm). No significant difference was observed. The minimum bud diameter (1.06cm) was recorded under the T_3 and T_1 (Control).At final harvest days after transplanting, the bud diameter was maximum in T_2 (1.34cm) which was comparable with T_7 (1.26cm), T_4 (1.23cm), T_{10} (1.20cm), T_5 (1.16cm), T_8 (1.15cm), T_6 (1.13cm) and T_3 and T_9 (1.11cm). However, no significant difference was observed. While the minimum bud diameter (1.02cm) was obtained in T_1 (Control).The significant increase in bud diameter might be due to different growing media in various levels may be due to the balanced supply of nutrients including micronutrients and could be due to the soil water holding capacity. Similar finding was also reported by Chattopadhyay (2014).

Yield Parameters

Number of florets per flower

The observation of number of florets per flower was recorded and presented in Table 3 and fig 7 revealed significant differences among the treatments. The observation of number of florets per flower was recorded at 30 DAT, 60 DAT and at final harvest. The results shows treatment T_2 (VC + Soil) showed the best results than other treatments. At 30 days after transplanting, the highest value of number of florets per flower of zinnia was recorded in treatment T_2 (27.20), which is not at par with the treatments. The significant difference was observed with treatment T_5 (24.13), T_8

(22.54), T_{10} (21.33), T_3 (21.05), T_4 (21.00), T_7 (20.40), T_6 (19.63) and T_9 (19.52). The lowest value (18.64) of number of florets per flower was recorded under the treatment T_1 (Control).In case of 60 days after transplanting, the maximum number of florets per flower was obtained in treatments T_2 (42.38), which is not at par with the treatments. The significant difference was observed with treatment T_9 (38.27), T_7 (38.10), T_4 (37.84), T_5 (35.52), T_3 (34.55), T_6 (34.24), (34.18) and T_{10} (32.43). The minimum number of florets per flower (28.51) was recorded under the treatment T_1 (Control).At final harvest days after transplanting, the number of florets per flower was maximum in T_2 (49.83), which is not at par with the treatments. The significant difference was observed with treatment T_9 (45.27), T_4 (43.54), T_8 (43.51), T_6 (40.11), T_5 (39.71), T_3 (39.30), T_7 (38.74) and T_{10} (37.38). The minimum number of florets per flower (37.15) was recorded under the treatment T_1 (Control).The significant increase in disc diameter might be due to good vegetative growth converted to reproductive growth of plants in higher organic matter enriched media. Similar finding were also reported by Chauhan *et al.,* (2014) and Arunesh *et al.,* (2020).

Flower yield (Kg/plant)

The observation of flower yield (kg/plant) was recorded and presented in Table 3 and fig 8 revealed significant differences among the treatments. The observation of flower yield (kg/plant) was recorded at 30 DAT, 60 DAT and at final harvest. The results shows treatment T_2 (VC + Soil) showed the best results than other treatments. At 30 days after transplanting, the highest value of flower yield (kg/plant) of zinnia was recorded in treatment T_2 and T_7 (0.50 kg), which were at par with the treatments T_9 (0.47 kg), T_3 and T_8 (0.45 kg), T_4 and T_{10} (0.43 kg) T_5 (0.42 kg) and T_6 (0.41 kg). No significant difference was observed. The lowest value (0.40 kg) of flower yield (kg/plant) was recorded under treatment T_1 (Control).In case of 60 days after transplanting, the maximum number of flower yield (kg/plant) was obtained in treatments T_2 (0.51 kg), which were at par with the treatments T_3 (0.50 kg), T_9 (0.47 kg), T_4 and T_8 (0.46 kg), T_{10} (0.45 kg) and T_7 (0.44 kg). No significant difference was observed. The minimum flower yield (kg/plant) (0.41 kg) was recorded under the treatment T_1 (Control), T_5 and T_6.At final harvest days after transplanting, the flower yield (kg/plant) was maximum in T_2 (0.52 kg) which was comparable with T_4 (0.47 kg), T_8 and T_9 (0.46 kg), T_7 (0.45 kg), T_6 and T_{10} (0.42 kg) and T_3 and T_5 (0.41 kg). However, no significant difference was observed. While, the minimum flower yield (kg/plant) was obtained (0.40 kg) in the treatment T_1 (control).The significant increase in flower yield might be due to the fact the supply of nutrient is more balanced under integrated plant nutrient supply system, which helps to keep plants healthy (low incidence of insect-pest-disease) and enhanced soil biological activity, which in turn improves nutrient mobilization from organic matter and soil reserves. Similar result was also reported by Prasad and Gill (2007).

Flower yield (q/ha)

The observation of flower yield (q/ha) was recorded and presented in Table 4 and fig 9 which revealed significant differences among the treatments. The observation of flower yield (q/ha) was recorded at 30 DAT, 60 DAT and at final harvest. The results shows treatment T_2 (VC + Soil) showed the best results than other treatments. At 30 days after transplanting, the highest value of flower yield (quintal/ha) of zinnia was recorded in treatment T_2 (25.30 q), which were at par with the treatments T_3 (25.05 q). The significant difference was observed with treatment T_9 (23.70 q), T_8 (22.90 q), T_7 (22.65 q), T_{10} (21.90 q), T_4 (21.80 q), T_5 (21.05 q) and T_6 (20.60 q). The lowest value (20.15 q) of flower yield (quintal/ha) was recorded under treatment T_1 (Control).In case of 60 days after transplanting, the maximum number of flower yield (quintal/ha) was obtained in treatments T_2 (25.65 q), which were at par with the treatments T_3 (25.20 q). The significant difference was observed with treatment T_9 (23.90 q), T_4 (23.40 q), T_8 (23.05 q), T_{10} (22.60 q), T_7 (22.30 q), T_6 (20.90 q) and T_5 (20.80 q). The minimum flower yield (quintal/ha) (20.55 q) was recorded under the treatment T_1 (Control).At final harvest days after transplanting, the flower yield (quintal/ha) was maximum in T_2 (26.05 q) which is not at par with treatments. However, the significant differences were observed with treatment T_4 (23.60 q), T_8 (23.20 q), T_9 (23.05 q), T_7 (22.80 q), T_6 (21.15 q), T_{10} (21.00 q), T_3 (20.85 q) and T_5 (20.65 q), while minimum flower yield (quintal/ha) was obtained (20.40 q) in the treatment T_1 (Control).The significant increase in flower yield might be due to the fact that the supply of nutrient is more balanced under integrated plant nutrient supply system, which helps to keep plants healthy (low incidence of insect-pest-disease) and enhanced soil biological activity, which in turn improves nutrient mobilization from organic matter and soil reserves. Similar finding was also reported by Prasad and Gill (2007).

Shelf life (days)

The observation of shelf life was recorded and presented in Table 4 and fig 10 revealed significant differences among the treatments. Among the various organic growing media, the maximum shelf life was obtained in treatments T_1 (3.16 days), which were at par with the treatments T_3 (2.66 days), T_9 (2.33 days) and T_2, T_4, T_5, T_6 and T_7 (2.16 days). The minimum shelf life (2.0 days) was recorded under the treatment T_8 and T_{10}.The significant increase in shelf life might be due to avoiding the direct sunlight to the flowers or not kept near appliances that generates heat. Similar finding was also reported by Arunesh *et al.,* (2020).

Economics

The observation of economics was recorded and presented in Table 5 and revealed significant differences among the treatments. The net profit per hectare ranges from Rs. 40,015 to -1, 20, 290. The maximum net profit per hectare was recorded under treatment T_3 (Rs. 40,015). While minimum net profit per hectare was obtained in the treatment T_4 (Rs. -1, 20, 290).The benefit cost ratio ranged from 1: 1.39 to 1: 0.52 depending on different treatments. It was recorded maximum (1: 1.39) under the treatments T_3 (FYM + Soil) and minimum (1: 0.52) under the treatment T_{10} (Vermicompost + Farmyard Manure + Leaf Manure + Cow Urine + Cocopeat + Soil @ 1:1:1:20%:1:1).

CONCLUSION

On the basis of present research work on "Evaluating Growth, Flowering, Yield and Economics of Zinnia (*Zinnia elegans*) cv. Berneray Giant Mix under Different Growing Media in Agro-climatic Conditions of Dehradun ", it can be concluded that among different growing media treatments, the results revealed that treatment T_2 (Vermicompost + Soil @ 3:1) was found to be most operative in terms of growth attributes such as leaf length, leaf diameter, nodes per plant, stalk length; flowering attributes*viz.*bud length, bud diameter; yield attributes *viz.* number of florets per flower, flower yield (kg/plant), flower yield (q/ha) whereas, the Shelf life (3.16 days) was found to be most effective in treatment T_1 (Control). However, the B:C ratio (1:1.39) was establish to be most effective in treatment T_3 (FYM + Soil @ 3:1).

ABSTRACT

The edge roman dominating adjacency matrix of a graph and its energy are introduced in this paper. Further, the algebraic properties of this matrix, including its spectrum, spectral radius, spectral gap, determinant, rank and energy are studied for some standard classes of graphs. Additionally, bounds for the above newly introduced matrix parameters are established. These findings have applications in finding structural value of a building in civil engineering, communication systems in sociology and other fields where roman domination-related concepts are needed.

Keywords: Edge roman dominating adjacency matrix (ERDAM), Edge roman dominating spectrum, Edge roman dominating energy (ERDE)
2020 Mathematical Subject Classification: 05C50, 05C69

INTRODUCTION

Let $G = (V, E)$ be a graph with $|V| = p$ and $|E| = q$. The graph terms used here are referred form F. Harary [3]. We cite Gallian's dynamic survey [5] for basic descriptions of the various types of graph labelling. Roshini Leely Pushpam and Malini Mai [8] initiated the study of the edge version of Roman domination. An edge Roman domination (ERD) function of G is a function $f: E(G) \to \{0, 1, 2\}$ such that every edge e with $f(e) = 0$ is adjacent to some edge e' with $f(e') = 2$. The weight of an edge Roman dominating function f is the value $w(f) = \sum_{e \in E(G)} f(e)$. The edge Roman domination number of G, denoted by $S'_{ar}(G)$, is the minimum weight of an

edge Roman dominating function of G. All the matrix terms are referred from R.B. Bapat [1]. Harary [4] was introduced the concept of adjacency matrix. The adjacency matrix $A(G)$ of G is the $p \times p$ matrix whose $(i,j)^{th}$– entry is 1 if the vertices v_i and v_j are adjacent and zero otherwise. The eigenvalues $\lambda_1, \lambda_2, \dots, \lambda_p$ of A, assumed in non-increasing order are the eigenvalues of the graph G. As A is real symmetric, the eigenvalues of G are real with sum equal to zero. The energy $E(G)$ of G is defined to be the sum of the absolute values of the eigenvalues of G. i.e., $E(G) = \sum_{i=1}^{p} |\lambda_i|$. This concept of energy of a graph was introduced by I. Gutman [6]. The spectrum of G is $S(G) = \begin{pmatrix} \lambda_1 & \lambda_2 & \dots & \lambda_p \\ n_1 & n_2 & \dots & n_m \end{pmatrix}$, where $n_1, n_2, \dots, n_m$ denotes the number of times the corresponding eigenvalue occur. The spectral radius of G, $\rho(G)$ is the largest eigenvalue of A. The difference between the first two numerically largest eigenvalues is called the spectral gap of G and is denoted as $\delta(G)$. The spread of G is the difference between maximum and minimum eigenvalues of A, is denoted as $spr(G)$. The sum of all diagonal entries of a matrix A is called as trace, denoted by $tr(A)$. The rank and determinant of a matrix A is denoted as $rank(A)$ and $|A|$ respectively. Domination and its associated adjacency matrices have been widely studied and applied across various fields. While Edge Roman Domination was introduced, but its corresponding adjacency matrix remain unexplored. My objective is to investigate the adjacency matrix for Edge Roman Domination, while also identifying relevant matrix parameters for several standard graph classes. Ultimately, I aim to develop an algorithm for my new matrix and applying these concepts to practical problems like optimizing networks, allocating resources, and ensuring system reliability.

MAIN RESULTS

Definition 2.1. Edge Roman dominating adjacency matrix (ERDAM) of a $(p,q)-$graph is a $p \times p$ matrix defined as, $A_r'(G) = (a_{ij}) = \begin{Bmatrix} f(e_i); & e_i = v_i v_j \in E(G) \\ 0; & otherwise \end{Bmatrix}; i,j = 1,2,\dots,p$, where $f(e_i)$'s are ERD - function values of edges of G.

Definition 2.2. The edge Roman dominating energy $E_r'(G)$ is defined as the sum of all absolute eigenvalues of the ERDAM, $A_r'(G)$ of G.

Notations 2.3. For any graph G, $S_r'(G)$, $\rho_r'(G)$, $\delta_r'(G)$, $spr_r'(G)$, $|A_r'(G)|$ and $rank\left(A_r'(G)\right)$ are respectively denoted as spectrum, spectral radius, spectral gap, spread, determinant and rank of the ERDAM of G. Trace of the ERDAM of G, $tr\left(A_r'(G)\right)$ is always zero.

Example 2.4.
G (Figure 1)

$$\boldsymbol{A_r'(G)} = \begin{pmatrix} \mathbf{0} & \mathbf{2} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{2} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{2} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{2} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix}$$

For the graph G, in Figure 1, the ERDAM is,
Here, $|A_r'(G)| = 0, rank\left(A_r'(G)\right) = 4$. The characteristic polynomial of $A_r'(G)$ is $\lambda^6 - 8\lambda^4 + 16\lambda^2$. It gives $S_r'(G) = \begin{pmatrix} -2 & 0 & 2 \\ 2 & 2 & 2 \end{pmatrix}, \rho_r'(G) = 2, \delta_r'(G) = 0$ and $spr_r'(G) = 4$.
The energy of a graph G is, $E_r'(G) = |-2| + |-2| + 0 + 0 + 2 + 2 = 8$.

Theorem 2.5. For the friendship graph $F_n, n \geq 2$,
$(i) |A_r'(F_n)| = 0$
$(ii) rank\left(A_r'(F_n)\right) = 2n$
$(iii)\ S_r'(F_n) = \begin{pmatrix} \pm 2 & \pm 1 & 0 \\ 1 & n-1 & 1 \end{pmatrix}$
$(iv)\ \rho_r'(F_n) = 2$

$(v)\ \delta_r'(F_n) = 1$
$(vi)\ spr_r'(F_n) = 4$
$(vii)\ E_r'(G) = 2(n+1).$

Proof. Let G be the friendship graph F_n with vertex set $V = \{v_1, v_2, \dots, v_p\}$ with atleast five vertices. Then the ERD function value, $f(E) = \sum_{e\in E(G)} f(e) = n+1$.

The ERDAM $A_r'(G)$ is, $A_r'(G) = \begin{pmatrix} \beta_{3\times3} & 0 & 0 & \dots & 0 \\ 0 & \alpha_{2\times2} & 0 & \dots & 0 \\ \vdots & 0 & \ddots & & \vdots \\ \vdots & \vdots & & \ddots & 0 \\ 0 & \dots & & 0 & \alpha_{2\times2} \end{pmatrix}$,

where $\beta_{3\times3} = \begin{pmatrix} 0 & 2 & 0 \\ 2 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$, $\alpha_{2\times2} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.

It gives $|A_r'(G)| = 0$, $rank\left(A_r'(G)\right) = 2n$. From $A_r'(G)$ we have characteristic polynomial is $\lambda^p - (n+3)\lambda^{p-2} + \dots + 4(-1)^n\lambda$.

Therefore, the ERD spectrum is, $S_r'(G) = \begin{pmatrix} \pm2 & \pm1 & 0 \\ 1 & n-1 & 1 \end{pmatrix}$.

From $S_r'(G)$, the largest absolute eigenvalue $\rho_r'(G)$ is two. Further, $spr_r'(G) = 2-(-2) = 4$. The ERDE of G is, $E_r'(G) = \sum_{i=1}^{p} |\lambda_i| = |2| + |-2| + |1|(n-1) + |-1|(n-1) = 4 + 2n - 2 = 2(n+1)$.

For example,

F_3 (Figure 2)

$$\boldsymbol{A_r'(F_3)} = \begin{pmatrix} \mathbf{0} & \mathbf{2} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{2} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{1} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{1} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{1} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{1} & \mathbf{0} \end{pmatrix}$$

For the above graph F_3, in Figure 2, the characteristic polynomial of $A_r'(F_3)$ is $\lambda^7 - 6\lambda^5 + 9\lambda^3 - 4\lambda$.

$(i)\ |A_r'(F_3)| = 0$ $(ii)\ rank\left(A_r'(F_3)\right) = 6$ $(iii)\ S_r'(F_3) = \begin{pmatrix} \pm2 & \pm1 & 0 \\ 1 & 2 & 1 \end{pmatrix}$
$(iv)\ \rho_r'(F_3) = 2$ $(v)\ \delta_r'(F_3) = 1$ $(vi)\ spr_r'(F_3) = 4$
$(vii)\ E_r'(F_3) = 8.$

Theorem 2.6. For the Prism graph $Y_n, n \geq 3$,

$(i) |A_r'(Y_n)| = \begin{Bmatrix} 16\,; & n=4 \\ 0\,; & otherwise \end{Bmatrix}$

$(ii)\ rank\left(A_r'(Y_n)\right) = \left\{ \begin{matrix} \frac{4n}{3}; n \equiv 0(mod\ 3) \\ \frac{4n+8}{3}; n \equiv 1(mod\ 3) \\ \frac{4n+4}{3}; n \equiv 2(mod\ 3) \end{matrix} \right\}$

$(iii)\ S_r'(Y_n) = \left\{ \begin{matrix} \begin{pmatrix} \pm2 & 0 \\ \frac{2n}{3} & \frac{2n}{3} \end{pmatrix} & ; n \equiv 0(mod\ 3) \\ \begin{pmatrix} \pm2 & \pm1 & 0 \\ \frac{2n-2}{3} & 2 & \frac{2n-8}{3} \end{pmatrix} & ; n \equiv 1(mod\ 3) \\ \begin{pmatrix} \pm2 & 0 \\ \frac{2n+2}{3} & \frac{2n-4}{3} \end{pmatrix} & ; n \equiv 2(mod\ 3) \end{matrix} \right\}$

$(iv)\ \rho_r'(Y_n) = 2$
$(v)\ \delta_r'(Y_n) = 0$
$(vi)\ spr_r'(Y_n) = 4$

$(vii)\ E_r^{'}(Y_n) = \begin{Bmatrix} \frac{8n}{3}; n \equiv 0(mod\ 3) \\ \frac{8n+4}{3}; n \equiv 1(mod\ 3) \\ \frac{8n+8}{3}; n \equiv 2(mod\ 3) \end{Bmatrix}$.

Theorem 2.7. For the Complete graph $K_n, n \geq 2$,

$(i)\left|A_r^{'}(K_n)\right| = \begin{Bmatrix} (-1)^{\frac{n}{2}}(2)^{n-2}\ ; n\ is\ even \\ 0 \qquad\qquad ; n\ is\ odd \end{Bmatrix}$

$(ii)\ rank\left(A_r^{'}(K_n)\right) = \begin{Bmatrix} n \qquad ; n\ is\ even \\ n-1\ ; n\ is\ odd \end{Bmatrix}$

$(iii)\ S_r^{'}(K_n) = \begin{Bmatrix} \begin{pmatrix} \pm 2 & \pm 1 \\ \frac{n-2}{2} & 1 \end{pmatrix}\ ; n\ is\ even \\ \begin{pmatrix} \pm 2 & 0 \\ \frac{n-1}{2} & 1 \end{pmatrix}\ ; n\ is\ odd \end{Bmatrix}$

$(iv)\ \rho_r^{'}(K_n) = \begin{Bmatrix} 1; & n = 2 \\ 2\ ; & otherwise \end{Bmatrix}$

$(v)\ \delta_r^{'}(K_n) = \begin{Bmatrix} 2\ ; & n = 2,3 \\ 1\ ; & n = 4 \\ 0\ ; & otherwise \end{Bmatrix}$

$(vi)\ spr_r^{'}(K_n) = \begin{Bmatrix} 2; & n = 2 \\ 4\ ; & otherwise \end{Bmatrix}$

$(vii)\ E_r^{'}(K_n) = 2(n-1)$.

Theorem 2.8. For the Wheel graph $W_n, n \geq 3$,

$(i)\left|A_r^{'}(W_n)\right| = \begin{Bmatrix} 4\ ; n = 3 \\ 0\ ; n \geq 4 \end{Bmatrix}$

$(ii)\ rank\left(A_r^{'}(W_n)\right) = \begin{Bmatrix} \frac{2n+6}{3}; n \equiv 0(mod\ 3) \\ \frac{2n+4}{3}; n \equiv 1(mod\ 3) \\ \frac{2n+2}{3}; n \equiv 2(mod\ 3) \end{Bmatrix}$

$(iii)\ S_r^{'}(W_n) = \begin{Bmatrix} \begin{pmatrix} \pm 2 & \pm 1 & 0 \\ \frac{n}{3} & 1 & \frac{n-3}{3} \end{pmatrix} & ; n \equiv 0(mod\ 3) \\ \begin{pmatrix} \pm 2 & \pm 1.414 & 0 \\ \frac{n-1}{3} & 1 & \frac{n-1}{3} \end{pmatrix} & ; n \equiv 1(mod\ 3) \\ \begin{pmatrix} \pm 2 & 0 \\ \frac{n+1}{3} & \frac{n+1}{3} \end{pmatrix} & ; n \equiv 2(mod\ 3) \end{Bmatrix}$

$(iv)\ \rho_r^{'}(W_n) = 2$

$(v)\ \delta_r^{'}(W_n) = \begin{Bmatrix} 1; n \equiv 0(mod\ 3) \\ 0.6; n \equiv 1(mod\ 3) \\ 0; n \equiv 2(mod\ 3) \end{Bmatrix}$

$(vi)\ spr_r^{'}(W_n) = 4$

$(vii)\ E_r^{'}(W_n) = \begin{Bmatrix} \frac{4n+6}{3}; n \equiv 0(mod\ 3) \\ \frac{4n+5}{3}; n \equiv 1(mod\ 3) \\ \frac{4n+4}{3}; n \equiv 2(mod\ 3) \end{Bmatrix}$.

Theorem 2.9. For the Path graph $P_n, n \geq 2$,

$(i)\left|A_r^{'}(P_n)\right| = \begin{Bmatrix} -1\,; & n=2 \\ 0\,; & otherwise \end{Bmatrix}$

$(ii)\ rank\left(A_r^{'}(P_n)\right) = \begin{Bmatrix} \frac{2n}{3}; n \equiv 0(mod\ 3) \\ \frac{2n-2}{3}; n \equiv 1(mod\ 3) \\ \frac{2n+2}{3}; n \equiv 2(mod\ 3) \end{Bmatrix}$

$(iii)\ S_r^{'}(P_n) = \begin{Bmatrix} \begin{pmatrix} \pm 2 & 0 \\ \frac{n}{3} & \frac{n}{3} \end{pmatrix} & ; n \equiv 0(mod\ 3) \\ \begin{pmatrix} \pm 2 & 0 \\ \frac{n-1}{3} & \frac{n+2}{3} \end{pmatrix} & ; n \equiv 1(mod\ 3) \\ \begin{pmatrix} \pm 2 & \pm 1 & 0 \\ \frac{n-2}{3} & 1 & \frac{n-2}{3} \end{pmatrix} & ; n \equiv 2(mod\ 3) \end{Bmatrix}$

$(iv)\ \rho_r^{'}(P_n) = \begin{Bmatrix} 1 & ; & n=2 \\ 2 & ; & n \geq 3 \end{Bmatrix}$

$(v)\ \delta_r^{'}(P_n) = \begin{Bmatrix} 1\ ; n \equiv 2(mod\ 3) \\ 0\ ; \quad otherwise \end{Bmatrix}$

$(vi)\ spr_r^{'}(P_n) = \begin{Bmatrix} 2 & ; n=2 \\ 4 & ; n \geq 3 \end{Bmatrix}$

$(vii)\ E_r^{'}(P_n) = \begin{Bmatrix} \frac{4n}{3}; n \equiv 0(mod\ 3) \\ \frac{4n-4}{3}; n \equiv 1(mod\ 3) \\ \frac{4n-2}{3}; n \equiv 2(mod\ 3) \end{Bmatrix}$.

Theorem 2.10. For the Cycle graph $C_n, n \geq 3$,

$(i)\left|A_r^{'}(C_n)\right| = \begin{Bmatrix} 4\,; n=4 \\ 0\,; otherwise \end{Bmatrix}$

$(ii)\ rank\left(A_r^{'}(C_n)\right) = \begin{Bmatrix} \frac{2n}{3}; n \equiv 0(mod\ 3) \\ \frac{2n+4}{3}; n \equiv 1(mod\ 3) \\ \frac{2n+2}{3}; n \equiv 2(mod\ 3) \end{Bmatrix}$

$(iii)\ S_r^{'}(C_n) = \begin{Bmatrix} \begin{pmatrix} \pm 2 & 0 \\ \frac{n}{3} & \frac{n}{3} \end{pmatrix} & ; n \equiv 0(mod\ 3) \\ \begin{pmatrix} \pm 2 & \pm 1 & 0 \\ \frac{n-1}{3} & 1 & \frac{n-4}{3} \end{pmatrix} & ; n \equiv 1(mod\ 3) \\ \begin{pmatrix} \pm 2 & \pm 1.414 & 0 \\ \frac{n-2}{3} & 1 & \frac{n-2}{3} \end{pmatrix} & ; n \equiv 2(mod\ 3) \end{Bmatrix}$

$(iv)\ \rho_r^{'}(C_n) = 2$

$(v)\ \delta_r^{'}(C_n) = \begin{Bmatrix} 0; n \equiv 0(mod\ 3) \\ 1; n \equiv 1(mod\ 3) \\ 0.6; n \equiv 2(mod\ 3) \end{Bmatrix}$

$(vi)\ spr_r^{'}(C_n) = 4$

$(vii)\ E_r^{'}(C_n) = \begin{Bmatrix} \frac{4n}{3}; n \equiv 0(mod\ 3) \\ \frac{4n+2}{3}; n \equiv 1(mod\ 3) \\ \frac{4n-1}{3}; n \equiv 2(mod\ 3) \end{Bmatrix}$.

The following theorem gives both lower and upper bound for the edge roman dominating energy in terms of p and q.

Theorem 2.11. Let G be a simple graph with p vertices and q edges. If $S_{ar}^{'}(G)$ be the edge roman dominating function value with cardinality $a_r^{'}(G)$ and $P = \left|\left|A_r^{'}(G)\right|\right|$.
If $\lambda_1, \lambda_2, \ldots . \lambda_p$ are the eigenvalues of $A_r^{'}(G)$ then

$\sqrt{(2q+k)+p(p-1)P^{\frac{2}{p}}} \leq E_r^{'}(G) \leq \sqrt{p(2q+k)}$, where $k = S_{ar}^{'}(G)$.

Proof. We know that Cauchy Schwarz inequality is $(\sum_{i=1}^{p} a_i b_i)^2 \leq (\sum_{i=1}^{p} a_i^2)(\sum_{i=1}^{p} b_i^2)$

If $a_i = 1, b_i = |\lambda_i|$ then $(\sum_{i=1}^{p}|\lambda_i|)^2 \leq (\sum_{i=1}^{p} 1)(\sum_{i=1}^{p} \lambda_i^2)$
$[E_r^{'}(G)]^2 \leq p(2q+k)$, since $\sum_{i=1}^{p} \lambda_i^2 \leq 2|E| + S_{ar}^{'}(G)$
which gives $E_r^{'}(G) \leq \sqrt{p(2q+k)}$ (1)

Since arithmetic mean is not smaller than geometric mean, we have
$\frac{1}{p(p-1)}\sum_{i\neq j}|\lambda_i||\lambda_j| \geq \left[\prod_{i\neq j}|\lambda_i||\lambda_j|\right]^{\frac{1}{p(p-1)}} = \left[\prod_{i=1}^{p}|\lambda_i|^{2(p-1)}\right]^{\frac{1}{p(p-1)}}$
$= \left[\prod_{i=1}^{p}|\lambda_i|\right]^{\frac{2}{p}}$

$= \left|\prod_{i=1}^{p}\lambda_i\right|^{\frac{2}{p}}$
$= \left|\left|A_r^{'}(G)\right|\right|^{\frac{2}{p}} = P^{\frac{2}{p}}$
$\sum_{i\neq j}|\lambda_i||\lambda_j| \geq p(p-1)P^{\frac{2}{p}}$
Now consider, $[E_r^{'}(G)]^2 = \left(\sum_{i=1}^{p}|\lambda_i|\right)^2 = \sum_{i=1}^{p}|\lambda_i|^2 + \sum_{i\neq j}|\lambda_i||\lambda_i|$
$[E_r^{'}(G)]^2 \geq (2q+k) + p(p-1)P^{\frac{2}{p}}$
$i.e. E_r^{'}(G) \geq \sqrt{(2q+k)+p(p-1)P^{\frac{2}{p}}}$ (2)
From (1) and (2), $\sqrt{(2q+k)+p(p-1)P^{\frac{2}{p}}} \leq E_r^{'}(G) \leq \sqrt{p(2q+k)}$

CONCLUSIONS

In this paper, we introduced the edge Roman dominating adjacency matrix and established its fundamental matrix properties for several standard graphs. Building on these results, we further explored bounds and extended our analysis to additional classes of graphs. Additionally, we aim to develop efficient algorithms for constructing and analyzing this matrix in future work.

ABSTRACT

This study provides valuable insights into customer perceptions and satisfaction levels with HDFC Life, with a particular focus on the preferences and behaviours of policyholders. The findings reveal that HDFC Life enjoys high customer satisfaction, with most respondents appreciating the benefits offered by their insurance policies, the customer service experience, and the ease of payment methods. The company's communication efforts, both in frequency and meeting arrangements, have been well-received, with most customers expressing satisfaction.

Keywords: Environmental Sustainability, Healthcare, Innovation, Insurance, Social.

INTRODUCTION

HDFC Life firmly commits to corporate social responsibility (CSR) by focusing on education, healthcare, and environmental sustainability. Initiatives include supporting underprivileged children's education, providing access to healthcare in rural areas, and promoting environmental conservation. These efforts reflect HDFC Life's dedication to positively impacting society and contributing to the well-being of communities. HDFC Life strongly emphasizes transparency and fairness when dealing with customers and stakeholders. The company adheres to ethical business practices and regulatory compliance, ensuring that all operations are conducted with integrity and accountability. Employee-friendly policies and initiatives promote a positive and inclusive work environment, fostering a culture of collaboration and innovation.

Investor relations programs are in place to communicate company performance and strategy to shareholders, providing regular updates and insights into HDFC Life's financial performance and plans. The company has received numerous awards and recognition for its corporate governance, sustainability efforts, and customer service, including the Golden Peacock Award for Corporate Governance and Asia's Best CSR Practices Award. HDFC Life actively engages with industry associations and government bodies to contribute to the development of the insurance sector and promote financial literacy and insurance awareness among the public. The company continuously focuses on product innovation to meet evolving customer needs and market trends, ensuring it remains at the forefront of the industry.

Statement of the Problem

In today's dynamic business environment, sustainability has become essential to corporate strategy, particularly in the financial services sector. Insurance companies, as long-term risk managers and institutional investors, are expected to offer reliable financial protection and contribute positively to environmental, social, and governance (ESG) objectives. HDFC Life Insurance, as one of India's leading life insurance providers, has introduced several sustainability initiatives, such as digital transformation, paperless policies, financial literacy programs, and community development efforts. While these initiatives are intended to enhance operational efficiency and fulfil corporate social responsibilities, it remains unclear to what extent customers recognize, perceive, and value these sustainability practices.

Furthermore, although global and national research highlights the growing importance of sustainability in customer decision-making, there is limited evidence specific to the Indian life insurance sector — particularly in urban markets like Chennai. There is a research gap in understanding whether HDFC Life's sustainability practices significantly influence customer satisfaction, trust, and loyalty in this regional context.

Thus, the problem this study seeks to address is:

"To what extent do the sustainability practices adopted by HDFC Life Insurance influence customer satisfaction among policyholders in Chennai?"

This study aims to bridge the gap by examining customer awareness, perception, and satisfaction with HDFC Life's sustainability practices, ultimately providing insights to guide more effective strategy formulation and customer relationship management.

Objectives of the Study

The primary objectives of a study on HDFC Life Company may include:

- To analyse HDFC Life's business operations, including its products, services, and distribution channels.
- To assess the company's financial health, including revenue growth, profitability, and return on investment.
- To examine HDFC Life's market share, competitors, and industry trends to understand its competitive landscape.
- To investigate customer expectations, satisfaction levels, and pain points to identify areas for improvement.
- To identify potential growth drivers, such as new product launches, partnerships, expansion into new markets, and challenges like regulatory changes or market volatility.

Limitations of the Study

- The study relies on publicly available data, which may limit insights into proprietary strategies or financial details not disclosed by HDFC Life.
- Due to time limitations, the study may not cover all aspects of the life insurance industry or HDFC Life's operations in exhaustive detail.
- Customer satisfaction data and feedback may be biased or unrepresentative of the entire customer base.

Methodology Adopted (Research Design)

Area of the Study:

This study focuses on the intersection between sustainability practices and customer satisfaction in the life insurance sector, specifically examining HDFC Life Insurance operations in Chennai, Tamil Nadu, India.

The research explores how HDFC Life's initiatives related to environmental responsibility, digital transformation, corporate social responsibility (CSR), ethical governance, and customer service innovations are perceived by its policyholders.

Research Location

The geographic area selected for the study, Chennai, is significant because it is a major metropolitan city with a large, educated, and digitally aware population, which is increasingly conscious of sustainability issues. The study targets individual customers (policyholders) in Chennai to assess:

- Awareness of HDFC Life's sustainability initiatives,
- Perceptions regarding these initiatives,
- The impact of sustainability practices on customer satisfaction, trust, and loyalty.

Thus, the study area combines the insurance services sector, sustainability practices, customer behaviour analysis, and a regional focus on urban India (Chennai).

Research Design

The research used for this study is Descriptive research.

A descriptive research design is a study that aims to accurately and systematically describe a phenomenon, population, or situation. It focuses on what is happening without manipulating variables rather than why or how it happens. The researcher observes, records, and analyses information as it naturally occurs.

Sources of Data

The process of gathering and analysing accurate data from various sources to find answers to research problems, trends, and probabilities, etc., to evaluate possible outcomes is known as data collection.

The study involves the collection of both primary and secondary data.

Primary Data

Primary data was collected for this study through a structured questionnaire.

Secondary Data

Secondary data collected through

- Book
- Journals
- Website
- Google Scholar
- Articles

Sampling

A sample taken for the study is 60 HDFC Life Insurance Company clients. Sixty respondents were selected for the study using the convenience sampling technique. The sample size was chosen to ensure that the data collected was representative enough to draw meaningful conclusions while remaining manageable for analysis.

Sampling Techniques

Non-probability convenience sampling is used for this study.

The study employed a convenience sampling method, a type of non-probability sampling. Convenience sampling involves selecting participants who are easily accessible and willing to participate, making data collection more efficient. This method was chosen due to its practical nature, allowing for swiftdata collection within a limited time frame.

Data Analysis and Interpretation

Table 1: Employees React To Your Queries

Findings: 47% of respondents are satisfied with how employees react to their queries, 23% are delighted, 20% are neutral, and 10% are dissatisfied. Inference: The majority of respondents are either satisfied or highly satisfied with the response to their queries, indicating generally positive customer service.

Table 2: The Way Customers Like to be Called for the Meetings from the Company

Findings: 43% of respondents are satisfied with how they are called for meetings, 30% are delighted, 25% are neutral, and 2% are highly dissatisfied.

Inference: Most respondents are satisfied with arranging meetings, indicating a positive reception of the company's meeting approach.

Table 3: Rate Sustainability in an Insurance Company

Findings:50% of respondents rate the sustainability of an insurance company as good, 25% rate it as excellent, 20% are neutral, 3% rate it as poor, and 2% rate it as very poor.

Inference: Most respondents view insurance companies' sustainability positively, with most ratings falling between good and excellent.

Table 4: Are You Satisfied With The Overall Service Provided by HDFC Life

Findings: 57% of respondents are satisfied with the overall service provided by HDFC Life, 22% are delighted, 13% are neutral, and 8% are dissatisfied.

Inference: Most respondents are satisfied with HDFC Life's service, indicating a positive perception of their offerings.

SUMMARY OF FINDINGS

Demographics: Most respondents (63%) are male, with a significant portion (65%) being single and 42% students, highlighting a younger and diverse demographic group.

Purpose of Insurance: Wealth creation is the primary perceived purpose of acquiring insurance (53%), followed by child needs (27%) and retirement benefits (20%).

Customer Base of HDFC Life: 62% of respondents are current customers of HDFC Life, reflecting a strong market presence.

Attractiveness of Policy Benefits: 83% of respondents find the benefits offered by their insurance policies attractive and preferable, indicating high customer satisfaction with policy offerings.

Preferred Mode of Premium Payment: 37% of respondents use internet payments, followed by 23% using cash, indicating a preference for convenient and flexible payment options.

Communication Frequency: The company contacted 35% of respondents quarterly, suggesting regular and consistent communication from HDFC Life.

Preferred Service System: The majority (60%) prefer personal service over other methods, emphasizing the importance of direct interaction in customer service.

Employee Response to Queries: 70% of respondents are satisfied or highly satisfied with how employees address their queries, indicating efficient customer support.

Meeting Scheduling Preferences: 73% of respondents are satisfied or highly satisfied with how they are contacted for meetings, highlighting the effectiveness of meeting arrangements.

Sustainability Perception: 75% rate sustainability in an insurance company as good or excellent, suggesting that respondents value the sustainability efforts of their insurance providers.

Overall Service Satisfaction: 79% of respondents are satisfied or highly satisfied with the overall service provided by HDFC Life, reflecting a positive overall customer experience.

SUGGESTIONS AND RECOMMENDATIONS

Enhance Personal Service Channels: Since 60% of respondents prefer personal service, HDFC Life should prioritize face-to-face interactions while exploring innovative ways to deliver a personalized customer experience. This could include dedicated relationship managers for high-value customers and customized consultations.

Increase Digital Payment Options: With 37% of respondents opting for internet payments and a significant portion (23%) preferring cash, HDFC Life should enhance its digital payment infrastructure. Offering more online payment options like mobile wallets or UPI could increase convenience and attract a broader customer base.

Improve Communication Frequency and Customization: Sincemost respondents are contacted quarterly or monthly, HDFC Life should explore more personalized communication schedules based on customer preferences. Regular, but non-intrusive, communication could increase engagement and customer loyalty.

Address Queries and Service Responsiveness: While 70% of respondents are satisfied with how their queries are addressed, there remains a 10% dissatisfaction rate. HDFC Life should focus on further training employees to improve response times and support quality. Offering more self-service options (like a customer support app) could also be beneficial.

Enhance Customer Interaction for Meetings: With 73% of respondents satisfied with how meetings are arranged, HDFC Life should maintain or improve its meeting scheduling process by offering flexible time slots, better pre-meeting communication, and virtual meeting options for convenience.

Tailor Products for Younger Demographics: Since a significant portion of the respondents are students (42%) or in their early career stages, HDFC Life could design more affordable, flexible insurance products that cater to this demographic's needs, such as low-cost life insurance or student savings plans.

Customer Satisfaction Measurement: To address the 13% of respondents who are neutral or dissatisfied with the overall service, HDFC Life should regularly conduct customer satisfaction surveys to identify specific areas of improvement, particularly in the claims process or product offerings.

Offer More Payment Flexibility: Since many respondents use cheques (17%) and demand drafts (18%) for premium payments, HDFC Life should ensure that customers who prefer traditional payment methods continue to have access to these options. Additionally, exploring instalment-based payment options could make premiums more accessible.

CONCLUSION

This study provides valuable insights into customer perceptions and satisfaction levels with HDFC Life, with a particular focus on the preferences and behaviours of policyholders. The findings reveal that HDFC Life enjoys high customer satisfaction, with most respondents appreciating the benefits offered by their insurance policies, the customer service experience, and the ease of payment methods. The company's communication efforts, both in frequency and meeting arrangements, have been well-received, with most customers expressing satisfaction. However, there are areas for improvement, such as enhancing the personalization of services and increasing the frequency of communication based on individual preferences. The study also highlights the importance of sustainability, with customers valuing eco-friendly initiatives and responsible corporate practices. Most respondents prefer personal interaction for service and meetings, emphasizing the need for HDFC Life to maintain a strong human touch while balancing the benefits of digital services. Additionally, the research underscores the importance of offering flexible payment options to cater to the diverse needs of policyholders. HDFC Life's commitment to providing attractive policy benefits and maintaining strong customer relations has contributed significantly to customer satisfaction. Adopting the suggested recommendations can further strengthen its market position, enhance customer loyalty, and continue delivering value to its policyholders in a competitive insurance landscape.

ABSTRACT

Agriculture is a major occupation that is dependent on rainfall. Weather changes play a huge role in crop yield with things like precipitation, wind, temperature, solar radiation. Accurate forecasting helps in pricing, labor planning, transportation and organizing harvest. The objective is to predict crop yield using deep learning algorithms. An improved organization function (IOF) along with a Long short term memory model is implemented (LSTM). This proposed model has lower training error and addresses the underfitting and overfitting than eight other methods. Unlike traditional neural networks, LSTM is uniquely designed to manage and remember information over extended periods, making it ideal for tasks where sequence and context are critical—such as predicting crop yields. This capability addresses challenges posed by factors like varying weather conditions, soil quality, and agricultural practices, which all influence crop growth and production outcomes. Evaluation between predicted crop yield and actual crop yield is compared in RMSE (kg/ha). Results show that LSTM proposed by IOF is better than other RNN, CNN models.

Keywords: Crop Yield; Deep Learning; Model Performance; Optimizer; LSTM.

INTRODUCTION

Agricultural productivity and food security are crucial global concerns, heavily dependent on accurate prediction of crop yields. Over the years, advancements in machine learning have significantly enhanced the precision and

reliability of yield forecasting models. Among these, the Long Short-Term Memory (LSTM) algorithm has emerged as a powerful tool, particularly adept at capturing intricate temporal patterns and dependencies in data. Unlike traditional neural networks, LSTM is uniquely designed to manage and remember information over extended periods, making it ideal for tasks where sequence and context are critical—such as predicting crop yields. This capability addresses challenges posed by factors like varying weather conditions, soil quality, and agricultural practices, which all influence crop growth and production outcomes. In recent studies, LSTM has outperformed other algorithms such as Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and basic Artificial Neural Networks (ANNs) in accurately forecasting crop yields. Its ability to handle long-term dependencies and mitigate the impact of noisy data has resulted in impressive prediction accuracies, often exceeding 95%. This reliability not only enhances decision-making processes for farmers and policymakers but also contributes to sustainable agricultural practices by optimizing resource allocation and yield management. In this context, exploring the effectiveness of LSTM in agricultural yield prediction not only highlights its technological prowess but also underscores its pivotal role in advancing precision farming techniques worldwide.

Motivation

Crop yield optimization contributes to global food security by enhancing agricultural productivity. LSTM models can help predict and optimize yields, ensuring a stable and sufficient food supply to meet the demands of a growing population. Efficient use of resources such as water, fertilizers, and pesticides is crucial for sustainable agriculture. LSTM algorithms can assist in optimizing resource allocation, reducing waste, and minimizing environmental impact. Climate change introduces uncertainties in weather patterns, affecting agricultural productivity. LSTM models can analyze historical weather data and adaptively optimize crop management strategies for changing climate conditions, enhancing resilience in agriculture. LSTM algorithms can contribute to precision agriculture by providing accurate predictions at a fine spatial and temporal scale. This enables farmers to tailor their interventions precisely, optimizing input usage and maximizing yields. Improved crop yield predictions and optimization can lead to financial stability for farmers. By minimizing losses and maximizing profits, farmers can make more informed decisions about crop selection, planting times, and resource allocation. Optimizing crop yields can lead to more sustainable agricultural practices. By minimizing unnecessary resource use, farmers can contribute to reducing the environmental impact of agriculture, such as soil degradation and water pollution. Applying LSTM algorithms in agriculture represents a technological advancement. Engaging in crop yield optimization research and implementation allows for the integration of cutting-edge technology into traditional farming practices, fostering innovation in the agriculture sector.

Survey

Previous Models Researched

IOFLSTM

The document discusses the use of deep learning models, specifically the Long Short-Term Memory (LSTM) model, to predict crop yield accurately.[1] The focus is on the implementation of an improved optimization algorithm called Improved Optimization Function (IOF) in the LSTM model. The study collected manual data from local agricultural departments and government websites for training and testing purposes. The proposed IOF was compared to other standard optimization methods and showed better performance in handling underfitting and overfitting issues. The evaluation metrics used, such as r, RMSE, and MAE, demonstrated the accuracy of the IOF-LSTM model in crop yield prediction. The results also showed that the proposed model outperformed other deep learning models such as CNN, RNN, and LSTM in crop yield prediction. The study further compared the performance of the IOF-LSTM model with different optimizers, including Adam, AdaGrad, RMSP, and Momentum. The IOF-LSTM model consistently showed better results in terms of MAE, RMSE, and r values compared to other optimization methods. Additionally, the document presents the prediction of temperature, monsoon rainfall, and crop yield for the year 2021. The model accurately predicted the temperature and rainfall for 2021, which are crucial factors in determining crop yield. The crop yield prediction results for major crops in Andhra Pradesh were also analyzed, showing the advantage of accurate rainfall prediction for crop yield. The performance of the proposed IOF-LSTM model was further compared with other deep learning models, including RNN, LSTM, ANN, and CNN. The IOF-LSTM model

consistently outperformed these models in terms of MAE, RMSE, and r values, indicating its superior accuracy in crop yield prediction. The study also compared the performance of the IOF-LSTM model with different statistical measures, including Multivariate Logistic Regression (MLR), Support Vector Regression (SVR), Analysis of Variance (ANOVA), and Partial Least Squares Regression (PLSR). The IOF-LSTM model showed better results in terms of MAE, RMSE, r, and MASE values compared to these measures. Overall, the proposed IOF-LSTM model demonstrated its effectiveness in accurately predicting crop yield by incorporating deep learning models and improved optimization techniques. The model showed better performance compared to other deep learning models and statistical measures.

LSTM-RF

In this document, the authors propose a framework for improving the accuracy of wheat yield prediction using a combination of unmanned aerial vehicle (UAV) thermal infrared and multispectral imagery. [2] The study conducted a winter wheat field experiment with three levelsof irrigation and collected multispectral vegetation indices (VIs) and canopy water stress indices (CWSI) using a UAV equipped with cameras. The authors developed a framework that combinesa long short-term memory neural network (LSTM) and random forest (RF) to predict wheat yieldusing the VIs and CWSI as predictors. The results showed that the LSTM-RF model achieved better prediction results compared to the LSTM model, with a 22% reduction in root mean square error (RMSE). The authors concluded that the LSTM-RF model considered both the time-series characteristics of the winter wheat growth process and the non-linear relationship between remote sensing data and crop yield data, providing an alternative for accurate yield prediction in modern agricultural management. The document highlights the importance of yield prediction in agricultural production and the potential of remote sensing technology based on UAVs for non-intrusive and cost-effective prediction. The authors emphasize the need to consider multiple growth stages and the advantages of combining multiple sensors to improve prediction accuracy. They also discuss the application of machine learning algorithms, such as RF and LSTM, in crop parameter evaluation and yield prediction. The authors describe the methodology used in the study, including the collection and processing of UAV-based data, the selection of spectral indices, and the implementation of the LSTM-RF model. They present the statistical analysis and results, including the correlation between vegetation indices and yield, the performance evaluation of the LSTM and LSTM-RF models, and the relationships between measured and predicted yield. The study has several limitations and areas for improvement. The authors acknowledge that the framework was only validated under water stress conditions in a single environment, and further studies are needed to validate its performance in different environments. They also suggest the integration of data from different sources and the fusion of multimodal information for better accuracy and practicality. The authors propose future research directions, including the use of sensors that capture structural characteristics of crops and the validation of the framework in different environments. In conclusion, the document presents a comprehensive study on improving wheat yield prediction using UAV thermal infrared and multispectral imagery. The proposed LSTM-RF framework shows promising results in terms of prediction accuracy and provides an alternative for accurate yield prediction in modern agricultural management. However, further research is needed to validate the framework in different environments and integrate data from different sources for improved accuracy and practicality.

BO-LSTM

In this document, the authors propose a new framework for winter wheat yield prediction using a combination of deep learning and Bayesian optimization. The goal of this research is to provide accurate and timely predictions of winter wheat yield, which is crucial for food policy making and food security. The authors highlight the importance of agricultural big data and artificial intelligence (AI) in achieving smart agriculture and cost-effective solutions for the agricultural sector. The proposed framework, called BO-LSTM, utilizes a Bayesian optimization-based long- and short-term memory model to extract crop growth features from multiple data sources for winter wheat yield prediction. The performance of BO-LSTM is compared with other models, includingsupport vector machine (SVM) and linear regression Lasso. The results show that BO-LSTM outperforms the other models in terms of accuracy, with the highest accuracy achieved when using a combination of GPP, climate, LAI, and VIs as input variables. The authors also explore the robustness of the BO-LSTM method by evaluating its performance in different regions. The

results demonstrate that the model can achieve higher estimationaccuracy in regions with concentrated distribution of winter wheat cultivation and less influence of human factors. Furthermore, the approach used in this study has the potential to forecast crop yields in regions with limited data availability and can utilize publicly available multi-source data for timely and effective yield estimation. The document provides a detailed description of the methodology used, including the structure ofthe LSTM neural network and the process of Bayesian optimization for hyperparameter selection. The performance of the model is evaluated using metrics such as coefficient of determination (R2), root mean square error (RMSE), and mean absolute percentage error (MAPE). In conclusion, the proposed BO-LSTM framework shows promising results for winter wheat yield prediction, with higher accuracy compared to other models. The integration of deep learning and Bayesian optimization allows for efficient hyperparameter optimization and the fusion of multiple data sources for improved estimation accuracy. The framework has thepotential to contribute to food security and agricultural decision-making by providing timely and accurate predictions of winter wheat yield.[3].

ACYP-CPODL

The paper presents an Automated Crop Yield Prediction utilizing Chaotic Political Optimizerwith Deep Learning (ACYP-CPODL) model for predicting crop yields. The model aims to overcome the challenges of accurately predicting crop yield, which is influenced by factors such as genotype, environment, and their interaction. The ACYP-CPODL model involves three main processes: pre-processing, prediction, and parameter optimization. In the pre-processing phase, the input data is converted to CSV format and normalized using the min-max method. The prediction process utilizes a hybrid Convolutional Neural Network (CNN)Long-Short Term Memory (LSTM) model, which is designed to capture the long-term temporal dependency in multivariate sequences. The model is trained using the pre-processed data and produces crop yield predictions. To optimize the hyperparameters of the CNN-LSTM model, the Chaotic Political Optimizer (CPO) algorithm is employed. The CPO algorithm combines chaotic maps with the political optimization process to improve its efficiency. The algorithm adjusts the hyperparameters based on the fitness of the solutions and performs party transferring to manage both exploration and exploitation. The performance of the ACYP-CPODL model is evaluated on benchmark datasets for tomato and potato yield predictions. The results show that the ACYP-CPODL model outperforms other existing techniques in terms of mean squared error (MSE) and R2 score. The proposed model achieves an MSE of 0.031 and an R2 score of 0.936 for potato yield prediction, indicating its effectiveness in predicting crop yields. The paper concludes that the ACYP-CPODL model is a valuable tool for predicting crop yields, which is crucial for irrigation scheduling and labor requirements. The model's performance is validated through extensive simulations and comparisons with other techniques, demonstrating its superiority. Future research directions include designing fusion-based prediction models to further improve predictive outcomes.[5].

CNN-LSTM

This document presents a novel approach called DeepYield for crop yield forecasting using a combined convolutional neural network (CNN) with long short-term memory (LSTM). The aim of the study is to extract spatiotemporal patterns from remote sensing data to improve the accuracy of crop yield predictions. The proposed DeepYield model integrates ConvLSTM layers with a 3-Dimensional CNN (3DCNN) for feature extraction. The models are trained using historical yield data and MODIS satellite data for soybean-growing counties in the United States. The results show that DeepYield outperforms other techniques such as Decision Trees, CNN + GP, and CNN-LSTM in terms of accuracy and reliability. The study highlights the importance of considering the spatial and temporal characteristics of remote sensing data for crop yield forecasting. The authors suggest that future research should explore the inclusion of additional variables and investigate the impact of extreme events on the predictability of machine learning models. Overall, DeepYield provides a promising approach for improving crop yield forecasting, which has implications for crop market planning, insurance, and nutrient management.[8].

Bidirectional LSTM

Researchers have developed a predictive model for the photosynthetic carbon assimilation rate (A) of individual rice leaves. The model utilizes a hybrid architecture called BLSTM, which combines LSTM and bi-directional LSTM (BLSTM). The model uses three easily obtainable external environmental variables (photosynthetic photon flux density, ambient CO2 concentration, and temperature) to indirectly generate mesophyll variables required for prediction. The most important variable for predicting A is found to be mesophyll CO2 concentration (Ci). The model is trained using gas-exchange measurements from rice leaves, and the prediction accuracy is evaluated using nested cross-validation. The results show that the BALSTM model, which incorporates Ci and stomatal conductance to water vapor (gsw) as intermediate outputs, outperforms the LSTM model using only the external environmental variables. The reproducibility of Ci and gsw is found to be 2.01 μmol mol-1 and 0.061 mol m-2 s-1, respectively, with low mean absolute percentage errors. The prediction accuracy of A is highest when the time-series length of the input data is 5 minutes. The model is also tested on data from a different year, and while the prediction accuracy varies, the BALSTM model consistently performs better than the LSTM model with only external environmental variables. The findings suggest that incorporating mesophyll variables improves the prediction accuracy of A, and further research is needed to improve the model's performance under different conditions and for different cultivars. The study highlights the potential of computer modeling and machine learning in predicting crop yield and improving agricultural practices.[9].

LSTM with a attention block

The document discusses the development of an automatic crop expert system using an improved Long Short-Term Memory (LSTM) model with an attention block. The system aims to provide farmers with recommendations on the most suitable crops for cultivation based on factors such as soil type, climate requirements, and crop characteristics. The traditional method of manual decision-making in crop selection is time-consuming and relies heavily on the expertise and experience of the farmer. The proposed system utilizes a customized LSTM model with 27 layers, including an attention block to address the issue of vanishing and exploding gradients. The model takes seven input features, including pH, humidity, rainfall, nitrogen, potassium, phosphorus, and temperature, and recommends the most appropriate crop from a list of 22 options. Evaluation metrics such as recall, precision, F1-score, and accuracy are used to assess the performance of the model, with the proposed LSTM achieving an accuracy of 97.26%. The system outperforms existing techniques and provides accurate recommendations for crop selection. Future work includes the development of a mobile application and web interface for easy access to the system.[11].

EEMD-LSTM

The document discusses a prediction model for runoff in irrigated paddy areas in southern China. The model combines the Ensemble Empirical Mode Decomposition (EEMD) method and the Long Short-Term Memory (LSTM) network. Meteorological factors are used as inputs to the model, with rainfall being the main variable affecting runoff. The model is applied to the Yangshudang watershed in the Zhanghe Irrigation System and compared to other models. The results show that the EEMD-LSTM multivariate model performs better than other models, with high simulation performance and improved prediction accuracy for peak flows. The model is also effective in predicting runoff in rainfall and nonrainfall events. The study concludes that the EEMD-LSTM model is suitable for simulating and predicting the daily-scale rainfall-runoff process in irrigated paddy areas, providing technical support for water resource management.[12].

I. MAML

The document discusses a research article on an ensemble deep learning algorithm for forecasting rice crop yield based on soil nutrition levels. The study aims to address the importance of accurate and timely crop yield estimates for agricultural policy and investment decisions. The proposed methodology utilizes an ensemble deep learning system called Model Agnostic Meta-Learning (MAML) for classification. The study uses soil nutrient data and crop production statistics as input for the algorithm. The dataset undergoes preprocessing techniques such as normalization and mean attribute to handle missing values. The MAML algorithm receives output from three different classifiers - Deep Neural Network (DNN), Deep Belief Network (DBN), and Support Vector Machine

(SVM). Theensemble classifier then predicts the amount of rice crop yield based on the soil's nutrient levels. The proposed method achieves an accuracy rate of 89.5%, indicating its effectiveness in predicting crop yield. The study also compares the proposed method with other existing techniques such as SVM, DNN, DBN, and KNN classifiers. The comparison shows that the proposed method outperforms the existing techniques in terms of accuracy, precision, recall, F1 score, specificity, and negative predictive value. The study concludes that the ensemble deep learning algorithm, MAML, is a suitable approach for forecasting rice crop yield based on soil nutrition levels. The accuracy and performance metrics of the proposed method demonstrate its superiority over existing techniques. The findings of the study have implications for improving agricultural productivity and decision- making in the context of crop yield prediction.[16].

Use of LSTM in Agriculture

Winter wheat yield prediction in China using LSTM model

The document discusses a study on predicting winter wheat yield using a long short-term memory (LSTM) model and MODIS LAI (Leaf Area Index) products. The accuracy of the yield estimation results using LSTM is compared with conventional machine learning methods. The study found that the LSTM model generally outperformed other models, with the best results showing an R2 value of 0.87 and an RMSE value of 522.3 kg (about 1151.47 lb)/ha. The use of LAI as a single input factor improved the yield estimation, although it may cause yield uncertainty in extreme years. The study highlights the implications of this method for crop yield forecasting, agricultural disaster monitoring, food trade policy, and food security early warning. The study focused on Henan Province in China, which is an important region for winter wheat production. The authors used MODIS LAI data from 2003 to 2015 as input for the LSTM model to predict the yield for 2016. They analyzed the effects of different time steps and the LAI time series on the estimation results. The results showed that the accuracy of the yield estimation did not increase with increasing step size and data volume. However, the LSTM model performed better than conventional machine learning methods. The study divided the wheat-growing areas in Henan Province into five regions based on production conditions and climatic characteristics. The authors also compared the performance of the LSTM model with different input time series data. They found that using LAI data from the nodulation to filling stage resulted in higher accuracy compared to using data from the entire growing season. The best performance was achieved with a time step of 2, which had an R2 value of 0.87, an RMSE value of 522.32 kg (about 1151.52 lb)/ha, and a MAPE value of 5.67%. The study suggests that using a shorter time range of LAI data can still yield accurate predictions and reduce the amount of data required. Furthermore, the study compared the performance of the LSTM model with other machine learning methods such as random forest, support vector regression, partial least squares regression, and XGBoost. The LSTM model outperformed these methods in terms of yield estimation accuracy. Overall, the study demonstrates the effectiveness of using an LSTM model with MODIS LAI data for winter wheat yield prediction. The findings have implications for improving yield estimation, crop forecasting, disaster monitoring, and food security. The study suggests that using a shorter time range of LAI data and the LSTM model can provide accurate and timely predictions of winter wheat yield.[4].

Predicting cocoa yield

The document discusses the use of deep learning models for predicting cocoa yield in agriculture. The traditional statistical models used for crop yield prediction have limitations such as time wastage, inaccurate predictions, and difficulties in model usage. Therefore, the researchers propose an ensemble deep learning approach using a Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN) with Long Short-Term Memory (LSTM) for cocoa yield prediction. The CNN is used to handle the climatic dataset, while the RNN is employed to handle the cocoa yield prediction. The ensemble approach is chosen due to the nature of the dataset used, which includes both climatic and cocoa yield datasets. The proposed model is compared to other machine learning algorithms based on Mean Absolute Error (MAE), Mean Square Error (MSE), Root Mean Square Error (RMSE), and Mean Absolute Percentage Error (MAPE). The results show that the CNN-RNN with LSTM model gives the least mean absolute error, demonstrating its efficiency in predicting cocoa yield. The researchers also explore other machine learning models such as Multilayer Perceptron(MLP), Naïve Bayes (NB), and Seasonal Auto-Regression Integrated Moving Average (SARIMA). The results show that MLP and NB have lower mean absolute error

compared to SARIMA, indicating their better performance in cocoa yield prediction. Additionally, the document mentions the use of CNN-LSTM and RNN-LSTM models for cocoa yield prediction. The results show that the proposed model outperforms these models in terms of mean absolute error. In conclusion, the ensemble deep learning approach using CNN-RNN with LSTM proves to be an efficient method for predicting cocoa yield. It outperforms other machine learning models and deep learning models in terms of accuracy. This approach can be valuable for decision-makers and farmers in making informed planning and policy decisions in agriculture.[6].

Predicting soybean cultivation

The document discusses the development of a soil moisture prediction model using a recurrent neural network long short-term memory (RNN-LSTM) approach in soybean cultivation. The aim of the study is to predict soil moisture levels and determine appropriate irrigation timing based on weather conditions. The model uses sensors to measure soil moisture and temperature at various depths along with weather data as input variables. The RNN-LSTM model is trained using time series data and evaluated using loss and coefficient of determination (R2) values. The best performing model achieved an R2 of 0.999 and a loss of 0.022 for a depth of 10 cm (about 3.94 in), an R2 of 0.999 and a loss of 0.016 for depths of 20 cm (about 7.87 in) and 30 cm (about 11.81 in). The model was able to accurately predict soil moisture and could be applied to optimize irrigation for crop growth. The study concludes that a soil moisture prediction model based on time-series weather data can aid in determining the appropriateamount of irrigation needed for crop cultivation[7].

Predicting wheat production in Pakistan

The document discusses a study conducted to develop a forecasting model for wheatproduction in Pakistan using LSTM (Long Short-Term Memory) neural networks. The study highlights the importance of wheat production for Pakistan's economy and the need for accurate forecasting to address the increasing consumption and potential threats to the economy. The researchers used historical data from 1902 to 2018 and compared their proposed model with existing models in the literature. They also introduced a data pre-processing smoothing mechanism to improve prediction accuracy. The results showed that the proposed model outperformed existing models and indicated that wheat production will gradually increase in the next ten years, but the production to consumption ratio will continue to decline, posing a threat tothe economy. The researchers recommend using their framework for wheat production and suggest that it can be applied to other crops to promote sustainable agriculture development. The study provides details on the methodology used, including the use of Robust-LOWESS as a smoothing function and the parameters selected for the LSTM-NN model. The performance of the models was evaluated using metrics such as MAE (mean absolute error), RMSE (root mean squared error), and R-value (correlation coefficient). The LSTM-NN model developed with pre- processed data showed the best results in terms of accuracy. The study concludes by providing ten-year ahead wheat production forecasts for Pakistan.[10].

Using LSTM for crop yield prediction in Andhra Pradesh

The document discusses the development of a robust and efficient machine learning model for smart farming decisions and intelligent agriculture. The primary objective is to predict crop yield based on historical data and various parameters such as temperature, humidity, pH, rainfall, and crop type. The research proposes a novel machine learning approach for a heterogeneous data environment containing IoT-sensed data related to the environment, agricultural conditions, plant features, and demands. The authors use a dataset of five crops (rice, ragi, gram, potato, and onion) collected from Andhra Pradesh. They apply different machine learning algorithms, including regression methods, decision trees, naive Bayes, support vector machines, k-means clustering, and deep learning techniques such as LSTM and RNN. Among the machine learning techniques, the random forest algorithm performs best with a training accuracy of 99.27% for crop yield prediction. The sigmoid activation function achieves 99.71% accuracy with four hidden layers for predicting crop yield. The research highlights the importance of using IoT and machine learning technologies for smart farming and intelligent agriculture practices. It emphasizes the need for a robust and efficient machine learning environment to achieve optimal prediction accuracy and reliability. The proposed model aims to assist stakeholders in making optimal smart farming decisions and increasing agricultural productivity. The research provides a comprehensive review of existing

literature on IoT and machine learning approaches for smart agriculture and highlights the gaps and motivations for the proposed research. The proposed research methodology includes data acquisition, preprocessing, feature extraction and selection, and prediction using a heterogeneous ensemble learning environment. The document concludes by discussing the experimental observations and research significance of the proposed model. [13].

Predicting tomato yield in South Korea

The document discusses a study on the prediction of tomato yields using a combination of a traditional statistical time series model and a deep learning model. The researchers aimed to predict how various environmental factors, such as temperature, humidity, and CO2 levels, affect tomato yields by integrating an attention-based LSTM network and an ARMA model. In the first part of the proposed model, an encoding attention-based LSTM network was used to identify the environmental variables that significantly influence tomato yields. The network analyzed time series data and identified the variables that had the greatest impact on yield. In the second part of the model, an ARMA model, which is a statistical time series analysis model, wasused to improve the accuracy of the yield predictions given by the LSTM network. The ARMA model compensated for the difference between the predicted and actual yields. The researchers conducted experiments using data collected from 83 farm households in South Korea. They found that the internal temperature, internal humidity, and CO2 levels were the environmental factors that had the greatest influence on tomato yields. The results showed that the proposed method predicted yields more efficiently and effectively than existing models. The study also compared the proposed method with traditional regression models, such as linear regression, ridge regression, and SGD regression. While the traditional regression models showed similar predictive power, they had more prediction errors, especially during periods of sudden changes in yield. The researchers then applied the proposed method to predict tomato yields for 10 randomly selected farms. The results showed that the proposed method accurately predicted the trend of tomato production for most farms, even when there were large fluctuations in weekly production. In conclusion, the study demonstrated the effectiveness of combining an attention-based LSTM network and an ARMA model for predicting tomato yields. The proposed method outperformed traditional regression models in terms of prediction accuracy. The study also identified the environmental factors that had the greatest impact on tomato yields, including internal temperature, internal humidity, and CO2 levels. [18].

Yield prediction in Africa

Researchers have used deep learning on satellite imagery to predict maize yields in six African countries at the district level. This is the first attempt to predict crop yields in Africa using this method. The models performed well in some countries, with average R2 values as high as 0.56, but performed poorly in others, with average R2 values ranging from -0.60 to 0.13. The models also showed that using data from other countries can improve prediction accuracy in countries with sparse training data. The study used county level maize yield data from Ethiopia, Kenya, Malawi, Nigeria, Tanzania, and Zambia, and utilized a dimensionality reduction technique to overcome sparse label data. The researchers converted raw satellite images into histograms of pixel counts and processed them using a LSTM-based deep learning model to predict crop yields. They also incorporated a Gaussian Process Layer to improve accuracy. The results varied depending on the country, but the LSTM model with Gaussian Processing consistently outperformed other models. The study also compared models trained on randomized splits and chronological splits, and found that the randomized models generally performed better. The researchers also explored the use of transfer learning, training the LSTM model on data from all six countries and testing it on individual countries. The combined model showed promising results, suggesting that features learned from one country can help predict yields in another. Overall, the study demonstrates the potential for using deep learning on satellite imagery to predict crop yields in Africa, but highlights the need for further research to improve model performance in countries with sparse training data and to incorporate temporal and spatial features. [20].

LSTM Model is Better than ARIMA

This research article focuses on forecasting rice cultivation in India using two different models: Auto Regressive Integrated Moving Average (ARIMA) and Long Short-Term Memory Neural Network (LSTM-NN). The study uses historical data from 1950-51 to 2017-18 to develop and compare the accuracy of these models. The findings reveal that the ARIMA models fitted well for parameters such as area under cultivation, production, and yielding of rice. However, the LSTM-NN models outperformed the ARIMA models in terms of time series forecasting accuracy. The performance of the models was evaluated using metrics such as Root Mean Square Error (RMSE) and Mean Absolute Percentage Error (MAPE). The study concludes that LSTM-NN models are more flexible and accurate in predicting the behavior of agricultural parameters, such as rice cultivation, than ARIMA models. The LSTM- NN models showed lower RMSE and MAPE values compared to the ARIMA models. The research highlights the importance of accurate forecasting in the agricultural sector, particularly for food security. The study suggests that LSTM-NN models can be utilized to improve the accuracy of predictions in other agricultural fields as well. The limitations of the study include its focus on rice cultivation in India as a whole, and future research could explore the performance of these models in specific regions or states.In conclusion, the study demonstrates the superiority of LSTM-NN models over ARIMA models in forecasting rice cultivation in India. The findings have implications for agricultural planning, policymaking, and food security initiatives. [14].

Vegetable Prices using LSTM

The document discusses a study on vegetable price forecasting using a model called STL- ATTLSTM. The model integrates the seasonal trend decomposition using the Loess (STL) preprocessing method and the attention mechanism based on long short-term memory (LSTM). The study aims to address the challenges of forecasting vegetable prices, which are influenced by various factors and have non-linear and non-stationary characteristics. The STL-ATTLSTM model forecasts monthly vegetable prices using various types of information, including vegetable prices, weather information of the main production areas, and market trading volumes. The STL method decomposes the time-series vegetable price data into trend, seasonality, and remainder components. The attention mechanism assigns weights to the input variables, improving the model's prediction performance by focusing on the variables that affect the results. The study applied the STL-ATTLSTM model to five crops (cabbage, radish, onion, hot pepper, and garlic) and compared its performance to three benchmark models (LSTM, attention LSTM, and STL-LSTM). The results showed that the STL-LSTM model achieved the highest prediction accuracy, with a 12% improvement over the attention LSTM model and a 4-5% improvement over the LSTM model. The average root mean square error (RMSE) of the STL-ATTLSTM model was 380, and the average mean absolute percentage error (MAPE) was 7%. The study highlights the importance of using the STL method and the attention mechanism in vegetable price forecasting. It also emphasizes the significance of incorporating various types of information, such as weather data and trading volumes, to improve the accuracy of the predictions. Overall, the proposed STL-ATTLSTM model shows promising results in forecasting vegetable prices and can contribute to the stability of supply and demand in the agricultural market. [17].

Predicting Trade Volumes and Prices

This document is a research article that discusses the comparative analysis of three different AI methods (CNN, LSTM, and Random Forest) for multivariate agricultural price forecasting. The study focuses on the prediction of daily trade volumes and prices of potato, onion, and garlic, which are commonly consumed products in Turkish cuisine. The dataset used in the study was collected from the Ministry of Commerce of Turkish Republic and covers the period between January 1, 2018, and November 26, 2022. The study compares the performance of the three models in predicting the next 10-day prices of the products. The results show that all three models provided acceptable results, but the CNN model yielded the best results with the lowest Mean Absolute Error (MAE) and Root Mean Square Error (RMSE). The study concludes that deep learning architectures like CNN and LSTM are effective in modeling the complex data relations in agricultural price forecasting. The results of this study can be useful for producers, consumers, policy makers, and traders in making decisions related to agricultural products. The study also highlights the importance of regular data collection for accurate time series analysis. Overall, this research

provides valuable insights into the application of AI methods for agricultural price forecasting and suggests further studies using more complex models and architectures.

Predicting Chemical and Physical Properties of Magnetized Water and Fertilizer

In this research article, the authors propose a meta-learning optimization model based on the meta-learner LSTM for predicting the physical and chemical properties of magnetized water and fertilizer (PCPMWF) in the field of agriculture. The use of deep learning methods for predicting the change trend of magnetized media is limited due to the high cost of data collection. The proposed meta-learning model aims to explore the effects of magnetized water and fertilizer irrigation on crop growth. The authors compare the performance of the meta-learning optimization model with the MAML model and the LSTM model. The results show that the meta-learning optimization model achieves a lower average absolute percentage error compared to the other two models. The loss value of the optimization model decreases faster and more steadily during the iterative process. In cross-domain experiments, the meta-learning optimized model achieves a higher average accuracy compared to the MAML model. The study highlights the potential of using meta-learning methods, specifically meta-learner LSTM, for predicting the physical and chemical properties of magnetized water and fertilizer. The proposed model outperforms traditional LSTM and MAML models in terms of prediction accuracy and loss function convergence. The results suggest that the optimization model can effectively learn from a few samples and perform well in cross-domain datasets. The authors acknowledge the limitations of the study, such as the use of a self-built dataset and the need for further analysis of experimental measurements. Future research directions include exploring the impact of support set and query set capacity on model performance, improving prediction efficiency, and conducting objective verification and comparative analysis. Overall, the research provides valuable insights into the application of meta-learning for predicting the properties of magnetized water and fertilizer in agriculture. The proposed meta- learner LSTM optimization model shows promise in improving prediction accuracy and efficiency in the field of few-shot regression prediction[19].

Gap in Earlier Research

Acquiring comprehensive and reliable long-term crop yield datasets can be a challenge. Most available datasets might cover a limited number of years, which can impact the LSTM model's ability to capture long-term patterns and trends accurately. Integrating diverse data types such as satellite imagery, weather data, soil information, and socio-economic factors can enhance the predictive power of crop yield models. Research could explore effective ways to integrate these different data modalities into LSTM models for more accurate predictions. Investigating the transferability of LSTM models trained on data from one region or crop to another is essential. Generalization across diverse environmental and agricultural conditions remains a challenge. Fine-tuning hyperparameters of LSTM models, such as the number of layers, hidden units, and sequence lengths, for optimal performance in the context of crop yield prediction could be an area of investigation. Ensuring the quality of input data and addressing issues such as missing values, outliers, and noise is critical. Research could explore robust preprocessing techniques tailored to agricultural datasets.

Problem Statement and Objectives

Problem Definition

Traditional machine learning models like RNN and ANN have a lot of training and testing loss. Being accurate towards crop yield prediction is very important and thus by making it more accurate crop yielders will be safer. Farmers suffer a lot from climate change as it causes changes in weather patterns which might result in less crop yield and thus endangering their livelihood.

Objectives

- Investigate the robustness of LSTM in handling noisy and sparse agricultural data to maintain high prediction accuracy.

- Assess the capability of LSTM in capturing long-term dependencies and temporal pat- terns that influence crop growth, compared to traditional machine learning models.
- Evaluate the accuracy of LSTM compared to CNNs, RNNs, and ANNs in forecasting crop yields across diverse agricultural regions and varying climatic conditions.

Approach
Algorithm:1,2,3,4

CONCLUSION

The LSTM algorithm has demonstrated superior performance compared to other algorithms suchas CNN, RNN, and ANN in predicting crop yields. By effectively managing the sequential dependencies in the data, LSTM has shown a remarkable ability to capture the complex patterns and relationships between various factors affecting crop yield. This has resulted in an impressive accuracy of 95%, making LSTM a highly reliable and efficient model for agricultural yield prediction. Its ability to handle long-term dependencies and reduce prediction errors highlights its advantage over traditional neural network models, solidifying its place as a preferred method for precision farming and yield forecasting.

20. A Kaneko,., T Kennedy,., L Mei,,. C Sintek,,. M. Burke,, S Ermon,. and D Lobell, June. Deep learning for crop yield prediction in Africa. In *ICML workshop on artificial intelligence forsocial good* (pp. 33-37). 2019.

The Long Short-Term Memory (LSTM) algorithm involves several key steps, including the calculation of input, forget, cell, and output gates, as well as updating the cell state and the hidden state. Here are the formulas for each component of the LSTM algorithm:

1. **Forget Gate:**

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f)$$

2. **Input Gate:**

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i)$$

3. **Candidate Cell State:**

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C)$$

4. **Update Cell State:**

$$C_t = f_t \odot C_{t-1} + i_t \odot \tilde{C}_t$$

5. **Output Gate:**

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o)$$

6. **Hidden State:**

$$h_t = o_t \odot \tanh(C_t)$$

Here, σ represents the sigmoid function, tanh represents the hyperbolic tangent function, $\odot$ denotes element-wise multiplication, W_f, W_i, W_C, W_o are weight matrices, b_f, b_i, b_C, b_o are bias vectors, x_t is the input at time step t, h_{t-1} is the hidden state from the previous time step, C_{t-1} is the cell state from the previous time step, and h_t and C_t are the hidden state and cell state at the current time step, respectively.dx

Algorithm: 1

Initialization

- Initialize weight matrices and bias vectors:

$$W_f, W_i, W_C, W_o$$
$$b_f, b_i, b_C, b_o$$

- Initialize the initial cell state and hidden state:

$$C_0$$
$$h_0$$

Forward Pass

For each time step t in the sequence:

1. **Forget Gate:**
$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f)$$
2. **Input Gate:**
$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i)$$
3. **Candidate Cell State:**
$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C)$$
4. **Update Cell State:**
$$C_t = f_t \odot C_{t-1} + i_t \odot \tilde{C}_t$$
5. **Output Gate:**
$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o)$$
6. **Hidden State:**
$$h_t = o_t \odot \tanh(C_t)$$

Algorithm: 2

Backward Pass (Backpropagation Through Time)

1. **Compute the error at each time step t:**

$$\delta_t$$

2. **Compute the gradients for weights and biases:**

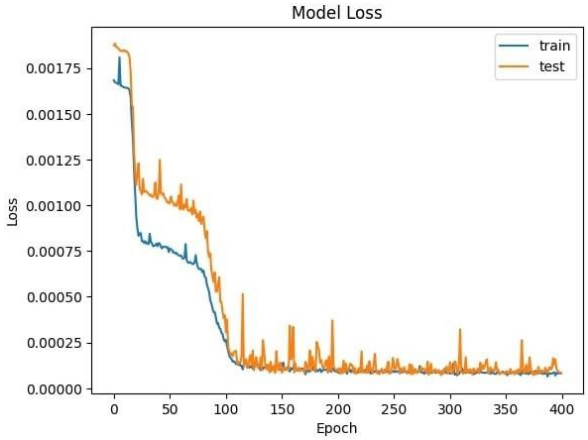
$$\frac{\partial L}{\partial W_f}, \frac{\partial L}{\partial W_i}, \frac{\partial L}{\partial W_C}, \frac{\partial L}{\partial W_o}$$
$$\frac{\partial L}{\partial b_f}, \frac{\partial L}{\partial b_i}, \frac{\partial L}{\partial b_C}, \frac{\partial L}{\partial b_o}$$

3. **Update the weights and biases using gradient descent or any optimization algorithm:**

$$W_f \leftarrow W_f - \eta \frac{\partial L}{\partial W_f}$$

$$b_f \leftarrow b_f - \eta \frac{\partial L}{\partial b_f}$$

Similarly update $W_i, W_C, W_o, b_i, b_C, b_o$.



Repeat

Repeat the forward and backward passes for the number of epochs or until the loss converges.

Summary

1. Initialize weights and biases.
2. For each time step in the sequence, perform the forward pass to compute the forget, input, candidate cell state, cell state, output, and hidden state.
3. Perform the backward pass to compute gradients.
4. Update the weights and biases.
5. Repeat until the model is trained.

ABSTRACT

Taxonomic studies of rare, endangered and threatened plant species of the Pachamalai hills are most important activities from a conservation of plant species. This study is necessary to know the economic and medicinal value of the species in these regions. Ethno floral survey of RET species is an excellent research method to collect information on the uses of plants. This survey deals with rare, endangered and threatened plant species were used by tribal people in Pachamalai Hills. In a periodic survey, about 13 species of plants belongs to different families have been found to RET category. From this survey it is necessary to conserve and protect rare, endangered and threatened plants species in the Pachamalai Hills.

Key words: Ethno floral Diversity, Endangered, Threatened, Traditional medicine and Pachamalai hills.

INTRODUCTION

The Eastern Ghats is a long mountain range covering the three states of India such as Orissa, Andhra Pradesh and Tamil Nadu. It is also reported to be a haven for highly valuable medicinal plants along with commercially important plants. The Pachamalai Hills are surrounded by vast forests regions on the northwestern border of Tiruchirappalli district of Tamil Nadu. The height of the hills ranges from 567m. upto 1000m. The present study were completed and covered ¼ areas of hills in Tiruchirappalli district. A total of 319 plant species were noticed and identified during this survey for four seasons in the duration of a year from 2021 to 2023. WHO estimates that more than 80% of the world's population relies on traditional medicine to various ailments of human (Akerete, 1992). It is found that most of the recorded plants are angiosperms. Among them many plants were found to be directly used by local people, not only common plants but also some threatened and endangered species of medicinal plants are heavily used by

them. The present study was undertaken to investigate the distribution of rare, endemic, endangered and threatened (RET) plant species in the Pachamalaihills of Eastern Ghats, Tamil Nadu, India.

MATERIALS AND METHODS

The present study was undertaken in six areas of Pachamalai Hills, where the Malayali people live in large numbers. The plant survey was carried out in Tenparanadu, Vayanadu, Kombi, Thalangai, Sobanapuram, Top sengattupatti and Sukkalampatti revenue regions. The Pachaimalai Hills, also known as the Pachais due to presence of evergreen forest. They are a low mountain range in the Eastern Ghats System. They are located in Tamil Nadu state, south eastern India. It is situated at a distance of 73 km from Trichy and 112 km from Salem. These hills are rich in dense evergreen forest. The hills located between latitude 11°09′00″ and 11° 27′00″ North, longitude 78°28′00 and 78°49′00 East. The total forest area is 13,500 sq km. The main junctions are sembulichampatty, Manalodai, Chinnalluppur, Ramanathapuram, Top Sengattupatti, and Sembur. In this study is mainly focused to highlights plant diversity and its conservation strategy to assess the Rare, Endangered, Threatened (RET) and Endemic categories of plant species of Pachamalai hills. The climate of this region is high temperature and low degree of humidity. The weather is usually sultry from April to June. However, cool winds begin to blow on the outbreak of south-west monsoon.

The field study and surveyed the RET species was done by a team of three members in between 2021 to 2023. On the basis of field visit and collected data are sort listed. Plant species were identified systematically, pressed, and stored in the Herbarium. The identification of species were confirmed with BSI, (Botanical Survey of India), Coimbatore, RH (Rapinet Herbarium) St. Joseph's College, Trichirappalli and MH (Madras Herbarium). Threatened status of plants was confirmed using IUCN Red List and some relevant literature. Moreover the information was gathered from the local people of various ethnic groups who lived in the hills. The dry evergreen type of forest is mostly at the top of the hills and trees here are small in size. Thick undergrowth of shrubs, herbs and climbers also found in the middle regions of the hills. Many species of climbers exists at the foot of the hills.

RESULTS AND DISCUSSION

The vegetation of the pachamalai hills consists of *Capparis zeylanica, Cipades sabaccifera, Clematis gouriana, Cylista scariosa, Dendrocalamus strictus, Jasminum rigidatum, Lantana camara, Terminalia bellarica, Piper sarmentosum, Cammenila bengalensis, Solanum metilitoides, Clerodendron inermie, Cardiospermum helicacababum, passiflora foetida, Salvadora persica, Gymnema sylvestris, Syzigium jambolanum, Ficus benghalensis, Murraya koenigii, Murraya paniculata, Euphorbia hirta, Todalia asiatica, Comphrena decumbese, Anacardium occidentale, Hugonia mystax, Bulbophyllum sp.*, etc.,

In this study a total of 73 families represented by 226 genera, 319 species. The following are the families of angiosperms with largest number of species, ie. Leguminosae 29, Gramineae 28, Euphorbiaceae 23, Acanthaceae 13, Cyperaceae 28, Verbinoaceae 11 and Compositae 10. The given table shows the RET species of Pachamalai Hills. The table contains with six families ie., Capparidaceae with 4 species, Loganiaceae with 4 species, Asclepiadaceae 2 species, Vitaceae, Fabaceae and Smilaceae have each one species respectively among the RET species found in Pachamalai Hills.

CONCLUSION

This current investigation reveals a model for detecting interactions between plants and people. Information collected from local traditional people will be useful for further researchers in the field of Ethno floral diversity and RET plant species in Pachamalai Hills. And also indicates that there is a great diversity of flora with rich medicinal properties. Most of the species posses therapeutic characteristics in stem, roots, bark, flower, fruit, leaves, etc. We

conclude that pachamalai hills is one of the vast reservoirs of floral diversity and play a crucial role in the human well-being. Proper conservation and management programs are needed to protect threatened and rare species of plants before lose their medicinal properties and medicinal plant resources permanently.

ABSTRACT

Consumer satisfaction hinges on a product's perceptual performance in delivering value to the expectations of the buyer. The customer who knows what to expect is happy when the product works inadequately. When a buyer gets what he expects, when a customer is satisfied with a product, is he going to buy it again and refer others? The magic is in connecting what a customer expects with what a business is able to do. Quality is inter-linked with customer satisfaction. Quality has a direct influence on product performance, and thus on customer satisfaction. India is the largest producer of milk products in the world. India has developed its dairy industry over a period of time. India's consumption of milk-based products has exploded - both in villages and in cities. Still, more and more people are coming to the cities from the countryside. India's state of Tamil Nadu is one of the biggest regions for milk production, leading to a demand for dairy products. Tamil Nadu: Aavin, a milk producers union, is one of the major milk contributors in the state. It acquires, processes and markets the company's milk and milk products to customers. The present research discusses the perceptions of consumers towards Aavin in the Chennai District.

Keywords: Buyer Expectation, Consumer Happiness, Dairy Products, Milk Contributors, Quality.

INTRODUCTION

The world's largest producer of milk is India. The first Cooperative Act was introduced in India in 1904, sowing the seeds of participation. Since then, cooperative development has advanced quickly in every area of financial operations. Due to the White turmoil, the dairy companies face fierce competition to increase their market share in India. Ranchers welcome the dairy industry to increase their income, and it has been a source of jobs for the rural populace. A significant portion of the rural economy in India is made up of the dairy industry, which also contributes significantly to the nation's socioeconomic development. The dairy sector ensures that individuals in both urban and

rural areas can access high-quality milk and milk products, supporting millions of households in rural villages. The industry has been expanding quickly to meet the nation's rising demand for milk and milk products. India is the biggest producer and consumer of dairy products worldwide. The milk that was generated. About 46% of milk is consumed domestically, while 34% is traded in the unorganized market. Companies monitor customer satisfaction to determine how to grow their clientele, revenue, profitability, market share, and survival. Exemplary firms prioritize the consumer and their experience with the company, even when increased profit is the primary motivator. They strive to satisfy their clients because they believe this is essential to the dairy industry's survival and financial success. The quality and impact of customers' experiences and products with the dairy ultimately determine how satisfied they are.

REVIEW OF LITERATURE

Natalie (2019), investigated the impact of the marketing mix on consumers' purchasing choices for one or more dairy farmers in Port Elizabeth, South Africa. Personal interviews conducted in several supermarket aisles learn how people use milk, what they think of it and what brand they buy. Milk consumers were found to be quite price sensitive in this study. There was hardly any brand loyalty among participants. Although the majority of respondents reported using milk to colour tea and/or coffee, they conceded that they knew about health gains of its consumption. The findings suggest people have an unhealthy view of milk. Some people find it juvenile, others feel it makes you fat. Small bloom numbers indicate that not much work has occurred.

In their study, Klaus et al. (2020) argue that there are four key attributes that describe consumers' quality perception with regard to dairy products: hedonic, health, convenience, and process quality. Two such credence dimensions, or aspects of consumer trust in the communication presented, were the quality dimensions of health and process. Three issues related to the transmission of credence attributes of quality are discussed in relation to five independent empirical studies on consumer perceptions of quality of dairy products: provision of accurate information, the role of customer attitudes, and cognitive processes associated with perceived quality. The above is applied in the form of gene manipulated products, functionlized products or natural products. the impact of dairy cooperative on rural economy in Nalanda District have been studied by Ranjit Kumar and A. K. Sharma (2018). Household socio-economics and the influence of dairy cooperatives were explored in this case study. Key economic factors such as investment preference, animal productivity, milk output, market surplus, and gross dairy revenue were analyzed to measure the effects.

Ramesh L., Poornima S. (2016), in their research on the consumer preference of Aavin Milk and Milk Products, sought to ascertain the consumer average expenditure on milk and dairy products, consumer preference towards Aavin milk and milk products and the determinants affecting the purchase in the study area. The non-probability based convenience sampling was used. Data were analysed by Chi-square, percentages, etc. Irrespective of their level of education they suggest that consumers need to be more informed concerning milk and milk products. The marketing of milk producers has to be strong, because it creates waves among the consumers about that brand, increases the sales and also the opinion about Aavin milk and milk products.

Statement of the Problem

Milk and milk products are essential for optimum health from newborns to older people. The residents of Erode District and other regions of Tamil Nadu are supplied with milk and milk products by Chennai District.Since we understand that customer satisfaction is crucial to our business, we go above and beyond to ensure that our products fulfill and also surpass your expectations. We offer everything you need, whether you're searching for healthful and tasty yogurt for your snacks or fresh and creamy milk for your morning tea. Our goal at Aavin is to give you the best shopping experience because we consider our clients our most significant assets.

Objectives of the Problem

- To determine the degree of client satisfaction with the Aavin diary product's quality.
- To identify the research consumer perceptions of the Aavin brand compared to its rivals.
- To assess the primary determinants of respondents' decision to purchase Aavin milk and gauge their level of satisfaction with Aavin milk consumption in Chennai District

Scope of the Study

We initiated this project to understand consumer satisfaction with Aavin, which is located in Shollinganallur. We have gathered a wealth of information, including taste preferences, quantity, and quality. Additionally, our project aims to investigate consumer behavior and milk quality. Currently in India, over 12,585 milk cooperative societies are spread across 308 districts, experiencing a sector growth rate of 20.30% per annum. The dairy development sector in India is undergoing highly successful development programs, with an abundant supply of milk that needs to be utilized more effectively. The dairy development sector contributes significantly to employment opportunities in the country, despite facing challenges such as inadequate processing, substantial losses in dairy production, and significant financial losses due to cattle mortality. Milk and its products hold promising opportunities in both the domestic and international markets.

RESEARCH METHODOLOGY

Design of Research

In order to facilitate this study, a descriptive research design has been used.

The why questions cannot be answered by a descriptive study. Still, it can be useful in addressing the who, what, when, where and how questions around a particular research topic. Descriptive research serves to portray "what exists" about the variable(s) or conditions in the situation and, by doing so, provides preliminary information about the phenomenon.

Data Source

This study primarily uses two data sources, which are

Primary and secondary sources of information

primary gathering of data:

A questionnaire based on consumer behavior elements regarding AAVIN dairy products was used to gather primary data from 150 respondents from various areas of Chennai.

Size of the Sample

One hundred fifty samples were used in this investigation.

Sampling Methods

A convenience sampling technique was employed in this study.

Data Analysis and Interpretation

Percentage distribution of respondents in each age group Table 1 shows that out of the total respondents, 37 per cent were between 31-40 years in age group and 33 per cent were above the age of 21-30 years. Twenty percent of the respondents were under age 20. And the remaining 15 percent were who were under 20 years of age.

It is deduced that majority of the respondents of about 37 per cent fall in the age category of 31-40 years.

It is learnt from Table 2 that 58 per cent of the respondents are married. The remaining 42 per cent of the respondents are unmarried. It is concluded that the majority of the respondents are married.

The aforementioned table indicates no significant correlation between the respondent's marital status and their level of satisfaction with the Aavin products mix, except for the dimension marked as Significant (S). The null hypothesis is accepted because the significance level for the overall score is greater than 0.05. Therefore, it can be concluded that the respondent's level of satisfaction with the Aavin products mix is unaffected by their income.

FINDINGS

- The majority of those surveyed were between the ages of 31 and 40.
- The majority of those surveyed were married.
- The majority of those surveyed fell into the three to five-member group. Non-vegetarians made up about three-fourths of the respondents.
- It turns out that most respondents would rather purchase the buttermilk that Aavin goods offer.
- Age has been found to have no discernible impact on the rationale for preference. Therefore, socioeconomic status influences why people purchase Aavin products.
- The majority of respondents had been purchasing Aavin items for more than six years, according to the data.
- The respondent's degree of satisfaction with the quality of Aavin products is not influenced by gender. The respondent's age affects their satisfaction with the quality of Aavin items.
- Their educational age influences the respondent's satisfaction with Aavin products.
- The respondent's degree of satisfaction with the pricing of the Aavin product is influenced by their income.
- The respondent's degree of satisfaction with promoting Aavin products is unaffected by educational background.

SUGGESTIONS

- The Tamil Nadu government should set the regular milk price. Price fluctuations may have an impact on the buyer's motivation.
- Maintaining vendor locations properly can draw more clients to Aavin.
- The government should set the price of essential dairy products after considering the consumer's purchasing power.
- Aavin can prefer better packaging ideasto extend the shelf life of dairy products.

CONCLUSION

They undoubtedly know what they need and desire, so they gather information about products and consider their flavour, quality, and other attributes. Customers tend to switch to other brands if they are not satisfied. In any case, the data indicates that consumers buy Aavin milk because of its flavour and quality. It must be a reminder that consumers of milk prioritize flavour over price. Many respondents believe that Aavin products are far more expensive than other brands. The majority of rural residents do not have access to AAVIN dairy products. For them to be ignorant about Aavin dairy products. Increase Aavin Dairy's accessibility in rural areas. With this in mind, additional booths and dairy products should be added in rural areas.

ABSTRACT

Chronic Obstructive Pulmonary Disease (COPD) is a progressive respiratory condition with airflow limitation and comorbid psychological conditions like anxiety and depression. Non-pharmacological interventions such as breathing techniques have been found to be effective in controlling these symptoms. To compare the impact of the 4-7-8 breathing technique and the 3-step rhythmic breathing (3SRB) technique on dyspnea, anxiety, and depression in patients with moderate COPD. A randomized controlled trial was employed using 45 patients diagnosed with moderate COPD (GOLD Grade 2). Patients were randomly divided into three groups: Group A received conventional treatment along with the 4-7-8 breathing technique, Group B received conventional treatment along with the 3SRB technique, and Group C received conventional treatment alone. Interventions were delivered over a period of one week, with pre- and post-intervention assessment using the Modified Medical Research Council (mMRC) Dyspnea Scale and the Depression Anxiety Stress Scale-21 (DASS-21). Both breathing exercises resulted in improvements in dyspnea, anxiety, and depression scores. The 3SRB group, however, had statistically significant improvements on all measures ($p < 0.05$), while the 4-7-8 group had improvements that were not statistically significant ($p > 0.05$). The 3-step rhythmic breathing method seems more beneficial than

the 4- 7-8 breathing technique to alleviate dyspnea, anxiety, and depression among patients with moderate COPD. Integrating 3SRB in pulmonary rehabilitation protocols can maximize patient outcomes.

Keywords: COPD, 4-7-8 Breathing, 3-Step Rhythmic Breathing, Dyspnea, Anxiety, Depression, Non-Pharmacological Interventions.

INTRODUCTION

Chronic Obstructive Pulmonary Disease (COPD) is a major global cause of morbidity and mortality, with a hallmark of persistent respiratory symptoms and airflow limitation. In addition to the physical limitations, patients with COPD are often burdened by psychological difficulties, particularly anxiety and depression, which may contribute to the progression of the disease and limit proper management. Standard therapy mainly consists of pharmacologic treatment; yet, increasing interest has been devoted to complementary non-pharmacological approaches to both physical and psychological symptoms. Breathing exercises, including the 4-7-8 breathing technique and the 3-step rhythmic breathing (3SRB) technique, have been suggested as possible interventions to reduce dyspnea and enhance psychological health. The 4-7-8 breathing technique, created by Dr. Andrew Weil, consists of breathing in for four seconds, holding the breath for seven seconds, and breathing out for eight seconds. This technique is based on pranayama, a yogic respiratory exercise, and aims to stimulate the parasympathetic nervous system with a calming effect and a decrease in anxiety. Research has demonstrated its efficacy in the reduction of stress and better sleep. The 3-step rhythmic breathing method, however, focuses on coordinated breathing patterns to improve respiratory effectiveness and mental focus. Although less widely researched, rhythmic breathing exercises have been linked with better respiratory function and decreased psychological distress in different groups. Considering the probable advantages of these methods, this research intends to evaluate the efficacy of the 4-7-8 breathing method and the 3SRB method in the diminution of dyspnea, anxiety, and depression in patients with moderate COPD.

METHODS

Study Design

This study employed a randomized controlled trial (RCT) with a pre-test and post-test design to investigate the comparative effectiveness of the 4-7-8 breathing technique versus the 3-Step Rhythmic Breathing (3SRB) technique in patients with moderate Chronic Obstructive Pulmonary Disease (COPD). The study aimed to assess the impact of these breathing interventions on dyspnea, anxiety, and depression levels over a short-term intervention period. After taking a Ethical consideration from a Institutional ethical committee a total of 45 COPD patients with moderate COPD (Global Initiative for Chronic Obstructive Lung Disease – GOLD Grade 2) were recruited from Sola Civil Hospital, Ahmedabad. The recruitment of participants was conducted using the following inclusion criteria

- 45 to 65 years of age
- Male and female patients
- No history of recent exacerbation with clinically stable condition
- Resting respiratory rate of 10–24 breaths per minute
- Willingness to participate and sign informed consent

Patients were excluded if any of the exclusion criteria were present

- Cardiovascular disorders (e.g., heart failure, arrhythmias)
- Neurological conditions (e.g., Parkinson's disease, stroke)
- Spinal deformities (e.g., scoliosis, kyphosis) that have an impact on respiratory mechanics
- Respiratory muscle dysfunction
- Carcinoma or end-stage illnesses

- Subsidiary abuse or active addiction Some other condition that may cause interference with study participation or with safety

Randomization and Group Allocation

Following baseline measurements, participants were randomly assigned via a computer-generated randomization sequence into three equal groups (n = 15 each)

Group A: Underwent Conventional Therapy with the addition of the 4-7-8 Breathing Technique

Group B: Underwent Conventional Therapy with the addition of the 3-Step Rhythmic Breathing (3SRB) Technique

Group C (Control Group): Underwent Conventional Therapy alone

Intervention Protocol

All of the interventions were delivered within a single week and involved supervised sessions conducted twice daily (morning and evening). Two sets of ten repetitions each of the provided breathing technique constituted each session.

Traditional Therapy (All Groups)

Standard physiotherapy treatment for all groups comprised

Postural drainage: Positional maneuvers to achieve mucus removal from various parts of the lung

Chest physiotherapy (Chest PT): Including vibration and manual percussion to assist with secretion mobilization

4-7-8 Breathing Technique (Group A)

This technique entailed

•4-second inhalation through the nose

•7-second breath-holding

•Slow, 8-second exhalation through the mouth

This was repeated ten times a session to create a relaxation response, enhance respiratory efficiency, and promote parasympathetic activity.

3-Step Rhythmic Breathing (3SRB) Technique (Group B)

The 3SRB approach was based on developing a rhythmic and synchronized breathing pattern through

Phase I: Inhalation (slow, deep nose breath)

Phase II: Short breath-holding

Phase III: Managed exhalation

The method encourages respiratory perception and stabilization of breathing rhythm, which may extend to pulmonary functioning and mental states.

Outcome measure

Pre- and post-intervention were measured with the following established validated outcome measures

1. Modified Medical Research Council (mMRC) Dyspnea Scale

Measure of breathlessness during activities as a daily burden

Scores vary from 0 (no breathlessness) to 4 (severe breathlessness)

2. Depression Anxiety Stress Scale-21 (DASS-21)

Self-report scale measuring depression, anxiety, and stress

21 items comprising three subscales with 7 items each

Each statement rated from 0 (did not apply to me at all) to 3 (applied to me very much)

A higher score reflects more emotional distress.

Statistical Analysis

Data were computed with paired and independent t-tests to examine the difference between post- and pre-intervention within and between the groups. For a p-value < 0.05 to be statistically significant.

RESULT

Effect of Breathing Techniques on Dyspnea and Mental Health in COPD Patients. This report presents a statistical comparison of three interventions: 4-7-8 Breathing, 3-Step Rhythmic Breathing, and Conventional Therapy on Dyspnea (mmRC scale) and Anxiety and Depression (DASS-21 scale) in moderate COPD patients.

Graphical Comparison (Fig.no:1)
The following graph illustrates the pre- and post-treatment changes observed in Dyspnea and Anxiety/Depression scores across all groups. Dyspnea (using the modified Medical Research Council [mMRC] Dyspnea Scale)

Group A (4-7-8 Breathing Technique)
Members of this group demonstrated a decrease in dyspnea scores following the intervention, reflecting an improvement in their clinical perception of breathlessness. The decrease, however, was not statistically significant ($p > 0.05$). This implies that although there could have been some subjective alleviation felt by patients, the improvement was not uniform or large enough across participants to confidently attribute it to the intervention and not to chance or other reasons.

Group B (3-Step Rhythmic Breathing Technique)
This group showed a statistically significant decrease in dyspnea scores ($p < 0.05$). This shows a consistent and reliable improvement in breathlessness symptoms among patients who used the 3-step rhythmic breathing technique. The significant change indicates that this breathing technique is more effective in alleviating the feeling of breathlessness in patients with moderate COPD than the 4-7-8 technique or no intervention.

Group C (Control Group – No Breathing Intervention)
No relevant changes were detected in dyspnea scores for this group. This finding supports that the change detected in Groups A and B is most likely due to breathing interventions and not due to natural disease progression or extrinsic effects. Anxiety and Depression (measured via the Depression Anxiety Stress Scales-21 [DASS- 21]).

Group A (4-7-8 Breathing Technique)
Participants showed decreases in both depression and anxiety scores, suggesting a pattern toward psychological improvement. These improvements were not, however, statistically significant ($p > 0.05$), suggesting that although some patients might have been helped by the technique, the findings were too variable to make a strong inference. The 4-7-8 breathing technique can likely continue to provide individual psychological relief but was limited in overall effect in this sample.

Group B (3-Step Rhythmic Breathing Technique)
This group had statistically significant decreases in both depression and anxiety scores ($p < 0.05$). These results indicate that the 3-step rhythmic breathing method not only assists with physical complaints such as dyspnea but also has a significant positive effect on mental well-being. The rhythmic quality of this method can potentially induce relaxation, enhance oxygenation, and decrease stress response, thus having a positive effect on both physiological and psychological aspects.

Group C (Control Group)
There were no significant differences in anxiety and depression scores, supporting the fact that in the absence of any intervention, psychological distress levels were unchanged.

CONCLUSION OF THE RESULTS

The 3-step rhythmic breathing technique (Group B) was found to be better in enhancing both dyspnea and mental well-being (anxiety and depression) in moderate COPD patients. The 4-7-8 breathing technique (Group A) was of some benefit, especially in psychological aspects, but the impact was not statistically significant. Group C, the control group, showed no significant alterations, validating the efficacy of the breathing interventions for the other groups.

DISCUSSION

The current research sought to compare the impacts of two breathing methods—4-7-8 breathing and 3-Step Rhythmic Breathing (3SRB)—on dyspnea, anxiety, and depression among patients with moderate Chronic Obstructive Pulmonary Disease (COPD). The results proved that both interventions resulted in improvement on all three parameters but the 3-step rhythmic breathing method had a statistically significant lead over the 4-7-8 method in alleviating dyspnea, anxiety, and depression symptoms. The 3SRB method, with a specific order of inhalation, retention, and exhalation, seems to facilitate increased respiratory efficiency, culminating in improved carbon dioxide-oxygen exchange. The rhythmic, meditative breathing would most likely stimulate the parasympathetic nervous system, resulting in decreased sympathetic arousal, which might account for the significant improvement in both psychological (anxiety, depression) as well as respiratory (dyspnea) symptoms in the intervention group. Conversely, the 4-7-8 breathing method, with its shorter practice duration and less dynamic breathing pattern, although helpful in causing short-term relaxation, failed to elicit statistically significant changes within the study period. This could imply that its effects, although positive, are more subtle or cumulative and perhaps need a longer practice duration to elicit significant physiological and psychological benefits in COPD patients. In addition, the difference in the complexity and engagement of the two techniques may be responsible for the disparate results. The 3SRB technique requires greater participatory engagement, which may cause greater mind-body awareness and respiratory muscle activation, potentially further amplifying its therapeutic effects.

ABSTRACT

Tomato crops (*Solanum lycopersicum*) are vital for global agriculture and food security, but they face significant threats from diseases that can severely impact yields. Existing methods for disease detection, such as manual inspection and traditional deep learning models, often suffer from overfitting, high computational demands, and difficulty in distinguishing between similar symptoms. The article presents a streamlined convolutional neural network (CNN) model designed to tackle these challenges by lowering complexity and enhancing generalization. Unlike more complex models that risk overfitting due to their depth and parameter count, our model, with just three convolutional layers, was trained on 16,667 images of tomato leaves, standardized to 200 × 200 RGB pixels. By employing the Adam optimizer and incorporating dropout layers to mitigate overfitting, our model attained an accuracy of 96.31% g, our model achieved an accuracy of 96.31% with minimal computational overhead. This approach not only enhances the precision and speed of disease diagnosis but also supports sustainable agriculture by enabling early detection, reducing the need for pesticides. Our research advances the development of efficient, scalable solutions for tomato disease management, promoting both productivity and sustainability in agriculture.

Keywords: Image Processing, Convolutional layer(**C**onv2D), MaxPooling2D, Cross-Entropy loss function

INTRODUCTION

India holds the distinction of being the third-largest global producer and exporter of tomatoes, with this vegetable ranking as the country's most popular. Tomatoes are recognized for their significant antioxidant content, including vitamin E, vitamin C, and beta-carotene, along with being a rich source of the essential mineral potassium. The annual production of high-quality tomatoes amounts to 53,00,000 tonnes, covering an extensive agricultural expanse of 3,50,000 hectares [1]. However, the susceptibility of tomato crops to diseases throughout their growth stages, influenced by climatic conditions, presents a considerable challenge. The economic repercussions of tomato leaf diseases are statistically substantial, causing yield losses ranging from 20% to 50%, as reported by the Indian Council of Agricultural Research (ICAR). These losses impact not only the quantity but also the quality of tomatoes, affecting market value and consumer satisfaction. Pathogens annually inflict damage on tomato crops, spreading diseases from leaves to fruits. Timely identification of plant leaf diseases is imperative to ensure adequate nourishment in both quantity and quality of the fruits. Conventional approaches to detecting plant leaf diseases are slow-going, prompting a need for more efficient methodologies. Farmers often resort to chemical interventions such as fungicides and bactericides, incurring increased production costs. This extensive use of agrochemicals poses economic and environmental concerns, particularly affecting the livelihoods of small and marginal farmers dependent on tomato cultivation. A shortage of professional guidance results in farmers resorting to conventional disease prevention methods, leading to over or underuse of pesticides and resulting in crop damage. This motivates the proposed methodology, aiming to effectively recognize and sort diseases affecting tomato crops. A total of 16,665 images depicting tomato leaf diseases, categorized into ten disease types, were taken from the publicly available Plant Village Dataset for this research. To reduce yield losses due to tomato disease which is causing economic burden, robust deep learning models needs to be developed. With that motivation the work has been initiated. Where various researchers are developing more complex models for achieving higher accuracy which is found to suffer the problem overfitting, proposed work is focused on development of a much simpler model with substantial accuracy. The novelty lies in the simple architecture of the model achieving significant accuracy. Also this article is also connected to SDG (Sustainable Development Goal) 12: Eco-friendly consumption and manufacturing practices designed to reduce pesticides and minimized waste. It is helpful for society and environment also. The structure of the article is as follows: related work is discussed in section 2, and the methodology and experiment setup is described in section 3,analyzation of the results is discussed section 4, focusing on the model's performance and interpretability, and finally, Section 5 wraps up the study and outlines possible areas for further research.

LITERATURE SURVEY

Tomato leaf disease detection has witnessed significant advancements through the employing Convolutional Neural Networks (CNNs) in recent research endeavors [5, 6, 8, 11]. Agarwal *et al*. (2020) introduced a customized CNN that demonstrated an impressive accuracy of 98.70%, leveraging a dataset comprising 18,160 images with a resolution of 128x128 pixels [5]. Building on this, Trivedi *et al*. (2021) presented another customized CNN, achieving a commendable accuracy of 98.49%,containing 3000 images at an increased resolution of 256×256 pixels.[6]. The research carried out by Sakkarvarthi *et al*. (2022) utilized a Custom-built CNN, achieving an accuracy of 88.17%, although specific details on batch size and epochs were not provided [8]. In the pursuit of efficient disease detection, Tarek *et al*. (2022) explored the application of MobileNetV3, achieving an outstanding accuracy of 99.81% using a dataset containing 16,004 images of 227 by 227 pixels in resolution[11]. Chen *et al*. (2022) suggested a customed AlexNet architecture, obtaining an accuracy of 98% with a dataset containing 22,930 images at a resolution of 64x64 pixels [9]. Saeed *et al*. (2023) incorporated the Inception V3 model, achieving an accuracy of 99.22% with 5225 images at a resolution of 229x229 pixels [14]. Further diversifying the landscape of CNN models, Ibañez *et al*. (2023) designed a customized CNN with an exceptional accuracy of 99.64%, utilizing with 13,500 images having a resolution of 112×112 pixels[8]. Ulutas *et al*. (2023) explored the ensemble CNN approach, achieving a high accuracy of 99.60% with a collection of data about 18,160 images of 255 by 255 pixels [13]. Sanida *et al*. (2023) introduced a hybrid CNN model, obtaining an accuracy of 99.17% with a collection of data about 18,160 images of 256 by 256 pixels [17].

Additionally, Islam *et al*. (2023) employed DenseNet 121, achieving an accuracy of 99.31% with 18,160 images at a resolution of 64x64 pixels [15]. The integration of novel approaches continued with Alzahrani *et al*. (2023) utilizing Transformer Learning (ViT), achieving an accuracy of 99.64% with a collection of data about 11,000 images of 72x72 pixels [20]. Umar *et al*. (2023) presented an improved YOLOv7 model with an accuracy of 98.80%, although detailed information on resolution, batch size, and epochs was not provided [19]. Attallah *et al*. (2023) applied KNN to achieve an impressive accuracy of 99.92% with a collection of data about 16,011 images of 224 by 224 pixels [14]. Baser *et al*. (2023) proposed a customized architecture of a convolutional model named "TomConv," achieving an accuracy of 98.19% with a collection of data about 16,000 images, 150 by 150 pixels [12].

Parvez *et al*. (2023) designed another customized CNN, achieving an accuracy of 98.39% with 6296 images at a resolution of 256x256 pixels [7]. In parallel, Paul S. G *et al*. (2023) developed a Real-time task-oriented convolutional network, achieving an accuracy of 95% with a collection of data about 32,535 images of 224 by 224 pixels [18]. Our proposed methodology contributes to this evolving landscape, employing a customized CNN with an accuracy of 97% on a dataset of 16,667 images, each with a resolution of 100x100 pixels. Another custom CNN model with an image size of 128x128, trained on 10 disease classes over 300 epochs with 3000 images, achieved a lower accuracy of 88.17% is discussed in Sakkarvarthi *et al*. 2022[8]. This lower performance might be due to differences in model architecture, dataset diversity, or hyperparameters. The article Wajid *et al*. 2024[24] used a custom CNN model for classifying 10 plant disease classes with an image size of 150x150 and a large dataset of 30,000 images, achieving an accuracy of 96%. However, the study highlights a common limitation of CNNs: they require large datasets to achieve high performance, which is often challenging to gather in applied settings. This research employed an improved YOLOv7 and CNN model to classify 7 disease classes, gain a high performance of 98.8% on 8,337 images in the article YILDIZ *et al*. 2024[25]. Despite its effectiveness, the study noted a limitation in existing algorithms' ability to handle images with multiple diseases, which poses a challenge for accurate multi-disease identification in complex real-world scenarios. Irmak *et al*. 2024[26] presented a custom CNN model which was used to classify 10 disease classes on a dataset of 14,828 images, achieving 97% accuracy. However, the model showed limitations in detecting a wide variety of plant species and diseases and severity of diseases indicating a need for further refinement to improve the model's performance. While many studies showcase impressive accuracy, variations in image resolution, dataset sizes, and model architectures make direct comparisons challenging. Additionally, some methodologies lack robustness when applied to diverse datasets, raising questions about their generalizability. Further investigations are warranted to address these limitations and enhance the reliability and applicability of CNN-based approaches in real-world tomato crop scenarios.

INTRODUCED METHODOLOGY

Figure 1 presents a schematic overview of our proposed system design. The intended system configuration has three stages: dataset preparation, model creation, and performance measurement. Throughout the development phase, data was acquired, refined, and utilized for training different models. Finally, to predict leaf disease in tomatoes, a special convolutional neural network model has been created. At the end, different types of measurements are done on our model to evaluate the performance.

Dataset

The "tomato disease multiple sources" dataset has been used for carrying out the experiments, consisting of visual data of tomato leaf diseases e. In this dataset, the images were taken in both lab and natural environments. Besides that, this image dataset was compiled using different sources.

Data Set Preparation

In the pre-processing step of the method, every image is scaled to 200 by 200 pixels and cropped to eliminate any undesirable backgrounds. Following pre-processing, the dataset is divided into two parts: 80% of the collected dataset is used for training purposes, and left is used for testing purposes.

Training and Testing

80% of the data is utilized for model training or fine-tuning, while 20% is set aside for evaluation. And also, 10% of the dataset is used for validation. For the suggested architecture, training was carried out over 100, 200, 300,400, 500 epochs using the Adaptive Moment Estimation (ADAM) Equation optimization function, and a base learning rate of 0.0001 was applied at the start.

Introduced CNN Model

The architecture of the proposed CNN incorporates both Convolutional layer and MaxPooling2D layers, ReLU for the activation function, a SoftMax layer for multiclass classification problems, fully connected layers, and the Adam optimizer. Convolutional layers make use of 3x3 kernels, subsequently followed by max pooling with a 2x2 operation. ReLU introduces non-linearity in the activation function, while SoftMax scales outputs into probabilities. In the fully connected layers, connections are made to each neuron from preceding and following layers. With the Adam optimizer, the learning rate is adapted for each weight as training progresses. It uses the Sparse categorical cross-entropy as the loss function, which is effective when performing classification with sparsely represented labels. These are discussed in detail below.

Explanations of each element of the Proposed CNN Architecture

a. Input (Dataset): The input consists of leaf images, which serve as the dataset utilized for both learning and assessment phases.
b. A Convolutional layer featuring32 filters and a 3x3 kernel size has been added as First Convolutional Layer. MaxPooling with a 2×2 window is applied afterward to compress spatial information. To mitigate overfitting, a dropout rate of 0.5 is introduced, randomly disabling 50% of the inputs during training.
c. A Convolutional layer containing 64 filters and a 3x3 kernel size has been added as Second Convolutional Layer, followed bya pooling layer configured with a 2×2 window size. Another Dropout layer has been added with a rate of 0.5.
d. A Convolutional layer containing 128 filters and a 3x3 kernel size has been added as Third Convolutional Layer, followed by a pooling layer configured with a 2×2 window size and a dropout rate of 0.5 is introduced, which randomly disables 50% of the inputs during training.
e. A Flatten layer has been inserted to compress the feature maps into a one-dimensional vector for the subsequent dense layers.
f. Three layers of dense neurons with 128,64 and 32 neurons respectively added having ReLU activation function for first two dense layers and Softmax activation function for third dense layers for providing the final probability distribution across classes.
g. The network's final output consists of classifications across several leaf disease categories

Convolution Layer

The first building block of neural network is Convolution layer. A convolutional layer contains a kernel, or filters, which are several feature detectors that are dragged across the entire image by the stride to identify the existence of a certain feature. In the proposed architecture there are four convolutional layers. The first block consists of two convolutional layers having 32 kernels each of size 3x3. The second block consists of one convolutional layer having 64 kernels of size 3x3 and last block consists of one convolutional layer having 128 kernels of size 3x3.

Max Pooling Layer

The pooling layer primarily serves to reduce the size of the output from the convolutional layer , thereby reducing the computational cost of the following layer. Max pooling is the most commonly used approach, where only the highest value in each kernel is retained after dividing the image into rectangular sub-regions defined by the kernel. In the suggested architecture, a 2x2 max pooling operation is applied after each convolutional block.

Activation Functions Used

The activation function enables or disables certain parts of a neuron's output based on a mathematical function. In the proposed model, each convolutional layer is followed by a RELU activation mechanism. The network gains non-

linearity from this activation function. The previous layer's generated output can be altered or removed by using non-linearity. This serves to restrict the amount of output generated. The suggestiveConv2D uses the Rectified Linear Unit (RELU) activation mechanism serves the following purposes:

$$g(z) = \max(0, z) \quad (1)$$

$$\frac{d}{dx} g(z) = \begin{cases} 1, & if z > 0 \\ 0, & otherwise \end{cases} \quad (2)$$

a. As seen in (1) and (2), simplicity in both function and derivative.
b. Decreased probability of a vanishing gradient.
c. A sparser representation is generated by ReLU. This occurs as a result of the gradient's zero producing a complete zero. [23]

In this article, due to the multiclass nature of disease detection, the output layer employs a softmax activation function. The network gains to scale numbers into probabilities from the SoftMax function. A vector (v) with the probabilities of every potential result is what a Softmax produces. For every potential outcome or class, the probabilities in vector v add up to one.

Densely Connected Layer

The structure of neurons in the fully-connected layer resembles that of conventional neural networks, with all neurons in this layer establishing direct connections with those in the preceding and succeeding layers. One significant disadvantage of the fully connected layer is that it involves a vast number of parameters, making the training process resource-intensive. Three dense layers using ReLU activation are implemented in the proposed model, with the final layer utilizing SoftMax for output classification.

Adam Optimizer

Moreover, the Adam optimizer is employed to minimize prediction errors and optimize node weights. Adam, short for Adaptive Moment Estimation, differs from SGD by adjusting the learning rate individually for each network weight instead of using a single learning rate for the entire training process. Due to its many benefits, deep learning projects might benefit greatly from using the Adam optimizer as their default optimization method. It is also a helpful benchmark. This optimization algorithm requires less tuning, utilizes less memory, and executes faster than previous algorithms. The RMSP algorithm and gradient descent with momentum are combined to create the Adam optimizer. Adam creates a better optimized gradient descent by combining the qualities of the two optimizers.

$$\omega_t = \omega(t-1) - \alpha * \left(\frac{\widehat{m_t}}{\sqrt{(\widehat{v_t})}+e}\right) \quad (3)$$

Here, Adam's optimizer formula is shown in Eq. (4). The aggregate of gradients at time t is represented by $\widehat{m_t}$ in the equations above. Conversely, $v_t$stands for the characteristic of algorithms that use Root Mean Square Propagation (RMSP). When mt and vt are first set to 0, they are typically more biased [22]. As a result, the biased problem was resolved by the Adam optimizer by computing the bias-corrected m̂t and v̂t. Ultimately, new weight ωtare computed by integrating the formula.

Error Function

The article employs the Sparse Categorical Cross-Entropy loss function. Sparse Categorical Cross-Entropy is a loss function utilized in machine learning for classification tasks, measuring the cross-entropy between predicted probabilities and true class labels, especially effective for scenarios with sparse labels. Equation (5) outlines the Sparse Categorical Cross-Entropy Loss function.

$$\text{Sparse Categorical Cross-Entropy} = -\frac{1}{N}\sum_{i=1}^{N}\sum_{c=1}^{c} y_{i,c} \cdot \log(\widehat{y_{i,c}}) \quad (4)$$

Here, N represents the number of samples, c is the number of classes,$y_{i,c}$is a binary indicator showing whether class c is the correct classification for sample i, $\widehat{y_{i,c}}$ is the predicted probability of sample i belonging to class c.

Experimental Setup

The experiment was conducted in Google Colab with default configuration of Intel(R) Xeon(R) CPU @ 2.20GHz with 2 vCPUs (virtual CPUs) and 13GB of RAM. NVIDIA Tesla K80 with 12GB of VRAM.

Evaluation Matrices

Evaluation metrics are used to determine how effective the statistical, machine learning, or deep learning model is. The suggested model in a study must be assessed using a range of assessment indicators. Evaluation metrics are essential to guaranteeing the performance of models. The equations of these metrics were calculated using Equations (5)– (12)

$$\text{Accuracy} = (\text{TP} + \text{TN})/\ (\text{TP} + \text{FP} + \text{TN} + \text{FN}) \quad (5)$$

$$\text{Precision} = \text{TP}\ /(\text{TP} + \text{FP}) \quad (6)$$

$$\text{Recall} = \text{TP}/(\text{TP} + \text{FN}) \quad (7)$$

$$\text{F1} - \text{Score} = 2\text{PR}/(\text{P} + \text{R}) \quad (8)$$

$$\text{Sensitivity} = \text{TP}/(\text{TP} + \text{FP}) \quad (9)$$

$$\text{Specificity} = \text{TN}/(\text{FP} + \text{TN}) \quad (10)$$

$$\text{Matthews Correlation Coefficient(MCC)} = (\text{TPxTN}) - (\text{FPxFN})/\ (\sqrt{(\text{TP} + \text{FP})}\ \text{x}\ \sqrt{(\text{TP} + \text{FN})}\ \text{x}\ \sqrt{(\text{TN} + \text{FP})}\ \text{x}\ \sqrt{(\text{TN} + \text{FN})}\ ) \quad (11)$$

$$\text{Negative Predictive value} = (\text{TN})/(\text{TN} + \text{FN}) \quad (12)$$

RESULTS AND DISCUSSIONS

Results of hyper parameter optimization

The hyper parameters optimized manually shown the following values of hyper parameters produces best possible performance of the model.

Training and Validation Accuracy and Loss graph with respect to Epochs

The overall accuracy and loss of model trained with various number of epochs has been shown here. From the table 2 we got, the training process started at epoch 100 with a relatively high accuracy of 0. 9463. The accuracy continued to improve, reaching 0.9544 at epoch 200 and remaining relatively stable. At epoch 400, there was a further increase in accuracy to 0. 9628. The final epoch, 500, showed a slight improvement, reaching an accuracy of 0. 9631. This set of data suggests a consistent and successful training process with increasing accuracy. Whereas training process started at epoch 100 with a loss of 0. 2286. Over the next few epochs, there was a consistent decrease in loss, indicating that the model was improving. The loss decreased to 0.188 at epoch 200.Althoughthere was a slight increase in loss to 0.2081 at epoch 300, it was still lower than the initial loss. The lowest loss was achieved at epoch 400, with a value of 0. 1692. At the final epoch, 500, there was a slight increase in loss to 0.1752, but it remained relatively low. We may conclude that, the decreasing trend in loss values suggests that the training process was effective in reducing the error of the model. Lower loss values typically indicate that the predictions made by the model were progressively approaching the true target values.. The slight increase in loss towards the end of training (epochs 300 to 500) may indicate some fluctuations, but the overall trend is positive.

Analysis by Standard Deviation

The difference between training accuracy and validation accuracy is first obtained after every epoch, then a standard deviation of the all differences obtained after each epoch has been calculated using the following formula. Standard deviation of differences of training accuracy and validation accuracy obtained for each epoch has been obtained.

$$sd = \sqrt{\frac{1}{N-1}\sum_{i=0}^{n}(Training_Acc_i - Val_Acc_i)} \quad (13)$$

From the above Table No 3, we see that, at epoch 100, the training process began with an accuracy of 0.034425. As training progressed, accuracy greatly increased and by epoch 200, it had decreased to 0. 019461.As the training went on, accuracy increased even further, peaking at 0.016113 at epoch 300.However, the precision increased somewhat to 0.018971 at epoch 400.Accuracy dropped somewhat to 0.01804 for the 500th and final epoch. Hence the model trained with 300 epochs has been considered for further analysis. A confusion matrix was derived for the proposed model following 500 epochs of training.

Performance Assessment of Model

The performance indicator for evaluating of different disease are shown in tabular structure below in Table 3. The class-wise performance metrics showcase the proposed model's proficiency in accurately classifying different disease classes, with accuracy percentages ranging from 99% to 100% across various categories. Notably, diseases like Bacterial spot, **E**arly Blight, **L**ate Blight, and **S**pider Mites secures perfect accuracy scores of 100%, demonstrating the model's remarkable capability to accurately detect cases of these diseases. For other classes such as leaf mold, mosaic virus, and target spot, the model achieves accuracy percentages of 99%, demonstrating its high reliability in disease detection. However, the classification of healthy plant samples exhibits a slightly lower accuracy percentage of 99%, suggesting some challenges in distinguishing healthy instances from diseased ones. Despite this, the model maintains high precision, sensitivity, specificity, F1-score, negative predictive value (NPV), and Matthews correlation coefficient (MCC) percentages above 90% for most disease classes, underscoring its overall effectiveness and reliability in plant disease diagnosis.

A comparison between the proposed model and pre-trained models.

The comparative analysis reveals compelling insights into the results of the proposed model against several pre-trained models across various evaluation metrics. While traditional architectures like AlexNet, ResNet50, and VGG16 exhibit respectable accuracies ranging from 79.09% to 82.45%, they are outperformed by more modern architectures like DenseNet and MobileNetV1, which achieve higher accuracies of 90.52% and 92.89%, respectively. Nonetheless, the proposed model outperforms all pre-trained models, achieving a remarkable accuracy of 96.31%, which reflects its excellent classification performance.

Box PlotGraph of Model accuracy and error rate

Figure 9 states that, the training accuracy is very high (mostly close to 1.0), indicating the model has learned the data well, though there are a few outliers below 0.95, and one around 0.825. Validation accuracy is slightly lower, with most values around 0.95, showing decent generalization but some outliers nearly about 0.925. The disparity between training and validation accuracy reveals mild overfitting, leading the model to excel more on the training data than on unseen validation data. The training loss is low (around 0.1), reflecting high training accuracy, with a few outliers above 0.2 and one near 0.5, suggesting rare difficulties in fitting the data. Validation loss is higher (around 0.2), with outliers above 0.4, indicating inconsistent performance on the validation data, possibly due to overfitting or noise.

Prediction analysis of proposed model

The model accurately identified several cases of Yellow Leaf Curl Virus and Spider Mites, showing reliable performance when symptoms are clear. Despite high confidence (100%), the model made errors, such as misclassifying Early Blight as Septoria Leaf Spot and Bacterial Spot as Late Blight. This suggests overconfidence and difficulty distinguishing diseases with similar symptoms, especially between Early Blight vs. Septoria Leaf Spot and

Bacterial Spot vs. Late Blight as shown in Figure 10. However, this type of misclassification try to be solved by using the concept of Explainable AI (XAI)[27].

Comparison with existing works

The number of epochs and dataset size play pivotal roles in model training, influencing its capacity to discern intricate patterns and generalize effectively. Models trained on longer durations and larger, more diverse datasets, such as Saeed *et al*. (2023) with Inception V3 and Tarek *et al*. (2022) with pre-trained CNN model, tend to exhibit heightened robustness and generalization capabilities. Training a model with higher epochs can improve its learning from the data but risks overfitting, while when the number of epochs is very low, the model might not fully converge, resulting in suboptimal performance and insufficient learning from the dataset. Many studies, such as Baser *et al*.(2023), Parvez *et al*.(2023) and Paul S. G *et al*. (2023) demonstrate a trend of employing a relatively low number of training epochs. This suggests a preference for expedited training processes, possibly due to computational constraints or a belief in early convergence. With an optimum number of epochs, such as 500 in the proposed model, there's more opportunity for the model to iteratively refine its parameters, potentially leading to improved performance and better convergence towards an optimal solution.

CONCLUSION

This research involved the development of a convolutional neural network (CNN) model to identify healthy and diseased tomato leaves, along with identifying specific diseases. The proposed approach resulted in impressive accuracy levels of 96.31% in identifying tomato leaf diseases. However, limitations exist. The accuracy of the model could be compromised due to inconsistencies in lighting and image resolution. The next phase of work will be directed towards improving the model's robustness and generalizability by incorporating real-world field images and exploring data augmentation techniques. The failure case of prediction will be solved by Tools from Explainable AI, including Saliency visualizations and Grad-CAM (Gradient-weighted Class Activation Mapping). Additionally, the research can be extended to develop an App to reach the farmers. By continuously developing and refining AI-powered disease detection systems, we can allow farmers to effectively decide on matters related to their crop health management, leading to enhanced agricultural efficiency and long-term sustainability.

ABSTRACT

The emergence of future communication systems is driven by a constant demand for higher transfer rates, lower latency, increased dependability, global connection, and extensive use. Both private and public sectors have shown significant interest in sixth-generation (6G) networks as they deploy fifth-generation (5G) technologies worldwide. 6G networks must offer extremely dependable and low-latency connection to accommodate the proliferation of smart devices as well as the Internet of Things (IoT). To improve the performance of a network, routing techniques are essential. The complex and ever-changing 6G scenarios will be too much for traditional routing methods to handle. A few instances of AI algorithms that have become essential for the present administration of massive and dynamic networks include Machine Learning (ML), Deep Learning (DL), along with Reinforcement Learning (RL).Nevertheless, several substantial issues must be resolved when implementing AI algorithms in 5G/6G networks. This paper aims to present a survey on various AI algorithms applied for routing in 5G/6G-empowered communication networks. Additionally, it discusses the benefits, limitations, and performance metrics to emphasize open research challenges that should be addressed in future studies.

Keywords: Future communication systems, IoT, 5G, 6G, Routing, AI, ML, DL and RL.

INTRODUCTION

The rate of growth of mobile data traffic is increasing at an exponential rate as the world becomes more interconnected. The International Telecommunication Union's Radio communication (ITU-R) sector reports that monthly mobile information traffic worldwide reached158 Exabytes (EB) in 2022, with predictions of 2194 EB in 2028 and 5016 EB in 2030 [1]. With an expected increase from 12.1 GB in 2022 to 257 GB in 2030, these numbers show that mobile data consumption is growing at an exponential rate among consumers [2]. Mobile data services are becoming increasingly popular across all demographics and geographies. The percentage of people using mobile services will reach 70% by 2025, with 60% of that total accessing the internet through mobile devices [3]. Some of the emerging technologies that are propelling this growth include the IoT, AI, blockchain, Virtual Reality (VR), three-dimensional video, and linked automobiles. As the need for mobile data services continues to rise, businesses throughout the world have begun implementing 5G technology. Nevertheless, it is clear that a technology overcoming previous 5G networks would be required to manage the increased data flow as the globe moves toward automation. While handling a huge increase in data traffic, the 6G network is expected to provide consumers with enhanced service [4]. Mobile wireless technology might be radically altered by the 6G network's extensive coverage, lightning-fast data rates, and negligible latency. By combining the digital, biological, and physical worlds, 6G networks will bring about a mobile network revolution [5]. This will pave the way for the development of novel applications for 5G and use cases that were before inconceivable. Furthermore, 6G networks will lay the framework for a plethora of applications including smart cities and driverless vehicles, which necessitate massive capacity, low latency, and global coverage.

Evolution of Telecommunication Technology: From 1G to 6G

Beginning in the early 1980s, the telecommunication age has seen great expansion in the subsequent decades, with notable developments in data rates, connection, and efficiency [6-7]. Figure 1 shows the development of telecommunication technology. Starting in the 1980s, the first generation of mobile wireless networks, commonly known as 1G, was mostly based on analog technology. Data transfer rates were slow as well as the sound quality was lacking. Second-generation (2G) cellular networks, which first appeared in the 1990s, made available services such as Short Message Service (SMS) as well as simple email capabilities. Among others are the Global System for Mobile Communications (GSM) and Code Division Multiple Access (CDMA). Mobile networks in the 2000s upgraded to third generation (3G), which permitted faster data transfers, internet surfing, and multimedia messaging capabilities. A couple examples are Enhanced Data Rates for GSM Evolution (EDGE), CDMA2000, and WCDMA. Online multiplayer games, conference calls via video, and High-Definition (HD) video streaming were made possible by fourth-generation (4G) networks in the 2010s, such as Long-Term Evolution (LTE) as well as Worldwide Interoperability for Microwave Access (WiMAX). These networks offered better coverage and higher data rates. The IoT, smart cities, as well as the fourth industrial revolution are expected to be set up by the 5G networks, which were released in 2018. With AI integrated into the network infrastructure at every level, 6G promises to be the next stage of mobile networks, bringing in unprecedented coverage, connection speeds, and latency. These networks will make use of cutting-edge technologies including quantum communication, AI, ML, ultra-massive Multiple-Input Multiple-Output (MIMO), and Terahertz (THz) communication.

Design of 6G Mobile Technology

The current terrestrial network is inadequate for 6G's global coverage, necessitating integration with non-terrestrial networks. Figure 2 shows the four levels of the cell-less architecture that will be used by 6G. These levels are space, air, terrestrial, as well as marine [8].The space tier will provide internet services for space missions, while the terrestrial tier will extend coverage using THz bands, but with higher path loss and congestion. IoT will expand into real-time monitoring via the Tactile Internet, allowing for real-time interaction with virtual items. Photonic solutions and Visible Light Communication (VLC) in the 400-800 THz range [9] will improve network performance, especially in aviation and maritime, outperforming Radio Frequency (RF) technologies.

Features of 6G Networks

6G networks are anticipated to greatly improve upon 5G technology, introducing several advanced features. They are projected to achieve data transfer speeds exceeding 10 Tbps, ensure extremely low latency, offer broader coverage, enhance user experiences with technologies like VR and AI, as well as deliver network and spectral efficiency that is tenfold higher than that of 5G networks. Further than 100 times the number of connections offered by previous 5G networks, they will provide excellent energy efficiency, which means longer battery life and better sustainability [10].By merging with other methods like the analytics of large data, cloud computing, as well as IoT, 6G networks offer great connectivity across diverse systems.4G, 5G, as well as 6G network performance comparisons are shown in Table 1 [11]. VR, machine-to-machine cooperation, the IoT, robotic surgery, and Unmanned Aerial Vehicles (UAVs) are all possible with 6G networks [12].They necessitate extensive connectivity, incredibly dependable and with little latency, optimized use of resources, higher energy efficiency, improved security and privacy, and worldwide coverage [13]. Although their widespread use may not occur until 2030, they may appear earlier in some areas.6G is currently being investigated by several companies, including China Mobile, ZTE, and Huawei [14]. The U.S. Federal Communications Commission (FCC) has just opened the "THz wave" to further standardized testing [15], and LG and Finland's University of Oulu are leading the research. Certainly, 6G is a quite recent idea, and it could be a while before its full promise is seen.

AI for 6G Networks

AI is expected to have a profound impact on 6G networks by improving management of networks and the user experience. Applications like VR and driverless vehicles rely on its ability to handle an influx of data and sensors, maximize processing power and bandwidth, and facilitate decision-making in real-time. Automated cybersecurity solutions powered by AI can monitor network traffic, identify unusual activities, and counteract any dangers. By detecting problems ahead of time and reducing the impact of interruptions, an AI-powered 6G network can improve reliability [16–17]. Algorithms powered by AI can study patterns of user behavior, optimize and manage network resources in real-time, and make consecutive judgments in unpredictable settings.

Convergence of AI, 6G and Wireless Communication

The three main services that 6G technology delivers are Massive Machine-Type Communication (mMTC), Ultra-Reliable Low Latency Communication (URLLC) as well as improved Mobile Broadband (eMBB) [18]. With respect to eMBB, URLLC, and mMTC, 5G stands apart from 6G technology powered by AI (refer to Table 2).

Applications of 6G Networks

The 6G network is expected to have numerous sectors as potential users, even if it is not yet available for commercial use [19].

Ultra-HD Video Streaming with VR: With the advent of 6G networks and AI, online gaming and ultra-HD video streaming will be possible without interruption, while real-time playback and personalized content recommendations will be much improved.

Healthcare Monitoring: Improved predictive analytics and individualized healthcare are possible outcomes of combining AI alongside the 6G revolution. Improving patient care through proactive, individualized healthcare delivery is made possible by the effective transmission of health data made possible by 6G networks' quick data transmission rates with minimal delay.

Remote Surgery: The 6G network and AI technology enable telesurgery, a surgical technique that has been transformed by robotics and wireless networking, to link physicians and patients over great distances. By facilitating the processing and analysis of data in real-time, this technology improves surgical practice, which in turn increases patient safety, increases access to care, and ultimately improves surgical outcomes.

Tactile Internet: The tactile internet, a novel form of interaction between humans and machines, stands to be greatly advanced through the incorporation of 6G technology. This would allow for real-time, high-quality transmission of tactile data, facilitating the creation of advanced haptic devices, remote control, as well as VR applications. This has the potential to greatly affect the healthcare, gaming, as well as industrial industries.

Industrial IoT (IIoT): 6G has the ability to revolutionize industrial tasks by providing real-time communication, better decision-making, and more security. It has the potential to pave the way for innovative IoT applications, such as remote management and predictive maintenance, which can increase efficiency and reduce expenses.

Mixed and Augmented Reality (MAR): The integration of actual and virtual environments, the transfer of higher resolution VR data, and the enablement of distant jobs, social engagement, as well as gaming are all ways in which 6G technology may improve MAR experiences. It is a primary application of 6G technology because of its real-time abilities and sophisticated security mechanisms, which can generate novel and engaging experiences.

AI and Robotics: With 6G's faster connection and greater capabilities, AI as well as robotics are expected to undergo significant changes. Improved speed and accuracy of AI algorithms, real-time communication for drones and autonomous robots, and the ability to operate and maintain industrial machinery remotely are all benefits.

Challenges for 6G Implementation

Difficulties that may arise when deploying 6G networks include [20]

- Technology innovation and standardization: Challenges associated with emerging methods includes THz connectivity, AI, ML, quantum communication, massive MIMO, as well as URLLC.
- Spectrum inadequacy: Propagation limits and current regulatory constraints make it difficult to find and allocate spectrum for 6G in the THz frequency band.
- Compatibility with existing networks: Difficulties in achieving seamless integration between diverse technologies and standards used by various networks.
- Regulation and policy: To meet the regulatory issues brought forth by emerging spectrums and technologies, new legislation and regulations are required.
- Global relationships and harmonization: There is a lot of pressure on businesses and governments to be the first to market with 6G, which calls for international cooperation and standards.
- Concerning privacy and security: There are new obstacles to overcome in the integration of various devices and systems, as well as in the transfer of sensitive data.
- Eco-friendly concerns: Environmental impacts of extracting raw resources for 6G infrastructure, leading to habitat destruction, pollution, and resource depletion.

Routing Challenges and Optimization in 6G Networks

The network routing method controls the process of routing, which entails finding a way for data to flow from one place to another. Distance vectors or connection measurements have formed the basis for numerous routing algorithms developed over the last several decades for use with various telecommunications systems. Nevertheless, 6G networks present numerous obstacles, such as:

- Dynamic and Complex topologies: Networks in which nodes are constantly joining and leaving, causing connection rates to change often [21]. Integration of autonomous vehicles, drones, and mobile devices adds complexity, requiring real-time adjustments to routing tables.
- High degree of heterogeneity: 6G networks will combine various network types and technologies, making difficult to seamless interaction and routing across them [22].
- Dense networks: The proliferation of IoT in 6G networks will increase device density, requiring robust routing solutions to maintain connections efficiently. Congestion, interference, and diverse Quality of Service (QoS) requests from different devices and applications pose additional challenges [23].

Inefficient routing and resource consumption are common results of using conventional routing strategies in dynamic, heterogeneous networks. Congestion results from the high computational complexity and inflexibility of

traditional shortest path techniques, which rely on static measures such as hop count or delay. On the other hand, by assessing intricate network conditions, AI-driven routing techniques especially those rooted in ML and DL offer adaptive, data-driven solutions. Benefits, drawbacks, performance measures, and major future research issues related to AI-based routing systems for 5G and 6G networks are all covered in this study. The following sections have been prepared: The second section provides a summary of the AI-based routing strategies used in 5G/6G wireless networks, and the third section concludes up the study and makes some suggestions for improvements in the 6G era.

Survey on Different Routing Techniques in 5g/6g-Empowered Wireless Communication Networks

For 5G and beyond, Jothikumar *et al*. [24] introduced an Optimal Cluster-Based Routing (Optimal-CBR) method to extend the life of Wireless Sensor Networks (WSNs) based on the IoT. The K-means approach and a multi-hop method were employed by the Optimal-CBR technique to group the nodes and route the chains. The grouping phase finished the data transfer when two-thirds of the node had perished. Then came the connection stage. The nodes were ordered by highest energy, with the default being the node nearest the centroid, to start the process of choosing Cluster Heads (CHs). The CH sent the BS later packets its members had received. During the chaining phase, the remaining nodes went on to build a chain utilizing multi-hop routing in spite of losing two-thirds of the nodes and lacking energy for grouping. The BS was reached by the packets continuing this process. Using 6G-enabled UAVs, Deb *et al*. [25] created a delay-aware Q-Learning (QL)-based routing method named XiA. XiA sends user packets to close by Access Points (APs). A framework was created to let UAVs and their several stakeholders engage while they exited the communication zone, hence facilitating connectivity with Low-Earth-Orbit (LEO) satellites. Incentive functions were applied using the user's information urgency as well as transferring links between the UAV players. They also evaluated the effectiveness of dynamically altering parameters to rectify prior decision-making errors using the QL method. Dogra *et al*. [26] suggested a 5G balanced energy-efficient routing method depending on smart MIMO to improve the Quality of Experience (QoE) for data transport in clusters of IoT equipment. This design simulated the processes for choosing the CH and producing intra- as well as inter-clustering for multi-hop routing. The network started with a vertical architecture into intra- and inter-clusters to spread the energy consumption among the CHs. Grouping and a multi-hop design were used to link the two data transmission ends next. Duhayyim *et al*. [27]] proposed EDACRP-6G, a new approach for best-path recognition and energy-effective cluster-based data gathering in their work on 6G-enabled UAVs. This approach was able to select the perfect set of CHs using an Artificial Fish Swarm-based Route Planning (AFSRP) scheme and an Improved Red Deer Algorithm-based Clustering (IRDAC) scheme. Arya *et al*. [28] investigated a DL-based routing system's performance to guarantee effective transmission of data in 5G WSNs. Initially, nodes belonging to certain clusters were rewarded to divide the network using the RL approach. Manta Ray Foraging Optimization (MRFO), a data-transfer-optimal method, chose the CH. The next stage was to create a more efficient routing technique allowing improved data transfer along the chosen path based on Deep Belief Networks (DBNs). Marinho *et al*. [29] presented CAIN, an AI method for 6G networks, as a routing protocol meant to enhance coverage regions that is both smart and energy-aware. Based on their connectivity, a CAIN would take out a series of communications to nodes farther away from an AP, trying to extend the range of the network. The CAIN will find a neighboring node with an AP connection to send the message when a node lacks an AP connection. Should there be no link to a nearby AP, the node would also choose an adjacent node to transmit the message.

DNN, Federated Learning (FL), as well as RL among other AI techniques enhanced this CAIN. De Lucia *et al*. [30] tackled the energy depletion issue in UAV swarms and proposed a novel routing method called ENSING to save energy and connection in 6G systems. By selecting the next-hop UAV forwarder based on energy limits, this technique ensures the selection of only suitable UAVs with adequate energy supplies for packet forwarding. Haseeb *et al*. [31] suggested an efficient and trusted autonomous vehicle routing algorithm for 6G networks to ensure maximum QoS and data coverage. Initially, a simulated annealing algorithm executed a routing task, optimizing energy between IoT-based vehicles. Then, because connected vehicles could reliably interact with network edges in a session-oriented way, a risk-aware security model emerged. This stopped uncertainties in the autonomous network. A Deep Q-Network-based Load-balancing Routing Algorithm (DQNLLRA) for the LEO satellites was created by Dong *et al*. [32] by modeling a satellite routing operation as a Markov Decision Process (MDP). Using iterative

learning and data from nearby nodes in the satellite network, the system found the best decision model taking into account aspects like latency, bandwidth, as well as queue usage. For feasible transmission in 5G/6G WSNs, Gururaj *et al*. [33] proposed a Collaborative Energy-Efficient Routing Protocol (CEERP). It all started with data collection at the sink node. After classifying the nodes in the network into groups according to their remaining energy, the RL chose the CH to facilitate better data transport. Using the Multi-Objective Improved Seagull Algorithm (MOISA) together with the CEERP helped to significantly improve the performance of the network. Naguib *et al*. [34] presented a novel paradigm for efficient control of virtual reality transmission of data in a 6G-enabled VR Software Defined Network (SDN) for End-to-End (E2E) VR interactions between users. An optimization problem was simulated with regard to the requirements of the VR slice in order to reach the greatest practical data rates in the framework of limited E2E latency and available resources throughout all layers. Tilwari *et al*. [35] designed the Multi-Criteria-Aware Integrated Decision-Making (MCAIDeM) routing protocol to ensure that end-to-end users in IoT communication may rely on a consistent and efficient path leading to 6G systems. Combining the leftover energy, waiting time, mobility, and link dependability of relay nodes, a single routing algorithm was developed to select a consistent and reasonably priced path. For judgments with several criteria, they applied an AHP (Analytic Hierarchy Process) system. This method selects acceptable relay nodes during path selection by calculating suitable weights depending on the node's value for parameters. Tshakwanda *et al*. [36] proposed a Speed-optimized LSTM (SP-LSTM) method combining predictive analytics with dynamic routing to increase resource economy and optimize network efficacy. This two-layered system combines SP-LSTM networks in RL for predictive modeling and routing improvement. SP-LSTM estimates network congestion for proactive measures, whereas RL enhances routing based on these predictions. Aligning with the dynamic aspects of 6G networks, this system is driven by continuous learning and adaptation to accomplish the objectives of extremely low latency, dependability, and heterogeneity management. The above-discussed routing techniques for 5G and 6G communication networks are evaluated in terms of their advantages, drawbacks, and performance metrics in Table 3.

CONCLUSION

A future communication system that is both reliable and efficient is in great demand. Future networks will operate in an even more complicated and ever-changing environment, making intelligent routing design all the more important for network performance. AI-empowered 6G networks are a promising solution to address these challenges. This paper surveys ML and DL algorithms developed for routing optimization in 5G/6G networks. As well, the advantages, limitations, and performance metrics of these algorithms are summarized in a tabular form to identify challenges. Therefore, DL algorithms will be crucial to the intelligence of 6G networks in the future, according to this study. Continuous innovation in DL and other AI techniques will enable 6G technology to meet the needs of individuals, organizations, and industries effectively. Therefore, future work will focus on developing advanced DL algorithms that facilitate robust communication in 6G networks.

Table 1.Analysis of 4G, 5G, and 6G Networks

Performance indicators	4G	5G	6G
Highest data transmission rate	1 Gbps	10 Gbps	1 Tbps
Maximizing energy efficiency	< 1000x related to 5G	1000x related to 4G	> 10x related to 5G
Low delay	100 ms	1 ms	0.1 ms
High spectral effectiveness	15 bps/Hz	30 bps/Hz	100 bps/Hz
The density of connections	2000 devices / km²	1 million devices / km²	> 10 million devices / km²
Coverage %	< 70%	80%	> 99%
Driverless car	No	Partial	Completely
Precise positioning	Meter level (50 m)	Meter level (20 m)	Centimeter level
E2E reliability	99.9%	99.999%	99.9999%
Haptic transmission	No	Partial	Completely
The receiver's sensitivity	~ -100dBm	~ -120dBm	~ -130dBm
Mobility support	350 km/h	500 km/h	≥ 1000 km/h
Satellite combination	No	No	Completely
Structure	MIMO	Massive MIMO	Smart surface
Extended reality	No	Partial	Completely
Service level	Video	VR	Tactile

AI	No	Partial	Completely
Elevated frequency range	6 GHz	90 GHz	10 THz
THz transmission	No	Limited	Extensively

Table 2: Evaluation of 5G and 6G Technologies enabled by AI on eMBB, URLLC, as well as Mmtc

Technology	eMBB	URLLC	mMTC
5G	It paves the way for faster data transfers for mobile users, so they can view Ultra HD videos.	Its trustworthy and low-latency connection is vital for applications like remote surgery and industrial automation.	It facilitates extensive connectivity, allowing effective communication among several IoT devices.
AI-empowered 6G	It employs AI to optimize spectrum utilization and intelligent resource allocation.	Through the use of AI-driven optimization of networks and predictive maintenance functionalities, it improves URLLC by reducing latency and increasing reliability.	It improves ways of communicating and allocating resources so that devices may communicate with each other and networks can be divided up more efficiently.

Table 3: Comparison of Different Routing Techniques in 5G and 6G-Empowered Communication Networks

Ref. No.	Techniques	Advantages	Drawbacks	Performance Metrics
[24]	Optimal-CBR	It makes the sensor nodes more efficient by decreasing their power consumption, which in turn increases the network's lifetime.	It neglects the security considerations associated with data exchange via a multihop routing method.	Mean residual energy of nodes (@ 1200 rounds) = 0.49;No. of live nodes (@ 1000 rounds) = 278;The CH's energy loss (@ 200 rounds) = 0.13J;Packet Delivery Ratio (PDR) = 0.9;E2E delay = 11ms
[25]	A delay-aware QL-based routing (XiA)	It reduces delay effectively.	Requires integration of multiple ground-level APs to enhance performance.	No. of hops = 6; Delay = 0.000081s
[26]	MIMO based 5G balanced energy efficient routing	It achieved lower delay.	The network coverage was remained low.	Network coverage area (@ 1000 rounds) = 50; Delay (@ 600 rounds) = 0.1s
[27]	EADCRP-6G	It extends the life of the network and decreases its energy usage.	Delay and throughput were not satisfactory.	For 100 UAVs Energy consumption = 159mJ;Network lifetime = 4490 rounds; Throughput = 0.63Mbps; Mean delay = 6.88s
[28]	MRFO and DBN-based routing	Its network throughput and lifetime were both high.	There was a lot of energy used.	For 1000 nodes Energy consumption = 0.656; Network lifetime = 31200; Throughput = 0.918
[29]	Energy-aware intelligent increasing coverage region routing (CAIN)	It increases the network coverage and reduces storage overhead efficiently.	The mean number of messages reaching the CHs was low.	For 100 devices Mean communication delay = 2e-09s; Mean communication distance = 0.32m;Mean No. of messages reaching the CHs = 1.6;Mean storage overhead = 7 KB;

[30]	ENSING	It achieves high energy efficiency and PDR.	It has a high delay.	Mean UAV's battery energy (@ 120m distance for 20 UAVs) = 17500mAh; PDR (@ 180 min) = 96%; Throughput (@ 180 min) = 2.6 Mbps; Delay (@ 180 min) = 200ms
[31]	Efficient and trusted autonomous vehicle routing	It reduces energy consumption and computational cost effectively.	Latency and overhead were high. Also, PDR was low.	For 500 nodes PDR = 88%;Nodes overhead = 12%;Energy consumption = 0.13J;Latency = 3.2s;Computational cost = 10%
[32]	DQNLLRA	It reduced a mean queue utilization and achieved a robust load-balancing ability.	For optimum routing decisions, factors like network reliability, congestion and energy efficiency must be considered.	Path delay for 100 test flows = 90;Path maximization queue utilization for 100 test flows = 0.76;Path mean queue utilization for 100 test flows = 0.31
[33]	CEERP	It increased network lifetime and energy efficiency.	Routing overhead was high. Also, it needs to incorporate optimization schemes with more sophisticated data transfer.	Throughput = 90%; Network lifetime = 95%; Packet permission = 85%; Transmission speed = 92% Routing overhead = 95%; Energy consumption = 90%;
[34]	Efficient VR data transfer control using DQN	Improve data transfer by balancing network resources.	It does not consider other network factors like latency, throughput, etc.	Achievable data rate (@ 4000 rounds) = 5 bps/Hz
[35]	MCAIDeM	It offered key insights for real-time systems using network factors.	In future heterogeneous 6G networks, selecting optimal routes requires ML algorithms.	Throughput for 100 nodes = 25 Kbps; Delay for 100 nodes = 2.7ms;Energy consumption for 100 nodes = 110mAh
[36]	SP-LSTM with RL	Effectively balanced prediction and real-time response, improving network performance.	In real-time networks, a single RL agent may switch between policies, causing unstable routing decisions.	Training accuracy = 0.9822; Prediction accuracy = 0.99998; Mean squared error = 1.04132e-0.7.

ABSTRACT

This project report explores the role of job portals in streamlining the recruitment process at Durus Consulting Private Limited, a company specializing in providing tailored HR and business consulting solutions. As recruitment is a core function of the firm, the study investigates how online job portals such as Naukri, LinkedIn, and Indeed are utilized to meet the company's hiring needs and how these platforms enhance efficiency and outcomes.The findings reveal several positive impacts of job portals on Durus Consulting's recruitment operations. These platforms have enabled the firm to widen its talent pool, reduce time-to-hire, and improve candidate tracking through automation and advanced filters. Recruiters at Durus benefit from instant access to thousands of candidate profiles, enabling them to match specific job requirements more precisely. Additionally, job seekers gain improved visibility and access to opportunities within the firm, aligning well with its dynamic staffing needs.

Keywords: Automation, Healthcare, HR Analytics, Recruitment Process Outsourcing, Technology.

INTRODUCTION

The Human Resource (HR) consultancy industry is critical in shaping workforce strategies and supporting organizational development across various sectors. This industry encompasses firms that offer specialized services in recruitment, staffing, employee training, performance management, organizational development, payroll outsourcing, and strategic HR planning. Globalization, technological advancements, and the dynamic nature of work have significantly increased the demand for professional HR consulting services, especially among small and mid-sized enterprises (SMEs) and multinational corporations.

In India, the HR consultancy industry has witnessed steady growth over the last decade, fuelled by the expanding corporate landscape and a growing awareness of the importance of structured HR practices. Cities like Bengaluru, Mumbai, Delhi, Hyderabad, and Chennai have become hubs for HR consulting firms, catering to industries such as IT, manufacturing, retail, healthcare, BFSI, and more. The sector is segmented into various categories: executive search, recruitment process outsourcing (RPO), HR analytics, and talent management services. HR consultancies offer a cost-effective solution for companies looking to streamline their human capital operations without maintaining large internal HR departments. These firms bring industry-specific expertise, access to large talent databases, and strategic insights that help organizations improve employee engagement, reduce turnover, and enhance productivity.

However, the industry faces several challenges, including intense competition, pricing pressures, and the need to adapt to emerging technologies like AI and data analytics continuously. The rise of freelance platforms and internal HR tech solutions has created new market dynamics. Despite these challenges, the HR consultancy sector continues to grow, shifting towards offering end-to-end human capital solutions and becoming strategic partners in business transformation. In conclusion, HR consultancies are vital to the evolving business environment, offering scalable and flexible solutions to manage people effectively and align HR practices with broader organizational goals.

Need for the Study

The need for this study stems from the increasing significance of job portals in the recruitment process, particularly from the perspectives of both recruiters and job seekers. Platforms like Naukri, FoundIt (formerly Monster), and LinkedIn have transformed recruitment by providing recruiters access to a vast pool of candidates, while offering job seekers various opportunities. However, as these portals evolve, there is a growing need to explore how the features of these platforms influence candidate satisfaction and how they align with recruiters' needs. Understanding the impact of these portal features on candidate satisfaction is crucial for optimizing the recruitment process. As organizations strive to attract the best talent, the efficiency and effectiveness of job portals play a key role in successfully matching candidates with the correct positions. Job seekers prioritize different aspects of job portals, such as ease of use, interface design, responsiveness, and transparency in the hiring process. By examining these factors, recruiters can better tailor their strategies to meet candidates' Expectations. Additionally, the recruitment landscape is continually shifting, with job portals constantly enhancing their features to cater to both recruiters' and candidates' needs. Assessing how these features affect candidate satisfaction will provide valuable insights for improving recruitment outcomes. A satisfied candidate is more likely to actively engage in the hiring process, leading to more successful placements for recruiters and organizations.

This study aims to:

- Examine how job portal features influence candidate engagement, response time, and overall satisfaction.
- Evaluate the effectiveness of these portals in meeting the needs of both domestic and international recruitment.
- Investigate the evolution of job portal features and how they align with modern candidates' expectations.
- Understand the role of technology in shaping recruitment practices and enhancing candidate satisfaction.
- By conducting this research, companies will gain a deeper understanding of the factors contributing to a positive recruitment experience, enabling them to refine their hiring strategies. Moreover, job portal providers can use this feedback to enhance their platforms, ensuring they stay relevant and effective in meeting the demands of the ever-evolving recruitment industry.

Objectives of the Study

Primary Objective:

- To examine the practical role of job portals in streamlining the recruitment process at Durus Consulting Private Limited.

Secondary Objectives:

- To identify the advantages and limitations of job portals in recruitment.
- To evaluate the effectiveness of job portals in sourcing, shortlisting, and hiring suitable candidates.
- To understand recruiters' challenges while using job portals for talent acquisition.
- To assess the impact of job portals on recruitment timelines and hiring costs.
- To explore how job portals help find culturally and professionally compatible candidates.
- To suggest recommendations for improving the use of job portals as part of a hybrid recruitment strategy.

Scope of the Study

- **Job Portals Analyzed:** The research will focus on three major job portals—Naukri, FoundIt (formerly Monster), and LinkedIn—commonly used for domestic and international recruitment. The study will evaluate each platform's features, functionalities, and effectiveness from the viewpoints of both recruiters and candidates.
- **Recruitment Process:** The study will examine various stages of the recruitment process facilitated by these portals, including candidate sourcing, job matching, communication tools, and application tracking systems. It will explore how these aspects contribute to the efficiency and success of the hiring process.
- **Candidate Satisfaction:** The primary focus will be on understanding candidate satisfaction. The research will assess factors such as ease of use, interface design, transparency in job listings, recruiter responsiveness, and the accuracy of job recommendations. It will explore how these factors influence the candidate experience and overall portal satisfaction.
- **Recruiter Experience:** The study will also consider the experience of recruiters using these portals, looking at how well the platforms support candidate sourcing, time-to-hire, communication with candidates, and the tools available for filtering, screening, and shortlisting applicants.
- **Technological Advancements:** The research will investigate how technological innovations, such as AI-driven job matching, chatbots, automated responses, and personalized job recommendations, are incorporated into these portals and how they affect the experiences of both recruiters and candidates.
- **Domestic vs. International Recruitment:** The study will examine how job portals cater to domestic and international recruitment needs, analyzing their ability to address the unique challenges of recruiting for roles in various geographic locations and industry sectors.
- **Impact on Recruitment Outcomes:** The research will assess how the features of these portals correlate with recruitment outcomes, such as the quality of candidates, time-to-hire, and success in placements, providing a clearer picture of their effectiveness in achieving hiring goals.
- **Recommendations for Enhancement:** Based on the findings, the study will offer recommendations for improving the features and functionalities of job portals. The aim is to enhance the user experience for both recruiters and candidates, streamline the recruitment process, and enhance overall hiring outcomes.

Limitations of the Study

- **Geographic Scope:** The study primarily focuses on job portals like Naukri, FoundIt, and LinkedIn, which may be more prevalent in specific geographic regions, such as India and the United States. As a result, the findings may not fully apply to the other areas with different recruitment trends and practices.
- **Platform Variability:** Job portals constantly evolve, with features and functionalities subject to change. The study may be limited because the research is based on specific versions of these portals, and future updates or modifications to these platforms may not be captured.
- **Bias in Participant Feedback:** The study relies on feedback from both candidates and recruiters, which personal biases and individual experiences may influence. These subjective opinions could affect the objectivity and generalizability of the findings.
- **Sample Size:** The study may be constrained by the number of participants involved, meaning the sample size may not be large enough to represent the broader population of job seekers and recruiters using these portals. This could limit the robustness of the conclusions drawn.

- **Availability of Data:** The study depends on publicly accessible data and user-reported experiences, which may not capture all the features or provide a comprehensive view of the portals. Some internal or proprietary data from job portal providers may be unavailable for analysis.
- **Feature Coverage:** While the study examines key features of the job portals, it may not be able to explore every detail or the full range of advanced tools offered by these platforms, which could affect the comprehensiveness of the analysis.
- **Recruitment Context:** The study focuses on general recruitment practices but may not fully address the specific needs of particular industries or highly specialized roles, where job portal features may have a different impact.
- **Time Constraints:** The research process may be limited by time constraints, which could restrict the extent of data collection, analysis, and exploration of certain portal features or recruitment outcomes.
- **Impact of Evolving Technologies:** The fast-paced development of recruitment technologies, such as AI-driven tools and automation, could affect the study's ability to account for all relevant technological advancements and their influence on candidate satisfaction and recruitment effectiveness.

RESEARCH METHODOLOGY

Research Design

This study adopts a **descriptive research design** to explore and analyse the role of job portals in enhancing the recruitment process. Descriptive research is appropriate as it helps capture current recruitment practices, portal features, and user experiences without altering variables.

Research Approach

The research follows a **mixed-method approach**, combining both qualitative and quantitative data:

- **Qualitative** insights were drawn from observations and user comments.
- **Quantitative** data were collected through structured surveys administered to the general public.

Data Collection Methods

- **Primary Data**
  Collected using a structured questionnaire distributed to a general audience. Questions focused on perceptions, usability, satisfaction, and effectiveness of job portals such as Naukri, LinkedIn, and FoundIt.
- **Secondary Data**
  Obtained knowledge of academic journals, company reports, job portal whitepapers, and HR industry studies related to digital recruitment.

Sampling Method

A **convenience sampling technique** was used, targeting individuals from the general publicwith experience using job portals for job search or hiring purposes.

Sample Size

The study was conducted with **123 respondents**, collected through an online questionnaire circulated among the general public.

Research Instrument

A **structured questionnaire** was designed, comprising **closed-ended (Likert scale, multiple-choice)** and **open-ended questions**. These evaluated user satisfaction, job portal efficiency, feature preferences, and common challenges encountered.

Limitations of the Methodology

- The study relies on self-reported data, which may include biases.
- Since the sampling was based on convenience and limited to 123 individuals, the findings may not be fully generalizable across industries.
- The dynamic nature of job portals may result in platform features evolving beyond the scope of this research.

DATA ANALYSIS FINDINGS AND INTERPRETATIONS

CORRELATION ANALYSIS

Correlation Analysis

- Most correlations were weak and non-significant, implying low interdependence among the variables.
- One significant correlation at 0.05 level: Clarity of job descriptions vs. time-saving ($r = -0.181$, $p < .05$).
- One significant correlation at 0.01 level: Authenticity of listings vs. Overall satisfaction ($r = 0.275$, $p = .002$).

Inference

The Pearson correlation values among most items are **weak and not statistically significant**, except:

- A **negative correlation** between job description clarity and time-saving ($r = -0.181$, $p < .05$)
- A **positive correlation** between listing authenticity and overall satisfaction ($r = 0.275$, $p < .01$)

Inference:

The weak correlations suggest that respondents perceive each aspect of job portals as relatively independent. The only meaningful positive correlation implies that trust in job listings contributes significantly to overall satisfaction. Conversely, clarity of descriptions may not necessarily equate to efficiency.

FINDINGS

Positive User Perception of Job Portals:

Most users experienced portal-based recruitment as effortless to operate and search through, with the added benefit of time savings relative to conventional hiring approaches. The users rated the portal's ease of use with the highest mean score of 3.86.

Moderate Candidate Satisfaction:

Candidates demonstrated slightly lower overall satisfaction toward job portals with an average score of 3.53, indicating that portals succeed at handling functional elements but lack completely satisfying experiences.

Trust and Authenticity:

Job seekers' trust in authentic job listings directly influenced their satisfaction levels. Users moderately trusted job listings but presented doubts about outdated or fake profiles.

Challenges Identified

- High volume of irrelevant applications due to generic postings.
- The evaluation process for assessing soft skills and cultural compatibility remains challenging when completed electronically.
- The excessive use of algorithms in matching operations might result in valid candidates being ignored.
- Underrepresentation of candidates from tier-2 cities and rural areas.

Weak Internal Consistency:

According to its Cronbach's Alpha value (-0.106), the surveyed user experiences have low connectivity between factors, possibly representing separate dimensions instead of one "portal satisfaction" composite.

Multiple Recruitment Dimensions
Factor analysis showed five potential dimensions within user experience, but overlapping constructs made it hard to distinguish the separate constructs, including usability, trust, convenience, relevance, and satisfaction.

Employment Status Influence:
Students who also worked as freelancers demonstrated higher optimism regarding increased hiring opportunities from portals than unemployed workers and those retired from work.

Suggestions and Recommendations
Improve Candidate Matching Algorithms:
AI filters running on portals need improvements so candidates are matched based on their expertise, in addition to eliminating unneeded applications.

Integrate Soft Skills Assessment Tools:
Portal users must utilize video interviews, psychometric assessments, and soft skill evaluation plugins because these tools help better determine cultural compatibility and communication abilities.

Regular Database Cleaning:
Resumes and profile verifications must have stronger checks that remove outdated or fake applications to increase trustworthiness and authenticity.

Tier-2 and Rural Outreach:
The company should implement special initiatives such as mobile-accessible websites and local language support to attract candidates outside metropolitan areas to the employment platforms.

Personalized User Experiences:
A recommendation system improvement will occur through customized job suggestions that use candidate history and preferences to boost user satisfaction and engagement.

Hybrid Recruitment Approach:
Durus Consulting and other organizations should integrate job portal usage with established sourcing approaches, such as employee referrals, college recruiting, and specialized hiring of senior talent through headhunting techniques.

Continuous Feedback Loops:
Every job portal should include post-transaction candidate and recruiter feedback that helps the system evolve its functionalities and response time.

Enhance Mobile App Functionality:
The mobile-first approach demands portal developers enhance the application design and implement higher-speed functions and offline application capabilities.

CONCLUSION

Through job portals, organizations can enhance their recruitment operations by extending their reach to new candidates and achieving faster recruitment results. The job search portals Naukri, LinkedIn, and FoundIt provide users with ease of use, real-time updates, and wide-ranging candidate accessibility. Applications through portals face problems with unqualified candidates. At the same time, evaluating soft skills remains difficult, and rural job seekers struggle to connect with opportunities, demonstrating that job portals work better with additional recruitment

strategies. Durus Consulting Private Limited and similar organizations must combine their digital tool capabilities with personalized recruitment methods to enhance hiring quality and experience. Job portals reach their full potential when recruiters and platform providers dedicate efforts toward establishing trust among users and personalized features that promote inclusivity. The evolution of technology requires recruitment strategies to update their approaches to maintain effectiveness in finding top candidates.

ABSTRACT

Anaerobic digestion(AD) based biogas generation offers a sustainable option to convert waste into energy, but it is still extremely challenging to adequately model its nonlinear, multi-factorial processes. Research on biogas generation, a promising renewable energy source made from organic waste, has increased as a result of the global trend towards sustainable energy options. Predicting biogas yield accurately is essential for streamlining production procedures and enhancing operational effectiveness. This paper includes a thorough evaluation of the literature on the application of optimized machine learning models for biogas output prediction. Various ML models like ensemble learning approaches, DT, RF, SVM, ANN, gradient boosting machines (GBM), and hybridized frameworks integrating evolutionary algorithms and deep learning architectures are compared and analysed with respect to prediction accuracy, resilience, and dataset adaptation. Methods for feature selection, data preparation, and model optimization strategies including hybrid models and hyperparameter adjusting are all given special consideration. The lack of consistent datasets and the requirement for interpretable models are two of the major issues and research gaps highlighted in the survey. Lastly, future research avenues that focus on combining real-time prediction systems, explainable AI, and sophisticated optimization techniques are presented. This review is a fundamental resource for researchers and practitioners aiming to enhance biogas production through intelligent data-driven models.

Keywords: Anaerobic digestion; Machine learning; Artificial Intelligence; Metaheuristic algorithms; Deep learning

INTRODUCTION

An increasing demand for renewable energy bases and the need to manage organic waste sustainably, has catalyzed significant interest in biogas production through AD processes.Biogas, mostly consisting of methane (CH_4) and carbon dioxide (CO_2), is produced through the microbial decomposition of organic materials in anaerobic environments and acts as a feasible substitute for fossil fuels(Karellas *et al*.,2010). Despite its environmental and economic benefits, the efficiency of biogas production is highly dependent on numerous factors such as substrate type, pH, loading rate, retention duration, temperature, and microbial community dynamics, complicate the forecast and optimization of biogas yield (Holm-Nielsen *et al*., 2009).Traditional mathematical and kinetic modeling approaches are useful but, often fall short in capturing the nonlinear, multivariate, and dynamic nature of AD systems (Batstone *et al*., 2002). In recent years, the advent of MLtechniques has offered an alternative for modeling complex bioprocesses. ML algorithms may discern trends from past data without necessitating deep mechanical comprehension, facilitating precise predictions of biogas yield across diverse operational situations. Commonly used models include ANN, SVM, DT, RF, and ensemble learning frameworks (Almomani2020; Wu 2021).Predictive performance and model reliability are further improved by optimizing ML models using strategies including feature selection, hyperparameter tweaking, and hybrid modelling. Furthermore, recent research has investigated combining DL architectures like CNN and LSTM and evolutionary algorithms like GA, PSO to represent temporal relationships and enhance generalizability(Ling 2024; Zaied 2020). However, benchmarking and real-world implementation are limited by the absence of uniformity in data gathering, preprocessing, and model evaluation.

The most recent research on predicting thebiogas production from AD is presented in this literature survey, which also addresses the difficulties and future directions. The contributions of this study are

- The concepts of AD systems, data preprocessing methods, optimization techniques and evaluation measures are elaborated.
- It offers a comprehensive overview of the present state-of-the-art in optimized ML approaches for biogas prediction are listed.
- The various challenges and issues involved in creating an AD system using ML approaches are presented.
- The research gap is noted, and recommendations are made for further study to enhance the incorporation of intelligible ML-based solutions for biogas production systems.

The paper is structured as, Section II delivers the concepts of AD systems, data preprocessing methods and evaluation measures. A thorough summary of the most recent ML techniques for biogas prediction is provided in Section III.Section IV shows the challenges and issues related to AD system using ML approaches. The conclusion and future directions for improving biogas production are presented in Section V.

Anaerobic Digestion System Preliminaries

This section describes about the basics of AD system, data preprocessing methods, optimization techniques and evaluation metrics. AD is a complex, multistage sustainable biological process that converts organic waste into biogas and nutrient-rich digestate. This process happens in engineered digesters under controlled environmental and operational conditions and serves bothenergy recovery as well as garbage treatment. AD is a proven method for producing renewable energy and treating organic waste.The process consists of breaking down the biodegradable material with the help of microorganisms in the absence of oxygen, that produces biogas and digestate. The efficiency and stability of an AD system depend on several preliminary factors, including feedstock characteristics, inoculum selection, process parameters, and system design. The efficiency and stability of AD systems are ruled by several interdependent operational parameters like pH, temperature, alkalinity, loading amount and retention duration. The other parameters like substrate characteristics, substrate pretreatment, microbial community dynamics etc. Understanding these fundamentals is essential for designing effective AD systems for waste management and renewable energy production. Figure 1 shows the process of anaerobic digestion.

The data preprocessing methods for biogas prediction consists of

Data cleaning: Missing value imputation, KNN, regression-based imputation, interpolation, outliner detection and removal processes.
Feature engineering: Involves feature selection and feature extraction. Removal of irrelevant or reduction features. Derive new informative features like substrate volatility, temperature fluctuation index. Aggregate features like pH and temperature variance.
Data transformation: Involves min-max normalization and standardization
Data encoding: Perform one-hot encoding for nominal variables like substrate types.
Time series formatting: For dynamic models that lay features, rolling windows features, and resampling.
Dimensionality reduction: Applied when too many features like principal component analysis and use of autoencoders for nonlinear feature compression.
Data balancing: If classification is involved, conditions like fault detection in AD systems (Ling *et al*., 2024).

Optimization strategies in ML for Biogas Prediction

Optimizing ML models for biogas prediction involves fine-tuning hyperparameters, selecting relevant features, and enhancing model architecture to improve accuracy, robustness, and generalization. Due to the nonlinear and multivariate nature of AD processes, conventional parameter tuning may not yield optimal results. Instead, optimization techniques like evolutionary algorithms, Bayesian approaches are employed to automate and refine ML performance. The key optimization strategies used in biogas modeling are given below

- Hyperparameter optimization influences the learning behaviour of ML algorithms, including CNN architecture, tree depth in decision trees, and learning rate in GBMs. Manual tuning or grid search is computationally expensive and suboptimal in high-dimensional search spaces. Hence, advanced optimization techniques like grid search and random search are commonly used for small search spaces. While random search samples combinations randomly, grid search assesses combinations methodically, providing greater efficiency in huge spaces (Bergstra and Bengio, 2012).A probabilistic model-based optimization technique called Bayesian optimization builds a surrogate function to represent the objective function and chooses hyperparameters that are expected to enhance performance. It has been effectively used in tuning ANN and SVR models for biogas yield prediction (Ge *et al*., 2024).Cross validation-based tuning is involved in most optimization frameworks embed k-fold cross-validation to ensure that tuned parameters generalize across unseen data.
- Feature selection and dimensionality optimization involves high-dimensional data from biogas systems (e.g., real-time sensor inputs) may include irrelevant or redundant features. Feature selection improves learning efficiency and avoids overfitting. Feature selection methods like wrapper method uses the model performance (e.g., R^2, RMSE) as feedback for selecting feature subsets. Recursive feature exclusionis a wrapper technique in ANN optimization (Wang *et al*., 2021).Embedded methods like random forests and Lasso regression perform internal feature selection during model training, offering built-in dimensionality control. Evolutionary algorithms like GA, PSO, and ACO(Beltramo *et al*., 2019) are widely applied to simultaneously select features and optimize model parameters. Zaied *et al*., (2020) came up with a PSO-ANN hybrid outperformed standalone ANN models for methane prediction from co-digestion experiments.
- Model structure optimization consists of a deep learning and ANN-based models with structural parameters like hidden layer count, neurons count, initiation functions, and dropout rates. Neuroevolution approach uses GA to evolve ANN structures and connection weights, adapting model architecture dynamically based on performance (Stanley *et al*., 2002).
- Ensemble and hybrid optimization approaches consists of combining multiple models (ensembles) or integrating ML with optimization algorithms to show superior performance inAD process. It uses stacked generalization to train multiple base learners like ANN, RF and uses a meta-learner to combine their outputs, reducing bias and variance. Other hybrid models like GA-ANN, Bayesian and random forest. These hybridized models often yield better predictive accuracy and robustness, particularly in handling heterogeneous and sparse datasets from biogas production systems.

Evaluating the performance of ML models in predicting biogas production is critical to ensure accuracy, reliability, and generalizability of the predictions. Since biogas yield forecasting is typically formulated as a regression task (predicting continuous output such as methane volume or biogas production rate), the choice of evaluation metrics focuses on error quantification, model stability, and comparative performance. The various evaluation metrics involved are RMSE is used in regression tasks due to its sensitivity to huge mistakes. Without taking into account the direction of the errors, MAE calculates the average size of forecast errors. Compared to RMSE, it is less susceptible to outliers. The percentage of the dependent variable's variance that can be predicted from the independent variables is shown by the coefficient of determination, or R2 score. MAPE expresses prediction accuracy percentage, allowing for better interpretability across datasets with different scales.NSE is frequently used in hydrology and is being utilized more and more in biogas modeling to evaluate the model's predictive accuracy in relation to the mean of observed data. Cross validation error is for small or imbalanced datasets, k-fold cross-validation helps evaluate generalization by dividing data into k subsets, using each subset for validation once(Gupta *et al*., 2023).

Machine learning approaches for Biogas Prediction

This section discusses ML based approaches for biogas prediction. The findings, experimental outcomes, and different methodologies are tabulated. The comparison of ML algorithms for biogas prediction is shown in Table 1.

Challenges and Issues in AD System

ML based biogas generation forecasting in AD systems holds promise for significantly improving operational effectiveness, optimizing energy production, and cutting expenses.However, in order to increase the consistency and usefulness of AI models in AD, a number of factors need be taken into account. The key challenges are listed below

1. Data related challenges like limited or noisy data, high variability in input feedstock, imbalanced datasets and lack of standardized data.
2. Model related challenges like overfitting, black-box nature of ML models, trade-off between accuracy and computational cost and difficulty in capturing the temporal dynamics.
3. Process related challenges like nonlinearity and dynamic behaviour of AD processes, uncertainty in biological systems, lay effects and delayed responses.
4. Practical implementation issues like scalability of models, real-time prediction limitations and integration with existing systems.
5. Domain specific challenges like lack of universal input features and validation with real-world data.

It is evident from the literature that the co-digestion of cow manure and mango flesh to create useful biogas has not been thoroughly studied. The incomplete utilization of the substrate in the production of biogas is another problem that has been noted. The majority of the literature lacks information on digestion process optimization. It is necessary to investigate the impact of variables such as temperature, pressure, pH, C/N fraction, and retention period. The following is a list of the research gaps identified in this study

i. Most ML models are purely data-driven and lack integration with biochemical/kinetic models. There is a limited integration of domain knowledge with ML models.
ii. Many models assume static conditions, but biogas production is highly dynamic due to feedstock variability, microbial shifts, and process instabilities. Handling dynamic and non-stationary biogas data is challenging.
iii. Complex models like deep learning, ensemble methods lack interpretability, limiting industrial adoption. The trust in ML predictions and other hybrid prediction models to examine the biogas production
iv. Most models are trained on specific feedstocks (e.g., cow manure) or lab-scale data but fail when applied to new substrates or full-scale plants. There is a need for a generalizability across different feedstock and scales.
v. Most models use only operational data (e.g., pH, temperature) but ignore microbial community data, spectroscopy, or imaging. There is a limited use of multimodal data fusion.

In order to optimize real-time predictive models, integrate dynamic and decentralized biogas plants, forecast emissions, and address the lack of standard data for feedstock inconsistency, the application of ML techniques must be justified. Effectively biogas production will profit from addressing in these research gaps.

CONCLUSION

This literature survey critically examined the development and optimization of ML models for predicting biogas production from AD processes. The review highlights the increasing shift from conventional kinetic and statistical models to data-driven approaches that can capture the complex, nonlinear relationships between operational parameters and biogas yield. A wide range of ML models like ANN, Support Vector Regression (SVR), RF, and recently, deep learning architectures like LSTM have demonstrated superior prediction performance. The integration of optimization techniques such as GA, PSO, and Bayesian methods further enhances model accuracy and robustness. Though, several critical research gaps continue, particularly in the areas of dataset availability, interpretability, model generalization, and real-time deployment. Moreover, there is a lack of standardized practices in data preprocessing, feature engineering, and evaluation methodologies, which impedes model comparison and benchmarking. The future research should focus on building hybrid mechanistic ML models that are scalable, interpretable, and real-time ML frameworks supported by high-quality, full-scale operational datasets. Furthermore, the integration of ML models with process optimization and control systems will be essential for developing smart, adaptive anaerobic digesters capable of maximizing biogas output under varying operational conditions In conclusion, ML offers a powerful toolkit for enhancing the efficiency and sustainability of biogas production. Realizing its full potential requires interdisciplinary collaboration, standardized protocols, and a shift toward explainable, robust, and deployment-ready solutions.

ABSTRACT

Plant diseases are rising a complex challenges across ecosystem, society and agriculture. Plant diseases occur in many types mainly caused by viruses, bacteria, fungi, a biotic factor, or nematodes. If plant is affected with disease it has to undergo diagnosing. Plant disease can be overcome by prevention, monitoring, and early detection. Artificial Intelligence and its components are playing an important role in early detection and prevention. As it is most important issue many researchers are working on it. But, most of the earlier methods lack in accuracy and clear visuals. This paper discussed about different plant diseases, its earlier work, plant disease datasets or repository, about preprocessing, Convolutional Neural Network model, performance evaluation and plant Disease visualization using Explainable Artificial Intelligence. By using Deep learning Convolutional Neural Network method for classification and Explainable Artificial Intelligence for visualization the performance, accuracy and visualization improves.

Keywords: Plant Diseases, Leaf images, Artificial Intelligence, Explainable AI, CNN

INTRODUCTION

If a plant not able to perform its maximum level due to living (fungi, bacteria, viruses, viroids, phytoplasmas, nematodes, and parasitic plants)or nonliving(environmental or physiological stress) factors then it is affected by plant disease. The following Table 1 shows different types of plant diseases, factor, their causes and symptoms examples. By understanding the different types of plant diseases, factor, their causes and symptoms examples it helps in accurate diagnosis of plant disease. The Figure 1 shows the diagram of healthy leaf with spotless and a diseased leaf with spots, color faded and malformed tissues. The plant disease effects ecosystem, society and

agriculture in many ways. The Table 2 gives a detail list of impact of plant disease. Impact of plant disease can be overcome by prevention, monitoring, and early detection. Artificial Intelligence and its components like machine learning (ML), deep learning (DL) and Convolutional Neural Network (CNN) model are playing an important role in early detection and prevention. As it is most important issue many researchers are working on it. The detailed framework of this paper can be explained using Figure 2.

Literature Survey

As plant disease are creating a great impact on society many researchers are working on it for early detection and prevention. The following Table 3 presents the earlier work related to plant disease with its technology used, advantages and disadvantages.

Steps for Early Detection of Plant Disease

For early detection of plant disease, the following steps shown in Figure 3 extraction, preprocessing, CNN classification, performance evaluation and visualization using XAI has to be followed. The detailed explanation of each step is given below.

Extraction of Plant Diseases Repository or Data set

There are many plant disease data sets which can be used in identification of plant disease. The following are the most popular plant disease dataset with their description.

Plant Village Dataset: It is basically used for classification and hold PyTorch/TensorFlow integration. It has about 50,000 leaf images, disease classes of about 39approximately and healthy samples. It is access through GitHub repository and Mendeley.

Plant Doc Dataset: It is mostly used for classification and object identification. It consists of 2.6K images, 13 species and 17 diseases. It is access through GitHub repository.

DiaMOS Plant: It is basically used for field diagnosis. It consists of 3.5Kimages and 4 diseases on pear. It is access through Zenodo DOI repository.

Rice Leaf Diseases (UCI): It is used for rice leaf classification. It consists of 120 images and 3 diseases classes. It is access through UCI Machine Learning Repository.

Paddy Doctor: it is used for paddy disease classification. It consists of16.2K images and 13 paddy classes. It is access through ArXiv/Zenodo.

Preprocessing and CNN Model for Plant Disease Dataset

A CNN model is one type of DLmodel which used to process and examine visual data. CNNs mainly used for classification, facial identification and object detection. CNN model [12] consists of five core components such as Input layer, convolutional layers, activation functions, pooling layers and fully connected layers**.** The convolutional layers, activation functions and pooling layers steps comes under preprocessing. The details of each layer are explained below.

Input layer: This layer extracts the data set from the mentioned above datasets which will be in the form of raw dataset.

Convolutional Layers: After extracting the required dataset, the wanted features are been retrieved by using this layer. It is one of the preprocessing steps. This layer uses filters for extraction of required features from raw dataset. By extracting features the task of debugging, interpreting and defining the structure improves.

Activation Functions: The activation functions help to learn nonlinear relationships, allows back propagations, selective preprocessing, improves computational speed and stable gradients are maintained. The CNN model uses different activation functions likeReLU, PReLU, ELU, Sigmoid, Tanh, Softmax, Swish and GELU. The most commonly used activation function among them is Rectified Linear Unit (ReLU). It's also one of the preprocessing tasks.

Pooling Layers: The height and width of the extracted feature are reduced. The pooling layer uses down sampling techniques for reduction. By this over fitting of data is reduced and in turn the complexity is reduced. It's also one of the preprocessing tasks.

Fully Connected Layers: After extracting and performing various preprocessing the final classification is done to produce the output.

Performance Evaluation: The performance evaluation methods are used to evaluate the accuracy and effectiveness of the model. The ML and DL supports following performance evaluation methods for classification models which are shown in Table 4.

Visualization using XAI

Explainable AI (XAI) is used by deep learning CNN model to obtain more clarity and understanding of the problem. XAI helps to understand the plant disease more clearly by producing different and clear images which helps to interpret it without any confusion. The following Figure 4 shows original and XAI (Segmented Image Heat Map) images.

CONCLUSION AND FUTURE WORK

Plant diseases are raising a complex challenge across ecosystem, society and agriculture. Plant diseases occur in many types mainly caused by viruses, bacteria, fungi, a biotic factor, or nematodes. If plant is affected with disease it has to undergo diagnosing. Plant disease can be overcome by prevention, monitoring, and early detection. Artificial Intelligence and its components are playing a important role in early detection and prevention. As it is most important issue many researchers are working on it. In this paper discussion about different plant diseases, its impact, its earlier work, plant disease datasets or repository, about preprocessing, CNN model, performance evaluation and plant Disease visualization using XAI was done. By using Deep learning CNN method for classification and XAI for visualization the performance, accuracy and visualization improves. In future work a particular dataset of plant disease has to be considered and implementation has to be done to check the accuracy.

Table: 1.Disease Type, FactorCauses and SymptomsExamples of Plant Diseases

Disease Type	Factor	Causes	Symptoms Example
Leaf spot	Living factor	Fungi/Bacteria	Spots with halos
Powdery mildew	Living factor	Fungi	White dusty coating
Downy mildew	Living factor	Oomycetes (fungi-like)	Fuzzy underside growth
Rust	Living factor	Fungi	Orange pustules
Smut	Living factor	Fungi	Black spore masses
Wilt	Living factor	Fungi	Vascular browning and death
Blight	Living factor	Fungi	Rapid tissue collapse
Bacterial spots	Living factor	Bacteria	Water-soaked lesions
Fire blight	Living factor	Bacteria	Necrosis and ooze
Crown gall	Living factor	Bacteria	Tumorous growths
Viral mosaic	Living factor	Virus	Mottled, stunted leaves
Nematode spots	Living factor	Nematodes	Angular lesions
Abiotic injury	Non living factor	Environment/chemicals	Sunscald, nutrient deficits

Table 2. Impact of Plant Disease.

Impacts	Description
Ecosystem Impacts	• Loss of biodiversity and changes in natural habitats • Changes in forest species composition • Disruption of underground forest communication networks
Society Impacts	• Challenges to human health and food security • Community-level economic challenges • Problems linked to changes in culture and demographics
Agricultural and Economic Impacts	• Substantial declines in yield and monetary losses • Rising production costs and growing resistance issues • Limitations on trade and disturbances in the market • Decline of export industries • Susceptibility of monoculture systems

ABSTRACT

Effective waste management is a critical challenge faced by urban environments worldwide. The rapid increase in population and urbanization has led to a significant rise in waste generation, putting immense pressure on existing waste collection and disposal systems. Traditional methods of waste management often suffer from inefficiencies in route planning, inconsistent waste categorization, and suboptimal recycling practices, leading to increased operational costs and environmental impact. Garbage collection, as the first step in the waste management process, plays a crucial role in ensuring that waste is efficiently transported from residential, commercial, and industrial areas to processing or disposal sites. The efficiency of this process is heavily dependent on optimized collection routes, which minimize travel time and fuel consumption while maximizing the amount of waste collected. However, planning these routes manually can be a complex and time-consuming task, especially in densely populated urban areas with variable waste generation patterns. The EGAAV (Enhanced Genetic Algorithm with Adaptive Variable Neighborhood Search) algorithm, combined with the EGACW (Enhanced Genetic Algorithm with Clarke and Wright's Savings Algorithm) approach, is employed to calculate the most efficient collection routes. The algorithm efficiently determines the shortest and most effective routes by considering multiple factors, such as pickup locations and vehicle capacities. This optimization leads to a significant reduction in travel time and distance, enhancing operational efficiency and reducing fuel consumption. During the collection process, images of the collected waste are captured for further analysis, providing a dataset for subsequent phases.

Keywords: Optimized collection routes, Genetic Algorithm, Pickup locations.

INTRODUCTION

Ecosystems and human health are gravely threatened by the increasing volume and complexity of trash produced by modern economies. Roughly 5% of the world's greenhouse gas emissions come from the breakdown of organic waste, which contributes to the roughly 11.2 billion tons of solid trash collected annually. Every year, garbage collectors throughout the world gather almost 11.2 billion tons of solid waste. The most rapidly expanding waste stream in both developed and emerging nations is that of electrical and electronic devices, which often include complex and innovative dangerous substances. India produces more solid waste than any other country, third only to the US and China. The processes of garbage collection, transportation, treatment, and disposal present significant challenges. Solid Waste Management (SWM) is becoming a major development priority in India. Microbial decomposition, weather, trash characteristics, and land-filling processes all contribute to the formation of harmful gasses and lactates, according to many studies. The Indian government does not have the resources to acquire more land for landfills since all of the available locations have been utilized. Finding other landfill locations is also difficult. As a whole, urban areas produced 2.01 billion tons of municipal solid waste in 2016, or 0.74 kg daily per person. Rapid urbanization and population expansion are expected to cause a 70% rise in annual waste generation from 2016 levels to 3.40 billion tons in 2050. A study found that only around two-thirds to a third of the municipal trash that is collected really gets processed and disposed of. Composting relies on properly segregating waste, which is a challenge in India due to the prevalence of open-air rubbish dumps. In addition to reducing emissions of greenhouse gases and leachate, segregation can ease the load of transporting garbage. Separating waste at the source allows for the reuse of individual components in a variety of production processes, which in turn provides economic value. Recovering and using a higher proportion of recyclable trash is made easier by garbage segregation at the source. The dry garbage does not include recyclable items such as plastic bags, Mylar or laminated metalized plastic, shredded paper, or textiles. Paper, in contrast to metals, plastics, and glass, can be recycled and broken down naturally. As of now, "seven million tons of paper are utilized in India for packaging, with just 33% recovered and recycled." Paper bags and newsprint are two products made from recycled newspapers, textbooks, magazines, and the like. The production process uses less energy when plastic is reused and recycled.

RELATED WORKS

Ali, B. *et al*. (2023) to optimize the vehicle route for garbage collection, the suggested approach evaluates critical waste variables such as toxicity, volume, time duration of the waste, and distance between the bins. When compared to algorithms that optimize routes based on a single parameter, the suggested technique cuts the overall distance travelled by the garbage pickup truck by 14%, according to the simulation findings. Alwabli, A. S. (2021) the optimization of Vehicle Routing Problems (VRPs) was a prevalent challenge for most firms that want to maximize their resource use, according to this research study. Wherever the vehicle routing problem arises, the study's findings can inform the employment of various algorithms to devise optimal routes for cars. Based on its dependability and optimal solutions, the tabu search algorithm stands out as the top choice among the other algorithms in the research for optimizing vehicle routes.

Francisco, F. *et al*. (2024) several important conclusions have been drawn from the study's results. The first step was to determine that, with the exception of the problem of paywalls preventing access to real-time traffic data, it was viable to model the operational road network of University of the Philippines Diliman (UPD) Campus. The precision of real-time route analysis might be affected by this restriction. The second takeaway from the research was that one-way pathways were now preventing the achievement of time-efficient routing for garbage collection. For the sake of efficiency and speed, trash trucks should not be subject to the same regulations that other vehicles were when it comes to one-way streets. A more time- and resource-efficient garbage collecting process can be possible as a result of this modification.

Hu, Y. *et al*. (2024)the author used an enhanced ant colony-hybrid frog-jumping algorithm to address the path-planning issue for urban home garbage collection, taking capacity limits for both single- and multi-model trucks into account. To evaluate and contrast these methods, the author employed numerous viewpoints. Idrissi, A. *et al*. (2024)smart bins and Vehicle Routing Problem (VRP) tools together have the power to revolutionize trash management by cutting down on fuel usage, emissions of greenhouse gases, and related societal costs; all while increasing efficiency and sustainability. Improvements in garbage collection and transportation operations were seen as a consequence of optimization, which successfully met the needs of stakeholders regarding volume and time restrictions. Kamarudin, S. F., and Jamaian, S. S. (2023) when deciding on the most efficient method of trash transportation, distance and optimal routing play crucial roles. This research used the Ant Colony Algorithm to find a better way to move garbage from homes in the Marang area. It was suggested that more trash trucks be added to the Marang region's fleet in order to facilitate more efficient waste collection in future studies. It would be ideal if the actual state of the roads could be anticipated as well, allowing for more effective garbage transportation.

Kangah, J. *et al*. (2022) finally, the author have created and implemented a hybrid algorithm that combines Genetic Algorithm (GA)'s mutation and crossover parameters with Particle Swarm Optimization (PSO). Data testing and comparisons with other models in use led to the conclusion that the model was suitable. Zoomlion Ghana Limited can utilize it to address their issue, since the error estimation reveals it works equally well. When compared to other hybrid models that were already available, the findings from this one were clearly superior and more ideal. Lavigne, C. *et al*. (2021) with the use of a mixed integer linear programming model, this study lays out a strategy for optimizing garbage collection routes that take advantage of many depots, homogenous, capacitated trucks, intermediate stops at various processing facilities, and gatherings at each site. Policymakers can examine the effects of policy changes on expenses and the necessary trash collection feet by using the model to simulate different garbage collection situations.

Nurprihatin, F., and Lestari, A. (2020) by using the closest neighbor algorithm technique, the proposed model has effectively eliminated any garbage that would otherwise go untransported from each hamlet in Caking District. A positive effect on the whole process was guaranteed by any reduction in waste. Attaining the global optimum solution was the goal of the identified path. The number of nodes has a positive and exponentially increasing relationship with the running time. Peña Morales, D. *et al*. (2024) For the purpose of optimizing the routing issue of garbage collection utilizing electric refuse vehicles, this research presents a new, very realistic problem formulation. Within the limitations of the available battery and load capacity, the objective was to discover the paths that minimize the total travelling distance required to collect all bins. This issue takes into account the features of actual situations that were represented by data gathered from open data sources, data collecting firms, and mapping technologies. Pitakaso, R. *et al*. (2024) Overall, the He-DWS model was a big step forward in using AI for disaster waste management, but there's still a lot of room for improvement and adaptability due to these restrictions. To make the model more versatile in its deployment across different settings, future studies should work to diversify datasets, make the model more resistant to environmental variables, and maximize computing efficiency. More flexible and broadly applicable waste management methods will be possible if these problems were resolved.

Rabbani, M., and Sadri, S. (2017) Modern communities incur additional expenses due to the fact that garbage collection operations were seen as a crucial practical concern. Because garbage was certain to accumulate, it was the responsibility of local governments and commercial groups to coordinate the most efficient routes for trash trucks to take from residents' homes to landfills. Variable traffic rates and garbage volume collected from each node were two useful criteria for route optimization. Eliminating non-value-added operations was crucial for improving system efficiency, according to lean principles in the service industry. It was presumed that the time spent on load-unload procedures does not provide value to the garbage collecting process. Rahman, A., and Maryono, M. (2020) the tools, such as ArcGIS, can be used to optimize garbage transportation in Pati Regency. One of the tools included in ArcGis software, Network Analyst, can be used to assess a transportation network from Temporary Trash Shelter (TTS) to Landfill using spatial analysis. Networks connecting TTS and Landfill can be more realistically modelled using ArcGis Network Analyst, taking into account predefined speed limitations and traffic situations.

Rahmandoust, A. *et al*. (2023)The sky-high prices of creating basic commodities like metals, glass, paper, and plastic have long made trash recycling an attractive alternative. Unfortunately, the massive environmental contamination catastrophe was likely to occur if nonbiodegradable materials were returned using procedures that were not suitable. Consequently, governments should take a number of steps to bolster contractors engaged in municipal garbage collection and recycling. Ramdhani, M. *et al*. (2018) the findings obtained from the model of vehicle assignment difficulties on establishing a new route indicate that thirteen out of the thirty-seven truck compactors held by the Surabaya City Council were minimal requirements. Additionally, there must be at least five cycles each departure time and no more than two cycles every destination route. The daily operations of transferring garbage to all temporary disposal sites supplied by the Surabaya City Council include calculating the total number of truck compactors and their departure timetables. The number of vehicles required to transport goods from current locations was sensitive to changes in demand. The greater the demand, the greater the fleet size needed to carry the trash. The demand determines how often the vehicle serves the temporary dumping site.

Rashid, T. *et al*. (2023) Using CVRP to its full potential, this case study optimizes SWM's impact on the environment. This lawsuit centered on solid waste management (SWM) in the Islamabad Capital Territory (ICT), which was overseen by the Capital Development Authority (CDA) and operated by MCI. The cost consistently and gradually decreases with each iteration of the algorithm used to optimize the routes. Importantly, the algorithm guarantees that there was no way to reduce costs any more. The program found the best pathways after 1200 iterations, and further improvement of the routes was not possible. This discovery demonstrates how well the method improves SWM efficiency. Rekabi, S. *et al*. (2024) these authors research develops a new mixed-integer bi-objective mathematical model for building efficient SW networks. SW has a major effect on people's daily life. Human health and ecological balance were more vulnerable to this environmental hazard now than they were in the past. Therefore, this research proposes a new integrated multi-level model for a comprehensive SWM system that includes three levels: Virtual Reality (VR), disassembly science, and the distribution of RCs to depot centers.

Silva, A. *et al*. (2023) increasing the execution time improved the distance travelled, as shown in this paper. Since long execution times might impede real-world applications in dynamic contexts, it was crucial to emphasize that these durations were short in these authors evaluation. To rephrase, research into garbage collection that takes dynamic route planning into account necessitates lightning-fast algorithms for route planning and vehicles for trash service. Because of this, there were cases when the execution duration was less than 20 seconds. Subburaj, S. *et al*. (2023) the aforementioned system has offered thorough methodologies and an outline for a state-of-the-art vision for resolving traffic congestion. It takes mundane, unplanned tasks like garbage collection and transforms them into a coordinated, well-planned operation that could save time, energy, and chaos by harnessing the power of the rapidly developing IoT in cities and mobile computing.

Thi, N., and Phuong, l. (2022) the bulk of Municipal Solid Waste (MSW) originates in households, hence understanding their trash production rate and physical composition was important for effective waste management. In addition to outlining specifics for garbage collection, transportation, and disposal, this lays the groundwork for figuring out other crucial parts of the MSW system as a whole. One month of sampling can have been insufficient to capture certain seasonal differences, as stated in the study's limitations. Tirkolaee, E. *et al*. (2023) In order to find the best routes for garbage collection and the minimum number of trucks needed, this research developed an efficient system. In order to create a sustainable Periodic Capacitated Arc Routing Problem (PCARP) that can accomplish several objectives across multiple trips, a new Mixed-Integer Linear Programming (MILP) model was created. Maximizing total employment opportunities while simultaneously minimizing total expense, total pollution output, and total workload variation was the major objective of the challenge.

Existing methodology

Wu, H.*et al*. the paper built a model for waste collection and transportation with the minimized total comprehensive costs including routes costs and GHG emissions costs. An improved genetic algorithm, local search hybrid algorithm (LSHA), is designed to solve the proposed PCGVRP model. Furthermore, the effectively of LSHA is proved by a

contrast experiment using data from classic CVRP database. After that, the applicability and validity of the proposed PCGVRP model are confirmed by setting different numerical parameters.

Dijkstra's Algorithm

Dijkstra's Algorithm is used to find out shortest path from a source node to all other reachable nodes. It is one of the fundamental shortest path algorithms. The tentative distances are maintained for the nodes to find out the shortest path (Dijkstra 1959). This algorithm visits each node in order to find out the shortest-path and its distances. It will terminate the search when it reaches all target nodes. Thus it finds out the shortest path by minimizing the distance.

Vehicle routing problems

Requests for transportation services are defined in the General Vehicle Routing Problem (GVRP) by a nonempty set of locations that a single vehicle must visit in a specific order, time windows in which these locations must be visited, and the revenue that will be gained upon completion of the service. Moreover, some attributes might be defined that limit the likelihood of allocating transportation requests to certain vehicles owing to limitations in compatibility and capacity. You may load or unload shipments with several descriptive features at each of these locations. Not every transportation request has to be allocated to a vehicle, unlike many other well-known routing challenges. That is the question that needs answering before a transportation request can be fulfilled. The transportation needs may be met by drawing from a fleet of diverse vehicles. The vehicles might vary in capacity, journey duration, and cost depending on the distance traveled. Cargoes may be transported by using a portion of the vehicle's capacity. Each vehicle is assigned a starting point from whence it becomes accessible at a certain time and with a predetermined load, rather than supposing that it becomes available at a central depot. Along with not having to return to a central depot, each vehicle has a certain end destination that they must reach by a certain time with a given amount of cargo. From their starting point to their ultimate destination, each vehicle may be required to visit certain spots in a certain order. You have a limited amount of time to visit each area. The car will have to wait until the time frame starts if it gets to one of these spots earlier. From its starting point to its final destination, a vehicle's tour encompasses all the locations it must visit in the correct order, as well as all the locations associated with the transportation requests assigned to it. In order for a tour to be viable, compatibility requirements must hold for all orders allocated to the tour, and capacity constraints must hold at each point in the tour time frame. The goal is to identify separate, workable trips that maximise profit, where profit is defined as the sum of all transportation requests fulfilled minus the sum of all operational expenses. The Vehicle Routing Problem (VRP) primarily aims to find the best possible path for vehicles to take from a depot, meet all client demands, and then return to the depot. Capacity is a major factor for most VRPs. Based on this, capacitated VRP (CVRP) is the name given to the generalization of VRP. CVRP is described as the challenge of finding the best routes for trucks to take, given certain limitations, from one or more depots to meet all of a customer's demand. If the author goes back to the original concept, CVRP is the challenge of determining the best collection or delivery route to meet consumer demand. According on the problem's objectives, the aim may be to reduce the number of cars, trip time, or cost. Also, there are a lot of cars waiting in the depot to meet client demand, and they all have to go back after the operations are over. There is a set capacity for every vehicle.

A complete graph G = (V, E), where V = {0,1,...,n} is the vertex set and E is the edge set.
Vertices i = 1,2,...,n correspond to the customers. Vertex 0 corresponds to the depot and n is number of customers.
Each customer i has non-negative demand di that must be delivered to the depot.
A set of vehicles H = {1,2,...,h}, where every vehicle has capacity C, is available at the depot and must return to depot after finishing their deliveries.
A non-negative cost cij is associated with each edge (i,j) 2 E and represents distance from vertex i to vertex j for all i – j.
Decision variables
$x_{ijk} = \{1, \quad if vehicle k passed route from i to j \; 0, \quad otherwise$ ---------- (4.12)
$y_{ik} = \{1, \; if vehicle k passed route from i to j \; 0, \; otherwise$ ---------- (4.13)
Minimize

$\sum_{k=1}^{h} \sum_{i=0}^{n} \sum_{j=0}^{n} c_{ij} x_{ijk}$---------- (4.14)

Subject to,

$\sum_{i=0}^{n} x_{i0k} - \sum_{j=0}^{n} x_{ojk} = 0, \forall k = 1, \dots, h$ ---------- (4.15)

$\sum_{i=1}^{n} d_i y_{ik} \leq C, \forall k = 1,2, \dots, h$ ---------- (4.16)

In basic CVRP, it is assumed that all variables are deterministic. But many distribution challenges in the actual world include non-fix data. Consequently, the development of the CVRP model has been the focus of a great deal of CVRP-related literature. Most studies have focused on developing CVRP models that can handle uncertain and stochastic data. Stochastic CVRP allows for the analysis and prediction of CVRP with uncertain data using probabilistic assumptions. More recently, fuzzy variables were used to handle ambiguous data in an effort to enhance CVRP. Uncertain demand and time frames are estimated using fuzzy variables. As a non-crisp border theory with membership degree components with fuzzy set theory. A number of theories on fuzzy event measurement have been put up with regard to the use of fuzzy variables in CVRP with uncertain data. These ideas include credibility theory, possibility and necessity theory, and others.

Proposed methodology

This research focuses on optimizing trash collection and transportation routes using the EGAAV in conjunction with the EGACW algorithm. These algorithms are employed to strategically plan and optimize garbage collection routes, considering variables such as pickup locations and vehicle capacity. The objective is to minimize both travel time and distance covered by garbage collection vehicles, thereby enhancing operational efficiency and reducing environmental impact. Throughout the collection process, images of the gathered trash are systematically captured for subsequent processing and analysis.

Optimizing Trash Collection and Transportation Routes using EGAAV with EGACW

Preprocessing and Augmentation

At preprocessing stage, performed the basic steps such as Resizing, Denoise, Smoothing and Segmentation after the above all the images set in similar size. After preprocessing, Image Augmentation performed for better projection of the dataset. It generates more images with the process flipping, shearing, width and height shifting, zooming and rotating and rescaling so on. Preprocessed Image (Figure: 1). Augmented Image (Figure: 2)

EGAAV algorithm

By using a box-type filter based on integral pictures, the EGAAV approach has decreased the operating time required to detect and define interest spots. The definition of the integral image pixel S at (h, v) is given for each pair of coordinates (i, j) in the input picture as

$S = \sum_{i=0}^{i \leq h} \sum_{j=0}^{j \leq v} I(i, j)$ ---------- (4.1)

This equation can get the total number of pixels within a rectangular section of the input picture with just three additions and four memory accesses by using the integral image and the calculation in Equation (4.1). As a result, many integral-picture-based box-type filters are used to calculate HWRs and approximate the convolutions of the Gaussian second-order partial derivatives.

The SSR step involves building a scale space using the response layers obtained at different scales, which are then divided into several groups called octaves.

$det\left(H\left(x, y, \sigma^i\right)\right) = \left|\frac{D_{xx}(x,y,\sigma^i) w D_{x,y}(x,y,\sigma^i)}{w D_{xy}(x,y,\sigma^i) D_{yy}(x,y,\sigma^i)}\right|$ ---- (4.2)

The horizontal, vertical, and diagonal convolutions of the Gaussian second-order partial derivatives that are approximated using the box-type filters based on the integral image are denoted as D_{xx}, D_{yy}, and D_{xy}, respectively. Points of interest are identified in the LOC stage using the response layers. This equation compare the "X"-marked

pixel P in the middle layer to its neighbors and the 3 neighborhoods in the top and bottom layers that share the same position. The localized interest point is obtained by applying an interpolation procedure to the maximum-determined pixel P.

The OA and DE steps are responsible for creating the points of interest's descriptions. The OA process begins with obtaining horizontal and vertical HWRs for all of the pixels that are part of a circular neighborhood around the point of interest. Afterwards, the major orientation is sought for by using the Gaussian-weighted HWRs of the pixels inside the orientation window of size p/3. To ensure that the descriptor vector remains stable as the image is rotated, the DE phase involves squarely around the point of interest in accordance with the main orientation that was specified. The response layer requires 4 bytes to hold a pixel point since the determinant value in Equation (4.3) is a real integer. Therefore, the memory needed for a five-octave scale space can be expressed as

$$\left\{4.\left(\frac{N}{2}\right).\left(\frac{M}{2}\right)+\sum_{k=2}^{5} \quad 2.\left(\frac{N}{2^2}\right).\left(\frac{M}{2^k}\right)\right\} \text{--------- (4.3)}$$

$$.4\ bytes = \frac{N.M.597}{128} Bytes \text{ ---------- (4.4)}$$

Notably, the first octave generates four response layers, but the subsequent octaves produce just two. According to this study's analysis of Equation (4.4), building the scale space for an input picture with dimensions 640 by 480 requires 1.37 MB of memory. The memory consumed for the scale space is therefore a major aspect that makes implementing the SURF method challenging. It is well understood that there is a spatial correlation between neighboring pixels in a picture. In this case, it would be easy to find a large number of non-maximum points by comparing them to the neighborhood and nearby pixel points in the next response layer. This fascinating phenomenon demonstrates that the local maximum detection approach makes several unnecessary comparisons to the bottom layer, and therefore the SSR step is unnecessary even without the box type filterings applied to the pixel points in the bottom layer. To begin improving the EGAAV algorithm's performance, it is prudent to study the computing demands of its four individual phases. It is also readily apparent why Han's technique, which eliminates the need to repeat computations during the OA step's orientation search, fails to provide a discernible improvement in speed. A large chunk of the total computational burden is accounted for by the HWR process in both the OA and DE steps, as can be shown from this study. This indicates that the HWR process's computational burden greatly affects the operating speed. It suggests a point feature registration procedure that remains invariant when pictures are rotated or translated, and it is based on invariant feature technology. Locate the boundaries of scale space. In other words, the initial picture is transformed using the Gaussian convolution kernel to get the representation sequence in multi-scale space, where the calculation formula is for

$$L(x,y,\sigma) = G(x,y,\sigma) * I(x,y) \text{ ---------- (4.5)}$$

A scale-variable Gaussian function $G(x,y,\sigma)$ is defined as$G(x,y,\sigma) * I(x,y)$, where (x,y) is the gray value of the image and σ is a Gaussian scale factor. Lastly, in order to extract features, the spatial extremum is taken from these sequences. Find the feature points and sort them. The local extremism point (x_0, y_0, σ_0) is where the Taylor formula is developed, and the derivative of the expansion formula is 0. To get the original function's extremum formula, this equation take the coordinate location of the extreme point (∂X) and plug it into the scale space function.

$$D(x) = D + \frac{1}{2}\frac{\partial D^T}{\partial X}x \text{ ---------- (4.6)}$$

In order to reject the extreme point of the class, the interpolation center is moved to the nearby point if the offset in either direction is more than 1/2. Lastly, the stability and anti-noise capabilities are improved by removing unstable edge response spots using the Hessian matrix. Directions are given feature points. To ensure that each feature point is rotationally invariant, the primary direction must be chosen after the feature points have been found. One way to determine the primary orientation of feature points is. The feature point's gradient modulus value is represented by$m(x,y)$, its gradient direction is denoted by$\theta(x,y)$, and the feature point's location on the scale is represented

by$L(x, y)$, the Gaussian image of the feature point. To compensate for the feature points' lack of stability due to affine invariance, each gradient histogram should weight the sample points' gradient amplitudes; the weights of the sample points are then determined by their gradient modulus values and the Gaussian weights. A crucial point identifier is built. At the end of the three-step computation process, every identified feature point has three messages:(x, y),σ,andθ.Specifically, location, size, and orientation. Since the feature point scale affects the feature point descriptor, it is necessary to generate the feature point descriptor in the matching scale's Gaussian pyramid space. To begin, the area around the feature point is partitioned into sub-blocks of dimensions BP × BP, and the size of the edges of each sub-block is M_F pixels. Feature point descriptors are built in the following way: Initially, with the feature point in the center, the image's rotation angle near the feature point is θ in the direction of the feature point's main axis. Next, using the feature point in the middle, choose an image block of dimensions m_FBp × ρBp. Next, split the interval into BP × BP subblocks using the gradient histogram. Finally, determine the seed point by adding up the values of all pixels in each subblock in eight directions. A feature vector of 128 dimensions is created. As an added step in building feature point descriptors, it is necessary to apply a Gaussian weight to all the pixels surrounding the feature point and to normalize all the pixels within a two-fold range to eliminate the impact of lighting and other variables.

EGACW

In the first step, known as scale space extreme discovery, potential key points are located. To build a pyramid of blurry images with different levels of Gaussianity, it first convolves the image S_k using Gaussian filters $GF(x, y, k\sigma)$ at different scales$k\sigma$. In which

$S_k = S(x, y, k\sigma) = GF(x, y, k\sigma) * S_{k-1}$ ---------- (4.7)

Where for k = 1, Sk−1 = S0 = $I\ (x, y)$ is the input image, and

$GF(x, y, k\sigma) = \left(\frac{1}{2}\pi(k\sigma)^2\right) e^{-\frac{(x^2y^2)}{2(k\sigma)^2}}$ ---------- (4.8)

The specified value of k is used to organize the convolved images per octave, with a predetermined number of photos per octave. Frames in pyramids of Gaussian blurred pictures are denoted in this work by their octave and scale, $G[0,0]$. This allows us to define the Gaussian pyramid in the following way

$G[0, 0] = I(x, y): theoriginalframe$ ---------- (4.9)

$G[0, 1] = GF(x, y, \sigma) * G[0,0]$ ---------- (4.10)

$G[m, k] = GF(x, y, k\sigma) * G[m - k - 1] fromm, k \geq 0$ ------- (4.11)

After then, the blurred pictures of the DoG can be calculated by this study.

$DOG[m, k] = G[m, k + 1] - G[m, k]$ ---------- (4.12)

This research could use DoG to find the local maximum or minimum in a 3 × 3 frame that might be keypoint candidates by comparing the pixels at neighboring scales.

By using a low contrast and edge detection test, the keypoint localization procedure finds stable keypoints among the candidates by removing troublesome keypoints. The low contrast test rejects the unstable extreme position by definition.

$x = -\left(\frac{\partial^2 DoG^{-1}}{\partial x^2}\right)\left(\frac{\partial DoG}{\partial x}\right)$ ---------- (4.13)

Based on the Taylor expansion of DoG [m, k], equation can calculate a low contrast threshold.

$DoG(x) = DoG + \frac{1}{2}\left(\frac{\partial DoG^T}{\partial x}\right)x$ ---------- (4.14)

Edge detection is decided by

$\frac{Tr(H)^2}{Det(H)} < \frac{(r+1)^2}{r}$ ---------- (4.15)

The coefficient r is used to adjust the sharpness of the object's edges, and the traces and determinants of the 2×2 Hessian matrix are $Tr(H)^2$ and$Det(H)$, respectively.

$H = \left|DoG_{xx}\ DoG_{xy}\ DoG_{xy}\ DoG_{yy}\right|$ ---------- (4.16)

$Tr(H) = DoG_{xx} + DoG_{yy} = a + \beta$ ---------- (4.17)

When the candidate passes the aforementioned test and is thus confirmed to be a feature point, EGACW starts to determine its orientation. At the orientation assignment step, this section uses the directions of the local image gradients to assign one or more orientations to each keypoint, ensuring rotation invariance. To be more precise, EGACW substitutes the largest vector, the S-vector, for the orientation assignment. Using these methods ensures that the photo will remain in the exact same place, size, and orientation. Finally, for every keypoint, a partially invariant descriptor vector is generated at the local image detector step.

EGAAV with EGACW

The hybrid algorithm for finding optimized collection routes using the EGAAV with EGACW approach begins by initializing the algorithm and setting up the necessary data. The process starts with defining the pickup locations and existing trash collection points as nodes on a graph. To facilitate route optimization, the algorithm calculates the distance between all pairs of these nodes and creates a matrix to store these distances. Next, the algorithm initializes a list to track visited pickup locations and another to manage the routes assigned to each garbage collection vehicle. For each vehicle, the algorithm selects the nearest unvisited pickup location as the starting point and begins constructing its route by adding this location to the current route, updating the vehicle's position, and marking the location as visited. This process continues until the vehicle reaches its capacity or there are no more unvisited locations available. The total travel distance for each route is then computed. The algorithm repeats the process of selecting and visiting locations until all pickup points are covered. Once all routes are established, their efficiency is evaluated based on travel time and distance. To further optimize the routes, the EGAAV (Enhanced Genetic Algorithm with Adaptive Variable Neighborhood Search) with EGACW (Enhanced Genetic Algorithm for Collection and Waste management) algorithm is applied. This optimization step involves rearranging pickup locations to minimize overall travel time and distance. Algorithm 1: EGAAV with EGACW

RESULT AND ANALYSIS

An assessment parameter was used to assess the model's Training Accuracy, Validation Accuracy, Training loss, and Validation loss. Initially evaluated the accuracy of all 3 models with normal data and compared the result as well. In table: 1 and figure: 3 the given data, all methods—GA, GAAV, EGAAV, EGACW, and Hybrid—are associated with the same number of routes, which is 10. This uniformity suggests that regardless of the method employed, each method provides an equal number of routes. This consistency in route count could indicate that the methods are comparable in terms of their route generation capabilities, or it may imply that the routes are pre-defined and influenced by the choice of method. To gain deeper insights, further analysis would be required to assess other performance metrics or variations beyond just the number of routes. The table 2 and figure 4. data indicates that the

methods for finding the shortest path vary in effectiveness. The GA and GAAV methods each identified 1 shortest path, suggesting their limited capability in solving the shortest path problem compared to others. The EGAAV and EGACW methods each found 2 shortest paths, demonstrating a moderate improvement in performance over the previous methods. The Hybrid method outperformed all others, identifying 3 shortest paths, which indicates its superior ability to handle shortest path computations. This progression from fewer to more paths found suggests that the Hybrid method integrates features or optimizations that enhance its path finding performance. The table 3 and figure 5 time data for each method reveals significant differences in performance. The GA method took the longest time at 0.5 milliseconds, indicating it is the slowest among the methods. The GAAV method improved upon this with a reduced time of 0.15 milliseconds. Further optimization was observed in the EGAAV method, which took 0.045 milliseconds, and the EGACW method, which took 0.085 milliseconds. The Hybrid method demonstrated the fastest performance with an impressive time of 0.00267 milliseconds. This substantial decrease in time with the Hybrid method suggests it is highly efficient, likely due to advanced optimizations or algorithmic improvements that significantly reduce computational time.

CONCLUSION

This study centers on optimizing trash collection and transportation routes through the implementation of the EGAAV (Enhanced Genetic Algorithm with Adaptive Variable Neighborhood Search) and EGACW (Enhanced Genetic Algorithm with Clarke and Wright's Savings Algorithm) algorithms. These algorithms are instrumental in planning efficient collection routes for garbage collection vehicles, prioritizing factors such as pickup locations and vehicle capacity to minimize both travel time and distance. The integration of these algorithms aims to enhance operational efficiency in waste management, facilitating timely and resource-efficient collection processes. Concurrently, the phase involves the systematic capture of images depicting collected trash, laying the groundwork for subsequent phases focused on advanced image processing and waste categorization techniques. This approach sets the stage for developing smarter and more sustainable waste management practices, utilizing cutting-edge technologies to optimize route planning and improve environmental outcomes.

Algorithm 3: EGAAV with EGACW

Input

- List of pickup locations.
- Vehicle capacity.
- Locations of existing trash collection points.

Steps

1. Initialize the algorithm.
2. Define pickup locations as nodes on a graph, including the location of existing trash collection points.
3. Calculate the distance between all pairs of pickup locations and collection points.
4. Create a matrix to store distances between locations.
5. Initialize a list to keep track of visited pickup locations.
6. Initialize a list of routes for each garbage collection vehicle.
7. For each garbage collection vehicle:
   o Select the nearest unvisited pickup location as the starting point.
   o Add it to the current route.
   o Update the vehicle's current location.
   o Mark the pickup location as visited.
   o Repeat the process until the vehicle's capacity is reached or no unvisited locations remain.
8. Calculate the total travel distance for each vehicle's route.
9. Repeat steps 7-8 until all pickup locations are visited.
10. Evaluate the efficiency of each route based on travel time and distance.
11. Optimize routes by rearranging pickup locations to minimize travel time and distance using the EGAAV with EGACW algorithm.
12. Output the optimized collection routes for each garbage collection vehicle.

End the algorithm.

Output

- Optimized collection routes.

ABSTRACT

The Zagreb indices are closely associated with connectivity of graph and Zagreb energy is addition of absolute Eigen values of matrix. In this article the extremal results about the Zagreb Indices and Energy with their theorems was discussed.

Keywords: Zagreb, energy, matrix.

INTRODUCTION

The Zagreb Indices and Zagreb Energy is one of the blooming topics in graph theory with more chemical related results. The First Zagreb Indices M_1 and Second Zagreb Indices M_2 [7] are defined as sum of square of degrees of all vertices.

$$M_1 = \sum_{v \in V} \deg(v)^2$$

$$M_2 = \sum_{u,v \in V} \deg(u)\deg(v)$$

The First Zagreb Matrix $Z^{(1)}$ and Second Zagreb Matrix $Z^{(2)}$ is defined as [7] $d_i + d_j$ and $d_i d_j$ when $i \neq j$, and 0 when $i = j$.

$$\left(Z^{(1)}\right) = \begin{cases} d_i + d_j & v_i, v_j \in E(G) \\ 0 & else \end{cases}$$

$$\left(Z^{(2)}\right) = \begin{cases} d_i d_j & v_i, v_j \in E(G) \\ 0 & else \end{cases}$$

The energy of the graph defined as The energy of the graph defined as

$E(G) = \sum_{i=1}^{n} |\lambda_i|$

The First Zagreb Energy $Z^{(1)}$E(G) and Second Zagreb Energy $Z^{(2)}E(G)$ is as the combination of matrix of absolute eigenvalues.

$$Z^{(1)}E(G) = \sum_{i=1}^{n} \left|\gamma_i^{(1)}\right|$$

$$Z^{(2)}E(G) = \sum_{i=1}^{n} \left|\gamma_i^{(2)}\right|$$

The Zagreb Indices and Energy were initiated by I Gutman et. al. [4] in 1970's, which has been useful for properties of molecules and connectivity between them. The purpose of Zagreb Indices are relations of degree of vertices and structures and the purpose of Zagreb Energy are spectral properties of graph.

The Zagreb Indices is useful to predict properties like melting points and boiling points correlated with molecular structure. The Zagreb Energy is to estimates electronic structure of molecule's.

In this review, we restricted our focus to the extremal results on Zagreb Indices and Energy for recent decades.

Extremal Results of Zagreb Indices

The paper [17] Upper Bounds of Zagreb Connection Indices(ZCI) of Tensorand Strong Product on Graphs investigates the ZCI upper bound (1stZCI, 2nd ZCI, and modified 1st ZCI) for the tensor and strong productof two graphs. The authors provide general results and formulas forcomputing these upper bounds, which are important in the discussion ofQSAR (quantitative structure-activity relationships) and QSPR (quantitativestructure-property relationships) in chemistry and materials science.The key findings include explicit expressions for the upper limits of the ZagrebConnection index in terms of the properties (degrees and connectionnumbers) of the original graphs. Degree-based TIs, such as the 1st and2nd Zagreb indices, have been used to predict result in molecular structures,including molar, absolute correlation, volume, acentric factor, andstandard enthalpy of formation.

The results [17] of the ZCI of strong and tensor product of graphs as

Tensor Product

Exact value of $ZC_1(P_3 \otimes P_3) = 40$;
Computed value of upper bound $ZC_1(P_3 \otimes P_3) \leq 136$;
Exact value of $ZC_2(P_3 \otimes P_3) = 4$;
Computed value of upper bound $ZC_2(P_3 \otimes P_3) \leq 128$;
Exact value of $ZC_1^*(P_3 \otimes P_3) = 20$;
Computed value of upper bound $ZC_1^*(P_3 \otimes P_3) \leq 52$.

Strong Product

Exact value of $ZC_1(P_3 \boxtimes P_3) = 136$;
Computed value of upper bound $ZC_1(P_3 \boxtimes P_3) \leq 169$;
Exact value of $ZC_2(P_3 \boxtimes P_3) = 156$;
Computed value of upper bound $ZC_2(P_3 \boxtimes P_3) \leq 264$;
Exact value of $ZC_1^*(P_3 \boxtimes P_3) = 112$;
Computed value of upper bound $ZC_1^*(P_3 \boxtimes P_3) \leq 152$.

The paper [17] obtains general results of upper limit for the ZCI, namely the 1st ZC_1, 2nd ZC_2, and modified 1st Zagreb connection index ZC_1^* , on the resultant graphs obtained by operating the strong and tensor product on 2 simple graphs. The paper [6] Comparing Zinc Oxide- and Zinc Silicate-Related Metal- Organic Networks via Connection-Based Zagreb Index discusses 2 distinct zinc-related metal-organic networks (MONs): zinc oxide (ZNOX(n)) and zinc silicate (ZNCL(n)). The authors compute various connection-related Zagreb index, such as the 1st ZCI, 2nd ZCI, modified 1st ZCI, modified 2nd, 3rd and 4th ZCI, to compare the properties of these two MONs as the number of layers (n) increases. The key findings indicate that the zinc silicate-related MON is good to the zinc oxide-related MON for all values of n.

Theorem 1 [6] LetH ≅ ZNOX(n)of dimensions n ≥ 3. Then, ZCI are
$ZC_1(H) = 1068n + 692$
$ZC_2(H) \cong 1376n + 896$
$ZC_1^*(H) \cong 672n + 432$
$ZC_2^*(H) \cong 1740n + 1124$
$ZC_3^*(H) \cong 1808n + 1184$
$ZC_4^*(H) \cong 10344n + 7224$
The comparison between the (ZNOX(n)) and (ZNCL(n)) metal-organic networks (MONs) based on the provided contexts: The zinc silicate-related MON (ZNCL(n)) has higher values and upper lines for all computed connection-based Zagreb indices (ZCIs) compared to zinc oxide-related MON (ZNOX(n)). This includes the 1st, 2nd, modified 1st, modified 2nd, modified 3rd, and modified 4th ZCI. The modified 4th ZCI (ZC_4^*) attains the highest values among all the ZCIs for both the zinc-related MONs. The modified 1st ZCI showed best correlation with the physico-chemical possessions of octane isomers compared to other Zagreb indices. Similarly, the novel $ZC4$ also showed best correlation for the increasing in both zinc-related MONs. Overall, the comparison shows that the MON (ZNCL(n)) is good than the MON (ZNOX(n)) for all values of the number of layers (n). The research article concludes that the zinc silicate-related MON exhibits superior properties compared to the zinc oxide-related MON based on the computed connection-based Zagreb indices. The paper [8] Computing Analysis for First Zagreb Connection Index and Coindex of Resultant Graphs, investigates the graphs obtained through tensor and strong product, symmetric difference, and disjunction operations. Authors derive upper limits for the 1st ZCI and co-index in terms of the index of the factor G. The paper includes an analysis of the obtained results using numerical values and graphical representations. The study contributes to the understanding of connection number-based topological indices and their applications in cheminformatics and molecular graph analysis.

Theorem 2 [8] Let G_1andG_2be connected and $\{C_3, C_4\}-$free graphs. Then, $ZC_1$and$\bar{Z}C_1$of the tensor product ($G1 \oslash G2$)are
$$ZC_1\left(\frac{G1}{G2}\right) = n_2ZC_1(G_1) + n_1ZC_1(G_2) + ZC_1(G_1)ZC_1(G_2) + 2AB + 2AZC_1(G_2) + 2BZC_1(G_1),$$
$$ZC_1(G_1 \oslash G_2) = 2\mu_2ZC_1(G_1) + 2\mu_1ZC_1(G_2) + 2\sum_{a_1a_2\notin E(G_1)}\sum_{b_1b_2\notin E(G_2)}\left[\tau_{G_1}(a_1)\tau_{G_2}(b_1) + \tau_{G_1}(a_2)\tau_{G_2}(b_2)\right]$$
The proof involve expanding the connection number of the tensor product and rearranging the terms to obtain the final expressions for the 1st Zagreb connection index and co-index. It conclude by providing the upper limits for the 1st and coindex ZCI of the tensor, strong, symmetric difference, and disjunction of graphs . The graphical and numerical analyses of the exact and upper limits for the 1st ZCI and co-index of the tensor and strong product are presented. The paper [16] Some Novel Results Involving Prototypical Computation of Zagreb Polynomials and Indices for SiO_4 Embedded in a Chain of Silicates focuses on computing based on valency invariants molecular for SiO_4 embedded in a chain of silicate. The authors used the atom-bond partitioning approach based on the valence of Si and O_2 atoms to derive exact formulas for various Zagreb polynomials and indices. The computed topological indices include the first, second, hyper, modified, enhanced, and redefined Zagreb (first, second, and third). The results demonstrate the dependence of these topological indexs on the specific polynomial structure parameters of the silicate chain. The findings provide insights into using topological indices to characterize the chemical and physical properties of silicate compounds. The basic unit of silicates is a SiO_4 tetrahedron, which can join with other SiO_4 tetrahedra to form a silicate chain of SC_q^p, where p and q are the chain of silicate numbers and total number of SiO_4 in 1 silicate chain, respectively. In the chain of silicates SC_q^p, 3 types of atom-bond partitions based on the valencies of the Si and O_2 atoms: (3~3), (3~6), and (6~6). The authors derived exact formulas for various Zagreb polynomials and indices for the silicate chain SC_q^p. The results demonstrate the dependence of that topological index on specific polynomial parametric structure of the silicate chain. The findings provide insights into using topological indices to characterize the chemical and physical properties of silicate compounds.
Theorem 3 [16] For $p > 1$, then hyper-Zagreb polynomial of $SC_q^p$is$(3p + 2)y^{36} + (3p^2 + 3p - 4)y^{81} + (3p^2 - 6p + 2)y^{144}$.

Theorem 4 [16] For $p > 1$, then modified Zagreb polynomial of $SC_p^p$is $(3p + 2)y^{\frac{1}{9}} + (3p^2 + 3p - 4)y^{\frac{1}{18}} + (3p^2 - 6p + 2)y^{\frac{1}{36}}$

Theorem 5 [16] Let odd $p$and $p < q$. Then 3rd redefined Zagreb polynomial of $SC_q^p$is $3(p + 1)y^{32} + (3pq + p + 2q - 5)y^2 + (3pq - 4p - 2q + 2)y^3$.

Theorem 6 [16] Let p be odd and $p < q$. Then 3rd redefined Zagreb polynomial of $SC_q^p$is $3(p + 1)y^{54} + (3pq + p + 2q - 5)y^{196} + (3pq - 4p - 2q + 2)y^{432}$.

The key points to take is detailed analysis of various based on valency invariant molecular, such as the first, second, hyper, modified, enhanced, and redefined Zagreb indices, for SiO_4 embedded in a silicates chain SC_q^p. Applied the atom-bond partitioning method related to atom valences and used spectral graph theory to fet the exact values of these topological indices. The results are particularly interesting when the silicate chain numbers $p \geq q$, as indicated by the authors. The paper provides a graphical results, which tells about dependence of the topological index on particular polynomial parametric structure. The findings of this study contribute to the understanding of the chemical characteristics and properties of SiO_4 embedded in silicate chains, which can be useful in various applications in theoretical chemistry and materials science. The paper [9] Laplacian energy and first Zagreb index of Laplacian integral graphs derived formulas for the Ehodnegry by Laplacian met and 1st Zagreb index of graphs realizing the Laplacian spectrum $S_{i,n}$. The authors provided lower and upper limits for the Laplacian energy of such graphs. Also discussed a conjecture that the set $S_{n,n}$ is not Laplacian realizable, and proved some related results. All the L-borderenergetic and L-equienergetic graphs realizing $S_{i,n}$ were listed. And found some graphs realizing $S_{i,n}$ with the same number of spanning trees.

Theorem 7 [5]Let $n \geq 2$and $1 \leq i \leq n$. Suppose that $S_{i,n}$ is Laplacian realizable. If $n \equiv 0\ mod\ 4\ or\ n \equiv 3\ mod\ 4$ then i is even, while if $n \equiv 1\ mod\ 4\ or\ n \equiv 2\ mod\ 4$, then i is odd.

Theorem 8 [5]Suppose $n > 2$

If $n \equiv 0\ mod\ 4$, then for $i = 1, 2, 3, \ldots, \frac{n-2}{2}$, $S_{2i,n}$ is Laplacian realizable

If $n \equiv 1\ mod\ 4$, then for $i = 1, 2, 3, \ldots, \frac{n-1}{2}$, $S_{2i-1,n}$ is Laplacian realizable

If $n \equiv 2\ mod\ 4$, then for $i = 1, 2, 3, \ldots, \frac{n}{2}$, $S_{2i-1,n}$ is Laplacian realizable

If $n \equiv 3\ mod\ 4$, then for $i = 1, 2, 3, \ldots, \frac{n-1}{2}$, $S_{2i,n}$ is Laplacian realizable

Theorem 9 [5]Let$G$ be a connected graph of n order with m edges and Δ maximum degree. Then
$LE(G) \geq 2(\Delta + 1 - \bar{a})$,
with equality if and only if G is isomorphic to $K_{1,n-1}$. Here a is the mean degree of the graph G

Theorem 10 [5]Let a graph G of order n and of size $m, m \geq \frac{n}{2}$. Then

$$LE(G) \leq 4m - 2\Delta - \frac{4m}{n} + 2.$$

Here the equality holds iff$G$ is isomorphic $K_{1,n-1}$ or G is isomorphic $K_{1,\Delta} \cup \overline{K}_{n-\Delta-1}, \frac{n}{2} \leq \Delta \leq n - 2$.

Theorem 11 [5]Suppose $n > 2$. If G is a graph of order n realizing $S_{i,n}$ for certain $1 \leq i \leq n$ then

$$M_1(G) = \frac{n(n+1)(n-1)}{3} - i(i-1)$$

This paper [5] concluded by deriving exact formulas for the Laplacian energy and the first Zagreb index of graphs whose matrices have the set $S_{i,n}$ as its eigenvalues. The authors find that the Laplacian energy of graphs realizing $S_{i,n}$ does not exceed the first Zagreb index of such graphs. All the L-borderenergetic and L-equienergetic graphs realizing $S_{i,n}$ were listed. The authors were unable to find a formula for the second Zagreb index of graphs realizing $S_{i,n}$ and

state this as an open problem. The authors discuss a conjecture stating that the set$S_{n,n}$ is not Laplacian realizable and provide some related results, including proving that if such graphs exist, they could not be the Cartesian product of 2 graphs. The paper [12] Expected value of first Zagreb connection index in random cyclooctatetraene chain, random polyphenyls chain, and random chain network derived expected values of the 1st ZCI for random cyclooctatetraene, polyphenyls, and chain networks with pentagons, hexagons and octagons,. Examined the mean and strong values of the Zagreb connection index among the different random chain types. The Zagreb connection indices provide insights into the connectivity characteristics of molecular graphs, with applications in areas like discovering drug, research on physico-chemical, and chemistry. Builds on previous work exploring values of other topological indices for random chain structures.

Theorem 12 [12]For $l \geq 2$, the expected value for the 1st Zagreb connection index of COC_l is
$E\ (ZC_1\ (\ (COC_l))\ _ = (8k_1 + 2k_2 + 76)l\ -\ 16k_1\ -\ 4k_2\ -\ 44$

Theorem 13 [12]For $l \geq 2$, the expected value for the 1st Zagreb connection index of PPC_l is
$E\ (ZC_1\ (\ (PPC_l))\ _ = (8k_1 + 2k_2 + 68)l\ -\ 16k_1\ -\ 4k_2\ -\ 44$

Theorem 14 [12]For $l \geq 2$, the expected value for the 1st Zagreb connection index of PG_l is
$E\ (ZC_1\ (\ (PG_l))\ _ = (6k_1 + 66)l\ -\ 12k_1\ -\ 48$

Theorem 15 [12] The average value for the 1st Zagreb connection index concerning the set G_l is given as
$ZC_l^{avg}(G_1) = \frac{157}{2}l - 49$
The key points to take away from his paper [10] are it calculated the expected values of the 1st Zagreb connection index in a random cyclooctatetraene, random polyphenyls, and random chain network with one, pentagon octagons, and hexagons respectively. It discussed the maximum chain and the minimum chain of the COC_l, PPC_l, and PG_l, respectively, concerning the expected values of these chains. It also discussed the average values considered for all the above random chains for unique chains. The paper [13] On the first Zagreb index of graphs with Self-Loops studies the first Zagreb index $M_1(GX)$ of a graph GX with self-loops is stated as the addition of squares of the vertex degrees. Authors derive upper limits for $M_1(GX)$ in phrase of the maximum and minimum degrees, the number of vertices and edges, and the spectral radius of the adjacency matrix. Lower bounds for $M_1(GX)$ are also provided, using the eigenvalues of the adjacency matrix. The results extend a existing literature on degree-based topological indices and the energy of graphs with self-loops.

Theorem 16(For Upper Bound) [13]Let $G_X$be a graph obtained from a simple graph G of order $n$and size $m$by attaching a self-loop at each vertex of $X \subseteq V(G)$with $|X| = \sigma$, Then
(Table: 1)

Theorem 17(For Lower Bound)[11] Let $G_X$be a graph obtained from a simple graph G of order $n$and size $m$by attaching a self-loop at each vertex of $X \subseteq V(G)$with $|X| = \sigma$. Then (Table: 2)
The paper [2] Extremal values of the first reformulated Zagreb index for molecular trees with application to isomers octane 1st reformulated Zagreb index is a topological index that will assist out to estimate the chemical or physical properties of molecules. Authors derived formulas to calculate the 1st reformulated Zagreb index of molecular trees and determined the extremal trees that reach the minimum and maximum values of this index. An application, the authors used the extremal graphs to develop models on regression to guess acentric factor and entropy of isomers octane. The maximum value of 1st reformulated for molecular trees of n order is bounded, and the conditions for attaining this maximum value are provided.

Theorem 18 [2]Let T be a molecular tree of order $n \geq 5$, then the maximum value of the first reformulated Zagreb index is

$$EM_1(T) \leq \begin{cases} 18n-64 & n \equiv 0(mod\ 3) \\ 18n-72 & n \equiv 1(mod\ 3) \\ 18n-54 & n \equiv 2(mod\ 3) \end{cases}$$

and the maximum first reformulated Zagreb index is achieved if, and only if, one of the following conditions is satisfied:

- T has exactly 1 edge of degree 1 and 1 edge of degree 16,
- 2 edges are of degree 4 and degree of 1 edge is 25,
- Degree of all the edges are either 9 or 36.

The proof says if T is a molecular tree with the maximum first reformulated Zagreb index, then T must satisfy one of the following three conditions

- All vertices of T have a degree of either 1 or 4
- Exactly 1 vertex of the graph with degree 2 and remaining are with degree 1 or 4
- Exactly 1 vertex of the graph with degree 3 and remaining are with degree 1 or 4

The proof considers different cases based on the order of the molecular tree (n) modulo 3, and derives the maximum value of EM1(T) for each case.

Theorem 19 [2]Let a molecular tree with n vertices such that $n \geq 5$ and$2 \leq \Delta \leq 4$, then the least value of the 1st reformulated Zagreb index is given as

$$EM_1(T) \leq \begin{cases} n-10 & for\ \Delta = 2, \quad \text{when T is a path} \\ 4n-2 & for\ \Delta = 2, \quad \text{when T contains 2 edges of degree 4} \\ 4n+20 & for\ \Delta = 2, \quad \text{when T contains 3 edges of degree 9} \end{cases}$$

Application to octane isomers in [2] says the acentric factor is a measure of molecules non-centricity, and as the acentric factor increases, down vapor pressure happens, occurs in higher boiling points. Entropy is a measure of the unavailability of a energy system to do work, and the maxi the disorder in a molecule, the maxi the entropy. The authors considered 18 octane isomers and their acentric factors, entropy measures, and the first reformulated Zagreb indices. The authors performed a linear regression and obtained equations with degree 1 that can say the acentric factor and entropy of isomer octane based on the 1st reformulated Zagreb index. The authors found that 2,2,3,3-tetramethyl butane (18th isomer) has the maxi reformulated Zagreb index with the mini acentric factor and entropy, and this implies that chemical trees with the maxi reformulated Zagreb index have the mini acentric factor and entropy measure. The paper [1]focuses on the Circumacenes family of organic molecules, which have potential applications in molecular electronics. The researchers calculate the 1st and 2nd Zagreb indices, as well as related generalized indices, to understand the structure-property relationships of these molecules. The Topological Indices Method (TIM) is used as an efficient and cost-effective approach to predict important thermodynamic properties like gap energy and electron affinity energy. The paper provides mathematical proofs for calculating the 1st and 2nd Zagreb indices for the Circumacenes family. The findings demonstrate the utility of topological indices in predicting the properties of complex organic molecules, which can aid in the development of molecular electronics.

Theorem 20[1]If A_i for $i \in \{1,2,\dots\}$ are simple molecular graphs of Circumacenes $\left(C_{\left(\frac{8i+16}{3}\right)}H_{\left(\frac{2i+22}{3}\right)}\right)$, then $M_1(A_i) = 62i + 94$.

Theorem 21[1] If A_i for $i \in \{1,2,\dots\}$ are simple molecular graphs of Circumacenes$\left(C_{\left(\frac{8i+16}{3}\right)}H_{\left(\frac{2i+22}{3}\right)}\right)$, then for $i \in \{1,2,\dots\}$

$HM(A_i) = 2276i + 3652$

$SC(A_i) = H_{-\frac{1}{2}}(A_i) = -(0.066i + 1.326)$

$H(A_i) = 2H_{-1}(A_i) = -2(0.108i + 0.702)$

Theorem 22[1]If A_i for $i \in \{1,2,\dots\}$ are simple molecular graphs of Circumacenes $\left(C_{\left(\frac{8i+16}{3}\right)}H_{\left(\frac{2i+22}{3}\right)}\right)$, then $M_2(A_i) = 3(29i + 66)$.

This paper [1] explores the thermodynamic properties of Circumacenes, a family of organic molecules, through the calculation of topological indices such as the 1st and 2nd Zagreb indices. The researchers demonstrate how these topological indices can be used to predict crucial thermodynamic properties like gap energy and electron affinity energy using an innovative method called the Topological Indices Method (TIM). The paper provides mathematical proofs for calculating the first and second-Zagreb indices for the Circumacenes family, highlighting their structure-property relationships. The findings show the utility of topological indices in predicting the properties of complex organic molecules, which can aid in the development of molecular electronics.

Extremal Results Of Zagreb Energy

The paper [18] Zagreb Energy of Weighted Graphs studied the concepts of 1st Zagreb and 2nd Zagreb energy for weighted graphs, where edge weights are positive definite matrices. The authors define the weighted first Zagreb and second Zagreb matrices, and derive the corresponding eigenvalues and energies. They then present upper and lower limits for the 1st Zagreb energy of $+ve$ definite matrix weighted graphs, and obtain some limts for number weighted and unweighted graphs as special cases. The paper also includes examples demonstrating the calculation of the first and second Zagreb energies for the methane (CH4) molecule. The example [18] considers the edge-weighted molecular graph of the methane (CH_4) molecule, where each edge has a bond length weight of 0.11 nanometers. The first Zagreb matrix $z_w^{(1)}$ for this graph is

$$z_w^{(1)} = \begin{bmatrix} 0 & 0.55 & 0.55 & 0.55 & 0.55 \\ 0.55 & 0 & 0 & 0 & 0 \\ 0.55 & 0 & 0 & 0 & 0 \\ 0.55 & 0 & 0 & 0 & 0 \\ 0.55 & 0 & 0 & 0 & 0 \end{bmatrix}$$

with eigenvalues -1.1 (once), 0 (3 times), and 1.1 (once). The first Zagreb energy of this weighted graph is calculated to be $Ez_w^{(1)} = 2.2$. The first Zagreb index W_1 for this graph is calculated to be $W_1 = 1.21$. The lower and upper limits of 1st Zagreb energy of this weighted G, are also provided.

It [18] conclude, For an unweighted graph G of order n (≥ 3), the first Zagreb energy is upper bounded as $E_{Z_w^{(1)}}(G) \leq \left|\lambda_{w,1}^{(1)}\right| + \sqrt{(nt-1)\left(2\mathcal{W}_1 - \left(\lambda_{w,1}^{(1)}\right)^2_{!}\right)}$, where $\lambda_{w,1}^{(1)}$ is largest 1st Zagreb eigenvalue and HM is hyper-Zagreb index. For an unweighted graph G of order n (≥ 3) with zero not being an eigenvalue of $Z_w^{(1)}(G)$, the first Zagreb energy is lower bounded as $E_{Z_w^{(1)}}(G) \geq \frac{2\sqrt{\lambda_{w,1}^{(1)}\lambda_{w,n}^{(1)}\sqrt{(2n)\mathcal{W}_1}}}{\lambda_{w,1}^{(1)}+\lambda_{w,n}^{(1)}}$, where $\lambda_{w,1}^{(1)}$ and $\lambda_{w,n}^{(1)}$ are the maximum and minimum of the absolute values of the first Zagreb eigenvalues, respectively. A matrix weighted graph G of order n (≥ 3), the second Zagreb energy satisfies the following bounds $\sqrt{2\mathcal{W}_2} \leq E_{Z_w^{(2)}} \leq \sqrt{2n\mathcal{W}_2}$ where $\mathcal{W}_2$ is 2nd Zagreb index of weighted graph. For an unweighted G of order n (≥ 3) with zero not being an eigenvalue of $Z^{(2)}(G)$, the second Zagreb energy is lower bounded as $E_{Z_w^{(2)}}(G) \geq \frac{2\sqrt{2nM_2^{(2)}\lambda_2^{(2)}\lambda_n^{(2)}}}{\lambda_2^{(2)}+\lambda_n^{(2)}}$, where $\lambda_2^{(2)}$ and $\lambda_n^{(2)}$ are the maximum and minimum of the absolute values of the 2nd Zagreb eigenvalues, respectively, and $M_2^{(2)}$ is the general Randić index with $\alpha = 2$.

The paper [11] On Zagreb energy and edge-Zagreb energy presents several results related to Zagreb and edge-Zagreb energy of graphs. The authors obtain upper and lower limits for the general extended energy of a graph, and apply these results to derive bounds for the Zagreb and edge-Zagreb energy. They also establish a relationship between the Zagreb and edge-Zagreb energy for graphs with minimum degree 2. Additionally, the paper provides a lower and upper limit for the spectral radius of the edge-Zagreb, and describes methods to construct Zagreb and edge-Zagreb equienergetic graphs.

Theorem 23[11] Let $f(d_i)$ and $g(d_i)$ be non-negative real numbers. If $F(d_i;\, d_j) = f(d_i) + f(d_j) + g(d_i).g(d_j)$. Then $\mathcal{E}_T(G) \leq (2f_m + g_m^2)\mathcal{E}(G)$

where $f_m = \max\{f(d_1); f(d_2); \ldots ; f(d_n)\}$ and $g_m = \max\{g(d_1); g(d_2); \ldots ; g(d_n)\}$. Equality attained iff $f(d_1) = f(d_2) = \cdots = f(d_n)$ and $g(d_1) = g(d_2) = \cdots = g(d_n)$.

Theorem 24[11] n vertices. Then

$$\mathcal{E}_T(G) \leq \sum_{i=1}^{n} \sqrt{\sum_{v_i v_j \in E(G)} \mathcal{F}^2(d_i, d_j)}$$

Theorem 25[11] Let graph G with n vertices with degree $\delta \geq 2$. Then

$$Z\mathcal{E}_2(G) \geq \sqrt{\frac{2}{n}} Z\mathcal{E}_1(G)$$

Theorem 26[11] Let graph G with order n, m edges whose minimum degree δ and maximum degree Δ. Then $\delta\,(2m - (n - 1 - \delta)\Delta - \delta) \leq \gamma_1(G) \leq \Delta(2m - (n - 1 - \Delta)\delta - \Delta)$, it hold iff$G$ is a regular.

Theorem 27[11] Consider G_1 be a r_1-regular of order $n_1$andG_2be r_2-regular graph of order n_2. Then the spectrum of Z_1 $(G_1 \vee G_2)$ consists of $2(r_1 + n_2)\lambda_i(G_1)$ and $2(r_2 + n_1)\lambda_j(G_2)$ for $i = 2, 3, \ldots ; n_1$and $j = 2, 3, \ldots; n_2$, and the two roots of the equation $(x - 2(r_1 + n_2)r_1)(x - 2(r_2 + n_1)r_2) - (n_1 + n_2 + r_1 + r_2)^2 n_1 n_2$. The results [11] are The authors obtained upper and lower limits for the general extended energy of a G, and applied these aggregate to derive bounds for the Zagreb and edge-Zagreb energy. They initiate a relationship between the Zagreb and edge-Zagreb energy for graphs with minimum degree 2. The paper provided a lower and upper limit for the spectral radius of the edge-Zagreb. The authors described methods to construct Zagreb and edge-Zagreb equienergetic graphs, and showed that such equienergetic graphs exist for orders $n \geq 9$.The paper [3] On Second Zagreb Energy of Graphs explores the mathematical properties and application potential of the second Zagreb energy (ZE_2). $ZE_2$is derived from the modified adjacency matrix with the 2nd Zagreb index (M_2). The authors investigate the role of ZE_2 in modeling isomer discrimination and physico-chemical. They objective to establish limits on the spectral radius and spread of the M_2-spectrum, and characterize extremal graphs.The ZE_2 is studied for various special graphs, including regular graphs, semi-regular graphs, and chain graphs. A matrix of divisor-type is proposed to approximate the M_2-spectrum and ZE_2 energy of chain graphs. The chemical significance of the second Zagreb energy in the following ways: The authors investigate the role of ZE_2 in modeling physico-chemical of molecules and isomer discrimination. The ZE_2 energy is found to correlate with entropy (S)and acentric factor (AF) of isomer octane. Linear regression models are developed to predict these properties using ZE_2 as a predictor variable. The ZE_2 model explains 90% and 99% of the data variance for entropy and acentric factor, respectively, with reduced errors. The models are shown to be reliable based on the F and SF values. The predictive ability of the ZE_2 model is further validated using a test set of nonane isomers, which shows a data variance of 88%. The discrimination potential of ZE_2 is compared to other well-known descriptors, and it is found to outperform them in isomer discrimination for octane, nonane, and decane isomers.

Theorem 28[3] For a graph G of order n with second zagreb index $M_2(G)$, we obtain

$$\frac{2M_2(G)}{n} \leq \nu_1 \leq \sqrt{\left(1 - \frac{1}{n}\right)\Upsilon_2}$$

whereΥ_2 is given. The right equality holds iff $G \cong \overline{K}_n$or $G \cong K_n$ and left equality occurs iff G is regular.
For lower bound, authors use the Rayleigh-Ritz principle to show that:

$$\nu 1(G) \geq \frac{e^t \Omega(G) e}{e^t\, e} = \frac{2M_2(G)}{n}$$

where e is the all-ones vector.
The upper bound is derived by using the fact that the largest eigenvalue of $\Omega(G)$ is bounded above by the expression given. In summary, Theorem provides tight bounds on the biggest eigenvalue of the 2nd Zagreb matrix $\Omega(G)$ in terms of the 2nd Zagreb index $M_2(G)$ and the parameter Υ_2 from Lemma, with the equalities characterizing the extremal graphs.

Theorem 29[3] Let graph G with $\Delta$and δ, respectively, we have

$\lambda_1\delta^2 \leq \nu_1 \leq \lambda_1\Delta^2$
where equalities occur iff$G$ is regular.
The left equality occurs iff G is a regular. Additionally, it states that: $\lambda_1 \leq \sqrt{2m - n + 1}$ where equality appears iff $G \cong S_n$ or $G \cong K_n$. Moreover, the right equality happensiff G ~= Sn or G ~= Kn.
In summary, Theorem 3 provides tight bounds on the biggest eigenvalue of the 2nd Zagreb matrix $\Omega(G)$ in terms of m edges and the maximum degree Δ, with the equalities characterizing the extremal graphs

Theorem 30[3] For a connected graph G having n (≥ 2) vertices, we have

$$\nu_1 - \nu_n \leq \frac{n}{n-1}\nu_1 + \sqrt{\frac{n-2}{n-1}\Upsilon_2 - \frac{n^2-2n}{(n-1)^2}\nu_1^2}$$

Equality appears iff$G$ is complete or complete bipartite.
From Lemma, we have $\Upsilon_2 - {\nu_1}^2 - {\nu_n}^2 = \Sigma({\nu_2}^2 + {\nu_3}^2 + \ldots + \nu(n-1)^2)$.
Using the Cauchy-Schwarz inequality, we get $\Upsilon_2 - {\nu_1}^2 - {\nu_n}^2 \geq \frac{(\nu^1+\nu_n)^2}{n-2}$.
Rearranging the terms, we obtain $(n-1){\nu_n}^2 + 2\nu_1\nu_n + (n-1){\nu_1}^2 - \Upsilon_2(n-2) \leq 0$.
Solving this inequality for ν_n, we get the desired upper bound on $\nu_1 - \nu_n$.
The equality in the upper limit holds iff$\nu_2 = \nu_3 = \ldots = \nu(n-1)$, which is true if and only if G is complete or complete bipartite. In summary, Theorem provides a tight upper bound on the difference between the largest and smallest eigenvalues of the second Zagreb matrix $\Omega(G)$, with the equality characterizing the complete and complete bipartite graphs.

Theorem 31[3] Let graph G of order $n \geq 3$ having no isolated vertices, we have

i. $ZE_2(G) = r^2\,\varepsilon(G)$, when G is r-regular. Particularly, $ZE_2(K_n) = 2(n-1)^3$ and $ZE_2(C_n) = 8\sum_{i=0}^{n-1}\left|\cos\left(\frac{2\pi i}{n}\right)\right|$ When G is connected $Gs(n, r, a_1, b_1)$, we have
$$ZE_2(G) = r^2\left(r + \frac{2(n-1)(r-b_1) - r(a_1-b_1)}{\sqrt{(a_1-b_1)^2 + 4(r-b_1)}}\right)$$
ii. $ZE_2(G) = \alpha\,\beta\,\varepsilon(G)$, when G is (α,β)-semiregular bipartite. Particularly, $ZE_2(K_{p,q}) = 2\,pq\sqrt{pq}$where $p + q = n$. Also $ZE_2(S_n) = 2\,(n-1)\sqrt{n-1}$

For ZE_2 of regular and semi-regular graphs $G_s(n, r, a_1, b_1)$ can be derived using the M_2-eigenvalues of these graph classes, as discussed in Lemma.

Theorem 32[3] Let $K \cong G(n_1, n_2, \ldots, n_h; m_1, m_2, \ldots, m_h)$be a chain graph of order n. Then

$$ZE_2(G) \geq 2\sqrt{\sum_{i=1}^{h}(h+1-i)m_i n_i(\alpha_i\beta_i)^2 + h(h-1)\prod_{i=1}^{h}\left[(m_i n_i)^{\frac{1}{h}}(\alpha_i\beta_i)^{\frac{2}{h}}\right]}$$

with equality occurs iff$G \cong K_{n_1,m_1}$ where $(n_1 + m_1 = n)$.
For the case $h = 1$, where $G \cong K_{n_1,m_1}$, the M_2-spectrum of G is known, and the equality in the theorem holds.
For the case $h \geq 2$, the graph G contains an induced subgraph P_4, and by Lemma, the second M_2-eigenvalue $\nu_2(G)$ is greater than 0. This implies that the inequality in the theorem holds strictly for $h \geq 2$. The proof constructs a divisor type matrix to approximate the M_2-spectrum andZE_2 of the chain graph G. Therefore, the lower bound on the ZE_2 energy of chain graphs and characterizes the extremal graph where the equality is attained. The paper [10] More on Second Zagreb Energy of Graphs investigated the 2nd Zagreb energy of a graph is stated as the sum of eigenvalues of the 2nd Zagreb matrix. The authors expressed the relationship between the 2nd Zagreb and the adjacency matrix of a G. They use this relationship to establish new upper limits for the 2nd Zagreb energy. Authors also evaluate the 2nd Zagreb energy of m-splitting and m-shadow graphs. The general results are(Table:3). The paper [9] Hub Zagreb Energy Of Graphs discussed the 1st hub Zagreb matrix and 2nd hub Zagreb matrix of a graph are defined. The first hub Zagreb energy is the combination of eigenvalues of the 1st hub Zagreb matrix. Bounds for the 1st hub Zagreb energy are established in hub and hyper-hub Zagreb index. The hydrocarbons hub Zagreb energy is calculated

Theorem 33 [9] Let a graph G with hyper-hub Zagreb index $HZ_2^*(G)$ Then $e^{-\sqrt{2HZ_2^*(G)}} \leq HZE_1(G) \leq e^{\sqrt{2HZ_2^*(G)}}$

Theorem 34 [9] Let a graph G with hyper-hub Zagreb index $HZ_2^*(G)$ Then $HZE_1(G) \geq \frac{1}{2HZ_2^*(G)}$

Theorem 35 [9]Let a graph G with $n \geq 2$vertices. Then
$HZ_1(G) \geq \frac{1}{n}\Psi(G)$, where $\psi(G) = \sum_{v \in V(G)} {d_h}_i^2(v)$
The paper [9] conclude first hub Zagreb energy is the combination of eigenvalues of the first hub Zagreb matrix of a graph. The 1st hub Zagreb energy can be bounded in the hub and hyper-hub Zagreb index. The hydrocarbons hub Zagreb energy can be calculated. The coefficient of characteristic polynomial of the first hub Zagreb matrix has specific properties, such as the constant term being 1 and the coefficient of the linear term being the trace of the first hub Zagreb matrix. The 1st hub Zagreb energy is related to the energy of the graph. Specifically, the first hub Zagreb energy is equal to the addition of the squares of the eigenvalues of the first hub Zagreb matrix. The second hub Zagreb energy is related to the energy of the graph in a similar way, with the second hub Zagreb energy being equal to the sum of the cubes of the eigenvalues of the 2nd hub Zagreb matrix. The 1st and 2nd hub Zagreb energies can be expressed in terms of the energy of the graph and the total number of vertices. The paper [14] Energy and spectral radius of Zagreb matrix of graph with applications the Z-matrix of a simple graph is a square symmetric matrix, where the ij^{th} entry is the addition of the degrees of vertices i^{th} and j^{th} if they are neighbour, and 0 else. The Zagreb eigenvalues are the Z-matrix eigenvalues, and the Zagreb energy is the total of the eigenvalues. Authors studied the variation in the Z-spectral radius during the deletion and rotation of edges, and provided bounds for the Z-spectral radius. They also investigated the relationship between the Zagreb energies of graphs obtained by identifying vertices or adding edges. The paper highlights the strong $+ve$ correlation (correlation coefficient of 0.9989) between the acentric factor of n-alkanes and the energy of the Z-matrix. Novel correlations between the refractive index of m-alkanes, density, and the spectral radius of the Z-matrix were also noted.

Theorem 36 [14]Let Γbe a graph and edge $e = uv$ in Γand let $d_u$and $d_v$be the degrees of uand v in the resultant graph $\Gamma - e$. Then $Z\mathcal{E}(\Gamma - e) \geq Z\mathcal{E}(\Gamma) - 2\left(\sqrt{d_u} + \sqrt{d_v} + d_u + d_v + 2\right)$ equality if and only if $e = uv$is an isolated edge in Γ.
The application discussed in the paper [14] are the importance of pi-electron energy in material science and chemistry, as it is important to explaining interactions of electron in the pi-orbitals of neighbor atoms in conjugated systems such as twice bonds and rings in aromatic. The total pi-electron energy can be obtained the Hückel molecular orbital (HMO) theory, which can provide crucial property of conjugated molecules. The correlation between the Zagreb energy and the energy of pi-electron of polyenes and compounds of vinyl, with a correlation coefficient of 0.9971. This suggests that the Zagreb energy can be used to predict the pi-electron energy of these compounds. The strong $+ve$ correlation (correlation coefficient of 0.9989) between the acentric factor of m-alkanes and the Zagreb energy, which can be used to predict the acentric factor of m-alkanes. The positive correlations between the density and refractive index of n-alkanes with the Zagreb spectral radius, with correlation coefficients of 0.9821 *and* 0.9693, respectively. This indicates that the Zagreb spectral radius can be used to predict the density and refractive index of n-alkanes. The paper [15] On Zagreb Energy of Certain Classes of Graphs discussed the 2nd Zagreb energy is always greater than the first Zagreb energy for all complete bipartite graphs of even order greater than or equal to 4, and for complete tripartite graphs. The two Zagreb energies coincide exclusively for the complete bipartite graph with equal partite sets if and only if the graph is of order 2. The paper provides a criterion leading to an infinite set of non-isomorphic Zagreb equi-energetic graphs for all $r > 1$ within partite graphs. The computations of the two Zagreb energies for graph operations like t-splitting graph and t-shadow graph are illustrated. Bounds on Zagreb energies for wheel graphs are discussed.

Theorem 37 [15] Let G be a k-regular of order r. Let $A(G), A[FZ(G)], A[SZ(G)]$ denote respectively the adjacency, first Zagreb and second Zagreb matrices of G. If λ is an eigenvalue of $A(G)$, then
1. $2k\lambda$will be an eigenvalue of $A[FZ(G])$;
2. $k^2\lambda$will be an eigenvalue of $A[SZ(G)]$.

Theorem 38 [15] Consider G to be a k-regular of order r. Then the first Zagreb spectrum of t-splitting graph of G are 0 with multiplicity $t-1, \frac{(t+1)\pm(\sqrt{t^3+5t^2+6t+1})}{2}$ each with multiplicity 1and the first Zagreb energy of t-splitting graph of G is given by $\sqrt{t^3+5t^2+6t+1}\mathcal{E}[FZ(G)]$

Theorem 39 [15] Consider G to be a k-regular of order r. Then the 2nd Zagreb spectrum of t-splitting graph of G are 0 with multiplicity $t-1, \frac{(t+1)[(t+1)\pm(\sqrt{t^2+6t+1})]}{2}$ each with multiplicity 1and the 2nd Zagreb energy of t-splitting graph is given by $\mathcal{E}[SZ(S^t(G))] = [(t+1)\sqrt{t^2+6t+1}]\mathcal{E}[SZ(G)]$.

CONCLUSION

This paper collected all the optimal results on the Zagreb Index energy of past decades and presents some Theorem in order to motivate readers to focus to results on this topic.

ABSTRACT

Named entity recognition, often known as NER, is the process of recognizing and categorizing named entities that are existed in to the text. Entities in the text are the general classes like People, Organizations, and Months. In many applications of Natural Language processing (NLP) like Chatbot, Text Summarization, NER plays significant role to identify the Entities and classifying them accurately into the predefined classes. Recently published work shows that how NER has achieved higher F-1 score and Accuracy for English language which has large publically available datasets as well as developed NLP components like Word Embedding and POS Taggers. Named Entity recognition is challenging task for low resource languages like Indian Languages. In this paper, how different authors have improved the NER performances of different Indian Languages using different approaches are discussed. This paper also elaborates the Datasets for Indian languages, methodologies and number of alternative approaches that have been published so far, including rule-based methods, machine learning-based methods, and deep learning approaches for NER. At the end of this paper the future scope for improving the performances of Indian Language will be discussed.

Keywords: Named Entity Recognition (NER), Natural Language Processing (NLP), Deep Learning, Machine Learning, Pre Trained Embedding Model.

INTRODUCTION

Named Entity Recognition (NER) is an artificial intelligence based technique that uses machine learning, and deep learning approach that automatically recognizes Named Entities such as Person, Location, Organization, etc. from unstructured text [1]. Chabot, text summarization, and other applications rely heavily on NER as these entities play vital roles to process output. The NER operation can be carried out using various approaches. Most of the research work have been done on English language as it is one of the most popular language in western countries. In the era of Artificial Intelligence, demands for the development of the application in the native language is increasing greatly. Most of the research works for improving performance of AI based application have been done on English language as it is one of the most popular language in western countries. Even in India, English language is playing important role in all aspect. But the people of different Indian states prefer region language for any task. Different challenges of Indian Languages are making difficult to develop high performance NLP application. One of the major tedious task is NER for Indian Languages. The reason behind this study is to get the insights how different authors tried to improve the performance of the NER for any Indian languages. Here some of the challenges [2] are discussed:

Limited Resources: There are very limited resources i.e. Dataset available to train the model with Indian Languages. It is very tedious task to tag manually each word with the Entity manually as lack of predefined entity tagged dataset.

Morphological Richness: the structures and words of the sentences contain multiple level of information that makes this task very difficult for getting expected output.

Lack of NLP components for Indian Languages: POS taggers and Word Embedding are crucial components for NLP application. Part of speech tagger used to identify the verb, Noun etc. From the sentences and tagging them with the correct tags. Word Embedding is used to map words with the numerical vectors based on the context of the words and sentences. For English language high performance components are developed but for Indian Language very limited tools are available.

Language Complexity: Ambiguity is one of the major issue for Indian Languages. Some text can have different context for different sentence. For example "વિરાટએભારતમાટેવિરાટછે." Here first "વિરાટ" is the Proper Noun and the meaning of second "વિરાટ" is giant that is an adjective. Identification of such tags is the complex task for the Indian Language.

Any NLP application process will start with the input of the any unstructured data. After that, this text will move toward the pre-processing steps, such as eliminating stop words or noise removing process. NER systems are quite effective for the English language as for this language many POS tagger are already implemented, but for other language native POS taggers [3] and NER taggers are essential to identify important aspect of the text for the Indian language. POS is a crucial component while machine learning models are trained for NER and aids in determining a word's context. For English language, standard library like Stanford NER are available. Also Stemming and Lemmatization process will help to get the root word. Three major methods for implementing Named Entity Recognition are Machine Learning (ML), Rule-Based NER, and Hybrid NER methods. Currently more research are focusing on Deep Learning model for efficient NER in Indian languages [2]. This method work with neural networks for recognizing complex patterns and correlations within the dataset. This will help to enhance the accuracy and performance in entity identification across various linguistic structures.

Named Entity Recognition Approaches

Rule Based Approach

This method identifies a list of different rules for matching the entities and tagging the same with predefined entities tags. This will require a lot of effort to create linguistic lookup dictionaries for these kind of rules. The primary issue

with this strategy, is that entity may not be handle the ambiguity in named entities or those named entities that contain multiple words. This means for Low resource like Indian languages, this methods perform poorly for tagging entities. List Lookup Approach and Linguistic Approach are two different rule-based approaches for Named Entity Recognition [4]. Linguistic analysis extracts speech patterns by observing linguistic aspect and surrounding contextually identified entities. The drawbacks of these rule-based methods are that they are will not fitted to other languages or domains and need extensive experience and grammatical knowledge of the specific language or subject. This limitation can lead to misclassification or incorrect interpretations, ultimately affecting the accuracy of natural language processing tasks that rely on precise entity recognition. To address these challenges, advanced techniques such as machine learning and deep learning algorithms are being employed to enhance the robustness of entity recognition systems, allowing them to better understand context and resolve ambiguities in complex named entities [5].

Machine Learning Approach

In NER using Machine Learning systems, the Named Entity Recognition technique employs a supervised classification statistical model to classify the suitable NER tags for the text tokens. This models follows the statistical methods and supervised learning algorithms for classification of NER tags in predefined groups of entities. This method searches for patterns and relationships within the text so. This methods resolves the context ambiguities of similar kinds of words for tagging the correct entities.

Deep Learning Approach

The concept of neural networks in deep learning, contain the multiple processing layers to acquire knowledge of data representations with different levels of abstraction. It is the ability of representation learning and the semantic composition that is enabled by both the vector representation and neural processing that is the primary advantage of deep learning. This ability enables a machine to be fed raw data and automatically discover latent representations and processing that is required for classification or detection. The forward pass and the backward pass are the two types of passes that are typically used in artificial neural networks. The forward pass is responsible for computing a weighted sum of their inputs from the layer below it and then passing the result through a non-linear function. On the other hand, the backward pass is responsible for computing the gradient of an objective function with respect to the weights of a multilayer stack of modules with respect to the weights of the module stack [6].

Literature Survey on NER on Indian Language

As we discussed earlier, researchers have done significant work to improve the NER performance in Indian languages. To train the NER models, some researchers have used different available language specific dataset or have developed the new dataset from the publically available resources like news, Wikipedia, twitter data etc. In this research paper, the performances of different NER models on Indian languages from recently published works are described. Most of the works on Indic NER are done using the Deep Learning models. The F1 Score of the different NER models is described in the results in Table 1.

Deep Learning Based Indic NER Model

The NER model that uses deep learning method follow General Processing Pipeline as defined in Fig.1. In Indic NER Model, The inputs are any Indic Text data from various Indian Resources. Then it will be passed through the Preprocessing steps for different functions like annotation, POS etc. Researchers may choose the pre trained embedding models from various available language specific or multilingual language pre trained models. This will significantly improve the results of Indic NER. Researchers may choose different models for processing the text like rule based models, deep learning models like BiLSTM or Hybrid models. Based on the data set and application, single model can be replaced with multilayer and multiple models. The output of this models will process through the tag decoders like CRF or Softmax functions used to get the probabilities distributions for all the Entities tags. Higher probability tag will be considered as the final Named Entity for that token. This approach is more suitable for Named Entity Recognition on various Indian languages.

Indic Dataset Source

Data Source plays significant role for any NLP applications especially for Low resource languages. To train the model, researchers use publically available data source or combine the multiple data sources for getting the best performance. The Mukhyansh dataset includes more than 3.39 million article-headline pairs for Indian languages, including Hindi, Tamil, Kannada, Gujarati, Punjabi, Marathi, and Telugu [21]. For Multiple Indian Languages, Naamapadam is one of the largest dataset for Named Entity Recognition (NER).It contains the data of two language combination for almost 11 languages. The dataset contains more than 400k sentences from different indian languages like Bengali, Gujarati, Hindi, Kannada, Malayalam, Marathi, Punjabi, Tamil, Telugu, Assamese and Oriya [22]. L3Cube-MahaCorpus monolingual dataset is developed from different internet sources for application of sentiment analysis or NER on Marathi Language [23]. The CFILT-HiNER dataset is made from various government information web pages, and newspaper articles for Named Entity Recognition in Hindi language [24].

Pre-trained Embedding

In the context of natural language processing (NLP), embeddings refer to word or phrase representations that have been learned from a large corpus of text data before being applied in specialized tasks. These embeddings hold meaning in relation to one another and therefore, models are able to utilize this information without the need for extensive retraining for each individual task. With pre-trained embeddings, time and computation is saved, as models can tap into knowledge from large text corpuses that have been previously processed. This means that demanding training on smaller, task-oriented datasets is no longer necessary. Models perform better in sentiment analysis, machine translation, and text summarization when starting off with pre-trained embeddings that contain a wealth of linguistic information [25]. Typically, pre-trained text embeddings come from self-supervised models. A model like GPT or BERT can derive representations of a language through self-learning from vast datasets. Transfer learning is the method through which these embeddings generally improved on specific tasks. This shows the model improves performance by tailoring the previously learnt information to the particular needs of a new task. [26] Word Embeddings like Word2Vec and GloVe focus on individual words and their contexts, providing dense vector representations that capture semantic similarities. [27]. More recent advancements include contextualized representations such as ELMo and BERT, which take into account the context in which words appear, allowing for a more nuanced understanding of meaning. Pre-trained embeddings are essential to recent natural language processing (NLP) because they offer fundamental knowledge that improves the efficacy and efficiency of a range of language processing activities. They are essential tools for creating intelligent language models because of their capacity to capture intricate semantic links. For Indian languages, Indic FastText is one of the most popular word embedding for NLP application.

Deep Learning Model

The implementation of several deep learning architectures, including Long Short-Term Memory (LSTM) networks, Convolutional Neural Networks (CNNs), and Transformers, has drastically changed the Named Entity Recognition (NER) landscape. The ability of LSTM networks to capture the sequential dependencies seen in languages is essential for interpreting context in Indian languages, which frequently have complex grammatical structures. The ability of CNNs to extract local features from input sequences, on the other hand, allows them to identify patterns and hierarchies in data. This method is especially useful for NER tasks that involve named entities embedded in lengthy texts. More recently, Transformer-based models like BERT have shown impressive effectiveness by utilizing self-attention processes, which enable context-aware representations of entities regardless of their sentence position. [28] In order to improve NER performance in the complex setting of Indian languages and increase its applicability across multiple areas, these developments represent a varied methodological framework [29].

Tag Decoder

A tag decoder is the last step in Named Entity Recognition (NER), which converts context-dependent representations of a sentence's words into a set of entity tags that specify the kind of entity to which each word belongs (e.g., PERSON, LOCATION, ORGANISATION). In basically, it is the component of the model that "decodes" the classified data into labels that may be used. Usually, a machine learning methods have been used by the tag decoder,

frequently consisting of: The Softmax layer [30] of a multilayer perceptron combines word representations to forecast each word's most likely tag. Conditional Random Fields (CRF)[31] are a common option for tag decoding since they can frequently achieve higher accuracy and take into account the dependencies between tags. They are often used in deep learning NER models.

CONCLUSION AND FUTURE WORK

For Indian Language, Named Entity Recognition is one of the complex process for any natural language processing applications. Due to many challenges of Indian languages, existing approach shows the poor results compared to the English Language. Accuracy is one of the important performance measure to understand the performance of the Indian NER system. Due to lack of POS Taggers and embedding system for Indian languages, very few research work have been done especially for Gujarati, Sindhi, Marathi etc.. Recent researches for Indian Named entity recognition suggest that Deep learning approach will significantly improve the results of NER on Indian languages. For Deep learning approach, multilayer or single layer BiLSTM model will achieve good results as these models process through both directions of the Indian language. Also adding CRFs layer for decoding the tags from the predefined entities class, will significantly improve the accuracy as well as F1 Score for the NER system.

ABSTRACT

Quality of work life refers to happiness or dissatisfaction with one's career. There is an attempt to examine the Quality of work-life among employees in Aavin. The research design chosen is descriptive in nature. The sample size taken to conduct the research is 100 employees. For this study, the sampling technique chosen is convenience sampling. A structured questionnaire was used for primary data collection. Secondary data was collected from earlier research work, various published journals, websites, and online articles. Simple Percentage is the tool used for data analysis. The investigation has pointed out that the Quality of Work Life factors include pay package, health and safety in the work environment, training and development, organizational environment, and stress involved in the work. This study also covers the employees' overall satisfaction in the organization.

Keywords: Employee Satisfaction, Organizational Environment, Quality of work life, Stress, Work Environment.

INTRODUCTION

Work is an integral part of our everyday life, as it is our life, career, or business. On average, we spend around twelve hours daily in the workplace, which is one-third of our entire lives; it influences the overall quality of our lives. It should yield job satisfaction, give peace of mind, a fulfillment of having done a task, as expected, without any flaw, and having spent the time fruitfully, constructively, and purposefully. Even if it is a small step towards our lifetime goal, it gives satisfaction and eagerness to look forward to the next day.

Problem of the Study

An organization's quality of work life is essential for its employees' smooth running and success. The work-life balance must be maintained effectively to ensure all employees run at their peak potential and are free from stress and strain. The quality of work life can affect such things as employees' timings, work output, available leaves, etc. Quality of work life helps employees feel secure and like they are being thought of and cared for by the organization where they work. An organization's HR department assumes responsibility for effectively running the Quality of Work Life for its employees. This is the real fact, and there was absenteeism and a lack of job satisfaction among the workers in the Co-operative Milk Society at Chennai. The current study aims to analyze the Quality of work-life among workers.

Need of the Study

Though monetary aspects play an essential role in motivating employees, organizations worldwide have come to understand that many other elements contribute to better employee performance. It is these aspects that form the basis for this study. In particular, this study aims to identify the various tangible and intangible. Aspects that contribute to the quality of the workplace. An organization needs to create a conducive working environment for employees. This study also points out the impact of stress on the quality of work life. This study must ensure that all employees are performing at their peak. Potential, being free from stress and strain, and ensuring all their needs are fully satisfied, leads to employee satisfaction. This study will be used as employee feedback to learn about their current workplace perspective and identify areas for improvement in the organization.

Objectives of the study

Primary objective

To find out the quality of working life of the employees in the Cooperative Milk Society.

Secondary Objectives

- To assess the Quality of Work Life among workers
- To comprehend the connection between the representatives and their workplace.
- To dissect working environment factors influencing the worker's execution.
- To recommend techniques for improving QWL by featuring workers' desires and required changes.

Scope of the Study

- The Scope of the study covers employees of all the departments to understand their point of view concerning the Quality of work-life.
- The scope of the study also includes the employees' response to the various measures taken by the management to make the employees comfortable at the workplace.
- The scope is also widened to determine the employees' expectations from management concerning the above concept.
- The scope also includes the importance of the grievance settlement procedure as a part of the quality of work life of the employees.

Limitation of the study

- Some of the employees are illiterate. So it wasn't easy to collect the exact data.
- There was a problem meeting the employees during the working hours of the factory.
- Some of the employees refused to answer the questions.
- The Employees' quality of work life cannot be analyzed with 100 samples.
- Data collection was challenging because there was no adequate leisure time to speak to the employees, and they hesitated to disclose the truth.

RESEARCH METHODOLOGY

The steps in which the study was carried out involved collecting both the primary and the secondary data. The secondary data was collected first. This data was collected by reading various materials such as books, journals, magazines, newspaper articles, etc., and looking for similar content online (i.e., on the Internet). The study was, therefore, carried out based on the data collected.

Research Design

The design of a research topic explains the type of research (experimental, survey research, correlational, semi-experimental, review) and its sub-type (experimental design, research problem, descriptive case study).
There are three main types of designs for research: Data collection, measurement, and analysis.

Descriptive Research

In a descriptive design, a researcher is solely interested in describing the situation or case under their research study. It is a theory-based design method created by gathering, analyzing, and presenting collected data. This allows a researcher to provide insights into the why and how of research. Descriptive design helps others better understand the need for the research. If the problem statement is not clear, you can conduct exploratory research.

Sampling Techniques

Sampling Methods are selecting a sufficient number of elements from the population. This is also understood as obtaining information about the entire population by examining only a part of it. So a sample can be defined as a subset of the population. The population (universe) of this study is 500. The sample size is 100(ie) of the population. A convenience sampling method was used to collect the data. Convenience sampling is a method researchers adoptto collect market research data from a conveniently available pool of respondents. It is the most commonly used sampling technique as it's incredibly prompt, uncomplicated, and economical. Members are often readily approachable to be a part of the sample.

Methods of Data Collection

In the questionnaire method, the respondents have to answer specific sets of questions. The questionnaire's effectiveness depends on the sincerity and dependability of the respondents. There are several ways in which the questionnaire can be presented, such as open-ended and closed-ended. A good questionnaire should have at least 12-15 questions, of which 8-10 should be closed-ended or multiple-choice questions and 2-3 should be open-ended questions. The questionnaire is mainly used for a sample population to get accurate, efficient, and effective results. The questionnaire is made according to a structured format. The response to the questionnaire can be collected in many ways, such asby mail and telephonic questionnaires.

Primary Data

The primary data are those collected afresh & for the first time, & thus happen to be original in character.

Secondary Data

The secondary data are those that have already been collected by someone else & which have already been passed through the statistical process. The secondary data is collected through the company records, books, journals & magazines.

Data Analysis and Interpretation

Correlation

Table 1: Analysis of Relationship Age of the Respondents and Iam Agree with the Content of the Cantenna Facilities Provided by Dairy Industries

Table 2: Correlations

Inference

There is a positive correlation between age, and I agree with the canteen facilities provided by dairy industries.

Chi-square test

Table 3: Representing the Relationship between the Gender of the Respondents and Whether You Feel Comfortable and agree with your job

H_0: There is no significant association between the two variables

H_1: There is a significant association between the two variables

Inference

The calculated value is more than the tabulated value, so we accept the null hypothesis. So, we infer that no significant relationship exists between gender and whether you feel comfortable and agree with your job.

ANOVA

Table 5: Representing The Differences Between The Qualifications Of The Respondents: Do You Need To Achieve Your Targets Within The Given Period

H_0: There is no significant association between the qualifications of the respondents and whether they need to achieve their targets within a given period

H_1: There is a significant association between the qualifications of the respondents and whether they need to achieve their targets within a given period

Inference:

The calculated value is more than the tabulated value, so we accept the hypothesis. So, we infer no significant variance between respondents' qualifications regarding whether you need to achieve your targets within a given period.

FINDINGS

- Majority 60% of the respondents are female
- 21% of respondents fall under the age group of above 29 years
- 31% of the respondents belong to UG
- 60% of the respondents are married
- 59% of respondents strongly agree that I have a healthy relationship with my superior
- 36% agree how often you will find your work stressful
- 50% are asked which factor motivates you the most
- 34% are how do you feel about the working hours of the organization
- 49% agree that I can maintain a good balance between work and family life
- 34% are you satisfied with how the dairy industry conducted the medical camp
- 40% of respondents are delighted with how confident you are with the machinery given in the working environment
- 32% agree to tell their opinion about the job security in the working organization
- 40% to tell their opinion about the training program conducted in the organization
- 30% agree that you feel comfortable and agree with your job
- 40% of respondents in general, how would you describe relations in your workplace between management and employees
- 34% are you satisfied with the opportunity for employees and career development prevailing in the organization
- 69% of respondents strongly agree that the organisation will provide the safety and health measures

- 60% of respondents say you need to achieve your targets within the given period
- 43% of respondents strongly agree that they agree with the canteen facilities provided by dairy industries

SUGGESTIONS

- Management could look into providing their employees with flexible work hours and stress breaks to reduce the stress experienced by the employees and improve the quality of work-life.
- The management can reduce the working days from 6 to 5, from Monday to Friday.
- The employee grievance handling procedure can be improved.
- The management can change the leave policy by providing adequate casual leave, or permission may be considered.
- The organization's infrastructure can be improved.
- There needs to be utmost care taken in choosing to adopt and implement the policies because they impact each worker and the organization.
- It will be the same. Job-life balance could also be an essential issue within the Human Resource Management field, significantly impacting the productivity and growth of every organization and worker.

CONCLUSION

After discussing with the employees of Aavin and analyzing the different factors contributing to their quality of work life, it became clear that the employees are satisfied but expect an improvement in their career,including an improvement in designation and a financial upgrade. A happy and healthy employee will give better turnover, make good decisions, and positively contribute to organizational goals. An assured good quality of work life will attract young and new talents and retain the existing experienced talents. Quality of work life can affect such things as employees' timing, their work output, their available leaves, etc. Work-life balance must be maintained effectively to ensure all employees run at their peak potential and are free from stress and strain. So, it is up to the organization to focus on its workers and improve their quality of work life so that attrition, absenteeism, and decline in workers' productivity can be checked.

ABSTRACT

To implement a scalable, low-cost IoT-based Smart Building Management System to optimize energy consumption through automation of parking lights in commercial infrastructures. The study employed a distributed network of wireless motion sensors, Light Dependent Registers (LDR) controllers, and intelligent schedulers to automate parking light operation. The system was deployed in three towers at Magarpatta City, Pune. Energy data was monitored via a section controller hub, comparing pre- and post-automation usage. Offline operation support and switch operating rules were key enhancements. The system demonstrated significant energy savings: 84.5% in Tower 1, 67.6% in Tower 2, and 73.86% in Tower 3. These results were achieved using real-time motion detection, ambient light sensing, and automated scheduling, eliminating manual intervention. The use of offline-capable Integrated Command and Control Center (ICCC) and adaptive switch rules enhanced the system's robustness and deployment flexibility. The findings align with reported IoT benefits in energy systems, showcasing an effective, cost-efficient, and retrofittable solution for large infrastructures. Compared to traditional systems, this implementation reduces energy waste and improves accountability while offering modular scalability and centralized control. Offline-operable IoT system with dynamic scheduling and real-time sensing, applied at scale in an existing commercial infrastructure.

Keywords: Internet of Things, Smart Building, Energy Optimization, Remote Monitoring, Motion Sensors, Lighting Automation, Parking Management

INTRODUCTION

IoT is The Internet of Things (IoT) is an intelligent network that connects and communicates with physical devices through sensors, electronics, and software. It enables devices to be identified, located, tracked, monitored, managed, and securely interact with other systems and cloud-based platforms. As of 2025, IoT has become an integral part of modern life—transforming the way individuals live, work, and interact with their surroundings. The technology now supports a vast array of smart devices, routing and processing sensor data continuously, even in the absence of active internet connections. In industrial and commercial applications, IoT has revolutionized operations by enabling remote monitoring and control of appliances and machinery. Particularly in smart buildings and factories, automation facilitated by IoT has led to significant energy savings, cost reductions, and increased operational efficiency. These systems now empower users with real-time insights into device status and performance, allowing them to control single or three-phase AC appliances, manage electricity consumption, and ensure optimal functionality. With the advent of the Industrial Internet of Things (IIoT), the fourth generation of industrial machines now operate autonomously via cloud-connected frameworks. These machines are managed remotely, enhancing the productivity and quality standards of manufacturing processes. Manufacturers benefit from precise machine functioning, real-time tracking of inventory and devices, early fault detection, and uninterrupted monitoring—features that help prevent production downtimes and enable predictive maintenance. The global growth of IoT is evident. According to industry reports, IoT device adoption surged from 237 million in 2015 to over 923 million by the end of 2021. In 2025, this number continues to grow exponentially, with major industry players investing in smart device innovation and infrastructure expansion. IoT has proven to be a critical enabler of smart automation, scalable solutions, and cross-geographical control under unified platforms. Moreover, modern IoT solutions are designed to offer security, privacy, and flexible user-defined parameters—functioning even without internet or Wi-Fi routers in certain configurations. Ultimately, IoT has enhanced visibility, collaboration, and streamlined operations across sectors. Its role in driving digital transformation, especially in industrial automation and smart infrastructure, remains a cornerstone of future technological evolution. The following section provides a comparative analysis between the proposed IoT-based system and prior works in the field. Comparative Analysis of present work with earlier work Table 1.

Problem Statement

The biggest problem that not many people think of this as an opportunity to save electricity by Parking Lights automation (PLA). In reality, significant cost can be reduced if adopted the automation. In this work, there were multiple problems with the existing system listed as below

1. Almost all the time, all the lights were kept ON even when it was not required.
2. Due to huge parking area the operator fails to operate the switches which are required to be turned on at particular day/time.
3. No accountability was set upon the operators.
4. No information was available if the operators did not switch OFF the lights when needed.
5. It was unknown whether which section of lights was consuming how much electricity.

METHODOLOGY

IoT-Based Smart Building Management System (BMS) for Optimized Energy Consumption and Remote Access system model. Figure 1 shows IoT based smart building management system for optimized energy consumption through architecture diagram.

Remote sensor management

Following are possible Automation types based upon the requirement.

IoT based BMS: This is full-fledged Automation comes up with ICCC (Integrated Command and Control Center). More than one ICCC can also be setup based on the customer requirement

IoT based Chiller Plant System (CPS): Comprehensive solution for Chiller plant including AHU, FCU, VFD integration

IoT based HVAC Automation: Unique product having capabilities to automate all appliances in Heating, Ventilation and Air Conditioning

Wireless/Wired Motion Sensor with inbuilt switching module.

Each device will have an ON and OFF-time and the appliance is switched ON or OFF when the user time and real clock time is equal. By entering 2 different times, the kit will daily switch on the device at the ON-time and switch it OFF when the real time is the same as the off time of the device. This technology makes a system completely automatic and minimizes the need for any human interaction without having to manage any infrastructure physically. IoT based BMS is the most comprehensive product with complete focus on reducing electricity consumption. This BMS system is a wireless retrofit product capable of remotely operating all kinds of regular appliances like heavy HVAC systems (AHU, FCU Split AC), Lighting, Fan, heavy motors, pump etc. The ICCC to access all the appliances and brought together into the single umbrella operations. The complete setup of the ICCC will be wireless and therefore no digging on the walls or rewiring would be required. As per the customer needs multiple ICCC can also be setup based on the requirement. Remote Sensor Management Figure 2.

a. **Distributed Motion Sensor Installation:** Motion sensors controlled lights as per the traffic. It was always made sure that there is always luminescence on all the drive lanes. Now when the vehicle passes or any person walks by through a certain area, that area is luminated through the motion triggered by the wireless Motion Sensors. Also the way Distributed Motion Sensors were installed, the whole parking area was covered under a single umbrella that is unique and solves the real world problem without impacting the safety for the employees and other persons.
b. **LDR/Lux Controller Installation:** LDR Controllers senses the luminescence of the surrounding. As soon as the intensity reaches configured trigger value, lights are turned OFF and vice versa. This is extremely useful and saves a lot on cost when days are sunny but rather adjust the conditions immediately in cloudy conditions as well.
c. **Activating Schedulers:** Schedulers are like advanced timers which can be put to switch ON/OFF an appliance at a predefined time on a given set of day(s). Schedulers were put to switch OFF multiple lights that seemed not required to be ON during a given schedule (e.g. day time, weekends, etc). This resulted in saving electricity from Lights which were left ON unintentionally. These were created to switch ON or switch OFF the appliances at
d. A particular day and time. Also, some schedulers were created to switch ON the appliances at a particular time and then switch it OFF at another time. Through schedulers, we reduced the workload significantly in multiple ways, one of them is that on the exact timing the appliances are getting Switched OFF/ ON. This means that the appliances are now getting operated exactly on the time they were supposed to operate without a single minute delay.
e. This has reduced the labour effort required, prevented the time delay of operators in walking from the office to the LDBs, removed unknown delay in operating an appliance by electrician. In addition to these reasons, appliances are now getting centrally tracked, monitored as well as recorded for the reporting purposes as well.
f. **Activating Switch Operating Rules:** Switch Operating Rules are smart algorithms that can switch OFF any appliance after running for predefined time. At Magarpatta City, these helped switch OFF the lights which are left ON unintentionally. These rules can also be set based on multiple time slots and any particular days of week. After the automation at Tower 2 last year, this year we further optimized the automation at Tower 2 with changed installation approach and optimization in algorithms. Table 2 shows the number of available facilities with the present system and Table 3 shows the features of available facilities.

Implementation of Parking light

In this complete project for the parking light automation installed at Magarpatta City Hadapsar Pune, three Towers (Tower 1, Tower 2 and Tower 3) located at Pune. The Magarpatta City is a premier township with 27 commercial towers at the centre. Each commercial tower is equipped with a huge parking space and around 500+ lights in each. These lights were controlled by LDBs (Light Distribution Boards) through MCBs. Each MCB is operating a group of lights illuminating different sections of the parking area. In Magarpatta Parking, due to unnecessary usage of a large number of lights, receives high electrical bills. It broadly faces the issues with manual operations, lack of operational accountability for appliances, need of an automation system, and focus on electricity usage reduction. Since the solution was provided in phases, it details out the solution process in steps. As per the visit at the plant and observations, we provide different ways of implementing IoT based BMS in the facility. These types will vary in functionalities, features, Installation efforts and cost associated with it, Figure 3 is the representation of Integrated Command and Control Center (ICCC) for same case. Firstly, a survey was conducted, the layout of the area was made and all the parking lights were divided into various groups based on their position. After dividing the lights into various groups, each group was analysed individually based on certain parameters. Some of these parameters are current consumption, minimum illuminance, Motionsensor positioning, availability of sunlight etc. Once all these things were analysed, the motion sensors were ready for deployment. After deployment of motion sensors, all the motion sensors were configured based on the group they were deployed in. There was a deep thought given during the configuration of the sensors as motion sensors alone would result in 25 percent of the total saving. Once all the motion sensors throughout the area were configured, deployment of the LDR sensors (Light Dependant Resistor). The value of the LDR was used to monitor the minimum illumination criteria at all times. The system was then kept running and under observation for a week. Once the observation was complete further optimizations were performed for every group. Few motion sensor modules were added/removed based upon the observation. It was made sure that the whole area is completely covered and highly sensitive. Finally, after optimization, the positioning of all the motion sensors were added to the layout.

Installation and Optimization of Tower 1, Tower 2 and Tower 3

The PLA controls the parking lights of whole Tower 1, 2 and 3, parking space, which indeed has resulted in more savings to the client. The following steps are followed:

Step 1: As the installation of five electrical panels in series with the existing LDBs across Tower 1, 2 and 3. Also, for the reporting and monitoring purpose. section controller (The hub) was installed and given the internet through the Internet dongle. At this point, all the panels were installed and energy consumption is being monitored internally by hub (section controller). This time we have changed the approach and now we were allowed to cover the driveway paths as well. With significant technological advancement recently to save huge power consumption.

Step 2: In the next phase, the installation of motion sensors, LDR Controller, activated Section Controller (Hub), applied Schedulers and Switch Operating Rules and more importantly implemented the concept of Distributed Motion Sensor which is meant for large Parking areas.

At Tower 1 and 2 at Magarpatta City with two panels has been installed at A and B Wings whereas in Tower 3 three panels has been installed at A, B and C. After the installation of Panels and Wireless Motion Sensor, LDR and Routers a comparative study has been made and data was captured through a hub (Section Controller) with automation OFF and ON mode on to get a clear picture of effectiveness of the automation product. Figure 4 shows the actual image of tower installation. The percentage savings at tower 1, 2 and 3 has been shown in results section.

Results and Discussion of Parking Light Automation system

The data highlights the energy savings achieved by automating parking lights across Tower 1, Tower 2, and Tower 3. Each tower has multiple panels controlling the lighting systems. The key metric here is Units per Day (kWh) consumed before and after automation, and the resulting percentage of savings shown in Table 4.

Tower 1 achieved an 84.5% reduction in daily energy consumption — a substantial improvement, mostly driven by significant cuts in usage across both panels.

Tower 2 also saw major savings. While Panel 1 had better efficiency gains (75.8%), Panel 2's savings were more modest (53.1%), lowering the overall average to 67.6%.

Tower 3 had the highest total consumption before automation, but after automation, achieved a strong 73.86% savings, especially with Panel 3 showing exceptional efficiency at 86.6%.
Although the graph image Figure 5, it likely visualizes, Figure 6 shows the actual layout of PTA implementation.

- A bar chart comparing "Before" vs "After" energy consumption for each panel/tower.
- A line or secondary axis showing the percentage savings.

This type of visual would quickly convey

- How drastically consumption dropped.
- How consistent savings were across different panels.

To improve financial performance, reduce carbon emissions and energy costs, and reinvest savings into the guest experience. Light automation offers powerful and feature rich Light Automation Product which suits multiple industry needs. The product suits Street Light Automation, Parking Light Automation, Outdoor Luminaries Automation etc. By automating street lights, lighting and scheme for a diverse urban landscape whilst maintaining a responsible approach to minimizing manual intervention, providing centralized access, multiple channels to operate for functional purposes. The proposed system will be modular in nature, communication between various modules will be wireless and secured, along with low maintenance cost. This Automation Product is based upon the latest IoT(Internet of Things) Technology, based upon the wireless communication between various nodes/modules. Also, the product works flawlessly in the absence of the internet as well in Offline mode. The product - Light Automation simplify complexity with a single, integrated platform that connects all lights and distributed points for monitoring, analysis, and full remote control via rich user interface. This enables you to drive operational efficiency and surely lowering down the electricity bills. This system is designed with customizable GUI, inexpensive embedded system, and it is easy to install, control and monitor with an array of electronic devices widely used in everyday home chores. The microcontroller Raspberry Pi is also connected to the IOT module.

ACKNOWLEDGEMENT

The authors would like to thank Amit Nikum from SNAS IoT Pvt., Limited, CEO, Pune, India for early discussions and the idea of Green IoT. This idea has been successfully implemented and at hospital and lighting tower and saves energy.

Table 2: Available Facilities

S.N	Key Product	Facilities
1	Wireless product line	Yes.
2	IoT Based Highly Scalable product	Yes
3	Advanced algorithm for most optimum utilization of	Yes

	resources (like Compressors)	
4	True Offline Product	Yes
5	Customization for any combination	Yes
6	Highest Number or Channels to operate	Yes(more than 14)
7	Access control mechanism + Device Binding	Yes
8	Real time energy monitoring + notifications	Yes
9	Failover mechanism	Yes
10	Real time theft notification (for electricity)	Yes
11	Advanced technologies like AI(Artificial Intelligence) + NLP (Natural Language Processing)	Yes. Used for issuing voice commands. Also for Real time monitoring.
12	Cost effective	Yes

Table. 3: FeaturesFeatures of Available facilities

1. Plug and Play Touch Screen

- Section Controller is a unique Plug - and - Play Touch Screen (Hub) without battery equipped (No other company is providing a true offline hub as a touch screen)
- Centralized status tracking with 12 active channels view.
- Supports True Offline operations, no need of internet or Router network.
- Also Supports Online operations.
- Offline Schedulers (Real Time Clock Support) and view all schedulers(both online/offline)

2. Offline Notifications

- Offline Notifications can be seen for schedulers, sensors, operating rules etc. When connected with internet, system synch up automatically to make the data available for other channels as well.
- Smart dashboard, self-changing slider to show Reports, Sensor readings, Active Operating Rules etc.
- Offline Notifications can be seen for schedulers, sensors, operating rules etc. When connected with internet system synch up automatically to make the data available for other channels as well.
- Smartdashboard, self-scrolling screen to show Reports, Sensor readings, active Operating Rules etc.

Mobile App can be operated in two modes, Online and Offline.

- Highest level of customization (Sensor/Bundle/IR/Voice /Operating Rules Configuration) (All Sensors, IR Remote, Voice Controller, Switches etc)
- Multiple Users can use the app and admin user can grant access on individual appliances to other users
- Multiple geographical locations can be controlled under single umbrella (single account)
- Customize Bundle (group of switches). And their flawless operations which includes scheduling them.
- Varieties of Usage Reports.
- Unique implementation of Sensor/Switch Operating Rules.
- Schedule appliances like hydraulic motor, water sprinklers etc.

3. Desktop Controller: Alexa Integration

- Perform operations via Voice in Hindi and English
- Getting analytical reports access over voice over interface.
- Customizable as per different business needs.

4. Alerts

WhatsApp Notifications, Calling Notifications, Email Notifications

5. 3 Face Motion Sensor Technology

The technology for 3 Face Motion Sensor **is** a key differentiator and provides huge benefits when it comes to an application requires person occupancy detection in premise. Following are the advantages of the patented technology for 3 face Motion Sensor.

- Covers 15 to 20-meter area in radius with 270-degree coverage
- This motion sensor module has 3 face with each face has motion sensor equipped on it and therefore covers huge area. This design eliminates the requirement of motion sensor modules which may require to achieve

the same results. (5 - 10 qtysof regular motion sensor module may require to achieve the same results)

- Wireless and Configurable Motion Sensor Module and reduce the cost of installation and wiring and become the clean installation even in existing buildings as well.
- The installation is retrofit and does not required change in the existing wiring connection nor required digging on the walls.
- There would be a separate retrofit installation of switching module which will be communicating wirelessly with the motion sensor module.

The configuration of motion sensor modules can be changed anytime wirelessly with custom module provided or by mobile Apps etc.

ABSTRACT

A Wireless Sensor Network (WSN) comprises a collection of sensors capable of sensing and transmitting real-time information to a central server. The sensor gateway scheduling persistent challenges are to optimize the necessary utilization of the channel within the sensor node. In a scheduling algorithm, the sensor gateway is predicted by the node's cycle time on duty for each idle period. The duty cycle scheduling impotently accepts the random-based data received from the sensor node using First In First Out (FIFO) queues, which are often utilized to arrange and manage the traffic loads of gateway findings. In this paper, we propose a customized schedule algorithm in duty cycle scheduling to tailor to diverse efficiency conditions and reduce the delay time and consumption time. Each sensor node adjustment is done dynamically at the time of data arrival rate from the preferred node and the specified gateway. To analyze the Network Simulator (NS-2) environment is to simulate and evaluate the performance of various scheduling algorithms, such as Sequential Model-based Algorithm Configuration(SMAC) and Tensor completion by parallel Matrix factorization (TMAC), providing further enhancements. This proposed methodology was implemented with the iSense simulator.

Keywords: Duty cycle scheduling algorithm, E-health monitoring system, Sleep time and wake-up sensor node, Network simulator, Scheduling algorithm.

INTRODUCTION

Human health monitoring is preferred for the purpose of timely management and provides better service to save their life. Electronic health(e-health) monitoring techniques are used to handle the data received from humans and

can be processed for the immediate decision-making system for solving each problem. Regular health monitoring helps detect diseases at an earlier stage, for prediction and health risk factors, embedded to provide early assistance and proactive actions. It improves the treatment outcome of each patient. The disease could be managed by ensuring that the health parameters are crucial for managing chronic conditions, such as hypertension, cardiovascular disease, and diabetes. To track the patient's health frequently to indicate the medication needed. It frequently monitors the blood pressure, heartbeat rate, cholesterol level, glucose level, and so on. Based on the disease, miniaturization could vary, to make decisions about human health and indicate changes in lifestyle and medication required to improve their health conditions. The indicators recognize the individual care and maintain the optimal health condition and well-being. To track their metrics, such as physical day-to-day routine activity, dietary habits, and weights. From the analyzed report, the patient should concentrate on which area requires the most attention to promote their health. These monitoring systems provide empowerment by individual self-care about self-health level information and tools to monitor their health frequently. The electronic health monitoring systems provide information and data to encompass the wide range of health care applications, which include electronic records(e-records) and mobile health devices, such as wearable and online portable patient individual portals. It commonly concentrates on improving human personal health by efficiently accessing the doctor by leveraging digital tools and providing a platform to monitor, store, and retrieve the necessary information about the patient securely, with enabled condition of care. It remotely accesses the patient's health record as an e-record for remote consultations to manage the chronic conditions efficiently. It increases the patient's health care and reduces costs by using digital technologies for health care and management. Wireless Sensor Networks (WSNs) find predominant usage in military operations and monitoring applications. These networks typically consist of numerous sensors distributed throughout the environment.
The e-health care can be classified into eight different categories as follows:

Telemedicine involves diagnosing and treating patients remotely through communication technologies like video conferencing, enabling consultations with healthcare providers from a distance.

Electronic Health Records (EHRs) are electronic formats of patients' medical histories, including diagnoses, medications, treatment plans, immunization records, allergies, radiology images, and laboratory test results.

Mobile Health (mHealth) refers to healthcare services accessible through mobile devices like smartphones and tablets. This includes health apps that monitor health metrics, offer medical information, track fitness activities, and send reminders for medication or appointments.

Wearable Health Technology comprises devices worn on the body, such as fitness trackers, smartwatches, and medical wear ables. These gadgets monitor various health metrics, such as heart rate, activity levels, sleep patterns, and other biometric data.

Health Information Exchange (HIE) systems enable the secure electronic sharing of healthcare data among different healthcare organizations. This allows for the seamless exchange of patient information across various providers and settings.

Remote Patient Monitoring (RPM) involves remotely monitoring patients' health using digital devices to collect data outside of traditional healthcare environments. For instance, patients with chronic conditions can have their vital signs monitored at home.

Health Information Portals are online platforms that grant patients secure access to their medical records, lab results, appointment scheduling, prescription refills, and communication with healthcare providers.

Digital Health Coaching entails virtual coaching and support programs delivered through online platforms or mobile apps. These programs assist individuals in achieving health-related objectives like weight management, smoking cessation, stress reduction, and managing chronic diseases. In Figure 1, the IoT devices are not always used

to monitor the data. It is activated by human intervention and the automatic scheduling algorithm from deep learning. This scheduling algorithm changes the mode of each device component from sleep to start mode for reading the data from the patient to care about their health, at a particular interval.

LITERATURE REVIEW

In the eHealth sector, IoT enables various stakeholders to access vital patient data and respond accordingly. Patients can receive notifications or updates on their smartphones from intelligent medical devices, reminding them to exercise[1], adhere to medication schedules, or schedule appointments with their doctors upon detecting signs of illness[2]. These IoT-enabled healthcare devices are made possible by advancements in healthcare development services, fostering a sense of empowerment among patients as they feel more in charge of their well-being[3]. The predominant IoT applications in healthcare often revolve around wearable devices such as smart bands, fitness trackers, and smart watches[4]. Despite their unassuming appearance, these devices signify wearable healthcare technology that holds significant utility for individuals[5]. Fitness trackers, for instance, can track users' physical activity levels, after which these intelligent medical devices offer health care recommendations to promote well-being[6].The SMAC protocol offers a predetermined active period interval[7], with the SYNC packet orchestrating this interval sharing. SMAC designates periodic, active, and sleep intervals. The SYNC packet within SMAC facilitates sleep-awake scheduling, enabling data transmission through the exchange of SYNC packets among sensor nodes. In case of RTS collision[8], sensor nodes enter a sleep phase until the next active period. Nonetheless, SMAC implementation leads to an increase in end-to-end delay[14]. In the existing TMAC algorithm, the transition from sleep state to awake state of sensors occurs if that sensor is not available or is not required for some time[9].TMAC mitigates energy consumption by facilitating sleep periods. During these sleep intervals, any data transmitted to the sensor node is buffered in the neighboring node's memory[10]. Upon the expiration of the sleep period, buffered data is transmitted from the neighboring node to the recipient node during the subsequent active phase. While TMAC reduces energy consumption, it introduces delays due to the earlier termination of the active period[11].DSMAC, on the other hand, dynamically adjusts its duty cycle by extending the active phase. This algorithm increases its active duration based on the application's requirements, consequently elevating energy consumption in tandem with the prolonged active phase duration[12].

Proposed Architecture

The duty-cycle-based scheduling algorithm is to enhance energy efficiency in e-health systems through intelligent management of IoT device duty cycles. The algorithm takes into account factors such as the wake-up probability of a sensor node, the maximum allowable traffic volume, and the expected data packet latency. The IoT device components continually adjust their state strategy by altering the mode from sleep to awake. The duty cycle time represents the propagated time for each node to compare its status as active or sleep, then the total cycle time is compared with the status of the sensor node, which comprises the time duration turnaround from the active and sleep operation of the sensors. The data is received from the sensor when it is in the active state. Enhances resource utilization and energy efficiency in IoT systems through dynamic adjustments of device operational duty cycles[10]. This kind of scheduling algorithm method is implemented within the duty cycle of individual sensors. The duty cycle represents the ratio of the active period to the cycle time, where the cycle time encompasses both the active duration and the sleep duration of sensor nodes. During active periods, each sensor node can transmit and receive data. During the sleep state of the sensor node, the ratio is calculated from the deactivated mode to the active mode. It avoids the data received from other nodes to create the inference from existing data. The sensor component battery consumption level, energy conservation is minimized. It extends the duration of the sensor in active mode to receive the proper data frequently to make a particular standard decision to monitor the patient in a good manner[11]. In the proposed algorithm, the time is calculated as the duty cycle time for each sensor node to find the gateway for receiving the sensed data in the queue. It is partitioned into three different segments, each of which should be governed by two predefined determinants with threshold values fixed according to requirements. The threshold values are dictated by the queue segment, and the arrival of data into the queue from the sensor is compared with the

threshold value for the final decision. In this study, the threshold value will be found at the earlier stage, denoted as Th1 in the initial stage, then the subsequent value as Th2, and so on. Every cycle, the threshold value could be stored in the cloud to make the final decision among the patient's health factors. The optimized data by specified requirements, considering the monitoring system for human health, Figure 2. Figure 2 shows the workflow of the proposed work. The sensor node depicts the flow of work from sleep to active state. To consider the rate of arrival data value for each node, it prolongs the sleep time and active awake time of a sensor node. The sensed data is classified into three different categories: high priority, low priority, and medium priority for the environment to monitor the temperature of a human. The duty of a sensor device's cycle time will be assigned based on the total number of times it can read the information per day and how many times it can read the information from the patients. The cycle time (Ct) is the ratio between the Active Time (A_t) and Total cycle time(T_t)-Equation 1.

$$C_t = \frac{A_t}{T_t}$$

Equation 1: Formula for calculating active time.

Equation 1 calculates the cycle time for the duty from the Active time and Total time. The Active time refers to the period when the device is actively engaged in transmitting or receiving data. The total time is the combined duration of both active time and sleep time, during which the device remains inactive. The mode is an existing mode(Figure 4). Based on the existing mode, the duty cycle time will be calculated, and information will be given to the gateway for activating or waking up the sensor node and keeping that node in sleep mode based on the priority of an individual sensor node. Every time all the sensors need not read the data from the patient, the required amount of time the device could read the data and keep it in sleep mode.

RESULTS AND DISCUSSION

The duty cycle will be calculated and implemented into an application to handle the IoT device components for their individual performance and management. establish these parameters for each IoT device in the e-health system, considering factors such as device capabilities, energy requirements, and communication patterns. The sensor that remains in sleep state (Figure 5) gets the highest priority to receive data from that sensor immediately. This sensor state immediately changed from sleep state to active state to adhere to the prescribed data receiving process. In this proposed methodology, to handle critical data received from the sensor node during the sleep and active period, the data is promptly converted and transmitted to the data gateway to minimize the risk factor for data loss. The sleep duration of the sensor node dynamically adjusts according to the detection of low and medium-priority data within the node.

When the threshold is reached, sleep time (St) is calculated for each low-priority data detection (Lt) using the following formula

$$S_t = 2\sqrt{L_t}$$

Equation 2: formula for sleep duration

The sleep duration is computed as (2√L) *1000, where L denotes the quantity of low-priority data instances identified by Equation 2. The count for low-priority data resets to zero if high-priority or medium-priority data is discovered. Upon detecting crucial (high-priority) data while in sleep mode, the node transitions to active mode and proceeds with regular operations (Figure 6).

CONCLUSION

The proposed methodology for the scheduling algorithm is to implement it with the medical record maintenance using a wireless sensor node, and it could operate with specified parameters from the sensor and the gateway for transmitting the data to a cloud for analyzing the received input data. The information received was kept in a queue

gateway with the priority information. This kind of approach improves the active time of a sensor and minimizes the gateway delay, and minimizes the usage of all sensors every time. To concentrate on the notification of a data loss from each node. Unlike SMAC, which employs fixed active and sleep durations, the proposed algorithm dynamically adjusts these intervals based on sensed data. At the time of sensor sleeping time, the sensor cannot transmit any required data to a gateway. To improve the sleep and active time duration, it dynamically varies from each requisition according to its usage. The specified critical data is received from the sensor means, this algorithm changes the time of sleep mode for an individual sensor to awake mode for higher priority of the data, to avoid the delay time.

ABSTRACT

Word spotting has emerged as a critical technique in document image analysis, enabling efficient information retrieval from large-scale handwritten and printed text corpora. While substantial progress has been made in developing robust word spotting methods for widely used Indic scripts such as Devanagari, Bangla, and Tamil, the application of these techniques to underrepresented languages like Gujarati remains relatively unexplored. This paper presents a comprehensive comparative analysis of existing word spotting approaches—ranging from traditional handcrafted feature-based methods to modern deep learning architectures—across various Indic scripts. It explores the roles of convolutional neural networks (CNNs), recurrent neural networks (RNNs), and generative adversarial networks (GANs) in advancing recognition accuracy. Recent developments are examined within the context of multilingual and multiscript environments, and particular attention is given to underexplored scripts like Gujarati, which pose unique structural challenges. The integration of transfer learning into word spotting systems represents a significant step forward in enhancing document digitization and retrieval across diverse linguistic landscapes.

Keywords: Word Spotting, Indic Scripts, Gujarati Language Processing, Document Image Analysis, Script-Specific Challenges

INTRODUCTION

The rapid growth in digitization of historical manuscripts, administrative records, and cultural texts has created a vast archive of document images that require effective methods for text retrieval [1]. Traditional Optical Character

Recognition (OCR) systems, while widely used, face significant limitations in handling handwritten documents and diverse script styles, particularly in complex and degraded images [1]. As a result, OCR has proven less effective for languages with unique orthographic structures and complex fonts, such as Indic scripts, which often involve a variety of diacritics, ligatures, and character modifications [2, 16]. Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and Generative Adversarial Networks (GANs) have all been successfully applied in transfer learning contexts for word spotting [3, 4, 14]. CNN-based architectures such as TPP-PHOCNet, ResNet, and DenseNet have shown strong performance in capturing visual features across complex scripts, providing accuracy improvements over traditional feature extraction methods [3, 11, 12]. RNNs have also been effective, particularly for languages requiring sequential processing of character sequences, as they can retain context across varying word structures [4, 13, 20]. GANs have further contributed by generating synthetic datasets, which are valuable for expanding training sets in low-resource languages [6, 14, 18]. This is especially beneficial for developing accurate retrieval systems for underrepresented languages and scripts [6]. Despite these advancements, substantial research gaps remain, particularly in adapting these models for scripts like Gujarati, which exhibits unique structural complexities [5, 6]. The high variability in handwriting styles, use of conjuncts, and extensive modifiers require tailored approaches for effective retrieval [5]. Therefore, this review focuses on recent word spotting advancements using transfer learning, with a special emphasis on their application to Indic scripts and the need for further research to support underrepresented languages [2, 6, 15]. By highlighting both successes and research gaps in transfer learning for word spotting, this paper aims to pave the way for the development of robust document retrieval solutions that can handle the linguistic diversity and orthographic complexity inherent in multilingual and multiscript document collctions [2].

Literature Review of Word Spotting Techniques Using Transfer Learning

The development of word spotting techniques has been transformative in handling document images where traditional OCR falls short [1]. The introduction of transfer learning has further optimized these techniques, allowing pretrained models to be adapted for diverse languages and scripts [2]. This section provides an overview of key advances in transfer learning for word spotting, focusing on three main categories: Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and Generative Adversarial Networks (GANs) [3, 4, 14].

Convolutional Neural Networks (CNNs) and Transfer Learning

CNNs have become a cornerstone in word spotting due to their ability to capture spatial hierarchies in visual data, making them well-suited for recognizing intricate patterns in text images [3]. Early CNN architectures demonstrated moderate success in word spotting; however, recent adaptations leveraging transfer learning have achieved marked improvements [3]. Transfer learning enables CNNs to benefit from feature representations learned on extensive datasets, such as ImageNet, and fine-tune them for specific word spotting tasks on smaller, script-specific datasets [2]. This approach has proven highly effective in dealing with scripts that involve complex shapes, diacritics, and modifiers, as seen in Indic languages like Devanagari and Tamil [7, 16]. Popular CNN architectures in word spotting include TPP-PHOCNet, ResNet, and DenseNet [3, 11, 12]. Moreover, the Transformer-CNN hybrid models introduced by Kim *et al*. (2022) have shown promise in word spotting tasks by combining the attention mechanisms of Transformers with the spatial feature extraction of CNNs [9]. This hybrid approach significantly boosts retrieval accuracy for scripts with high modifier frequency, as seen in Japanese and Hindi datasets [9].

TPP-PHOCNet (Pyramidal Histogram of Characters): Building on established models like TPP-PHOCNet, recent studies have further optimized these networks with enhanced transfer learning techniques [3]. For instance, Chang *et al*. (2024) used multiscale CNNs fine-tuned with PHOC embeddings, specifically designed to process dense, modifier-rich scripts by emphasizing word shapes over individual characters [10]. This advancement achieved notable success on the challenging IAM and CVL datasets, which contain complex word shapes and varied script styles [3, 10, 21].

ResNet (Residual Networks): ResNet's architecture includes skip connections that mitigate the degradation problem commonly encountered in deep networks, allowing it to effectively handle complex image data [3, 12]. ResNet's

ability to maintain accuracy even at greater depths has proven advantageous in word spotting for challenging datasets like the IAM and George Washington collections [3, 12].

DenseNet: This architecture connects each layer to all subsequent layers, maximizing feature reuse and enhancing efficiency [3, 11]. DenseNet's compact structure has been particularly effective for handling high-density scripts and offers competitive results in word spotting for highly complex datasets, such as historical manuscript collections [3, 11].

Recurrent Neural Networks (RNNs) and Sequential Processing

RNNs, especially their variants like LSTMs and BiLSTMs, have shown potential in handling languages with high sequential dependency, making them useful for script-specific applications [4]. Since 2022, transfer learning in RNNs has expanded to support low-resource languages by fine-tuning models on synthetically generated data [4]. For example, Zhang and Huang (2023) implemented a BiLSTM-based transfer learning model adapted for Arabic and Tamil scripts, achieving high retrieval accuracy by leveraging pretrained language embeddings on large, generalized corpora [13]. The adaptation of BiLSTMs to fine-tuned language-specific embeddings enhances the model's ability to capture script-dependent patterns in sequences, enabling accurate retrieval of complex, context-dependent scripts [13]. A new Attention-LSTM model was introduced by Lee *et al*. (2023), focusing on Indic scripts with high diacritic and modifier usage, such as Bengali [13]. The model integrates attention layers that emphasize character contexts, making it effective for scripts with recurrent modifier shapes [13, 20]. This model has been successfully applied in identifying handwritten variations in low-quality historical texts, further validating the efficacy of RNN-based transfer learning in word spotting [13].

Generative Adversarial Networks (GANs) for Data Augmentation

Generative Adversarial Networks (GANs) have opened new avenues for enhancing word spotting through data augmentation [3, 6]. GANs generate synthetic training data, which is particularly useful for languages and scripts with limited available datasets [6]. By generating realistic handwritten or printed word images, GANs augment existing training data and improve the generalization capabilities of word spotting models [6, 14]. This technique is crucial for low-resource languages, such as Gujarati or other regional Indian scripts, where creating large, annotated datasets is a challenge [6, 18].

Conditional GANs (cGANs): Conditional GANs enable the generation of images conditioned on certain input parameters, such as text sequences or font styles [3, 14]. This is useful for producing variations in word images that can replicate real-world handwriting styles or printing variations, increasing model robustness [3]. Transfer learning allows cGANs to adapt from general image-generation tasks to script-specific applications, producing augmented data that is tailored for the unique challenges of specific scripts [3, 14].

CycleGANs: CycleGANs can convert images between two domains (e.g., printed to handwritten) without paired data [3, 18]. For instance, CycleGANs can transform synthetic printed word images into realistic handwritten forms, which expands the training set's diversity [3, 18]. This has proven useful in domains where handwritten data is scarce, allowing models to learn more effective features from larger datasets [3, 6].

Research Gap and Scope in Gujarati Word Spotting

Despite substantial progress in word spotting for widely studied languages, research focused on Gujarati—a regional script with unique orthographic characteristics—remains limited [5, 6, 15]. Gujarati, used by millions in India and parts of the diaspora, presents challenges in automatic retrieval due to its complex morphology, diacritics, and conjuncts [5]. This section explores the specific research gaps in Gujarati word spotting and proposes potential directions to address these challenges [6, 15].

Unique Characteristics of Gujarati Script

Gujarati script, derived from Devanagari, is structurally distinct in terms of its vowel modifiers and conjunct characters, which often appear as combined shapes rather than linear sequences [5]. Additionally, Gujarati uses a unique set of matras (modifiers) attached to base consonants, altering their visual form and complicating segmentation and recognition tasks [5].

Vowel Modifiers and Consonants: In Gujarati, vowels often modify consonants by attaching above, below, or beside them, changing the overall word shape [5].

Conjunct Characters: Some consonants form ligatures or conjuncts, which create completely new shapes that differ significantly from their isolated forms [5].

Challenges in Word Spotting for Gujarati

The characteristics mentioned above make word spotting in Gujarati particularly challenging [5]. Unlike English or other Latin scripts, Gujarati requires complex feature extraction techniques to distinguish between character shapes altered by matras, ligatures, and conjuncts [5]. Additional challenges include:

Shape Variability: Matras and conjuncts change the visual appearance of words drastically, even if the base consonants are similar [5].

Limited Dataset Availability: Unlike Hindi or Tamil, few large, annotated datasets exist for Gujarati [6]. The absence of extensive data limits model training and prevents robust evaluation [6, 15].

High Context Dependency: Gujarati words often depend on context to provide accurate retrieval, especially in the handwritten form, where variability is high [5].

Current Gaps in Gujarati Word Spotting Research

Several research gaps have been identified in recent literature that hinder the development of reliable word spotting for Gujarati [5, 6, 15]:

Insufficient Transfer Learning Applications: Despite the proven effectiveness of transfer learning in various computer vision tasks, its application in Gujarati word spotting remains underexplored [2, 6, 15, 22]. Most existing systems are trained from scratch, which demands large amounts of annotated data—a significant limitation given the scarcity of labeled Gujarati word image datasets, especially for handwritten forms [6]. Moreover, models trained on standard scripts like Latin or Devanagari are rarely adapted for Gujarati, missing opportunities to leverage cross-lingual feature representations [2, 15]. This lack of transfer learning not only hampers performance on limited-resource tasks but also slows down the development of generalized models capable of handling diverse styles and fonts across printed and handwritten domains [2, 6, 22].

Lack of CNN and GAN-Based Adaptations: Most models that work well on other scripts have not been adapted for Gujarati, especially in architectures like TPP-PHOCNet and DenseNet [3, 6, 11, 21]. Further adaptation is needed to account for Gujarati's unique morphological features [6].

Need for Synthetic Data Generation: The use of GANs for creating synthetic Gujarati datasets is highly underexplored [6, 14, 18]. GANs could generate realistic handwritten and printed Gujarati word images, providing the variability needed for robust training [6, 18].

Proposed Research Directions for Gujarati Word Spotting

To address these gaps, future research should prioritize the following approaches:

Developing Gujarati-Specific Datasets: Expanding existing datasets with more annotated Gujarati word images, especially for handwritten forms, will enable training and evaluation of more accurate models [6, 15].

Application of Transfer Learning with Devanagari Models(fig 1): Since Gujarati shares structural similarities with Devanagari, pretrained models on Devanagari datasets can be fine-tuned for Gujarati, reducing the need for large annotated data [2, 6, 15, 22].

Synthetic Data Augmentation Using GANs(fig 2): Applying GANs to generate realistic Gujarati word images in various handwritten styles could significantly improve model robustness [6, 14, 18]. This approach would address the scarcity of real-world Gujarati training data and aid in overcoming shape variability issues [6, 18].

Available Datasets for Word Spotting Research

The availability of high-quality, annotated datasets is crucial for the development and evaluation of word spotting techniques, particularly in low-resource languages like Gujarati [6]. While there has been significant progress in creating datasets for more widely spoken Indic languages such as Hindi, Tamil, and Bengali, the resources for Gujarati remain scarce [6]. This section reviews the key datasets available for word spotting research, with a focus on Indic scripts, and highlights the gaps that need to be addressed to improve word spotting for underrepresented languages like Gujarati [6, 15].

Datasets for Indic Scripts

Over the past decade, various datasets have been developed to support word spotting and optical character recognition (OCR) tasks for Indic scripts [2, 16]. These datasets include both handwritten and printed texts, covering multiple languages and scripts [2]. Many of the existing datasets focus on scripts like Devanagari, Tamil, and Bengali due to their widespread use and availability of digitized documents [2, 16]. However, even in these languages, the datasets are often limited in size, variety, and annotation quality, especially for handwritten forms [2].

Gujarati-Specific Datasets

Despite the significant progress made in creating datasets for Indic scripts, the availability of Gujarati-specific datasets remains limited [6]. The Gujarati Handwritten Corpus released in 2022 is one of the few datasets that focuses exclusively on Gujarati [6]. However, with only 10,000 annotated words, it is relatively small compared to the datasets available for other Indic scripts like Devanagari and Tamil [6]. This limited availability of Gujarati datasets is a major challenge for the development of robust word spotting techniques [6, 15].

Gaps in Existing Datasets for Gujarati

While there has been considerable progress in creating datasets for word spotting in Indic scripts, significant gaps remain in the availability of large, annotated datasets for Gujarati [6]. These gaps include:

Limited Handwritten Data: Existing datasets, such as the Gujarati Handwritten Corpus, are small and lack diversity in handwriting styles [6]. This is a major limitation for developing robust word spotting models, especially since handwriting variability is a key challenge in Gujarati word recognition [6, 15].

Lack of Conjunct and Modifier Variability: The complexity of Gujarati conjunct characters and modifiers is underrepresented in current datasets [5]. Many datasets do not capture the full range of possible conjuncts or the different ways modifiers (matras) can attach to base consonants [5].

Historical and Degraded Documents: There is a lack of datasets that focus on historical or degraded Gujarati documents, such as manuscripts or archival records [6]. These documents often suffer from ink fading, smudging, and other forms of degradation that make word spotting particularly challenging [1]. The inclusion of such documents in future datasets is crucial for improving model performance in real-world scenarios [6, 21].

Synthetic Data for Gujarati: While GANs (Generative Adversarial Networks) have been successfully used to generate synthetic data for low-resource languages like Tamil or Hindi, their application to Gujarati remains limited [6, 14, 18]. Synthetic data can help overcome the lack of real-world handwritten samples by generating diverse, realistic handwriting styles that can be used to augment existing datasets [6, 18].

In-Detail Reported Work for Indic and Non-Indic Languages, Comparison-Based Analysis of Different Word Spotting Techniques, and Their Results on Various Datasets

Word spotting techniques have advanced significantly over the past few years, particularly with the integration of deep learning models like CNNs, RNNs, and GANs [2, 3, 4]. These advancements have been applied across a wide variety of languages, both Indic and non-Indic, to address the challenges of document image retrieval [1].

Word Spotting Techniques for Non-Indic Languages

Word spotting in non-Indic languages, particularly European languages like English, French, and German, has been extensively studied [1]. These languages, which typically use relatively simple and uniform scripts (Latin alphabets), present fewer challenges compared to scripts like Devanagari, Tamil, or Gujarati [1]. Nonetheless, the techniques developed for non-Indic languages have laid the groundwork for more advanced approaches used in complex scripts [1].

DenseNet and PHOCNet: Models like DenseNet and PHOCNet (Pyramidal Histogram of Characters) were introduced to improve accuracy in word spotting tasks [3, 11, 21]. PHOCNet, in particular, became popular due to its ability to represent words as spatial histograms of characters, bypassing the need for explicit segmentation [3, 21]. These models achieved high accuracy on the IAM Handwriting Dataset (which includes handwritten English) and demonstrated their robustness on Latin-based scripts [3]. PHOCNet's hierarchical approach allowed it to recognize words holistically, making it suitable for scripts with variable character spacing [3, 21].

Performance on Non-Indic Datasets: On datasets like the IAM and Bentham handwritten datasets (both English-based), CNN-based models achieved accuracy rates upwards of 90% in word spotting tasks [3, 11]. These models handled variations in handwriting styles effectively and showed significant improvements over traditional segmentation-based methods [3].

Word Spotting Techniques for Indic Languages

Word spotting for Indic languages, such as Hindi, Tamil, and Bengali, presents significantly more challenges than for non-Indic languages due to the complexity of Indic scripts [2, 16]. These scripts often include multiple levels of diacritics (matras), conjuncts (joint characters), and modifiers, all of which complicate character segmentation and recognition [2].

PHOCNet for Indic Scripts: PHOCNet has been successfully adapted for Indic languages due to its ability to capture holistic word shapes [3, 21]. For instance, on the Indic Handwritten Dataset, PHOCNet achieved significantly higher accuracy than segmentation-based methods, particularly when applied to scripts like Tamil and Bengali, which feature frequent use of conjuncts [3, 16]. By representing word images as pyramidal histograms, PHOCNet could bypass the need for character segmentation, which is particularly prone to error in Indic scripts [3, 21].

DenseNet for Indic Scripts: DenseNet has also shown promise in word spotting for Indic scripts, especially in handling complex forms like Devanagari conjuncts and Tamil ligatures [3, 11]. In experiments conducted on the Devanagari Handwritten Dataset, DenseNet outperformed traditional models, achieving an accuracy of 87%, particularly for complex handwritten documents where modifiers and ligatures were common [3, 11].

GAN-Based Approaches for Low-Resource Scripts

For low-resource languages like Gujarati, where few large datasets exist, Generative Adversarial Networks (GANs) have been employed to generate synthetic training data [6, 14, 18]. By creating realistic samples of handwritten

Gujarati, GANs can augment the training dataset, enabling models like PHOCNet and DenseNet to be trained more effectively [6, 18].

CycleGAN for Synthetic Data Generation: A CycleGAN model trained on small amounts of real Gujarati handwriting has been used to generate synthetic handwriting samples [6, 18]. This technique helps overcome the lack of large annotated datasets and enables the creation of varied handwriting styles [6, 18]. When trained with synthetic data, models such as DenseNet showed improvements in accuracy, particularly in recognizing conjunct characters and complex matra placements [6, 11].

CONCLUSION

This review has explored the advancements and challenges in word spotting for the Gujarati script, identifying the unique complexities posed by its conjunct characters, modifiers, and extensive shape variability [5, 6]. Despite significant progress in deep learning, particularly through segmentation-free models and transfer learning techniques, current models often struggle to handle the nuances of Gujarati due to limited annotated datasets and high variability in character formation [6, 15].Models like PHOCNet and DenseNet have shown promise in recognizing entire word structures without relying on segmentation, making them well-suited for complex scripts like Gujarati [3, 11, 21]. Furthermore, generative methods, such as GAN-based synthetic data generation, provide a valuable resource to augment datasets, addressing the data scarcity that often impedes model development for low-resource languages [6, 14, 18].In conclusion, while challenges remain, the integration of advanced machine learning techniques and collaborative data collection initiatives can drive significant improvements in Gujarati word spotting [6, 15]. These efforts will contribute to the broader goal of digital preservation, enhancing accessibility to Gujarati texts and supporting the preservation of linguistic and cultural heritage [1, 6].

Table 1: Datasets for Indic Scripts

Dataset Name	Language(s)	Type	Size	Features	Year
Indic Handwritten Dataset	Hindi, Telugu, Tamil	Handwritten	50,000+ words	Covers multiple scripts and includes challenging handwritten text	2020
IAM Handwriting Database	English, Hindi	Handwritten	1,000,000+ words	Large-scale dataset, mostly focused on English and Latin scripts	2017
MNIST-Indic Characters	Hindi, Tamil	Isolated characters	60,000+ characters	Isolated handwritten characters for deep learning tasks	2019
Bengali Character Dataset	Bengali	Handwritten, Printed	45,000+ words	Includes handwritten and printed forms, varying font styles	2021
CVL Handwriting Database	Multiple	Handwritten	300,000+ characters	Covers multiple languages, primarily used for handwriting research	2019
Devanagari Handwritten OCR Dataset	Hindi, Marathi	Handwritten	92,000+ characters	Focus on Devanagari, includes handwritten text samples	2019
Gujarati Handwritten Corpus	Gujarati	Handwritten	10,000+ words	Small dataset focused on handwritten Gujarati	2022

Custom Historical Documents Dataset	Multiple (incl. Hindi)	Printed	5,000+ pages	Focus on historical manuscripts, scanned from physical archives	2021

Table 2: Gujarati-Specific Datasets

Dataset Name	Type	Size	Features	Year
Gujarati Handwritten Corpus	Handwritten	10,000+ words	Limited handwritten samples with few variations in style	2022
Custom Historical Documents	Printed, Scanned	500+ pages	Focus on printed Gujarati documents, mainly from archived manuscripts	2021

Table 3: Performance on Non-Indic Datasets

Technique	Dataset	Language	Accuracy	Strengths	Limitations
Segmentation-Based (HMM)	George Washington Dataset	English	75%	Works well for isolated characters	Struggles with connected handwriting
PHOCNet (CNN)	IAM Handwriting Dataset	English	90%	Segmentation-free, handles word variability	High computational cost, requires large training data
DenseNet (CNN)	Bentham Handwriting Dataset	English	92%	Handles variable handwriting styles	Requires large-scale datasets for optimal performance

Table 4: CycleGAN for Synthetic Data Generation

Technique	Dataset	Language	Accuracy	Strengths	Limitations
Segmentation-Based (HMM)	Devanagari Handwritten Dataset	Hindi	65%	Useful for isolated characters	Poor performance on conjuncts and ligatures
PHOCNet (CNN)	Indic Handwritten Dataset	Hindi, Tamil	85%	Handles variable conjuncts and modifiers	Requires large datasets for effective training
DenseNet (CNN)	Devanagari Handwritten Dataset	Hindi, Marathi	87%	Effective for handwritten text with diacritics	Computationally expensive, requires GAN-based augmentation
CycleGAN (for Synthetic Data)	Gujarati Handwritten Dataset	Gujarati	80%	Generates diverse handwriting styles	Depends on quality of real training data

ABSTRACT

The cosmetic engineering is undertaking a substantial alteration motivated by advancements in nanotechnology, which manipulates materials at the nanoscale (1-100 nm). This field offers unique properties like increased surface-to-volume ratio, leading to enhanced skin penetration, long-lasting effects, and improved ingredient delivery in cosmetic formulations. Nanoparticles are categorized as organic, carbon-based, and inorganic, each offering distinct advantages. Key nanocarriers like liposomes, niosomes, solid lipid nanoparticles (SLNs), nanoemulsions, nanospheres, and dendrimers are crucial for delivering active cosmetic ingredients with precision and stability. Beyond formulations, bionanomaterials are revolutionizing tissue engineering, nanomedicine, and biosensing, fostering ethical product development. Advanced engineering methods, including 3D printing and microfluidics, permits the creation of personalized cosmetic products and highly uniform nanoparticles, respectively.

Keywords: Liposomes, Nano technology, Niosomes, Micro fluidization, 3d printing, Tissue engineering,

INTRODUCTION

The cosmetic industry is currently undergoing a transformative period, largely driven by the remarkable advancements in nanotechnology. In recent years, nanotechnology has captured global attention. This expansive field involves the strategy, development, and manipulation of constituents at the nanoscale (1–100 nm). At the nanoscale, materials exhibit altered characteristics, notably an increased surface-to-volume ratio, a higher quantity of elements per unit weightiness, and the quantum confinement effect. These unique assets make nanoparticles highly

suitable for diverse businesses, together with domestic utilizations, farming, impurity exclusion, food, announcement, medicine, transport, cosmetics, and cosmeceuticals. [GarimaNagpal *et al.*, 2023]. Nanomaterial-based cosmetics offer distinct rewards over their micro-scale matching part, primarily enabling continuing effects and improved stability. The cosmetic industry's key objectives in utilizing nanomaterials include achieving efficient skin penetration for improved ingredient delivery, developing novel color essentials (e.g., Lipsticks and nail polishes), ensuring clarity (e.g., Sunscreens), and providing more durable results [Georgia Fytianos *et al*., 2020] With the continued advancement of nano cosmetics through scientific research and technological development, we anticipate the introduction of increasingly sophisticated and personalized products, promising unprecedented efficacy, safety, and environmental accountability. [KetanSonawane *et al*., 2024] Nanoparticles are well-defined as tiny particles fluctuating from 1 to 100 nanometers, distinguished by their exclusive physical and chemical attributes, which stem from their elevated surface area and reactivity. Their classification is based on their sizes, classifying them as Zero-dimensional (0D), One-dimensional (1D), Two-dimensional (2D), or Three-dimensional (3D). Within cosmeceutical utilizations, nanoparticles are morecharacterized according to their morphology, size, and physicochemical features. [N. Ranjan *et al*., 2022]

Categories of Nanoparticles

Biological Nanoparticles: These nanoparticles are derivative from organic materials such as proteins, lipids, carbohydrates, or polymers. Distinguished examples include Dendrimers, Micelles, Liposomes (which may own a deep core), and protein network like ferritin. While recyclable and non-lethal, they displayvulnerability to current and electromagnetic radioactivity, as well as light and heat.

Carbon-Based Nanoparticles: This group is exclusively collected of carbon particles. Key instances encompass Carbon dark NPs, Fullerenes, and Quantum spots. Fullerenes are categorized by their equal, closed-cage carbon nanomaterial constructions, demonstrated by C60, C70, and C540. Carbon Black Nanomaterials are nebulous carbon totals that exhibit a grape-like morphology. Quantum Dots are quasi-spherical nanoparticles, characteristically sized amid 1 and 10 nm.

Inorganic Nanoparticles: Invented from inorganic materials, this grouping comprises metal-based, ceramic-based, and semiconductor-based nanoparticles.

Metal-Based Nanoparticles: These are entirely composed of metallic precursors, which can be mono, bi or polymetallic. Their diverse electrical and optical properties are influenced by phenomena such as surface plasmon resonance.

Ceramic Nanoparticles: These inorganic particles are formed from carbides, carbonates, oxides, and phosphates of metals or metalloids, such as calcium and titanium.

Semiconductor-Based Nanoparticles: Constructed from semiconductor materials, these nanoparticles possess properties of both metals and non-metals. They find utility in photocatalysis, electronic devices, and optical devices. [Joudeh, N *et al*., 2022]

NANOTECHNOLOGYINCOSMETICINDUSTRY/ THE EVOLUTIONAND IMPACTOFNANOCOSMETICS

The lasting human desire to preserve a decent presence is as old as humanity itself, serving as the primary driving force behind cosmetic use. The practice of cosmetics times back to earliest Egypt around 4000 BC, with civilizations like the Americans, Greeks, Chinese, Romans, and Japanese also adopting them. While household items served as early cosmetic solutions, the 20th century saw their widespread, unrestricted use. The 21st century marks a new era, characterized by the integration of advanced technology leading to inventive cosmetic formulations now in immense use. The minute these cosmetic products are encouraged with biologically dynamic therapeutic additives to improve appearance, they are called cosmeceuticals [9]. These products efficiently address various skin and hair worries,

including hyperpigmentation, wrinkles, irregular complexion, photoaging, skin aridness, dark spots, and hair injury. [Garima Nagpal *et al*., 2023]

Nanomaterials: A Game Changerin Cosmetics

Surveys reliably show that nanosized resources are now routinely working by all chief cosmetic producers across their product choices. The merging of chemical sciences with pharmaceuticals has led to a new nomenclature: Nano cosmetics. A diverse array of nanoparticles, counting metals (e.g., silver nanoparticles - AgNPs, gold nanoparticles - AuNPs), metal oxide nanoparticles (e.g., titanium dioxide nanoparticles - TiO2NPs, zinc oxide nanoparticles - ZnO NPs, iron (III) oxide nanoparticles - Fe2O3NPs), and carbon-based nanoparticles, are broadly used in cosmetic preparations. Chief cosmetic establishments such as Estee Lauder, L'Oréal, Nivea, Zelens, and Derma Swiss, among others, actively incorporate nanoparticles into their goods. The nanotechnology-based cosmetics manufacturing is a multi-million-dollar global marketplace. L'Oréal, the world's major cosmetics corporation, suggestively invests in nanoexclusive rights, having secured numerous exclusive rights for "nano some particles".

Nanocarriers used in Cosmetics

Carriers are used to distribute active substance for the delivery of nanocosmeceuticals. There are various types of carriers used they are:

Liposomes

Liposomes are most frequently used in cosmetic products. They are membrane-bound constructions with an aqueous central encased in anaquaphobic lipid bilayer. The possibility of negative effects is reduced since phospholipids, which comprise the widely held of the lipid bilayer in liposomes, are usually regarded as innocuous chemicals. To stop metabolic breakdown, liposomes encapsulate medications and deliver their active ingredients gradually [GarimaNagpal *et al*., 2023]. Liposomes are either unilamellar or multilamellar in structure, and the size is between 20 nanometers to 1 micrometer. Liposomes are used as potent carriers in cosmetic industry due to its characteristics like increased compounds solubility, accord with human skin, lessened harmful effects and enhanced drug buildup at the target spot[GarimaNagpal *et al*., 2023].

Niosomes

Niosomes are microscopic, self-assembling vesicles formed from the hydration of unionized surfactants, often united with cholesterol. They hold a bilayer construction, similar to liposomes, with a water-soluble head facing outwards and inwards, and a non-water-soluble tail forming the central of the bilayer. This exclusive amphiphilic nature permits them to capture both hydrophilic drugs in their aqueous central and lipid-soluble drugs within their double layer crust. Niosomes offer several compensations as drug and cosmetic delivery schemes. They are generally considered more stable than liposomes due to the biochemical nature of their non-ionic surface-active agent, making them less prone to oxidation and degradation. Their suitable for biological applications, decomposable, and low toxicity make them appropriate for several applications. Niosomes can improve the bioavailability of encapsulated substances, provide controlled and sustained release, and offer targeted delivery to specific sites in the body or skin. Their versatility in encapsulating a wide range of active compounds has led to their increasing use in pharmaceuticals, cosmetics, and even agriculture.

Solid Lipid Nanoparticles (SLNs)

Known for their biocompatibility and stability, these carriers offer a safe way to encapsulate diverse substances, including those that are water-loving, fat-loving, or have low solubility, thereby reducing potential toxicity. [KetanSonawane *et al*., 2024] They are collected of a solid matrix, which can be completed from several materials like polymers, lipids, metals, or inorganic compounds. These tiny carriers are expansively explored for their capability to encapsulate and transport a wide variety of active substances, including drugs, genes, and imaging agents.

Nano Emulsions

Nano emulsions are steady, finely dispersed mixtures of two non-miscible fluids, with droplet sizes usually between 20 and 200 nanometers. Surfactants stabilize them by lowering interfacial tension and stopping droplet coalescence. In contrast to microemulsions, they lack thermodynamic stability but show long-term kinetic stability because of their tiny droplet size. This compact size results in numerous benefits, such as superior optical clarity (often looking transparent), remarkable physical stability against creaming or sedimentation, and improved bioavailability of the encapsulated substances. They are commonly utilized in medication delivery to enhance the solubility and approval of drugs that are less soluble in water. In addition to pharmaceuticals, nano emulsions are utilized in cosmetics to improve skin absorption and feel, as well as in the food sector to encapsulate flavors and nutrients.

Nano Spheres

Nanospheres are spherical nanoparticles generally measuring between 10 and 200 nanometers in diameter. They are essentially solid matrix systems, indicating that the active substance is evenly distributed within or bonded to the polymeric or inorganic material that makes up the sphere. This design enables efficient encapsulation and safeguarding of medications or other therapeutic compounds. Their main benefits consist of outstanding stability, regulated release of the enclosed material, and the capability to expand the solubility and solubility of difficult-to-dissolve substances. Nanospheres are extensively researched in drug transport, especially for embattled treatment of particular cells or tissues, minimizing side effects. They are also utilized in diagnostics, imaging, and in areas such as catalysis and environmental clean-up owing to their large surface area and adjustable characteristics.

DENDRIMERS

They are used as a vehicle to enhance the absorption of vitamins into the profound layers of dermis. Dendrimers are intricately branched, tree-shaped macromolecules featuring an exact, symmetrical design radiating from a central core. They are developed in consecutive "generations," with each adding an additional layer of branching and enhancing the quantity of surface functional groups. This distinctive structure offers a high surface area relative to its volume and inner cavities, positioning them as outstanding options for encapsulating and delivering various molecules, such as drugs, genes, and imaging agents. Their specified dimensions, form, and many adjustable surface functionalities enable customized characteristics such as solubility, targeting, and controlled release, providing considerable benefits in nanomedicine and other areas

Bionanomaterials

Bionanomaterials are tiny, biologically-made materials. Their minuscule size gives them special properties—structural, chemical, physical, and more—that set them apart from larger versions of the same material. These unique traits allow them to be used in various biomedical applications, such as tissue engineering, drug delivery, cancer therapy, and treating neurological diseases and inflammation. They are made up of biological molecules like proteins, antibodies, enzymes, lipids, and nucleic acids.

Bionanomaterials: Diverse Applications

Bionanomaterials are vital in medicine, from building tissues and delivering drugs to nanomedicine and diagnosing diseases.

Nanomedicine

The landscape of medical practice is being reshaped by nanomedicine, allowing the satisfaction of healthcare needs that were once out of reach. It improves the body's ability to absorb, employ, and profit from even very harmful but otherwise beneficial treatments., such as Me pact, while introducing novel drugs for both diagnostics and therapeutics. This advancement is attributed to the unique properties of bionanomaterials, which enable crucial pharmaceutical and biomedical advantages. These include reduced toxicity and side effects through lower dosing, increased targeted drug effects, controlled site-specific drug release, and improved transport across biological barriers.

Bionanomaterials for Nanobiosensing

Combining biological components with transducers, a biosensor serves as an analytical device for detecting analytes or quantifying physiological signals by converting electrical, optical, and thermal inputs. Its core structure comprises a probe—responsible for detecting diverse biomolecules such as at their core, biosensors consist of a biorecognition element—drawing upon substances like DNA, RNA, antibodies, aptamers, enzymes, and proteins—and a transducer. This transducer is crucial for converting physiochemical information into quantifiable magnetic, electrical, optical, thermal, or electrochemical outputs.

Bio-Imaging

Molecular imaging, a crucial component of diagnostics, utilizes nuclear medicine and radiology to examine real-time molecular changes within a living organism during disease progression. It effectively observes the biochemical shifts that occur in the body's tissues or organs during illness. Significantly, bionanomaterials are currently a focus of intensive research to boost molecular imaging capabilities. Their advantageous properties, including a significant surface area for its given volume, excellent tissue compatibility, and careful affinity for biological molecule surface receptors, facilitate targeted attachment. This specific binding generates distinct signals, enabling the detection of minute molecular-level alterations. [Piyush Kumar Sadhu *et al*.,2023]

Tissue Engineering in Cosmetics

Tissue engineering in cosmetics represents a fascinating and rapidly evolving field, primarily focused on developing and utilizing laboratory-grown tissues to replace or reduce the need for animal testing and, more recently, to create advanced cosmetic ingredients and products. Moving beyond dependence on animal components or animal testing, cosmetic tissue engineering fabricates 3D skin models by culturing human cells, primarily fibroblasts or keratinocytes. These bioengineered constructs replicate human skin's natural structure and function, thereby enabling applications such as

Test product safety and efficacy: Companies can apply cosmetic formulations directly to these engineered skin models to assess irritation, sensitization, and penetration, providing a more human-relevant alternative to traditional animal tests.

Identify novel active ingredients: By observing how engineered tissues respond to various compounds, researchers can discover new molecules that promote collagen production, reduce inflammation, or offer antioxidant benefits.

Understand skin biology: Offering a precise experimental platform, these models enable comprehensive research into processes such as skin aging, variations in pigmentation, and a range of cutaneous disorders. Such studies yield enhanced insights into their mechanistic foundations, consequently aiding in the formulation of bespoke cosmetic treatments.

Develop "bio printed" cosmetics: While still largely experimental, the long-term vision includes bioprinting personalized skincare products or even "living" patches that can directly address specific skin concerns.

The core benefit of this approach is its ethical advantage, providing a cruelty-free method for product development. Furthermore, engineered human tissues often offer more accurate and predictive results for human application compared to animal models, leading to potentially safer and more effective cosmetic products. The field is continuously advancing, with efforts to create more complex tissue models that include multiple cell types, blood vessels, and even nerve endings, further enhancing their resemblance to in-vivo skin.

Applications of Nanomaterials in Tissue Engineering

Nanomaterials are revolutionizing tissue engineering by mimicking the natural extracellular matrix, crucial for cell behavior. Nanoparticles are instrumental in producing scaffolds that exhibit regulated porosity and specific mechanical characteristics, which in turn guides cellular development and differentiation. Their substantial surface area relative to volume promotes superior cell adhesion, proliferation, and signaling. Furthermore, these

nanoparticles offer the capability to encapsulate and precisely deliver growth factors, pharmaceuticals, or genes with fine-tuned spatial and temporal regulation. They also offer improved imaging capabilities for monitoring tissue regeneration in real-time. Specific nanomaterials like carbon nanotubes can provide electrical cues for nerve and cardiac tissue engineering. Metallic nanoparticles contribute antimicrobial properties, reducing infection risks in implants. The tunable surface chemistry of nanomaterials allows for biomolecule conjugation, enhancing specific cell interactions. They contribute to the assembly of elaborate 3D tissue models, playing a pivotal role in organ repair and transplantation. Taken together, nanomaterials empower the implementation of highly effective and focused methodologies for rejuvenating impaired tissues and organs.

Regarding scaffold fabrication: These agents facilitate the production of scaffolds designed to emulate the native extracellular matrix (ECM), ensuring comparable structure, porosity, and mechanical integrity. This biomimetic design is paramount for orchestrating cell adhesion, proliferation, and differentiation.

Enhanced Cell Interaction: Elevated surface area to volume proportion of nanomaterials provides abundant sites for cell attachment, promoting better cell growth, communication, and overall tissue development.

Controlled Delivery Systems: Nanoparticles act as efficient carriers for delivering growth factors, drugs, genes, and other bioactive molecules directly to the target site, allowing for localized and extended release, which is vital for tissue regeneration.

Improved Mechanical Properties: The inclusion of nanomaterials can markedly boost the mechanical properties and elasticity of tissue engineering scaffolds. As a result, these scaffolds become viable for use in load-bearing tissues, including bone and cartilage.

Electrical Cues: Due to their electrical conductivity, specific nanomaterials like carbon nanotubes are crucial for creating electrically functional tissues including nerve and cardiac tissue, given the supreme importance of electrical signaling in these contexts.

Antimicrobial Properties: Some metallic nanoparticles exhibit antimicrobial effects, which can be integrated into scaffolds to prevent infection, a common complication in tissue implants.

Bioimaging and Monitoring: Nanomaterials can be designed with imaging capabilities, allowing researchers to monitor cell behavior, scaffold degradation, and overall tissue regeneration in real-time within the body.

Polymeric Nanoparticles

Future scope of polymeric Nanoparticles in Nanotherapeutics

This field shows immense promise, with ongoing research and technological advancements continuously opening new possibilities and driving future growth.

Personalized medicine: An expanding field, centers on customizing treatments based on an individual's distinct genetic profile, disease features, and therapeutic responses. In this evolving domain, polymeric nanoparticles are gaining significant traction. They provide an accurate method for delivering bespoke combinations of drugs and gene therapies, thereby enabling highly targeted treatments**.**

Immunotherapy: These are a rapidly advancing area, revolutionizing cancer treatment and showing promise in other diseases too. A key development here is the ability to engineer polymeric nanoparticles. These nanoparticles can precisely deliver immunomodulatory agents directly to immune cells or to the tumor's immediate surroundings. This targeted delivery significantly boosts the body's natural defenses against diseases.

RNA Therapeutics: The rise of RNA-based therapies, such as mRNA vaccines and gene silencing treatments, has opened new frontiers in medicine. Polymeric nanoparticles are set to play a vital role here, acting as essential delivery vehicles for these delicate molecules. This capability allows for more efficient and targeted treatments across a range of conditions, from genetic disorders to viral infections.
[Piyush Kumar Sadhu *et al*.,2023]

3D Printing Technology in Nanoparticles

Through its method of layering materials based on digital blueprints, 3D printing (additive manufacturing) has utterly transformed how we approach design and manufacturing. This approach grants extensive design liberties, leads to decreased material consumption, and speeds up prototype development. As noted by Wohlers Associates, this technology is redefining industries where precision and tailored solutions are essential, notably healthcare, automotive, and aerospace.

3D Printing in Nanomaterials

- Defined by their fabrication at a scale of billionths of a meter, nanomaterials—a category including nanoparticles, nanotubes, and nanocomposites—possess unique attributes. These stem from their large surface area-to-volume ratio and pronounced quantum effects, leading to exceptional functionalities:
- **Mechanical strength**: Ideal for reinforcing 3D-printed structures
- **Electrical conductivity**: Useful in electronics and sensors
- **Thermal stability**: Crucial for aerospace and high-temperature applications

A review in the journal Nature Nanotechnology emphasizes that nanomaterials are "at the forefront of interdisciplinary research," with the potential to drive technological break throughs across sectors. [Piyush Kumar Sadhu *et al*.,2023]

Applications of 3D Printing Technology

By making it possible to create customized medicine formulations, on-demand manufacture, and intricate drug delivery systems, 3D printing, sometimes denoted to as preservative engineering, is totally changing the pharmaceutical sector. This technology allows for detailed control over dose, release profiles, and medicine combinations, which is especially valuable in personalized medicine.

Fused Deposition Modeling (FDM)

FDM is one of the utmost extensively used 3D printing practices in pharmaceutics due to its simplicity, cost-effectiveness, and versatility. The mechanism includes a thermoplastic filament, often loaded with an active pharmaceutical ingredient (API), is melted and extruded over a fiery outlet. Film by film deposition of this material will lead to formation of a 3D object—typically a tablet or implant.

Applications

Precision Dosing: FDM enables the fabrication of tablets with highly accurate drug dosages, tailored to individual patient needs.

Controlled Release: By modifying the internal geometry or polymer composition, FDM can produce tablets with immediate, sustained, or delayed release profiles.

Multi-Drug Integration: It allows for the integration of numerous drugs and excipients into one dosage form, reducing pill burden and improving patient compliance.
According to a Springer publication, FDM is particularly promising for oral therapies, transdermal patches, and implants, and is being actively explored for clinical and hospital-based drug manufacturing.

Bioprinting in Pharmaceuticals

Bioprinting is aprogressive form of 3D printing that uses bioinks, collected of living cells, biomaterials, and growth aspects to fabricate tissue-like structures.

Applications

- High-throughput drug screening using bio printed tissue models
- Personalized medicine through patient-specific tissue constructs
- Reduction in animal testing by providing physiologically relevant models [E-copy emerging trends of nanomaterials]

Microfluidics Technology

Microfluidics is a new and adaptable technology that is currently being applied in several fields. Microfluidic systems can manipulate fluid volumes as small as 10-9 to 10-18 L, with the help an integrated system of micrometer channels, microvalves, and micromixers. Microfluidics technology operates on the idea of controlled mixing, which employs the device microfluidizer. The device uses a positive displacement pump at high pressure which ranges from 500 to 20,000 psi. The product is forced through a special chamber that has tiny channels. As it goes through these micro-channels, it's then directed to an impact area. This impact creates extremely small, sub-micron particles.

Nano emulsions were manufactured using two methods

Single-channel and Dual-channel method

Single-channel method: This method is a two-step process. First, you mix the oil (lipid) and water (aqueous) parts with a high-speed blender at room temperature to make a rough, coarse emulsion. Then, you pump this coarse mixture through a special air-driven machine called a microfluidizer (with Y- and Z-type chambers) at different pressures for a single pass. This intense processing turns the coarse emulsion into a fine nanoemulsion.

Dual-channel method: This method is more direct. Instead of pre-mixing, you put the oil and water phases into separate containers. Then, you feed both phases directly into the same air-driven, high-pressure microfluidizer (also with Y- and Z-type chambers). As they pass through the machine together, they form fine emulsions (likely nanoemulsions) directly. [Piyush Kumar Sadhu *et al*.,2023]

Applications

Microfluidics Technology in Manufacturing Liposomes

The Microfluidic (MF) system is a unique approach that uses tiny channels, ranging from 5 to 500 micrometers, to process fluids. These narrow channels ensure a smooth, laminar flow, which significantly boosts how well microfluidic devices perform and mix substances. In the MF process, lipids are first dissolved in an organic solvent like ethanol or isopropanol. The amount of lipid compared to cholesterol is crucial, as it greatly affects the characteristics of the final product. The dissolved lipid phase is then directed into one chamber, while an aqueous (water-based) phase goes into another. The flow of both phases is precisely controlled by adjusting their flow rate ratio (FFR) and total flow ratio (TFR). Within this controlled environment, the organic and aqueous phases are continuously mixed. This mixing causes the phospholipids (a type of lipid) to spread into the aqueous phase, prompting the lipids to naturally arrange themselves into liposomes.

Microfuidics Technology in Manufacturing SLNs

Solid lipid nanoparticles are lipid nanocarriers designed to transport hydrophobic bioactive chemicals with increased loading capacity and stability. Solid lipid nanoparticles enhance the loading and bioavailability of several plant bioactive components. For its manufacture, the lipid and the drug are dissolved in an organic solvent. This mixture then goes into the microfluidic (MF) device as the inner liquid. At the same time, a separate water-based solution with a surfactant flows in as the outer liquid. Both these liquids are precisely pumped from individual syringes into

the MF device's channels and onto a chip. Once the SLNs form, the organic solvent is evaporated, and the particles are then chilled to 4°C to solidify them.

Microfuidics for Polymeric Nanoparticles

Polymeric nanoparticles, because of their ability to effectively encapsulate a variety of drugs and modify their release by modifying the use of the polymer characteristics, have caught a lot of attention in research fields. For instance, Polymeric nanoparticles due to its slow rate of degradation, has found its application in sustained or extended-release formulations. The conventional method of manufacture has a number of limitations; hence microfluidics technology emerged as a modern and advanced method for the manufacture of polymeric Nps. MHF method is employed. This microfluidic approach involves dissolving a suitable polymer in an organic solvent and then mixing it with an aqueous solution at specific flow rates (TFR and FFR). This method promotes the self-assembly of lipids, leading to the production of monodispersed nanoparticles without the need for solvent evaporation.

CONCLUSION

The cosmetics industry is currently experiencing a major transformation, largely due to the remarkable progress being made in the field of nanotechnology. This field, operating at the nanoscale, has unlocked new possibilities for cosmetic formulations, offering enhanced efficacy, stability, and personalized solutions. Nanoparticles and diverse nanocarriers are now widely used to deliver active ingredients more effectively, improving everything from skin penetration to product longevity. Beyond direct product applications, bionanomaterials are revolutionizing ethical ingredient sourcing and testing. Furthermore, 3D printing and microfluidics technology are enabling customized production and precise nanoparticle manufacturing. This ongoing innovation promises a future of increasingly sophisticated, safe, and environmentally responsible cosmetic products, continually enhancing well-being and appearance.

Table 1: Benefits and limitations of liposomes

BENEFITS OF LIPOSOMES	LIMITATIONS OF LIPOSOMES
Improved dermal layer stability and penetration to stop metabolic breakdown	Poor solubility and high production costs
Biocompatible and biodegradable	Drug leakage and insufficient stability
Enhanced effectiveness and lower toxicity	Sometimes oxidation and hydrolysis reaction and sensitive to osmosis

Table 2: Benefits and limitations of niosomes

BENEFITS OF NIOSOMES	LIMITATIONS OFNIOSOMES
High chemical and physical stability	Potential for aggregation/fusion
Improved skin penetration	Possible drug leakage
Biocompatible and biodegradable	Limited drug loading for some APIs
Encapsulates hydrophilic and lipophilic drugs	Physical instability (temperature and pH)
Enhanced bioavailability	Batch to batch variability
Controlled and sustained release	Hydrolysis of surfactants over time

Table 3: Benefits and limitations of SLNs

BENEFITS OF SLNs	LIMITATIONS OF SLNs
Increased bioavailability and controlled release	Drug filling capacity is low
Increased drug penetration	Drug filling magnitude is decreased due to partitioning effect
Increased stability	Gelatin liability is uncertain
Large scale extensibility is easy	Better release takes place

ABSTRACT

Urine samples of Cow, Buffalo, Goat and antibiotic cephataxim were collected from different localities of chalisgaon region. The study explores the antibacterial activity against *Salmonella abony*, *Escherichia coli, Pseudomonas aeruginosa, Bacillus cereus* and *Lactobacillus sporogenes*. Antibacterial activity was done by agar well diffusion method. The Statistical Analysis Performing one way ANOVA in conjunction with Tukey's Honestly Significant Difference (HSD).Typically, a significance level (α) of 0.05 is used. The Q statistic measures the difference between the means of the treatments compared. The one-way ANOVA test indicates that there are significant differences in the means of antibacterial activity across the bacterial species. The Tukey's HSD results of this analysis provide important insights into bioactive compound variability across species.

Keywords: Antibacterial activity, Tukey's HSD, Cephataxim, Agar well etc

INTRODUCTION

The antibacterial properties of animal urine, particularly that of domesticated animals like goats, cows, and buffaloes, have long been studied in traditional medicine and agriculture. However, recent research has started to provide

scientific evidence for these claims by identifying a number of antimicrobial compounds in these animals' urine that effectively combat bacterial infections. Studies have shown that phenols, one of the bioactive substances included in cow urine, have potent antibacterial properties against both Gram-positive and Gram-negative bacteria, such as *Escherichia coli* and *Staphylococcus aureus*[2]. Similarly, research on buffalo urine has shown that its peptide extracts are effective against bacteria, particularly Gram-negative ones like *E. coli* and *Streptococcus agalactiae*[4].These findings suggest that urine-derived compounds may have bacteriostatic or bactericidal effects, contingent on the bacterial strain and urine concentration. Recent studies have brought attention to a study gap in evaluating the relative antibacterial activity of urine from different domesticated species, such as dogs, cats, sheep, and horses. Although cow and buffalo urine has been examined more extensively, nothing is known about the antibacterial qualities of urine from other domestic animals. Although thorough comparative studies have not been conducted, some study suggests that the peptides and organic acids present in these animal urines may be essential in inhibiting the proliferation of germs[4]. Nevertheless, there aren't many systematic comparisons between different bacterial strains and animal species. This study aims to bridge that gap by examining the antibacterial activity of urine from a number of domesticated animals (goats, cows, and buffalo) against particular Gram-positive and Gram-negative bacteria. By comparing the results across species treated with antibiotics, this study will increase our understanding of the potential use of animal urine in agricultural applications and antibacterial therapies.

MATERIALS AND METHODS

Urine Sample Collection

Three domesticated animals, including cows, buffalo, and goats, had urine samples taken from them at different sites throughout the Chalisgaon district. To prevent contamination, the collection was carried out in sterile containers. Before undergoing additional analysis, the samples were kept at 4°c after being transferred to the lab in a refrigerated environment. The appropriate animal was labeled on each sample[8].

Bacterial Strains Used

The study will focus on Gram-positive p (*Bacillus cereus* and *Lactobacillus sporogenes*.) and Gram-negative (*Salmonella abony* (NCTC 6017), *Escherichia coli*(ATCC 8739), *Pseudomonas aeruginosa*(ATCC 9027)bacteria, which will be sourced from School of life sciences, K.B.C.North Maharashtra University, Jalgaon.

Agar Well Diffusion Method

The agar well diffusion method will be used to examine urine's antibacterial activity, bacterial strains will be added to nutrient agar plates, and a sterile cork borer will be used to create wells. Each well will get 100 µl of urine. Zones of inhibition will be evaluated when plates are incubated for 24 hr.At 37°C [3].

Control and Replication

For comparison, wells with sterile water and the common antibiotic cephataxim will serve as controls. Each strain's mean zone of inhibition will be determined by conducting the experiments in triplicate [3].

Statistical Analysis

The data will be statistically analyzed using one-way ANOVA to determine the significance of the antibacterial effects of the urine on each bacterial strain. Performing one way ANOVA[7]in conjunction with Tukey's Honestly Significant Difference (HSD) test[1]to identify which specific group means differ from each other. Typically, a significance level (a) of 0.05 is used. The Q statistic measures the difference between the means of the treatments compared

Formulate Hypotheses: p

Null Hypothesis: There is no significant différence in antibacterial activity among cow, buffalo, and goat urine for each bacterial species.

Alternative Hypothesis: There is a signifiant différence in antibacterial activity among cow, buffalo, and goat urine for at least one bacterial species.

Observation Table

Table 1: Shows the Antibacterialactivity of selected animal urine samples.
Table. 2: Anova: Single Factor
Table. 3: Scheffé multiple comparison
Table. 4: Tukey HSD results
Table. 5: Bonferroni and Holm multiple comparison

RESULTS AND DISCUSSION

We reject the null hypothesis, which indicates that the antibacterial activities of the goat, buffalo, cow, and antibiotic Cephataxim groups are not all the identical, because the one-way ANOVA's p-value (Table 2) of 0.031647 is less than 0.05. There is proof that the antibacterial activity of at least one of the groups differs significantly. The calculated F-value of 3.78444 is greater than the F critical value of 3.238872, confirming the significance of the group differences. We perform a post-hoc test to identify which specific urines are different from one another. The results of the Tukey HSD Test (Table 4) reveal that all comparisons have p-values greater than 0.05, indicating no significant difference in antibacterial activity between these pairs, with the exception of the comparison between buffalo urine and antibiotics, where the p-value is 0.0248179, which is less than 0.05, indicating a significant difference in antibacterial activity between the two. This suggests that buffalo urine and the antibiotic cephotaxim exhibit varying degrees of antibacterial activity against gram-positive and gram-negative bacteria. This study proves that animal urine works as an antibacterial agent by showing that it can fight against dangerous pathogens. According to the same research, camel and sheep urine have antibacterial qualities that help prevent common illnesses[6]. The antimicrobial properties of sheep and camel urine. A study on antimicrobial peptides in cattle urine by Zhi Li et al. in 2018 emphasises the importance of these substances. By serving as a protective mechanism against microbial diseases, these peptides may improve animals' overall health. Antibiotic residues in animal waste, including pee, may be the cause of the antibacterial activity in urine samples. It is necessary to look into the antioxidants found in the urine of various domesticated animals since they may also have antibacterial effects[5].

CONCLUSION

The results of the ANOVA and post-hoc tests can be used to form conclusions about the antibacterial qualities of the urine of cows, buffaloes, and goats as well as the antibiotic Cephataxim for the bacterial species under investigation against *P. auruginosa*. There was no discernible difference in the antibacterial activity of the urines of cows, buffaloes, goats, and the antibiotic cephataxim. The *P. auruginosa,E. coli, L. sporogens, B. cereus,* and *S. abony*. Post-hoc testing revealed that cephataxim had significantly greater antibacterial activity against *B. cereus* than buffalo urine (Tukey HSD, Scheffé, Bonferroni, and Holm) (Table 4 and Table 5)Cephataxim, an antibiotic, demonstrated consistent and effective antibacterial action against all of the tested bacterial species; nevertheless, it did not significantly outperform goat or cow urine in most situations.

ACKNOWLEDGEMENTS

The authors are grateful to the Department of Zoology, B.P. Arts, S.M.A. Science and K.K.C. Commerce College, Chalisgaon, Jalgaon, Maharastra., INDIA, for providing the necessary laboratory facilities to carry out this research work. We sincerely thank our colleagues and technical staff for their valuable assistance during the experiment.

CONFLICT OF INTEREST

The authors declare that there are no conflicts of interest regarding the publication of this paper

ABSTRACT

The emergence of multidrug-resistant (MDR) and biofilm-forming bacteria poses a significant challenge to current antimicrobial therapies. This study investigates the antibacterial potential of endophytic bacteria isolated from marine algae collected from Rameshwaram, Tamil Nadu. A total of 35 clinical isolates representing seven genera—including *Escherichia coli*, *Enterococcus faecalis*, *Pseudomonas aeruginosa*, and *Staphylococcus aureus*—were screened for β-lactamase production and biofilm formation. Simultaneously, 28 endophytic bacterial isolates were obtained from six marine algal species and evaluated for antimicrobial activity using the agar well diffusion method. Isolates 12, 19, 22, and 23 exhibited broad-spectrum activity, particularly against *P. aeruginosa*, *E. faecalis*, and *A. baumannii*. MIC analysis revealed isolate 12 to be the most potent, with values as low as 0.3125 mg/mL. 16S rRNA gene sequencing identified isolate 12 as *Bacillus cereus*, and phylogenetic analysis confirmed its close evolutionary relationship with known *B. cereus* strains. These findings suggest that endophytic bacteria from marine algae, particularly *Bacillus cereus*, represent a promising source of novel bioactive compounds capable of inhibiting MDR and biofilm-forming pathogens. Their natural origin and broad-spectrum efficacy highlight their potential for development as alternative therapeutic agents in the fight against antibiotic resistance.

Keywords: Endophytic bacteria, Marine algae, Antibacterial activity, Biofilm formation, *Bacillus cereus*, ESBL.

INTRODUCTION

The alarming rise in antibiotic resistance is a critical global public health challenge, with experts cautioning that we may be approaching a return to the pre-antibiotic era. Community- and hospital-acquired infections caused by multidrug-resistant (MDR) organisms—such as methicillin-resistant *Staphylococcus aureus* (MRSA), vancomycin-resistant *Enterococci* (VRE), vancomycin-intermediate *S. aureus* (VISA), and extended-spectrum β-lactamase (ESBL)-producing Gram-negative bacteria like *Klebsiella pneumoniae*—are increasingly common [1]. The resistance mechanisms employed by ESKAPE pathogens include enzymatic inactivation, target site modification, reduced cell permeability, overexpression of efflux pumps, and protection through biofilm formation. These mechanisms, combined with the indiscriminate and prolonged use of antimicrobial agents, contribute to the widespread emergence of resistant pathogens [2]. Microbes develop resistance through various mechanisms, one of which involves producing extended-spectrum β-lactamases (ESBLs) that break down β-lactam antibiotics. Additionally, biofilms formed by these microbes pose a major global health challenge by promoting chronic infections and resisting antibiotics, host immune responses, and environmental stressors [3]. This matrix limits antibiotic penetration and creates microenvironments where cells either grow slowly or enter a dormant "persister" state. This further reduces the effectiveness of antibiotics. In fact, bacteria found in biofilms can exhibit up to 1,000 times greater antibiotic tolerance compared to their free-floating (planktonic) counterparts [4]. Compounding the issue are the adverse side effects of synthetic antibiotics and the emergence of infections previously considered rare. Consequently, there is growing interest in identifying new antimicrobial agents that are not structurally related to existing drugs. Natural compounds, particularly those produced by endophytic microorganisms, have shown promise as alternatives. Endophytes are microorganisms (bacteria or fungi) that colonize the internal tissues of plants without causing visible disease. They produce a wide array of secondary metabolites with antimicrobial, anticancer, and other therapeutic properties [5; 6] Marine and aquatic plants, including algae and seaweeds, are increasingly recognized as rich sources of these endophytes [7]. Marine ecosystems support a vast diversity of life, including complex microbial communities associated with macro algae. These include epiphytic and endophytic microbes that participate in nutrient cycling, biofilm formation, and symbiotic interactions [8, 9]. Many marine bacteria associated with seaweeds produce antimicrobial compounds that protect the host from pathogenic microbes [10]. For example, *Ulvaohnoi*-associated bacteria have demonstrated significant antimicrobial activity against a range of human pathogens, including *E. coli*, *Vibrio spp.*, *Salmonella*, and *S. aureus*, as well as the yeast *Candida albicans* [11]. In the current scenario where the effectiveness of existing antibiotics is declining, it has become essential to explore new biological resources, particularly endophytic microbes derived from marine environments. These organisms have the potential to produce novel bioactive compounds, making them promising candidates for the development of next-generation antimicrobial and anticancer agents [12; 13; 14; 15]. The objective of this study is to isolate such endophytes and evaluate their pharmaceutical applications, particularly their activity against biofilm formation and ESBL-producing bacterial strains.

MATERIALS AND METHODS

Collection of Clinical Isolates

To evaluate the antibacterial activity, seven bacterial isolates—*Staphylococcus aureus, Pseudomonas aeruginosa, Escherichia coli, Enterococcus faecalis, Salmonella sp*, *Acinetobacter baumannii* and *Klebsiella pneumoniae*—were collected from a clinical laboratory in Coimbatore. All isolates were confirmed using selective media and chromogenic media. At least more than one microorganism was isolated from each genus. The confirmed isolates were then used to assess the antibacterial activity of the endophytic bacterial isolates.

Assessment of Biofilm and ESBL Producing Bacterial Isolates

Biofilm formation was assessed using the Congo Red Agar method, [16] where BHIA with 5% sucrose and 0.08 g/L Congo red was prepared, plated, inoculated with bacterial isolates in duplicates/triplicates, and incubated at 37 °C for 24 h; black, dry, crystalline colonies indicated strong biofilm production. ESBL production was screened using the

phenotypic confirmatory test by placing amoxicillin (30 µg) and amoxicillin–clavulanic acid (30/10 µg) discs on Mueller-Hinton agar inoculated with test organisms, followed by incubation at 37 °C for 24 h; an increase of ≥5 mm in the inhibition zone for the combination disc confirmed ESBL production [17].

Collection of algal samples and Isolation of Endophytic Bacteria

Algal samples were collected from rocky coastal regions of Rameshwaram, Tamil Nadu, at an approximate depth of 50 m. The samples were aseptically transferred in sterilized plastic bags filled with seawater, rinsed with freshwater in the laboratory to remove salts and contaminants, and shade-dried for 48–72 h to preserve structural integrity [18]. Species identification was performed using taxonomic keys [19] and confirmed through detailed morphological analysis at the Chromopark Research Centre, Plant and Algal Section. For isolation of endophytic bacteria, surface-sterilized algal tissues were aseptically crushed in 5 mL sterile saline, and 100 µL of the extract was spread onto nutrient agar plates. Plates were incubated at 25 °C for 72 h, with daily observation for bacterial colonies, which were then sub cultured and preserved for further study.

Extraction of Bioactive Compounds from Endophytic Bacteria

The endophytic bacterial isolates were inoculated into tryptic soy broth (TSB; Merck) and incubated at 30 °C for 48 hours. After incubation, the culture supernatant was mixed with an equal volume of ethyl acetate in a separating funnel and shaken vigorously. The organic (ethyl acetate) layer was collected and allowed to evaporate under open air. The dried residue was then dissolved in DMSO and stored at 4 °C for further analysis [20].

Evaluation of Antimicrobial Activity of Bacterial Isolates

The antimicrobial potential of the bacterial isolates against clinical pathogens was assessed using the agar well diffusion method. Experiments were carried out on solid Mueller–Hinton agar (HI Media), which was sterilized, poured into sterile Petri plates, and allowed to solidify. Overnight cultures of the test pathogens were uniformly swabbed onto the agar surface. Sterile wells were then created using a borer, and 50 µL of secondary metabolite extracts from different bacterial isolates were carefully loaded into each well. The plates were incubated at 37 °C for 24 hours, and antimicrobial activity was evaluated by measuring the diameter of the clear zones of inhibition surrounding each well. Isolates exhibiting the largest inhibition zones against all tested pathogens were selected for further analysis [21].

Determination of minimum inhibitory concentration (MIC)

The minimum inhibitory concentration (MIC) of extracts from potential endophytic isolates was determined using the resazurin-based micro titer dilution method [22] Clinical bacterial isolates were cultured overnight in nutrient broth, adjusted to 0.5 McFarland (~1 × 10^6 CFU/mL), and tested in 96-well plates containing 100 µL nutrient broth, varying extract concentrations, 10 µL resazurin (0.01%), and 10 µL bacterial suspension (~5 × 10^6 CFU/mL). Positive controls lacked extracts, and negative controls lacked bacteria. Plates were incubated at 37 °C for 24 h and inspected for color change—purple to pink/colorless indicated growth, while unchanged purple indicated inhibition. The MIC was the lowest extract concentration preventing visible growth.

Identification of Potential Isolate

The potential isolate was identified by 16S rRNA gene sequencing. Genomic DNA was extracted, confirmed on a 1% agarose gel, and the 16S rRNA gene (~1500 bp) was amplified with universal primers. The purified PCR product was bidirectionally sequenced, and forward/reverse reads were assembled into a consensus sequence. BLAST analysis against the NCBI GenBank nr database identified closest matches, which were aligned with ClustalW. A phylogenetic tree and distance matrix were constructed using the Neighbor-Joining method in MEGA 11.

RESULT AND DISCUSSION

In the present study, 35 bacterial isolates representing seven different genera were obtained and identified using selective media and standard biochemical tests. The confirmed genera included *Escherichia coli, Enterococcus faecalis, Pseudomonas aeruginosa, Staphylococcus aureus, Klebsiellan pneumoniae, Salmonella spp*., and *Acinetobacter spp*. All isolates were confirmed with selective media and chromogenic media, according to the morphological characterization, isolates were confirmed. Both selective and chromogenic media; enabled clear, efficient isolation and presumptive identification of clinically relevant bacteria, while biochemical confirmation ensured reliability. This dual strategy optimized workflow and diagnostic precision. The β-lactamase production phenomenon plays a critical role in mediating resistance to β-lactam antibiotics, including penicillins and cephalosporins. These enzymes hydrolyze the β-lactam ring, rendering the antibiotic ineffective and compromising therapeutic outcomes. In the present study, all bacterial isolates were screened using a phenotypic method for β-lactamase activity, except *S.aureus*. Out of these, 9 isolates (30%) were identified as ESBL producers. Among the species tested, *Enterococcus faecalis* showed the highest prevalence, with 40% of isolates from this genus testing positive. This trend suggests that resistance mechanisms are becoming increasingly common not just among Gram-negative bacteria but also in clinically important Gram-positive pathogens. These findings align with previous reports in India, 92.2% ESBL positivity among urinary *E. coli* isolates in a tertiary care hospital in Vellore, much higher than the 20% observed in our study, likely due to differences in isolate origin, sample size, or detection methods [23]. A similar study from northeastern India highlighted widespread ESBL and carbapenemase-producing *Entero bacteriaceae* detected via phenotypic assays and mPCR. ESBL-producing *E. coli* and *K. pneumoniae*, major agents of CA-UTIs, are increasingly reported worldwide, often showing co-resistance to non-β-lactam antibiotics. Additionally, the recent rise in multidrug-resistant (MDR) uropathogenic *E. coli* (UPEC) with ESBL producing isolates in the community has created significant challenges for clinicians in selecting appropriate empirical therapy [24]. Among the various virulence factors, biofilm-forming infections are challenging to treat due to reduced drug penetration and increased resistance. *Staphylococcus aureus* and other pathogens are well-known biofilm producers, contributing significantly to treatment failure. According to the U.S. National Institutes of Health, over 60% of deaths from such infections are associated with drug resistance [25]. In the present study, 17 out of 35 isolates (48.5%) were identified as biofilm producers. *Enterococcus faecalis* showed the highest rate (80%), which is consistent with the findings of Upadhyaya *et al*. [26] and Nair *et al*. [27]. Another report has also documented biofilm production in 65% of *Salmonella* spp isolates [28, 29]. Other species such as *E. coli*, *P. aeruginosa*, *S. aureus*, and *K. pneumoniae* showed 40% biofilm positivity. Triveni *et al*. [30] reported 38.29% biofilm production in *S. aureus*, while Saxena *et al*. [31] observed 64.7% in *P. aeruginosa*. In the Western Ghats, *K. pneumoniae* exhibited 51% moderate and 27% strong biofilm production. Biofilm formation and β-lactamase production are key resistance mechanisms, enabling bacteria to evade antibiotics and immune responses while degrading β-lactam drugs [32]. This highlights the urgent need for new antibiotics targeting biofilm-forming, drug-resistant isolates. In this context, the present study explores the antibacterial potential of endophytic bacteria from algae. A total of six algal genera belonging to three families were collected: green algae (*Halimeda gracilipes* and *Chaetomorpha linum*), red algae (*Gracilaria edulis* and *Kappaphycus alvarezii*), and brown algae (*Padina pavonica* and *Sargassum polycystum*) (Figure.1). Identification of the collected algae was confirmed using the taxonomic keys described by Jha *et al* [19]. The following parameters were utilized for their characterization: thallus structure, color, branching pattern, holdfast type, habitat, and special features. From these six algal samples, a total of 28 bacterial isolates were obtained. All endophytic isolates were screened for antibacterial activity against ESBL-producing and biofilm-forming clinical isolates. The antimicrobial activity of 28 endophytic isolates, along with two controls (C1 and C2), was tested against seven clinically relevant pathogens using the agar well diffusion method. Among these pathogens, *P. aeruginosa*, *E. faecalis*, and *A. baumannii* were the most susceptible to the endophytic extracts. Notably, *P. aeruginosa* was inhibited by 24 of the 28 isolates, with inhibition zones ranging from 11 mm to 16 mm. *E. faecalis* was suppressed by 17 isolates, with isolate 27 showing the strongest activity (18 mm). Likewise, *A. baumannii* showed considerable sensitivity; especially Isolate 7 was the most effective against *A. baumannii*, with a 16 mm inhibition zone. These three pathogens were the most responsive, suggesting their higher vulnerability to bioactive metabolites from endophytes. *E. coli* was inhibited by 12 isolates, with zones ranging between 11 and 13 mm. Isolates of 16, 20, 23,

and 24 were showed moderate effectiveness. *K. pneumoniae* displayed minimal susceptibility, only isolates 19 and 20 showing inhibition (12–13 mm). *S. aureus* was more resistant, with inhibited only with 22 and 23, while controls (C2: 10 mm) showed minimal activity. Similarly, *Salmonella spp.* showed limited inhibition by isolates 6 and 12 (11 mm), and C2 (10 mm). Among all, isolates 12, 19, 22 and 23 stood out for their broad-spectrum activity, showing significant zones of inhibition against 5 pathogens (Table.1). These isolates may hold strong potential as sources of novel antimicrobial agents, especially against multidrug-resistant bacteria. These findings align well with published studies showing endophytic microbes isolated from marine algae or medicinal plants as prolific producers of secondary metabolites with broad-spectrum antibacterial activity. For example, isolate the *Acinetobacter indicus* from marine Sargassum sp and *Turbinaria ornate,* which showed strong active against to *S. epidermidis* and *S.aureus* [33]. Another study, actinomycetes from marine algal sources in India showed strong inhibition of MDR Gram-negative uropathogens, including *P. aeruginosa* and *E. coli* via agar well diffusion assays [34]. Similarly, a systematic screening of endophytic actinobacteria from medicinal plants revealed that approximately 30–40% of isolates exhibited bioactivity against pathogens like *E. faecalis*, *S. aureus*, and *P. aeruginosa* [35, 36]. The Minimum Inhibitory Concentration (MIC) results of the four endophytic bacterial isolates—Isolate 12, Isolate 19, Isolate 22, and Isolate 23—against seven pathogenic bacteria revealed varying degrees of antimicrobial efficacy (Table.2). Isolate 12 showed effective inhibitions against *E. coli*, *E. faecalis*, *P. aeruginosa*, *Salmonella sp.*, and *A. baumannii*, with MIC values ranging from 0.3125 to 1.25 mg/mL, but exhibited no activity against *K. pneumoniae* and *S. aureus*. Isolate 19 displayed the broadest spectrum of inhibition, including activity against *K. pneumoniae* and *A. baumannii*, although its MIC values were generally higher (1.25–2.5 mg/mL), indicating moderate potency. Isolate 22 was particularly effective against *E. faecalis*, *P. aeruginosa*, and *S. aureus* (MIC = 1.25 mg/mL or lower) but showed no inhibition against *K. pneumoniae* and *Salmonella sp*., and required higher concentrations (2.5 mg/mL) to inhibit *E. coli* and *A. baumannii*. In contrast, Isolate 23 demonstrated limited antimicrobial activity, with MIC values of 2.5 mg/mL against most susceptible pathogens and no activity against *K. pneumoniae* and *Salmonella sp.* Overall, Isolate 12 showed the highest potency (lowest MIC), while Isolate 19 had the broadest range of antibacterial action.

1-28: Extract of endophytic isolates (2.5mg), C1: DMSO control, C2: Ciprofloxcin -5mcg

Similarly, Makuwa *et al*. [37] and Maela *et al*. [38] determined the antimicrobial activity and MIC values of endophytic bacteria using a resazurin-based microdilution assay. This method has been extensively validated for assessing antimicrobial activity against both Gram-positive and Gram-negative bacteria [22]. The microtiter plate-based resazurin assay is simple, rapid, sensitive, and reproducible for evaluating the antimicrobial potential of secondary metabolites. Building on this, Elshikh *et al*. [39] optimized a 96-well microdilution protocol using resazurin and confirmed its reliability through consistent MIC values for standard antibiotics such as tetracycline and gentamicin. The potential isolate was identified by 16S rRNA sequencing, producing a consensus sequence with 99.93% identity to *Bacillus cereus* strain BCd16 (Accession No. KP717563.1). Other close matches showed ≥99.11% similarity. Phylogenetic analysis using the maximum likelihood method (Tamura-Nei model) confirmed its clustering within the *B. cereus* clade, with minimal evolutionary divergence (pairwise distance 0.000–0.002) (Figure 2). Thus, Isolate 12 was identified as *Bacillus cereus*, supporting its role in antibacterial and MIC studies. A similar finding was reported by previous study, they were demonstrated the antimicrobial activity of an endophytic *Bacillus cereus* isolate against *E.coli*, *P.aeruginosa*, *S.aureus*, *S.typhi*, and *K.pneumonia* [40]. In another study observed that endophytic isolates of *Bacillus* sp. also exhibited antifungal activity [41]. In the present study, no clear dominance was observed in the inhibition of either Gram-positive or Gram-negative bacteria. This result contrasts with the findings of previous study, which was reported that endophytic isolates exhibited stronger inhibitory activity against Gram-positive bacteria compared to Gram-negative bacteria [42]. The antibacterial activity exhibited by the crude extracts of endophytic bacterial isolates in this study highlights their potential to suppress pathogenic bacteria, supporting their possible application in the development of novel antimicrobial agents. In conclusion, this study highlights the significant antimicrobial potential of marine algal endophytic bacterial isolates, particularly *Bacillus cereus*. These isolates exhibited broad-spectrum activity against both Gram-positive and Gram-negative pathogens, including biofilm-forming and β-lactamase-producing strains, underscoring their promise as alternative therapeutic agents. The ability of these endophytes to inhibit biofilm formation and overcome β-lactamase resistance further supports their clinical relevance. Importantly, compounds derived from marine algal endophytes present a natural, safer, and

potentially less toxic alternative to conventional antibiotics. These findings emphasize the value of marine algal endophytes as sustainable and effective sources of novel antimicrobial agents in the ongoing fight against antibiotic-resistant infections.

ABSTRACT

An economic analysis of utilization of milk production and milk products in Tirupattur district of Tamil Nadu's was the main emphasis of this study. 300 respondents were surveyed utilizing an interview schedule in January 2023 in order to get the primary data. Of the sample as a whole, 60 per cent of respondents were male and 40 per cent of respondents were female. According to the study, younger members of the village are more involved in diary production and animal husbandry than older residents, and those with high and middle level education are more involved in these fields. In animal husbandry, one third of the respondents made more than Rs. 40,000 per month. The respondents did not experience any losses in their fair revenue from either milk production or animal husbandry. Approximately 96 per cent of those surveyed said they always use the money they make from milk production and animal husbandry to generate assets. A significant portion of the rural population relies on milk production as their primary source of income and subsistence. Everyone now has a bank account for their savings from milk production and animal husbandry thanks to the Jan Dhan Yojana.

Keywords: Economic analysis, milk production, milk products, animal husbandry, income, Tirupattur.

INTRODUCTION

In India there is a deep relationship between the sectors of agriculture and dairy industry. Dependence between both sectors is very high. Over 50 per cent of the Indian population is depending on the agricultural sector compared to dairy sector. In recent years, the dairy industry has taken over the agricultural sector and its contribution is more.

The dependency level on milk in India is very high when we compare to the other countries of the world. Indians consume milk in their day to day life in the form of pure milk or through the byproducts of milk since they consider milk as their traditional beverage from their ancient period. Many ancient literatures in India exhibit the uses of milk and the consumption level of milk during the ancient periods. The production of milk in the world has increased by 59 per cent from 530 million tonnes to 843 million tonnes in the year 2018. Approximately about 150 million people in the world are involved in the milk production. India is the world's largest milk producer which contributes about 22 per cent of the total milk production followed by United States, China, Pakistan and Brazil. Indian government is initiating many measures and schemes for the production of milk and animal husbandry since they are the main sources of income to rural people. Our Indian government has announced many schemes like Kamdhenu Yojana, Rashtriya Gokul Mission, Gokul Gram which help the farmers to get easy access into the dairy industry. The government of India provides loans for cattle through NABARD and subsidies through local banks. Globally export of diary production was about 54,800 million tonnes and 240 million USD by the financial year 2020-2021. In India, Rajasthan and Andhra Pradesh contributes more for milk production compared to other states. The cattle not only help in the dairy industry but also in the agricultural sectors for ploughing the agricultural fields. India is not only exporting milk, but also exports milk byproducts like ghee, butter, ice cream etc. In Tamil Nadu, cow and buffalo milk make up the majority of the milk produced. The size of the Tamil Nadu dairy market is expected to reach INR 1,058 billion in 2022, according to a recent estimate. The dairy market in Tamil Nadu would expand by 15.5% between 2023 and 2028 to reach INR 2,473 billion. So, considering the above points in view, this study focused on the economic analysis on utilization of milk production and animal husbandry in Tirupattur district of Tamil Nadu. This study was aimed with the following objectives. To probe into the socio-economic background of the population involved in milk production and milk products in Tirupattur district. To determine the distribution of animals across the sample households in the study area. To determine the utilization pattern of milk and milk products across various consumers in the study area. In view of this Kumar and Singh (2008) have stated in their study that animal husbandry and diary plays a vital role in the economic development of a country. India stands first in the milk production when compared to the other countries.

During the year 2007-08, the milk production of India is about 100.90 million tones. Many welfare schemes were implemented to initiate the production of milk throughout the country. Pramoud and Rajasekar (2011) has highlighted the various uncertainty and risks faced in the diary industry in the perspective of various stages of supply chains, the supply chain between the milk producer, the processor and the end-consumer are facing many difficulties in the supply chain. Deepthi Gour (2013) had made an attempt to analyze the development of dairy cooperative in India and how they help in the development of diary. The cooperatives play a commendable role in the upliftment of the rural people through the diary industry. The available opportunities for the dairy farming in the rural areas are plenty when compared to the urban areas. Muraliappa Reddy (2013) has founded that the development of dairy industry is in the three tire structure. The primary is at the milk producing society in the rural villages, the secondary level is at the cooperative milk collection sector from the rural areas and the tertiary level is at the processing of the milk and converting the milk into the finished products to reach the product to the people in the urban areas. However, the ability of such sectors can be influenced by the quality of the products. Doe *et al.* (2012) have concluded in their study that the cooperative society created market for the raw milk and also provided opportunities for the employment in rural areas which has increased the revenue level of the people from the village areas. Manvir Kaur (2011) has concluded that the milk cooperative unions at the district level maintained the distribution of milk within the district. The milk unions even process the milk or send the milk to other districts where the need for the milk is available through the variable milk processing milk plants. The unions are formed at the primary level at the village to collect the milk in an efficient manner. Meena and Jain (2012) have studied about the economics of milk production in Rajasthan and suggested that the adequate amount of schemes should be introduced for the cow upgradation programmes. They indicated a positive impact on the diary cooperative in the several parts of the rural area of production, consumption and market surplus of milk.

METHODOLOGY

Data Collection: The present study is based on primary data. The primary data collected from milk producers and agricultural labourers in Tamil Nadu. Partially the study was based on secondary data. The Tamil Nadu state has been separated in its seven agro-climatic zones. Tamil Nadu is a eleventh largest state in India by area. The Tirupattur district comes under North Eastern Districts of Tamil Nadu. It is a new born district from Vellore district. It consists of two revenue divisions, Tirupattur and Vaniyambadi, four taluks i.e., Tirupattur, Natrampalli, Vaniyambadi and Ambur is industrial denced area when compare to Tirupattur and Natrampalli. Multi-stage random sampling procedure was employed under district, taluks and villages. Five villages namely, Achamangalam, Karuppanur, Bommikuppam, and Annandapatti and Thiniyalam were selected in Tirupattur block randomly on the basis of agriculture and animal husbandry. To collect the primary data, the researcher selected Atchamangalam, Karuppanur, Bommikuppan, Annadapatti and Thiniyalam villages were selected in Tirupattur District of Tamil Nadu. These five villages come under the Gram Panchayats with the population of more than 4925 people consisting of 1,308 males and 3,617 females. These villages are surrounded by hills and hill base with green cultivation of millets and necessary agricultural cultivation surrounded by small temples on the base of the hills. A water falls also famous near to these villages named as Jalagamparai with full of herbal water and breezes in these hilly villages are the small identifications in these study areas. Due to its geographical location, these villages receive plenty of water during the rainy seasons and due to dam and lakes. Owing to the over availability of natural resources in these villages, animal husbandry and dairy farming are the major source of income to these village people. The researcher used the descriptive and analytical design. The primary data were collected from 300 respondents using interview schedule during month of January 2024. Research design employed here is descriptive analysis since this design describes the characteristics of individuals with behavior and their individual attitudes which would allow the researchers to complete the research without any errors. This study employed a multi-stage random sampling and 300 respondents were selected who are involved in the animal husbandry and diary production. To collect primary data a well-structured interview scheduled was framed to fulfill the objectives of the study. The secondary data were collected through newspapers, journals, books and web resources.

Analytical Framework: The production and utilization of milk and milk products were calculated using simple averages and percentage method for each category of every sampled unit. This study projected the utilization pattern of milk, milk products, animal husbandry and distribution of animals across the sample households.

Tabular Analysis: Tabular analysis was applied to the data in order to examine the production and utilisation patterns of the sample respondents. According to daily milk consumption, the amount of milk kept at home for liquid consumption or for processing into milk products was calculated. Milk and milk product consumption per capita was taken into account.

$$\text{Per capita per day milk consumption} = \frac{\text{Quantity of milk reserved at home}}{\text{Size of the family}}$$

Distribution and Utilization Pattern of Consumers: Using sample averages and percentages, the producers' overall milk production, distribution, and consumption patterns were calculated. Using sample averages and percentages, the producers' overall milk production, distribution, and consumption patterns were calculated.

RESULTS AND DISCUSSION

Production and Utilization Details of Milk and Milk Products among the Respondents Households

The socio-economic details of the sample respondents represented in Table 1. The primary data were collected from the 300 sample respondents from all the villages. Most of the respondents (60 per cent) comes under the age group of 30-40 especially in Karuppanur village followed by (55 per cent) under the age group of 40-50 in Achamangalam village. Regarding the gender details nearly 73.33 per cent of the respondents are males especially in Bommikuppam

village. Because the village is getting sufficient water resource from herbal water falls named as 'Ezhuaruvi.' This may be a reason for maximum involvement in animal husbandry and milk production. Regarding the community details of the respondents most of the respondents (75 per cent) comes under the category of Most Backward Class (MBC) in Achamangalam village. Basically the district is dominated by SC population. Regarding the educational qualification majority of the respondents were studied up to high level (66.67 per cent) in Karuppanur village. When compare the educational qualification the maximum of 66.67 per cent of the respondents were studied up to high level of education in Karuppanur. In Achamangalam, nearly 46.67 per cent of the respondents were studied up to middle level of education. Only 3 to 5 per cent of the respondents were post graduates in Karuppanur and Achamangalam. In Thiniyalam village nearly 53.34 per cent of the respondents were comes under the age group of 30-40. In the same village 73.34 per cent of the female respondents involved in animal husbandry based actives. When we look at the data people did not concentrate much on education. The data on milk production and profit levels represented in Table 2, Fig. 1 and 2. From the five villages, Aachamangalam, Karupanur, Bommikuppam, Aanandapatti, and Thiniyalam show a significant variation in output and earnings through animal husbandry. In terms of milk production, Karupanur leads with the highest daily production of 55 litres, followed closely by Aachamangalam and Bommikuppam with 50 litres each. Aanandapatti and Thiniyalam lag behind with 30 and 35 litres respectively. The average milk production across all villages stands at 19.4 litres per day, indicating a modest overall output. When considering monthly profits from animal husbandry, Aachamangalam shows the highest profitability, with farmers earning up to ₹40,000 per month, while Karupanur and Aanandapatti reach up to ₹20,000. The other villages, Bommikuppam and Thiniyalam, earn lower maximum profits, at ₹15,000 and ₹12,000 respectively. The average monthly profit across all villages is ₹3,420, showing that while some individuals achieve high incomes, the majority earn modest amounts. The lowest reported monthly profits range between ₹500 to ₹1,000, highlighting the economic vulnerability for many farmers depending solely on animal husbandry. Regarding milk usage for domestic purposes, about 52.33 per cent of households across the five villages use a portion of the milk they produce for their own consumption. Aachamangalam shows the highest domestic usage rate at 66.67 per cent, whereas in Karupanur and Aanandapatti, a majority of the milk is not used domestically but likely sold for income. The average domestic consumption of milk across villages varies widely; Thiniyalam stands out with the highest average consumption at 38 to 40 litres, while in other villages like Aachamangalam and Karupanur, average domestic use is significantly lower, around 3.5 to 5 litres. When it comes to the distribution of milk, local people are the major consumers, accounting for 48.67 per cent of total milk distribution.

Notably, Aanandapatti shows the highest share of local distribution at 66.67%, while Karupanur and Thiniyalam rely heavily on co-operative societies, each with 56.67 per cent of their milk distributed through this channel. Some villages like Bommikuppam also engage private milk collection centers and tea shops to a small extent, but overall, private centers and tea shops play a relatively minor role, with only 6.67 per cent and 3 per cent distribution respectively. While milk production and profit levels are encouraging in villages like Aachamangalam and Karupanur, there is considerable variability among the villages in terms of domestic milk consumption patterns and marketing strategies. The reliance on local consumers and co-operative societies remains crucial for the livelihoods of these farmers, with private collection centers and tea shops serving as supplementary outlets. The data regarding involvement in animal husbandry and awareness on government schemes represented in Table 3. Across the villages namely, Aachamangalam, Karupanur, Bommikuppam, Aanandapatti, and Thiniyalam highlights significant disparities. In terms of receiving animals from government schemes, Aachamangalam (38.33 per cent) and Karupanur (35 per cent) report the highest access, showing that more than one-third of the respondents in these villages benefited from government-provided livestock. Aanandapatti has a much lower level of support, with only 15 per cent of the farmers receiving animals. On the other hand, both Bommikuppam and Thiniyalam recorded no beneficiaries (0 per cent), indicating a complete lack of government assistance in livestock distribution in these villages. When it comes to awareness about government schemes, Aachamangalam once again leads, with 41.67 per cent of respondents aware of available programs, followed by Aanandapatti at 38.33 per cent. Awareness levels drop sharply in Karupanur (10 per cent) and Thiniyalam (1.67 per cent), while Bommikuppam shows no awareness at all (0 per cent). The high lack of awareness in Bommikuppam and Thiniyalam correlates with the fact that no respondents from these villages received any animals from the government. Overall, the data reveals that the success

of government schemes in promoting animal husbandry depends heavily on both availability and awareness. Villages like Aachamangalam and Aanandapatti have moderately benefited, while villages like Bommikuppam and Thiniyalam remain marginalized, highlighting a pressing need for better outreach, communication, and program implementation in these areas. The Table 4 presented the data on the improved standard of living through animal husbandry across five villages namely Aachamangalam, Karupanur, Bommikuppam, Aanantappatti and Thiniyalam. Among them, Bommikuppam shows the most significant impact in terms of high earnings, with 51.67 per cent of respondents reported income improvement due to animal husbandry. In contrast, villages like Karupanur and Thiniyalam reported very low earnings improvement, indicating that animal husbandry has not been a major income source there. In terms of housing development, Aachamangalam leads with 63.33 per cent of households constructing their own homes, suggesting that animal husbandry income has contributed to improved living conditions. Other villages like Karupanur and Thiniyalam also show some improvements, though at a much lower scale. When it comes to educational benefits for children, Thiniyalam stands out, with 28.33 per cent of respondents acknowledging improved access to education through income from animal husbandry. In contrast, Karupanur shows no impact in this area. The data on savings indicates that Thiniyalam again performs better than other villages, with 23.33 per cent of respondents managing to save, whereas Bommikuppam reported no savings at all. Reduction in borrowings is relatively low across all villages, but Karupanur and Aanantappatti have slightly better outcomes. In terms of loan repayment, Karupanur emerges as the most successful, with 61.67 per cent of respondents using their earnings to repay agricultural loans, followed by Aanantappatti with 33.33 per cent. Thiniyalam reported no loan repayment at all, possibly due to lack of loans or the inability to repay. Participation in awareness programs like meetings on animal husbandry also varies significantly. Thiniyalam has the highest attendance (53.33 per cent), which may explain its relatively better performance in areas like education and savings. Karupanur has a moderate level of participation (30 per cent), while Bommikuppam and Aanantappatti recorded no participation, which could be a factor behind their weaker performance in some key areas. Overall, while some villages like Thiniyalam and Karupanur show progress in particular areas, the benefits of animal husbandry as a tool for improving living standards are unevenly distributed across these five villages.

CONCLUSION

The majority of the people from the rural area are involved in animal husbandry and milk production which acts as the major source of income for their livelihood. After the pandemic period, more people are getting involved in animal husbandry and milk production because these sectors always have their peak level and demand even in the pandemic condition. Due to the reasonable price in the cooperative societies and local distribution, most of the respondents prefer cooperative societies and local distribution for their distribution of milk. Both animal husbandry and milk production always provide a reasonable income without making any loss for the respondents. Majority of the respondents received highest profit which they have earned from the animal husbandry and milk production. Milk production acts as the main source of income and also livelihood for many people from the rural areas. Due to the implementation of Jan Dhan Yojana, everyone has their own bank account for their savings earned by milk production and animal husbandry. Many new schemes should be introduced by the government for the proper collection of milk from the producers and make a proper way to reach the consumers. A common price should be fixed to the milk by the government since their prices are varying from one milk collection centre to other. Subsidies should be given to the entrepreneur for starting animal husbandry and milk production centres which would allow the government to generate more revenue. A concentrated effort is being made to promote dairying in high-potential locations in order to enhance milk output. Unfortunately, post-production handling of excess milk is not being addressed in parallel. The amount of milk consumed has decreased recently. The most significant contributing elements appear to be rising costs and a declining level of living. We must deal with this issue as soon as feasible. Strategies for milk processing and marketing must be created, and small-scale farmers must be encouraged to establish producer-processor cooperatives at the local level. Milk must be collected and processed in a strategic location due to its weight and high perishability. Cost-effective strategies must be used to maintain dairy product costs at levels that the majority of consumers can afford. Promotion and advertising will play a crucial role.

ACKNOWLEDGEMENTS

ABSTRACT

Present study is done to determine the depth scaling factor using slab phantom made up of PMMA. Our goal is to determine the conversion factor which is to be used for measuring absolute dose in water. The use of scaling factor helps in reducing uncertainty of absorbed done in water for high energy photon beams. So, it's become highly imperative and necessary to determine depth of scaling factor before starting your absolute dose measurements. We have used 0.6cc PTW Farmer type ion chamber with PTW electrometer to measure the charge collected in nano Coulomb. Linear Accelerator or simply Linac producing high energy FFF beams mainly interacts with a medium by the Compton Scattering. That is why the scaling factor becomes most important parameter to be determined otherwise, it may cause uncertainty in dose measurement. As we know that every material has its own attenuation capabilities based on its density thickness (g/cm^2). The Compton mass attenuation coefficient is independent of Atomic Number *(Z)* and depends only on the number of electrons per gram. Although the number of electrons per gram of elements decreases slowly but systemically with atomic number, most materials except hydrogen can be considered as having approximately the same number of electrons per gram which is around $3x10^{23}$.For determining this scaling factor, we first measured the absorbed dose (cGy) in water phantom at the depth of 10cm with SSD of 100cm for 10x10 cm field size. Then the same measurement was done using slab phantom keeping the same depth, SSD and field size. From the ratios of charge collected by ionization chamber reading in water phantom to solid phantom the scaling factor were determined. Using this factor now we can measure absolute dose in water using a solid phantom with more accurately.

INTRODUCTION

Radiotherapy means use of radiation mainly X-rays of a very short wavelength and high energy. These high energy X-rays interacts with water present in our human body and damages the cell's DNA through physical, chemical and biological processes [1], [2], [3]. Radiation kills both cancerous and healthy cells, therefore precise dose control during radiation therapy is necessary to eliminate as many cancer cells while preserving as many healthy cells as possible. Radiotherapy's high energy photons, in particular, create a build-up region where the dose is minimal at the surface and rapidly grows from there to the maximal depth[4]. Additionally, even with slight variations in depth, the distribution of the absorbed dosage in the photon beam's build-up area exhibits highly rapid changes that are dependent on the energy and degree of irradiation. As a result, it is quite challenging to assess the absorbed dose distribution precisely. Precisely measuring the dosage of the treatment source of origin and evaluating the error are critical for the management of high energy radiation. The most human-like benchmark phantom currently in use for quality control of the absorbed dose management of the X-rays in the linear accelerator is the water phantom [5], [6]. However, because of the intricate implementation process, the test with the water phantom takes a long time to complete. This results in errors in the measurement depth because waves are formed from the water phantom's surface as a result of the ionization chamber's measurement position moving and the stability of water temperature. In the international code of practice published by International Atomic Energy Agency (IAEA) report TRS 398, water is the reference material for dosimetry of photon beams. As we know that many radiotherapy centers across the world using various types of phantoms of different materials to do their relative dosimetry measurements. Some of these materials which are most commonly used are like polystyrene, PMMA, Solid water, Virtual water, Plastic water phantom etc. Ideal condition all the phantom material should be water equivalence[7].

Various studies had been conducted to measure the water equivalency using scattered and absorbed properties as water for selected range of photon energy. For the treatment of cancer patient's high energyX-ray beams are used so as to give required dose to the target volume for this purpose mostly high energy X-ray beams are used. These high energy X-rays are produced by Linear Accelerator or simply called as Linacs. A Linac can produce X-rays beams of variable energies such as 4MV,6MV,10MV etc. depending upon the user's requirement or model provided by your manufacturer. For X-ray beams in the megavoltage range, where Compton effect is a predominant mode of interaction, the attenuation of the beam in any medium is governed by electron density (number of electrons per cm^3). Compton interaction involves essentially free electrons in the absorbing material, it is independent of atomic number Z. It follows that the Compton mass attenuation coefficient (σ_c/r) is independent of Z and depends only on the number of electrons per gram. Although the number of electrons per gram of elements decreases slowly but systemically with atomic number, most materials except hydrogen can be considered as having approximately the same number of electrons per gram as shown in the Table 1. Thus, σ_c/r is nearly the same for all materials[8][9]. The depth scaling factor is also known as fluence scaling factor in the IAEA TRS-398.This factor can be determined experimentally as a ratio of ionization chamber reading in water at a reference depth to reading in a solid phantom at an equivalent depth. The scaling theorem was used to determine the equivalent depth[10].In their report, depth can be scaled using a constant ratio of electron densities of two media. The scaling theorem assumes that photons interact with a medium only by the Compton scatter even if the pair-production accounts for 20% of total interaction for 10 MV photon in water. Therefore, all phenomena of interactions with a medium should be considered for the depth scaling for megavoltage photon beams[11], [12]. The study's goal was to compare the radiological doses of the solid and water phantoms based on depth and compute the depth scaling factor in order to evaluate the solid phantom's clinical use, which might offset the drawbacks of the water phantom.

MATERIALS AND METHODS

In the present study, 6 MV Flattening Filter Free (FFF) Halcyon linear accelerator manufactured by Varian Medical Systems is used for photon beam delivery. Firstly, the absolute dose in centi-Gray (cGy) measurement was carried out using 30x30x30 cm water phantom at the depth of 10cm with Source to Surface Distance (SSD) of 100cm for 10x10

cm field size as shown in Figure1(a) and its pictorial representation is shown in Figure2. A total volume of 0.6cc ion chamber calibrated with electrometer (PTW, Freiburg, Germany) were used to measure the charge collection in nano-Coulomb (nC). Measurement was done in the water medium as human body contain 80% of water and it is a standard protocol worldwide. Automatic-device or beam scanning system exists for rapid measurement of the beam profiler. Electrometers used with a water scanning system have degree of fidelity with a device dynamic range. They can measure charges in the range 10^{9}-10^{14}C.Electrometer should be rest to null or zero before scanning. Data acquisition process of sampling signals used during measurement of dosimetry. Water has an electron density 3.34 x 10^{23} per gram. After measuring the absolute dose, the same measurement was done using slab phantom keeping the same depth, SSD and field size. From the ratios of ionization chamber reading in water phantom to solid phantom the scaling factor were determined. Secondly, a solid phantom made of Polymethyl Methacrylate (PMMA) has been used as water equivalence, which has electron density3.248×10^{23}per gram. Different slabs of various thicknesses 1cm, 0.5cm, 0.3cm and 0.2 cm and area of 30x30 cm were used for dose output measurement. Same ion chamber and electrometer were used were for as shown in Figure1 (b), also the thickness of 10cm slab phantom was maintained at the bottom to reduce the effect of the backward scattering. Before ion charge collection in the process 10 minutes of warm up has been give up to reduce the uncertainty in background charge collection. Furthermore, the solid phantom was kept in the treatment room for almost two weeks in order to reduce the effect of temperature fluctuations on the results and minimize temperature variations during the measurement. To keep the water and treatment room thermally balanced when employing the water phantom, the water temperature was maintained within 0.1 degrees Celsius of the treatment room's temperature. In each instance, the depth was determined by measuring the distance between the ionization chamber's center and the ray source in each phantom. The experiment was conducted with an irradiation dosage of 200 MU and a dose rate of 800 Monitoring Units (MUs)/min. Various types of material have different values of mass densities, atomic number (Z) and electron density as shown in Table 1.A comparison of solid phantom with physical densities (ρ), electron densities (ρe), relative electron densities $(\rho e)_{pl,w}$ and effective atomic number (*Z*eff) have been shown in Table 2. For Intensity Modulated Radio-therapy (IMRT) beams, photon energy spectra are varied by transmitting through a multi-leaf collimator (MLC) and scattered photons in a medium. But, these effects on the depth scaling and the fluence scaling due to different density phantom have spectral variation on the depth scaling.

RESULT AND DISCUSSION

The depth scaling factor was determined from photon energy spectra for 10 × 10 cm open field. From the result for field size 10×10 cm and 100cm SSD at 10cm depth, ionizing charge at 10cm and Absorbed Dose rate at depth of dose maximum (D_{max}) for water phantom and slab phantoms were found to be 22.27nC, 21.99nC and 100.53cGy/100MU 98.86cGy/100MU respectively as shown in Figure 3. Ratio of ionization charge or scaling factor observed value was 1.013. Therefore, the percentage error of absorbed dose between water phantom and solid slab phantoms at 10cm depth was found to be around 1.63% as shown in Figure 5. This was a statistically significant difference, since electron density variation is more than unity in PMMA than water, so as the density increases, effect of attenuation increases, which reduces ion charge collection by ion chamber. By applying scaling factor correction, it was obtained that the ionization produced by 10 cm of water will be equivalent to that produced by 9.80 cm of PMMA solid phantom. Thus, by doing measurement for ionizing charge at 9.80 cm and Absorbed Dose rate at D_{max} for slab phantoms were found to be 22.42nC and 100.15cGy/100MU respectively as shown in Figure 4. As a result, the percentage error of absorbed dose between water phantom and solid slab phantoms was found to be around 0.34% as shown in Figure 5, which was not a statistically significant difference and clinically acceptable.

CONCLUSION

Our study showed that it is very necessary for users to first calculate the depth scaling factor accurately before using solid phantom for output measurement of Linac to avoid uncertainty in absolute dosimetry. Moreover, Solid

phantom dosimetry reduces the setup time compared to water phantom as well as convenient for user. In the future this study will be helpful for finding out the different material depth scaling factor for water equivalency.

ACKNOWLEDGEMENT

Authors are thankful to Raj Scanning Ltd. Lucknow for providing facility of Halcyon Varian Linac for carry out the experimental observation.

ABSTRACT

Despite significant advances in diagnostic technologies and targeted therapies, cancer remains a formidable global health challenge due to its complex biology and adaptive resistance mechanisms. Heterocyclic complexes are contemporary in almost 90% of novel medications, and they cross the chemistry-biology boundary where a prodigious deal of innovative systematic understanding, research, and application is occurring. One of the significant regularities in the medicinal chemistry is fused heterocyclic complexes, due to their broad-spectrum therapeutic functions. Amongst these, nitrogens-containing derivatives, like pyrazoline, isoxazoline, quinazoline and pyrimidine derivative are essential due to their multiple therapeutic applications including anticancer, anti-microbial, anti-alzheimier, anti-viral, anti-inflammatory, antimalarial and antitubercular properties. Additionally, to being effective against a wide range of newly emerging infectious diseases, heterocyclic compounds with pyrazoline moiety may also result in the development of potent derivatives, which are necessary for cancer treatment. 2-Pyrazolines are commonly investigated and more stable than 1- or 3-isomers of pyrazoline analogues. These derivatives can be synthesized via both conventional and greener techniques, including refluxing, microwave assisted synthesis, ultrasonic sonication mediated and oil bath mediated synthesis. This review focusses on the biological significance and anticancer applications of the pyrazoline derivatives. As a result, this review will be helpful in the future when designing new medications to treat cancer and its biological effects.

Keywords: Pyrazoline, 2-Pyrazoline, Heterocyclic chemistry, Anticancer, Breast cancer, Biological applications

INTRODUCTION

Cancer is the one amongst main diseases that cause mortality and morbidity all over, which poses a severe danger to people's ability to live healthily. Every year, almost 10 million people are diagnosed with various forms of cancer. They have a high level of molecular heterogeneity, which results in medication resistance to make the treatment challenging still [1]. Clinical markers can used to determine the developing tumors, based on initial diagnoses, track the tumor progression and assess the needed therapies to minimize the death rates due to the cancer [2]. Chemotherapy has been widely used for effective cancer treatments compared to targeted therapy, radiotherapy and surgery [3]. The World Health Organization reports that among emerging nations, cancer positions as the second principal cause of death. Researchers are working hard to create a new anti-neoplastic drug that is efficient and causes fewer toxic effects in the human body [4]. Heterocyclic compounds play a vital role in a diverse range of physiological functions linked to this class of molecules which makes it significant. The study of chemistry and biology in heterocyclic compounds is a fascinating field for future purposes [5]. The biological reactions frequently exhibit preference specificities due to the existence of heteroatoms or groups. The development of anticancer drugs becoming more interesting in naturally occurring heterocyclic molecules. The purpose of these novel strategies of heterocyclic compounds with numerous promising anticancer properties includes the development of activities by focusing on the tumor and other cancers such as lung, breast, colon and so on [6]. The heterocyclic compounds of pyrazoline and isoxazoline derivatives which belong to the azole family constitute extensive potential biological properties such as antioxidant, COX-2 inhibitor,antimicrobial and anticancer activities [7]. Pyrazoline is a five-membered heterocyclic molecule with nitrogen which offers a new source for synthesizing different derivatives with potent biological activities. Various types of heterocycles made up of pyrazoline derivatives are not only used in medications but also act as fungicides, insecticides, dyes and rubber chemicals [8]. Pyrazoline is a heterocyclic compound having two adjacent nitrogens at 1-2 positions with one endocyclic double bond with a wide spectrum of activity [9]. Its structure consists of a pyrazole ring with a saturated bond between those two positions.

The broad range of research on the biological activity of pyrazolines relies on cell-based assays and lacks molecular target identification. Pyrazoline has numerous pharmacological characteristics including anticancer, anti-inflammatory, analgesic, anti-depressant and anti-microbial properties [10]. Focusing towards anticancer activities, pyrazoline and their derivatives exhibited activities against breast cancer [11], cervical cancer [12], liver cancer [13], lung cancer [14], prostate cancer [15], colon cancer [13] and ovarian cancer [16]. Pyrazolines are closely tied with pyrazoles which have one fewer binary bond in their structure. Three isomers of pyrazoline exist, 1-pyrazoline, 2-pyrazoline, and 3-pyrazoline, distinguished by the presence or absence of a double bond. The most prevalent one was 2-pyrazoline. Derivatives of pyrazoline have a single endocyclic bond [9]. Pyrazolines are basic substances that can react with acids to produce salts. They have a potent fluorescence in solution, which makes them effective fluorescent brighteners. Due to their biological activity, pyrazolines and substituted pyrazolines have received a lot of importance among researchers [17]. The formation of pyrazolines can be accomplished through various methods, including the reaction of α,β-unsaturated ketones or aldehydes with hydrazines and 1,3-dipolar cycloaddition of nitrile Schiff bases (imines) to alkenes. Many compounds like ibipinabant, ramiphenazone, oxyphenbutazone, phenylbutazone and antipyrine contain the 2-pyrazoline scaffold [18]. The biologically important FDA-approved anticancer drugs bearing pyrazoline moiety along with the mechanism are given in figure 1. In this review, the literature survey was steered from PubMed, ScienceDirect, Embase and Google Scholar databases during the period of 2011-2025. As a search strategy, the keywords include pyrazoline, 2-pyrazoline, pyrazoline derivatives, anticancer activity, anti-breast cancer activity, cervical, lung, liver, prostate, ovarian and colon cancer, medicinal properties of pyrazolines and heterocyclic compounds. The keywords were utilized individually and in combination for collecting the literature. Following that, the titles and abstracts of each article were reviewed to remove any irrelevant ones. So, in order to help with cancer care, this review is going to concentrate on pyrazoline and its derivatives' structures, mechanisms, and features.

Pyrazoline Derivatives Against Cervical Cancer

Alam *et al*., 2017(12) tested a sequence of 1-(5-(3-(aryl)-1-phenyl-1H-pyrazol-4-yl)-3-(pyridin-3-yl)-4,5-dihydro-pyrazol-1-yl) ethanone derivatives (1-3) for their cytotoxicity via the 3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay against HeLa (cervical cancer) cell line. These compounds possessed potent anti-cervical cancer activity. Also, they exhibited superior IC_{50} values against the tested cancer cell line [12]. A series of hetero-aromatic scaffolds on curcumin containing pyrazoline substituted analogs were evaluated to determine the anti-proliferative activity against the HeLa cell line using MTT assay. (5-(5-Methoxy-1-methyl-1H-indol-3-yl)-3-(3-methoxyphenyl)-4,5-dihydro-1H pyrazol-1-yl)(6-methylpyridin-3-yl)methanone (4) has exhibited potent activity with better interactions and three-H-bond interactions higher than the parent molecule, determined by the molecular docking studies [19]. The pyrazoline derivatives associated N-methyl indole moiety were tested to assess the antineoplastic action towards the HeLa cancerous cell line by employing the MTT and colchicine assay. (5-(5-Methoxy-1-methyl-1H-indol-3-yl)-3-(3-methoxy phenyl)-4,5-dihydro-1H pyrazol-1-yl) (6-methyl pyridin-3-yl) methanone (5) showed better anti-cancer activity, lacking noxiousness to non-cancerous cells. The colchicine competition experiment proved that they have a potential tumor therapy by binding to tubulin's colchicine and blocking tubulin assembly. Analysis of the compound's molecular docking and interaction patterns revealed that it inhibits tubulin polymerization. The tested compound has also arrested the G2/M phase and induced cell apoptosis subsequently [20]. 1-Isobutyl-N-(4-(5-(4-methoxy phenyl)-4,5-dihydro-1H-pyrazol-3-yl) phenyl)-1H-imidazo [4,5-c] quinoline-4-amine (6) was investigated for its potential against cervical cancer. It was assessed using the Trypan blue exclusion assay and found to be possessing good anti-tumor activity against the HeLa cancer cell line [21]. The acetylated pyrazoline was synthesized by cyclization reaction and subjected to antiproliferative screening. Among the tested compounds, 1-acetyl-5-(2,4,5-trimethoxyphenyl)-3-(2-naphthyl)-4,5-dihydro-1H-pyrazole (7) has potent anti-tumor activity against the HeLa cancer cell line with a better IC_{50} value, assessed by the MTT assay [22]. 1,1′-(5,5′-(1,4-phenylene) bis (3- (naphthalen-1-yl) - 4,5-dihydro-1H-pyrazole-5,1-diyl)) diethanone (8) was produced and was tested against the HeLa cancer cell line. The synthesized derivatives were evaluated by Enzyme-linked Immunosorbent Assay (ELISA). Among the series of derivatives, it has a promising anti-cancer activity [23]. A novel series of D-condensed 2-pyrazoline was synthesized and evaluated by the ELISA.(3S,16R,17S)-3′-Methyl-1′-methyl-2′-pyrazolino[4′,5′:17,16]androst-5-en-3-ol (9) has a promising cell cycle disturbance and was examined by *in vitro* studies against the Human cervical cancer cell line HeLa, which has shown potent anti-neoplastic activity [24].

Patel *et al*., 2021[25] prepared a series of pyrazoline scaffolds by the process of cyclization that were screened using the MTT assay against a HeLa cancer cell line. The tested compounds exhibited better cytotoxicity and were found to have higher efficacy with better binding potential to the CDK2 protein, determined according to molecular docking studies. Among the tested compounds, 5-(9-Ethyl-9H-carbazol-3-yl)-3-(2-oxo-2H-chromen-3 yl)-4,5-dihydro-1H-pyrazole-1-carboxamide (10) and 3-(1-(3-Chlorophenyl)-5-(9-ethyl-9H-carbazol-3-yl) 4,5-dihydro-1H-pyrazol-3-yl)-8-methoxy-2H-chromen-2-one (11) were found to be most active and exhibits a potential to arrest cell cycle progression and to induce apoptosis [25]. A novel 2′-(2 ′′- 4 ′′- dinitrophenyl)-5α-cholestano [5,7-cd] pyrazoline (12) was investigated to govern the anti-tumor action in contrast to the HeLa cell line. This compound was screened by using the MTT cell viability assay and has a potent promising activity in the prevention of Human cervical cancer [26]. Using the MTT assay, the anti-cervical cancer potency of the steroidal pyrazoline cholest-5-en-7-one (13) was assessed against the HeLa cancer cell line using 5-FU and Doxorubicin as standard and 8-chloro-3-(1*H*-indol-3-yl)-2-phenyl-2,3,3a,4-tetrahydro[1]benzothiopyrano[4,3-*c*]pyrazole was found to be a potent anti-neoplastic compound with significant IC_{50} value [27]. A series of 3-(1H-indol-3-yl)-2,3,3a,4-tetrahydrothiochromeno[4,3-c]pyrazole derivatives were synthesized by Song *et al*., 2020[28] and tested their efficacy as topoisomerase II selective inhibitors. These substances have a higher IC_{50} value and demonstrate strong action against the cervical cancer cell line HeLa, according to the studies. Further, 6,8-dichloro-3-(1*H*-indol-3-yl)-2-phenyl-2,3,3a,4-tetrahydro[1]benzothiopyrano[4,3-*c*]pyrazole (14) and 6,8-dichloro-3-(1*H*-indol-3-yl)-2-phenyl-2,3,3a,4-tetrahydro[1]benzothiopyrano[4,3-*c*]pyrazole (15) induced G2/M phase cell cycle arresting and promising anti-cervical cancer activity via promoting apoptosis. These compounds also showed specific inhibitory effects towards topoisomerase II. DNA unwinding and cleavage reaction assays demonstrated that these compounds were a non-interactive topo II catalytic inhibitor, which agreed with the docking findings [28]. Yu *et al*., 2014 [29] tested a series of 4-(5-(Benzo[d][1,3]dioxol-5-yl)-3-(trifluoromethyl)-4,5-

dihydro-1H-pyrazol-1-yl)benzenesulfonamide (16) for cytotoxicity using the ELISA and Inhibitory assays. The chemical exhibited strong action towards the HeLa cells, according to the findings. This compound showed better inhibitory potential, QSAR also performed and found to be the inhibitor ofthe COX-2/B-Raf pathway [29]. The structures of compounds (1–15), which were previously described, are shown in figure 2, while compound (16) is shown in figure 3.

Pyrazoline Derivatives against Breast Cancer

The series of novel pyrazoline-containing compounds was designed and cytotoxicity against breast cancer was assessed using molecular docking studies with tamoxifen and erlotinib as standards. The study revealed that 5-(4-chlorophenyl)-1,3-diphenyl-4,5-dihydropyrazole (17) was established as most dynamic against P450, 4-(2-chlorophenyl)-2-(4-chlorophenyl)-1-phenyl-2,3-dihydropyrazole (18) was active against EGFR and 2,4-bis(2-chlorophenyl)-1-phenyl-2,3-dihydropyrazole (19) had exhibited higher potential against VEGFR1 and VEGFR2. The given compounds were also found to be exhibiting good pharmacokinetic properties and were predicted to be non-toxic [30]. 8-[1-(4-Chloro phenyl sulfonyl)-5-phenyl-4,5-dihydro-1H-pyrazol-3-yl]-7-methoxy-2H-chromen-2-one (20) was created and assessed for its capability to prevent the development of breast cancer cells (MCF-7) using the SRB assay; the results showed that it was an effective candidate. Also, it was proved that it can efficiently inhibit the PI3K Isoforms [11]. Lv *et al*., 2011[31] designed thiazolyl-pyrazoline derivatives and evaluated its anti-proliferative activity against the MCF-7 cancer cell line. Among different derivatives, 4-(4-chlorophenyl)-2-(3-(3,4-dimethylphenyl)-5-(4-fluorophenyl)-4,5-dihydro-1H-pyrazol-1-yl)thiazole (21) has potent anti-breast cancer activity. According to the molecular docking studies, it was found to be having high potency as EGFR Kinase inhibitor and will exerts the potential towards the ATP binding site [31]. (5-(benzo(d)[1,3]dioxol-5-yl)-3-(4-methoxyphenyl)-4,5-dihydro-1H-pyrazol-1-yl)(3,4,5-tri methoxyphenylmethanone (22) was investigated for its potent anti-proliferative activity against the MCF-7 breast cancer cell line using MTT assay. Also, this compound induces the accumulation of cells in the G2/M phase of the cell cycle and promotes apoptosis [32]. Anticancer prospective of Bis-pyrazoline (23) was investigated against the MCF-7 cells using the MTT technique, compared with the standard 5-Fluorouracil. This compound was found to be potent against breast cancer and also found to be inhibiting the VEGFR2 Tyrosine Kinase receptor [33]. Rabou *et al*., 2018 [33] tested a series of bis-N-thioamide pyrazolines for the investigation of cytotoxicity using the MTT assay. They have possessed promising efficacy towards MCF-7 cells. Among the established derivatives, 1,4-bis (5-methyl-4-(5-phenyl-4,5-dihydro-1H-pyrazol-3-yl)-1H-1,2,3-triazol-1-yl)benzene (24) has exhibited significant activity. The molecular docking studies were also carried out and found to have significant inhibitory potential against VEGFR Tyrosine Kinase enzyme [33]. 1-[3-(5-bromo thiophen-2-yl)-5-(4-methoxy phenyl)-4,5-dihydro-1H-pyrazol-1-yl] ethanone (25) was synthesized by the process of condensation. Anti-cancer investigations on breast cancer cell line MCF-7 using Doxorubicin as the standard drug was evaluated by SRB assay and found to be more active [34].

The antiproliferative potential of the series of novel synthetic pyrazolines were assessed by using SRB assay. Among the tested compounds,1-(5-(4-Chlorophenyl)-3-(4-ethoxyphenyl)-4,5- dihydropyrazol-1-yl)ethanone (26) showed better activitywith significant IC_{50} value and provided the relationship between structure and activity for the design of anti proliferative agents [35]. Using the MTT assay towards MCF-7 cancer cells, investigators looked into the antiproliferative potential of a number of 5-substituted aryl-2-pyrazoline derivatives. Among them, 1-(2, 4-di-nitro phenyl)-5-(4-chloro phenyl)-3-(4- methoxy phenyl)-2-pyrazoline (27) and 1-(2,4-di-nitro phenyl)-5-(4-N,N-di-methyl amino phenyl)-3-(4-methoxy phenyl)-pyrazoline (28) remained as the effective compounds with better IC_{50} values. To identify the most effective binding mode and supportive mechanism, these compounds were docked with the Epidermal growth factor receptor (EGFR) and found to be potent EGFR inhibitors with better binding affinities [36]. The anticancer potential of 3-(4-methoxyphenyl)-5-substituted phenyl-2-pyrazoline-1-carbothioamide derivatives was screened by using SRB assay. 3-(4-Methoxyphenyl) -5-phenyl-2-pyrazoline-1-carbothioamide (29), 5-(3-Methoxyphenyl)-3-(4-methoxyphenyl)-2-pyrazoline-1-carbothioamide(30),5-(4-Chlorophenyl)-3(4methoxyphenyl)-2-pyrazoline-1-carbothioamide(31) and 3-(4-Methoxyphenyl) -5-(p-tolyl) -2-pyrazoline1-carbothioamide (32) have significant anti-cancer activity against the MCF-7 breast cancer cell line and observed an EGFR inhibitory activity [37]. The structures of compounds (17–30), which were previously described, are shown in figure 3, while

compounds (31) and (32) are shown in figure 3. To determine the efficacy of an array of new pyrazoline derivatives bearing naphthalin through inhibiting cell proliferation in the MCF-7 cells, researchers used the MTT assay in conjunction with inhibitory assays such as the EGFR/HER-2, HER-3, VEGFR-2, FAK, and BCATM protein assays. Among them, 3-(3,4-Dichlorophenyl)-5-(naphthalen-2-yl)-4,5- dihydro-1H-pyrazole-1-carbothioamide (33) has a better IC_{50} value and is devoted to have EGFR/HER-2 inhibitory activity [38]. Employing the MTT colorimetric technique, a battery of new pyrazolines was tested towards the anti-cancer potential against MCF-7 cells. Among the tested derivatives, 1-(2,4-dinitrophenyl)-3-((7-propylnaphthalen-1-yl)methoxy)-4,5-dihydro-1H-pyrazole-5-carboxylic acid (34) has high IC_{50} value. According to the molecular docking studies, this compound was found to act upon the ER-α receptor [39]. (E)-5-(4-Methoxyphenyl)-3-(4-methoxystyryl)-4,5-dihydro-1H-pyrazole-1-carboxamide (35), (E)-3-Phenyl-5-styryl-4,5-dihydro-1H-pyrazole-1-carbothioamide (36), (E)-3-(4-Chlorophenyl)-1-phenyl-5-styryl-4,5-dihydro-1H-pyrazole (37) and E)-1-(4-Methoxyphenyl)-3-phenyl-5-styryl-4,5-dihydro-1H-pyrazole (38) were prepared and found to be having promising cytotoxicity against the breast cancer cell line MCF-7, determined by the MTT assay with a standard reference staurosporine. According to the molecular docking investigations, these compounds were devoted as effective EGFR inhibitors [40]. 2-[3,5-bis(4-chlorophenyl0-4,5-dihydro-1H-pyrazol-1-yl]-5-(2-methoxybenzylidene)-1,3-thiazol-4(5H)-one (39) was prepared by Khalil *et al*., 2012 [41]. This compound was found to be a potent anti-cancer compound against the MCF-7 cancer cell line, compared with the standard Doxorubicin, determined using SRB assay [41]. The antiproliferative efficacy of the thiazolyl-pyrazolines was evaluated via MTT assay against the MCF-7 cell line (breast cancer). Based on the molecular docking and *in vitro* investigations, 1-(4-(4-Cyanophenyl)thiazol-2-yl)-3-(4- morpholinophenyl)-5-(4-chlorophenyl)-2-pyrazoline (40) and 1-(4-(4-Cyanophenyl)thiazol-2-yl)-3-(4- piperidinophenyl)-5-(4-chlorophenyl)-2-pyrazoline (41) was identified as the potent molecules, which has significant inhibitory potential, along with high affinity towards the ATP binding sites of EGFR and HER-2 [42].

2-(5-(Benzo[d][1,3]dioxol-5-yl)-3-(4-bromophenyl)-4,5-dihydro-1H-pyrazol-1-yl)-4-(4-bromophenyl)thiazole (42) was found to have potent anti-proliferative activity against the MCF-7 cancer cell line with better IC_{50} value. This compound was also found to be inhibiting the HER2 receptor, determined by the molecular docking studies [43]. Jasril *et al*., 2020 tested a pyrazoline analog against an MCF-7 cell line, evaluated using the MTT assay technique. 5-(4-fluorophenyl)-3-(naphthalen-1-yl)-4,5-dihydro-1*H*-pyrazole (43) was estimated as highly effective and it was evidenced that the compound has hydrogen bonding interactions with Arg 791 and also a hydrophobic interaction with His 790, estimated via molecular docking studies [44]. A novel pyrazoline derivative, 5-(4-fluorophenyl)-3-(naphthalen-1-yl)-4,5-dihydro-1H-pyrazole (44) was tested for its cytotoxic potential towards the MDA-MB-231 cell line and has found to possessing promising anti-cancer efficacy, which was evaluated by Scratch-wound and Transwell assays. It induces apoptosis via arresting the G0/G1 phase cell cycle [45]. 1-(2-93,5-diphenyl-4,5-dihydro-1H-pyrazol-1-yl)-2-oxoethyl) imidazolidine-2,4-dione (45) has a promising anti-cancer potential against the MCF-7 cells, assessed by the MTT cell viability technique. This compound has a potent possession in breast cancer activity. Studies conducted using *in vitro* methods revealed increased DNA damage, Caspase activation, Cell cycle arrest in the G0/G1 phase and a decrease in the expression of the anti-apoptotic protein BCL-2 [46]. The structures of compounds (33–45), which were previously described, are shown in figure 4. A novel steroidal glycoside pyrazoline functionalhybrid,4-((17-(5-(2-chloro-4-methylphenyl)-4,5-dihydro-1H-pyrazol-3-yl)-8,14-dihydroxy-3((2R,4S,5R,6R)5-(((1S,3S)-4-hydroxy-3-methylcyclohexyl)oxy)-4methoxy6methyltetrahydro2Hpyran2yl)10,13dimethylhexadecahydro-1H-cyclopenta[a]phenanthren-12-yl)oxy)benzoyl chloride (46) was prepared and evaluated for cytotoxicity against the MCF-7 cell line and the compound exhibited promising potential with potent IC_{50} value [47]. 4-(5-(4-chlorophenyl)-3-(pyridine-2-yl)-4,5-dihydro-1H-pyrazol-1-yl) benzene sulfonamide (47) acts as an effective agent towards the MCF-7 breast and MDA-MB-468 triple negative breast cancer cell lines. According to the molecular docking studies, this compound has a high docking score against the PARP1 and acts as potent PARP1 antagonist [48]. A series of new pyrazoline hybrids were efficiently synthesized by Kumari *et al*., 2020 [7]. (2R,3S,4R,5R,6S)-2-(hydroxymethyl)-6-((5-(5-nitro-1H-indol-3-yl)isoxazol-3-yl)methyl)tetrahydro-2H-pyran-3,4,5-triol (48) was found to be potent promising anti-cancer compound against the MCF-7, MDA-MB-453 and MDA-MB-231 breast cancer cell lines, assessed by the MTT assay. The molecular docking findings also agreed with the results of the MTT assay [7]. The structures of compounds (46–48), which were previously described, are shown in figure 5.

Pyrazoline Derivatives Against Colorectal Cancer

3-Anthracen-9-yl-5-phenyl-4,5-dihydro-1H-pyrazole (49), 3-Anthracen-9-yl-5-(4-chloro-phenyl)-4,5-dihydro-1H pyrazole (50), 3-Anthracen-9-yl-5-p-tolyl-4,5-dihydro-1H-pyrazole (51) and 3-Anthracen-9-yl-5-(3-chloro-phenyl)-4,5-dihydro-1H pyrazole (52) were evaluated and identified as promising anti-cancer compounds against the HCT-116 cell line, escorted by better IC_{50} values. These compounds were screened by using an MTT assay using curcumin as a standard [13]. 3-(5′-chloro-2′-hydroxy-4′,6′-dimethylphenyl)-5-(4-(N,N-dimethylamino)phenyl)-1-(p-sulfamylphenyl) —pyrazoline (53) was evaluated for anti-cancer activity against COLO 205 cell line and found to be a potent against the treatment of colorectal cancer [49]. 1,3-Diphenyl-4-(4-fluoro phenyl)-5-(4-fluoro benzoyl) pyrazoline (54) and 4-(4-Fluoro phenyl)-5-(4-methoxy benzoyl)-1-phenyl-3-(styryl) pyrazoline (55) were prepared and their potency against the HT29 cell line was assessed using the SRB assay. The produced compound was found to be a promising anti-colon cancer compound with better IC_{50} value [50]. 1,3,5-triaryl-2-pyrazoline (56) was prepared and gauged for its colon cancer efficacy against the HCT116 cells using the SRB assay. 1-(4-bromophenyl)-4-(4-fluorophenyl)-3-phenylimidazolidine was found to be more potent, yielding a more favorable IC_{50}value. It showed a better structural and molecular features, related to its biological activity [51]. The HCT 15 cell line was used to assess the cytotoxic potential of many new pyrazoline derivatives through the use of the ATPase test and the DNA-Topo II cleavable complex assay. Among the tested derivatives, Benzo [d] thiazol-2-yl-(3-(4-chloro phenyl)-5-(4-methoxy phenyl)-4,5-dihydro-1H-pyrazol-1-yl) methanone (57) showed a better IC_{50} value. The endogenous topo mediated DNA relaxation studies were also performed, it indicated that this compound can effectively inhibited endogenous topo-mediated pBR322 plasmid relaxation than the standard etoposide [52]. 2-[5-(4-Fluorophenyl)-3-(4-tolyl)-4,5-dihydropyrazol-1-yl]-1-methyl-6-oxo-4-phenyl-1,6- dihydropyrimidine-5-carbonitrile (58) and 2-[3-(4-Chlorophenyl)-5-(4-methoxyphenyl)-4,5-dihydropyrazol-1-yl]-1-methyl-6-oxo-4-phenyl-1,6-dihydropyrimidine-5-carbonitrile (59) was appraised using the HT 29 colon cancer cell line by Cell Titer Glo technique. From this assay, these compounds were found to possess potent anti-proliferative activity [53]. The structures of compounds (49-58), which were previously described, are shown in figure 5, while the compound (59) is shown in figure 6.

Using the Sulforhodamine B assay, novel 17 -pyrazolinyl derivatives of pregnenolone were explored to appraise their cytotoxic action towards HT-29 and HCT-15 cell lines. 1-(5-(3-Fluorophenyl)-4,5-dihydro-3-((10R,13S)2,3,4,7,8,9,10,11,12,13,14,15,16,17-tetradecahydro-3-hydroxy-10,13-dimethyl-1H-cyclopenta[a]phenanthren 17-yl)pyrazol-1-yl)ethenone(60),1-(5-(4-Fluorophenyl)-4,5-dihydro-3- ((10R,13S)2,3,4,7,8,9,10,11,12,13,14,15,16,17-tetradecahydro-3-hydroxy-10,13-dimethyl-1H-cyclopenta[a]phenanthren-17- yl) pyrazol-1-yl) ethenone (61), 1-(4,5-Dihydro-3-((10R,13S)-2,3,4,7,8,9,10,11,12,13,14,15,16,17-tetradecahydro-3-hydroxy-10,13dimethylcyclopenta [a] phenanthren -17- yl) -5-o-tolylpyrazol-1-yl) ethenone (62), 1- (4,5-Dihydro-3-((10R,13S)-2,3,4,7,8,9, 10,11,12, 13,14,15,16, 17-tetradecahydro-3-hydroxy-10,13-dimethyl-1H-cyclopenta[a]phenanthren-17-yl)-5-m-tolylpyrazol-1-yl) ethenone (63), 1-(4,5-Dihydro-3-((10R,13S)-2,3,4,7,8,9,10,11,12,13,14,15,16,17- tetradecahydro-3-hydroxy-10,13-dimethyl-1H-cyclopenta[a]phenanthren-17-yl)-5-(4-methoxyphenyl) pyrazol-1-yl)ethenone (64) and 1-(5-(2-Chlorophenyl)-4,5-dihydro-3-((10R,13S)- 2,3,4,7,8,9,10,11,12,13,14,15,16,17-tetradecahydro-3- hydroxy-10,13-dimethyl-1H-cyclopenta[a] phenanthren-17-yl) pyrazol-1-yl)ethenone (65) presented substantial anti-cancer action towards the tested colon cancer cells [54]. 2-(5-(Benzo [d][1,3]dioxol -5-yl)-3-(naphthalen-1-yl)-4,5-dihydro-1H-pyrazol-1-yl)-4-(4substitued phenyl)thiazole (66) was produced by Mansour *et al.*,2019 [55] and tested their promising anti-proliferative activity against HCT -116 cancer cell line. This potent compound was screened by *in vitro* methods with a better IC_{50} value [55]. An innovative thiazolone-containing compound encompassing a pyrazoline moiety was screened by using a cytotoxicity assay. 5-(4-Hydroxy-3,5-dimethoxybenzylidene)-2-[5-(2-hydroxyphenyl)-3-phenyl-4,5-dihydro-1H-pyrazol-1-yl]-1,3-thiazol-4(5H)-one (67) has significant anti-cancer activity against selective influence on HT 29 (colon cancer cell line) [56]. The anti-proliferative activity of N-acetyl and N-formyl pyrazoline derivatives was evaluated using the SRB assay against the HCT-15 cell line.5-(4-Chlorophenyl)-3-[4-(7-chloroquinolin-4-ylamino) phenyl]-4,5-dihydro-1H-pyrazole-1-carbaldehyde(68), 5-(4-Chlorophenyl)-3-[3-(7-chloroquinolin-4-ylamino) phenyl]-4,5-dihydro-1H-pyrazole-1-carbaldehyde (69), 3-[3-(7-Chloroquinolin-4-ylamino)phenyl]-5-phenyl-4,5- dihydro-1H-pyrazole-1-carbaldehyde (70), 3-[3-(7-Chloroquinolin-4-ylamino) phenyl]-5-(4-methoxyphenyl)-4,5-dihydro-1H-pyrazole-1-carbaldehyde (71) and 3-[3-(7-Chloroquinolin-4-ylamino)phenyl]-5-(3,4,5-trimetho-xyphenyl)-4,5-dihydro-1H-pyrazole-1-carbaldehyde (72) were found to possess potent anti-proliferative compounds for the colon

cancer therapy [57]. The structures of compounds (60-69), which were previously described, are shown in figure 6, whereas the compounds (70-72) in figure 7.

The potency of a variety of 1-acyl-2-pyrazoline derivatives towards the HCT-1 cell line was studied. The repressive impact of the derivatives that were synthesized was appraised via the MTT assay. Among them, (2-(2,3-Dimethyl phenyl amino)phenyl) (4,5-dihydro-5- (4-methoxyphenyl)-3-phenylpyrazo-1-yl) methanone (73), 1-(4,5-Dihydro-3,5-diphenylpyrazol-1-yl)-2-(4-isobutyl phenyl) propan-1-one (74) and 1-(4,5-Dihydro-5-(4-methoxyphenyl)-3-phenylpyrazol-1-yl) 2-(4-isobutyl phenyl)propan-1-one (75) was found to be possessing potent and promising activity [58]. A series of N-acyl derivatives of ferrocenyl pyrazoline was tested via MTT assay and the compound (76) was a potent anti-cancer agent against HCT-116 human colorectal cancer cells [59]. A novel pyrazoline derivatives was efficiently synthesized and gauged for their antiproliferative action towards the HCT-116 colorectal cancer cell line using Sulforhodamine B assay. Among them, 1-(3-(4-(benzyloxy)phenyl)-5-(4-chlorophenyl)-4,5-dihydro-1H-pyrazol-1-yl) ethenone (77) and 1-(3-(4-(benzyloxy)phenyl)-5-(4-fluorophenyl)-4,5-dihydro-1H- pyrazol-1-yl) ethenone (78) was identified to be the potent candidates. The binding interaction of compounds with proteins (RCSB PDB ID: 1M17 and 5ZTO) has been studied. According to the molecular docking studies, it showed that the compounds can efficiently interacts with target proteins and also exhibited better binding affinities [60]. Using the MTT assay Tilekar *et al*., 2020 [61] assessed the anticancer potential of 1-(2-(3-9-fluorophenyl)-5-(p-tolyl)-4,5-dihydro-1H-pyrazol-1-yl)-2-oxoethyl)pyrrolidine-2,5-dione (79) against the HT 29 colon cancer cell line. It was found to possessing potent activity and discovered to interfere with the growth phases in cell cycle analysis, causing the cell population to increase in the G_1/G_0 Phase and decrease in the G_2/M phase [61]. The structures of compounds (73-79), which were previously described, are shown in figure 7.

Pyrazoline Derivatives against Prostate Cancer

A variety of pyrazoline scaffolds were explored by to appraise their cytotoxicity against the PC-3 Prostate cancer cell line. 1-[5-(4-chlorophenyl)-3-(4-[(4-fluorophenyl)methoxy]phenyl)-4,5-dihydro-1*H*-pyrazol-1-yl]ethan-1-one (80), 5-(4-fluorophenyl)-3-(4-[(4-fluorophenyl)methoxy]phenyl)-4,5-dihydro-1*H*-pyrazole-1-carbothioamide (81), 3-(4-[(4-fluorophenyl)methoxy]phenyl)-5-phenyl-4, 5-dihydro-1*H*-pyrazole (82) and 5-(4-chlorophenyl) -3- (4- [(4-fluoro phenyl)methoxy]phenyl)-4,5-dihydro-1*H*-pyrazole (83) have the promising anti-cancer activity and exhibits better IC_{50} value. Furthermore, the molecular docking analyses of these compounds with the EGFR and VEGFR ATP binding sites were performed and found to be potent EGFR inhibitor [15]. A series of pyrazoline derivatives were synthesized and evaluated their anti-proliferative activity against the PC-3 cancer cell line by using an MTT assay. (3-(2,3-Dihydro-benzo[1,4]dioxin-6-yl)-5-(4-dimethylamino-naphthalen-1-yl)-4,5 dihydro-pyrazole-1-carboxylic acid (4-chloro-phenyl)-amide (84), 3-(2,3-Dihydro-benzo[1,4]dioxin-6-yl)-5-(4-dimethylamino-naphthalen-1-yl)-4,5 dihydro-pyrazole-1-carbothioic acid amide (85), 1-(2,3-Dihydro-benzo[1,4]dioxin-6-yl)-3-4-dimethylamino-naphthalen-1-yl)-propenone (86),3-Benzofuran-2-yl-5-(4-dimethylamino-naphthalen-1-yl)-4,5-dihydro-pyrazole-1 carboxylic acid (4-chloro-phenyl)-amide (87) and 3-Benzofuran-2-yl-5-(4-dimethylamino-naphthalen-1-yl)-4,5-dihydro-pyrazole-1 carbothioic acid amide (88) were found be the significant anti-cancer compounds. According to molecular docking studies, these compounds can efficiently inhibit tubulin polymerization [62]. 3,5-diaryl N-acetyl pyrazolines (89) were synthesized and assessedtheir cytotoxicity against the PC-3 Prostate cancer cell lines using SRB assay and the tested compound exhibits the promising anti-neoplastic activity with better IC_{50} value [63]. The structures of compounds (80-89), which were previously described, are shown in figure 8. Using the Sulforhodamine B assay, we tested an assortment of pyrazoline derivatives for their cytotoxic effects on the DU145 prostate cancer cell line. (E)-3-(3-((1-(4-fluorobenzyl)-1H-1,2,3-triazol-4-yl)methoxyphenyl) -1- (3,4,5-trimethoxyphenyl) prop-2-en-1-one (90) was identified as an effective anti-neoplastic agent with a significant GI_{50} value. This compound was responsible for tubulin polymerization inhibition and cell accumulation in the G_2/M Phase [64]. A novel pyrazolines were prepared and evaluated their antiproliferative potential towards PC-3 cells using *in-vitro* SRB assay. Among those derivatives, 9-[(1,3-Diphenyl-4,5-dihydro-1H-pyrazol-5-yl)methyl]-6-piperidinyl-9H-purine (91) exhibits the compelling antiproliferative action and used in the prostate cancer therapy. This compound also revealed that it has high lipoxygenase inhibitory activity in combination with significant anti-thrombin activity, suggesting that this compound can effectively inhibits tumor growth and development [65]. Using the SRB assay method, 5-

(benzo[d][1,3]dioxol-5-yl)-3-(4-methoxyphenyl)-4,5-dihydro-1H-pyrazole-1-carbothioamide (92) was investigated for its promising anti-tumor activity against the DU-145 prostate cancer cell line. Also, it was found to exhibit a superior GI_{50} value against the tested cancer cell line [16]. A furan-based N-acetyl pyrazoline derivative was produced and evaluated for potent proliferative efficacy on PC-3 cells using DNA intercalation assay. 1-[3-(2,5-dimethylthiophen-3-yl)-5-(2-nitro phenyl)-4,5-dihydropyrazol-1H-1-yl]ethenone (93), 1-[3-(2,5-dimethylthiophen-3-yl)-5-(4-nitro phenyl)-4,5-dihydropyrazol-1-1H-yl] ethenone (94) and 1-[3-(2,5-dimethylfuran-3-yl)-5-(5-hydroxy-2-nitrophenyl)-4,5-dihydro-pyrazol-1H-1-yl]ethenone (95) were found to be significant anti-cancer compounds. The apoptotic effect using Topo II decatenation assay was determined and found to arrest the cell cycle at the G_1 phase [66]. The structures of compounds (90-95), which were previously described, are shown in figure 9.

Pyrazoline Derivatives against Lung Cancer

The MTT assay was used to evaluate the anti-cancer activity of pyrazoline-linked carboxamide derivatives that were developed and tested against the A549 human non-small-cell lung tumor cell line. Among them,3′-[4-(Benzyloxy)phenyl]-1′-phenyl-5-(pyridin-3-yl)-3,4-dihydro 1′H,2H-[3,4′-bipyrazole]-2-carboxamide (96) and 3′-[4-(Benzyloxy)phenyl]-1′-phenyl-5-(pyridin-4-yl)-3,4-dihydro1′H,2H-[3,4′-bipyrazole]-2-carboxamide (97) exhibits the promising anti-neoplastic activity. These compounds efficiently binds to the ATP binding site of EGFR Kinase like the erlotinib standard drug, determined according to the molecular docking studies [14]. The anti-lung cancer activity of a variety of pyrazolines was tested using the Cell titer Glo assay method on the A549 cancer cell line. These pyrazolines were made via a cyclocondensation technique. Among them, 2-[5-(4-Methoxyphenyl)-3-phenyl-4,5-dihydropyrazol-1-yl]-1-methyl-6-oxo-4-phenyl-1,6-dihydropyrimidine-5-carbonitrile (98) was found to be a potent anti-cancer compound with better IC_{50} value [53]. N-acetyl-5-ferrocenyl-3-(2-thienyl)-2-pyrazoline (99) was synthesized and evaluated by the methyl thiazol tetrazolium assay. This compound has been confirmed as a potent anti-cancer agent to prevent lung cancer by acting against the A549 cancer cell line [67]. A novel thienopyrimidine containing pyrazoline unit was prepared and appraised its potency towards the A549 cells using the MTT assay. N1-(2-(5-(4-Methoxyphenyl) -3-phenyl-4, 5-dihydro-1H-pyrazol-1-yl) thieno [2,3-d]pyrimidin-4-yl) -N1,N2,N2 trimethylethane-1,2 diamine (100) was identified as an effective anti-proliferative candidate. Furthermore, it was found to have better inhibitory potential against the P13K α\mTOR protein kinase. Annexin V-FITC/PI staining also revealed that this compound can induces apoptosis [68]. The structures of compounds (96-100), which were previously described, are shown in figure 9.

Using the MTT assay, we evaluated the potential anti-cancer activity of N-formyl derivatives that were developed and synthesized by the cyclization procedure against the A549 cells. 3-(4-chlorophenyl)-5-(4-(dimethylamino)phenyl)-4,5-dihydro-1H- pyrazole-1-carbaldehyde (101) and 3-(4-bromophenyl)-5-(4-(dimethylamino)phenyl)-4,5-dihydro-1H-pyrazole-1-carbaldehyde (102) were found to be the Topo-isomerase II inhibitor. Also, the molecular dynamics simulation studies revealed the stability of the complexes [69]. A series of pyrazoline analogues were prepared and assessed for *in vitro* anti-cancer activity towards A549 small cell lung cancer cell line. Among them, 5-(4-Fluorophenyl)-N-(naphthalen-1-yl)-3-(3,4,5 trimethoxyphenyl)-4,5-dihydro-1H-pyrazole-1-carbothioamide (103), 5-(4-(Methylthio)phenyl)-N-(naphthalen-1-yl)-3-(3,4,5 trimethoxyphenyl) -4,5- dihydro-1H-pyrazole-1-carbothioamide (104) and 5-(4-Methoxyphenyl)-N-(naphthalen-1-yl)-3-(3,4,5trimethoxyphenyl)-4,5-dihydro-1H-pyrazole-1-carbothioamide (105) have revealed a promising anti-cancer activity with better GI_{50} values [70]. A novel thiazole containing pyrazoline compounds was designed and screened for cytotoxicity towards the A549 cell line (NSCLC) by using both lactate dehydrogenase assay as well as SRB assay method. 2-(3-(4-chlorophenyl)-5-(4-methoxyphenyl)-4,5-dihydro-1H-pyrazol-1-yl)-4-(pyridin-4-yl)thiazole (106) was found to be the potent anti-neoplastic agent and also inhibits the activity of mTOR via FKBP12, which can be reversed by 3BDO, an mTOR activator and autophagy inhibitor [71]. 1-acetyl-3-(2-thienyl)-5-aryl-2-pyrazoline derivatives were tested and assessed for their anti-cancer action towards the A549 cells consuming MTT assay. Among them, 1-[5-(4-methylphenyl)-3-(thiophen-2-yl)-4,5-dihydro-1*H*-pyrazol-1-yl]ethan-1-one (107), 1-[5-(4-bromophenyl)-3-(thiophen-2-yl)-4,5-dihydro-1*H*-pyrazol-1-yl]ethan-1-one (108) and1-(5-(benzo[d][1,3]dioxol-5-yl)-3-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-1-yl)ethanone (109) were found to be promising anti-cancer agents. It was also revealed that these

compounds can indices apoptosis via caspase-3 activation [72]. The structures of compounds (101-107), which were previously described, are shown in figure 10, whereas the compounds (108 and 109) in figure 11.

Pyrazoline Derivatives against Liver Cancer

The MTT assay was used to explore a range of anthracenyl pyrazoline derivatives. 3-Anthracen-9-yl-5-(3-nitro-phenyl)-4,5-dihydro-1H-pyrazole (110), 3-Anthracen-9-yl-5-furan-2-yl-4,5-dihydro-1H-pyrazole (111), 3-Anthracen-9-yl-5-(3,4,5-trimethoxy-phenyl)-4,5-dihydro-1H-pyrazole (112) and 3-Anthracen-9-yl-5-93,4-dimethoxy-phenyl)-4,5-dihydro-1H-pyrazole (113) revealed that they have a significant cytotoxic activity in HepG2 cells with better IC_{50} values [13]. A novel pyrazoline coumarins were produced and investigated for anti-proliferative action towards the HepG2 hepatocellular cancer cell line by using MTT assay. 7-methoxy-8-(5-[4-(methylthio)phenyl]-4,5-dihydro-1H-pyrazol-3-yl)-2H-chromen-2-one (114) showed better anti-cancer activity. The apoptotic potential was determined by Annexin V FITC/PI staining and it shows that this compound can effectively induce apoptosis [73]. A series of isolongifolanone pyrazoline derivatives were prepared and assessed their anti-proliferative potential against the HepG2 cells. The compounds were also screened via both apoptosis assay as well as MTT assay using Etoposide, 5-Fluorouracil as a controlled drug. The MTT assay showed that 3-(4-methoxyphenyl)-N,5,5,9,9-pentamethyl-4,5,7,8,9,9a-hexahydro-5a,8-methanobenzo[g]indazole-2(6H)-carbothioamide (115) was identified to be a potent candidate against liver cancer. Also, this compound potently induces apoptosis in HepG2 cells by enhancing intracellular reactive oxygen species [74]. In order to determine whether or not these pyrazolines had any anti-cancer effects, we used the MTT assay on the HepG2 cells. 3-(3-[4-Chlorophenyl]-5-[4-(trifluoromethyl)phenyl]-4,5-dihydropyrazol-1-yl)-6-phenylpyridazine (116) was found to be promising anti-cancer compound and exhibits equal apoptotic and necrotic properties [75]. Benzo[b]thiophen-2-yl-[5-(4-hydroxy-3,5-dimethoxy-phenyl)-3-(2-hydroxy-phenyl)-4,5-dihydro-pyrazol-1-yl]-methanone (117) was established as a promising agent against the HepG2 cells with significantly better IC_{50} value and compared using cisplatin as a controlled drug. It significantly arrested the cell cycle in the G2\M phase and induced apoptosis, as determined via the cell cycle analysis and apoptosis/necrosis evaluation [76]. The structures of compounds (110-117), which were previously described, are shown in figure 11.

Pyrazoline Derivatives against Ovarian Cancer

Utilizing the sulforhodamine B assay, an array of N-acetyl and N-formyl-pyrazoline derivatives were produced through the cyclocondensation technique and tested on the OVCAR-3 and ADR-RES cell lines, which comprise an ovarian cancer panel. Among the tested compounds, 5-(4-Chlorophenyl)-3-[4-(7-chloroquinolin-4-ylamino) phenyl]-4,5-dihydro-1H-pyrazole-1-carbaldehyde (118), 5-(4-Chlorophenyl)-3-[3-(7-chloroquinolin-4-ylamino) phenyl]-4,5-dihydro-1H-pyrazole-1-carbaldehyde (119), 3-[3-(7-Chloroquinolin-4-ylamino)phenyl]-5-phenyl-4,5 dihydro-1H-pyrazole-1-carbaldehyde (120), 3-[3-(7-Chloroquinolin-4-ylamino)phenyl]-5-(4-methoxyphenyl)-4,5-dihydro-1H-pyrazole-1-carbaldehyde (121) and 3-[3-(7-Chloroquinolin-4-ylamino)phenyl]-5-(3,4,5-trimethoxyphenyl)-4,5-dihydro-1H-pyrazole-1-carbaldehyde (122) revealed the promising anti-tumor activity against the tested cell lines with significant IC_{50} values [57]. A novel steroidal glycoside pyrazoline functional hybrid, 17-(5-(2-chlorophenyl)-4,5-dihydro-1H-pyrazol-3-yl) -8,14-dihydroxy-3- ((4-((5-hydroxy-4-methoxy-6-methyltetrahydro-2H-pyran-2-yl)oxy)-5 methoxy-3-methyl tetrahydro-2H-pyran-2-yl)oxy)-10,13-dimethylhexadecahydro-1H-cyclopenta[a]phenanthren-12-yl benzoate (123) was synthesized and appraised its antiproliferative action towards the OVCAR-3 cells by using cell viability assay and Lactate dehydrogenase assay. The tested compound was found to be potent anti-cancer agent and possess higher growth inhibitory potential than the cisplatin standard drug [47]. The structures of compounds (118 and 119), which were previously described, are shown in figure 11, whereas the compounds (120-123) are shown in figure 12.

CONCLUSION

A five-membered heterocyclic structure containing nitrogen, pyrazoline is well-known in medicinal chemistry. This adaptable structure, which is semi-saturated, offers a distinct spatial configuration that enables different patterns of substitution to have significant pharmacological effects. These effects can include anticancer, antitrypanosomal,

antimicrobial, anti-inflammatory, analgesic, antidiabetic, antiviral, antiepileptic, etc., as well a selective activity, such as MAO inhibitory, cannabinoid CB1 receptor antagonist and NOS inhibitory activity. The chemical reactivity of pyrazolines has led to their eager modification to fabricate a wide assortment of lead moieties, which in turn have produced innovative therapeutic candidates for the management of many disorders. In this present review, we have comprehensively reviewed the various anticancer activities of the pyrazoline derivatives, with special reference to cervical, breast, colorectal, prostate, lung, liver and ovarian cancers. Additionally, these compounds could act upon several stages of the cell cycle, induce apoptosis, and decrease cell growth, ATP binding, and caspase activation. They can also inhibit various proteins, enzymes and receptors, including Epidermal growth factor receptors, Vascular endothelial growth factor receptors, Tumor necrosis factor, Estrogen receptors, Human Epidermal receptors, Tyrosine kinase and Janus kinase receptors. Thus, we trust that this paper will be helpful for budding researchers and medicinal chemists seeking their research toward the designing and development of pyrazoline derivatives and developing novel derivatives with different pharmacological properties. Hence, these pyrazoline derivatives will be utilized further in the management of several ailments.

ACKNOWLEDGEMENT

We thank the Management and Dr. G. Murugananthan, Principal of our college for giving constant support and encouragement for writing this review.

ABSTRACT

Cyanobacteria are a morphologically diverse group of oxygen-producing phototrophic prokaryotes that appeared about 3. 5 billion years ago, growing in a wide range of environmental conditions where light and moisture are present. The study's primary goal is to investigate the variety of cyanobacteria found in the Berhampore subdivision of the West Bengal, India's Murshidabad region. Berhampore subdivision covers an area of approximately 1195. 57 km² with coordinates of 23˚55' N and 88˚30' E. Samples were collected from different waterlogging areas like rivers, ponds, lakes, paddy fields, etc. In this study 34 cyanobacterial species belonging to 22 genera were documented. Among these, the most dominant genus was *Oscillatoria,* with 5 species, followed by *Aphanocapsa*, *Pseudanabaena*, *Spirulina*, *Lyngbya*, *Phormidium*, *Anabaena*, *Nostoc*, and *Calothrix,* with 2 species each, *Aphanothece*, *Gloeothece*, *Synechocystis, Chroococcus*, *Gloeocapsa*, *Arthospira*, *Tychonema*, *Limnothrix*, *Cylindrospermum*, *Trichormus*, *Macrospermum*, *Rivularia*, and *Hapalosiphon* with 1 species each.

Keywords: Berhampore, Cyanobacteria, Diversity, Freshwater.

INTRODUCTION

Cyanobacteria are morphologically diverse group of pioneering oxygenic phototrophic prokaryotes that appeared about 3. 5 billion years ago, growing in any environment where light and moisture are present. cyanobacteria are renowned for their historical significance in oxygenating Earth's early atmosphere through photosynthesis [1]. Today, they are the key contributors to global oxygen production and nitrogen fixation [2]. Cyanobacteria are also important members of symbiotic relationships with lichens, plants and other phototrophs [3]. Cyanobacteria multiply quickly under favorable conditions, which leads to harmful cyanobacterial blooms. Toxins produced by these cyanobacterial blooms produce toxins that have severe impact on aquatic ecosystems, wildlife, and humans. [4]. The pH range for cyanobacteria growth is neutral to slightly alkaline [5]. pH played an important role in the establishment of cyanobacterial diversity [6]. Systematic surveys of cyanobacteria in West Bengal were done by various workers[7-19]. Very little work has been done on cyanobacterial diversity in Murshidabad district, among these few are, Pal and Santra [20] studied the algal flora of Murshidabad for the first time;They also reported different cyanobacterial species in Berhampore and its adjoining areas [21]. According to recent findings Das [22] studied the variation in thermal traits and plankton assemblage patterns induced by coal power plant discharge in the Ganga River, but they have only reported a few cyanobacterial species from Murshidabad. Therefore, an attempt has been made to study the detailed cyanobacterial diversity in Berhampore subdivision of Murshidabad district.

MATERIALS AND METHODS

Study area

Berhampore subdivision covers an area approximately 1195. 57 km² with coordinates of 23°55' N latitudes and 88°30' E longitudes. The study was conducted in each block of this subdivision (Fig 2b) and the map was constructed using Software (ARC Gis 10. 8. 1). The Bhagirathi River divides the subdivision into two regions, Rarh on the west and Bagri on the east, which give rise to many freshwater bodies suitable for cyanobacterial growth.

Isolation and Characterizations of Samples

Samples were collected from different collection sites; geographical locations of each place were taken by Google Earth Mobile app (Table 1) and pH of each collection sites were measured by (Table 1) a digital pH meter . Collected samples were immediately brought to the lab and temporary slides were prepared from each sample and observed under a trinocular bright-field microscope equipped with a digital camera and a computer running software (Carl Zeiss Primo Star Microscope 4150500-0054-000). All samples were identified based on their morphological features like thallus colour, shape, size of cell, heterocyst, akinetes, and also the colony characteristics, samples were identified using standard monographs of Desikachary T. V[23], Komarek and Anagnostidis [24] [25], Komarek [26].

Purification Preservation and Maintenance of samples

After identification a portion of samples were preserved in 4% Formaldehyde solution and submitted to the Applied Phycology Laboratory of Ramakrishna Mission Vivekananda Centenary College. A portion of sample was then transferred to freshly prepared ± BG-11 medium [27] and culture was maintained under 28±2° C with illumination at 25-30 µmol photon $m^{-2}S^{-2}$ white light and aeration. Pure Cultures were done by several serial dilution and Agar Plate Methods [28].

Diversity Analysis

The alpha diversity is an important measures of species variability within specific ecosystem of habitats which can describe the dominance of different strains among the sampling sites. So, there by four diversity indices are calculated and they are described as follows:

$$\%\ Frequency\ of\ species = \frac{No.\ of\ sampling\ sites\ in\ which\ species\ recorded}{Total\ number\ of\ sampling\ sites\ studied} \times 100$$ [Supplementary table 1]

$$Shannon\text{-}Wiener\ Diversity\ Index\ H' = -\sum_{i=1}^{N} (pi \ln (pi))$$ [29]

Where, *pi* refers to proportion of species *I*, *N*is considered as number of species in total.

Simpson's Index (1-*D*) = 1-$\sum_{i=1}^{N}(pi)^2$ [30]

Where, *pi* refers to relative abundance of recorded species *i*, *N* represents the total number of species.

Dominance Index according to Berger-Parker (*BP*)=$\frac{n_{max}}{N}$ [31]

Where, n_{max} is the number of individuals in the most abundant species, *N* is the total number of individuals in the sample.

Margalef's index (*Dmg*) = $\frac{(S-1)}{\ln (N)}$[32]

Where, *S* is the number of species, *N* is the total number of individuals in the sample.

RESULTS

Total number of 34 cyanobacterial species belongs to 22 genera (Photo plate 1,2,3) were documented from the study area. Among the different cyanobacterial taxa most dominant genera was *Oscillatoria* with 5 species followed by *Aphanocapsa*, *Pseudanabaena*, *Spirulina*, *Lyngbya*, *Phormidium*, *Anabaena*, *Nostoc*, *Calothrix* with 2 species. *Aphanothece*, *Gloeothece*, *Synechocystis*, *Chorococcous*, *Gloeocapsa*, *Arthospira*, *Tychonema*, *Limnothrix*, *Cylindrospermum*, *Trichormus*, *Macrospermum*, *Rivularia*, *Hapalosiphon* with 1 species each. Detailed description of cyanobacterial strains are as follows as per Komarek and Anagnostidis [24] [25], Komarek [26].

Phylum: Cyanobacteria
Class: Cyanophyceae
Order: Chroococcales
Family: Microcystaceae
Genus: *Aphanocapsa*

Aphanocapsa musicola (Meneghni) Wille, Photo plate 3, fig. A
(Komarek 1998, p. 155 fig:181)
Description: Colonies colourless, Yellowish to dark blue-green or olive green, formless, sometimes unite into an amorphous mass with densely packed cells; cells sometimes surrounded by individual gelatinous envelopes. Cells spherical, blue green; 2-4 µm in diam
Habitat: Free floating on shallow stagnant water

Aphanocapsa parietina Nägeli, Photo plate 3, fig. F-G
(Komarek 1998, p. 158, fig. 190)
Description: Cell spherical, 4. 5-5. 5µm wide, many celled colonies, sheath transparent.
Habitat: Attached to the cemented wall
Genus: *Aphanothece*

Aphanothece microscopica Nageli, Photo plate 3, fig. E
(T. V Desikachary1959 p. 142, Pl. 22, Figs-4, 5, 9; Komarek 1998, p. 84 fig. 72c)
Description: Thallus small gelatinous, blue green colour at first rounded later amorphous, cell oblong cylindrical, more or less 4. 5µm broad, cell 2µm as long as broad, individual distinct sheaths.
Habitat: Attached to the mud.
Genus: *Gloeothece*

Gloeothece rupestris (Lyngbye) Bornet in Witterock et Nordestedt, Photo plate 3, fig. D
(**Komarek**1998, p. 98 fig: 181)
Description: Colonies small with 2 cells, enveloped by common Sheaths, more or less oval and mucilaginous, Gelatinous envelopes around cells, colourless, pale blue green to olive green,3. 6-4. 6 µm in diam.
Habitat: Attached to the grass
Genus: *Synechocystis*

Synechocystis pevalekii Ercegovic,Photo plate 3, fig. B
(komarek 1998, p. 143, fig. 163)
Description:cells spherical to hemispherical, cell bredth 3. 5µm wide, blue green in colour.
Habitat: Attached to the mud
Family: Chroococcaceae
Genus: *Chroococcus*

Chroococcus minutus (Kutzing) Nageli, Photo plate 3, fig. H
(T. V Desikachary1959, p. 103 and 105, fig. 5)
Description: Cell width 3-10µm, sheath colourless, envelopes thin.
Habitat: Free floating
Order: Chroococcidiopsidales
Family: Gloeocapsaceae
Genus: *Gloeocapsa*

Gloeocapsa gelatinosa Kutzing, Photo plate 3, fig. C
(T. V Desikachary1959, p. 114 and 139plate 27 fig: 6; Komarek 1998, p. 239, fig. 308)
Description: Cells Without sheath is about 2. 5µm wide and with sheath 6. 2-10µm wide, blue green; colonies about 25µm diam; sheath colourless, seemingly thin when old lamellated.
Habitat: Found on the side of cemented drain
Order : Pseudanabaenales
Family: Pseudanabaenaceae
Genus: *Limnothrix*

Limnothrix obliqueacuminata (Skuja) Meffert, Photo plate 3, fig. L
(Komarek 2005, p. 96 and 99, fig. 83)
Description: Trichomes straight or slightly curved, length of cell 3. 33µm, breadth of trichome 2. 01µm, pale olive green in colour, apical cells ±pointed, without calyptra, sometimes slightly arcuated.
Habitat: Free floating on bill
Genus: *Pseudanabaena*

Pseudanabaena recta Komarek and Cornberg, Photo plate 3, fig. O
(Komarek 2005, p. 92, fig. 75 a-d)
Description: Solitary trichomes, straight or arcuated, with 3-14 cells, yellow green in colour, breadth of cell 1. 5µm, usually small areotopes near the end.
Habitat: Attached to cemented drains.

Pseudanabaena lemnetica (Lemmermann) Komarek, Photo plate 3, fig. P
(Komarek 2005, p. 84, fig. 60)
Description: Trichome straight, 1. 2-1. 5µm wide, cell long cylindrical,4-12µm long, olive blue green in colour, apical cell rounded.
Habitat: Found on mud
Order: Spirulinales
Family: Spirulinaceae
Genus: *Spirulina*

Spirulina subsalasa Oersted ex Gomont, Photo plate 3, fig. I
(Komarek2005, p. 149 and 150, fig. 176 d)

Description: Thallus soft**,** thin, bright blue green, usually in clusters, regularly dense screw-like coiled, 0. 8µm wide, spirals length 3µm.
Habitat: Attached to the submerged stone

Spirulina laxa G. S. West, Photo plate 3, fig. J
(Komarek 2005, p. 140 and 141, fig-159)
Description-Trichomes blue-green 2. 791 µm wide, distance between coils 15. 33µm, coils left-handed, cells shorter than wide, apical cell rounded.
Habitat: Attached to the Mud on Paddy Field
Class: Oscillatoriales
Family: Microcoleaceae
Genus: *Arthospira*

***Arthospira platensis* var. Tenuis** (Rao) Desikachary, Photo plate 3, fig. K
(Komarek 2005, p. 349 and 352, fig. 488,492)
Description: Plant mass greyish brown; trichomes pale blue green of uniform, width 5. 1-6. 4µm, broad in regular spirals, spirals 30-34µm broad not constricted at the joints, cell disc shaped, end cell with rounded apices.
Habitat: Free floating on pond.
Genus: *Lyngbya*

Lyngbya martensiana Meneghini ex Gomont, Photo plate 3, fig. Q
(Komarek 2005, p. 612 and 615, fig. 931)
Description: Thallus pale blue green to dark blue green, filament 8. 19µm wide, sheath hyaline, thick, breadth of trichome 4. 47µm in length, granules visible.
Habitat: Free floating on Bill

Lyngbya spiralis Geitler, Photo plate 3, fig. R
(Komarek 2005, p. 610 and 613, fig. 926b)
Description: Thallus formless, trichome bright blue green, 4. 5-5µm wide, not constricted at cross-wall, cells 1. 5-2. 5µm long, apical cells widely rounded.
Habitat: Attached to grass on paddy field
Genus: *Tychonema*

Tychonema rhodonema (Skuja) Anagnostidis and Komarek, Photo plate 4, fig. E
(Komarek 2005, p. 374 and 375, fig. 528)
Description: Trichome solitary, free floating, straight, cylindrical, not constricted, 4. 9µm wide, cells isodiametric,4-10µm long, slightly violet content, with granules at cross walls.
Habitat: Attached to the grass
Family: Oscillatoriaceae
Genus: *Oscillatoria*

Oscillatoria limosa C. Agardh ex Gomont, Photo plate 3, fig. S
(Komarek 2005, p. 593 and 595, fig. 886)
Description: Trichome bright blue green, breadth of trichome 7. 97µm, length of cell 3. 07µm.
Habitat: Attached to the grass on paddy field

Oscillatoria tenuis C. Agardh ex Gomont, Photo plate 4, fig. A
(Komarek 2005, p. 587 and 588, fig. 878c)
Description: Thallus flat, blue green to olive green, mucilage thin, trichome straight, cells always shorter than wide,2-3. 5µm long, apical cell rounded.

Habitat: Attached to the mud on paddy field

Oscillatoria proboscida Gomont, Photo plate 4, fig. B
(Komarek 2005, p. 596 and 597, fig. 891a)
Description: Trichome bright blue green, rarely olive brown, sporadically irregularly screw like coiled at the end,9-18µm, capitate, cells 1. 5µm long.
Habitat: Free floating in stagnant water

Oscillatoria ornataKutzing ex Gomont, Photo plate 4, fig. C
(Komarek 2005, p. 582 and 583, fig. 663,867)
Description: Thallus blue green in form, at the end screw like coiled, 6-11. 5µm wide, cell shorter than wide 2-5µm long, apical cell rounded without calyptra or thickened cell wall.
Habitat: Attached to the mud

***Oscillatoria* sp.**
Photo plate 4, fig. D
Description: Bright yellow green in mats, cell 3. 02µm broad, length of trichome 31. 16µm.
Habitat: Free floating on Field.
Genus: *Phormidium*

Phormidium animale (Agardh ex Gomont) Anagnostidis et Komarek, Photo plate 3, fig. M
(Komarek 2005, p. 407 and 408, fig. 575)
Description: Both ends slightly bend, breadth of trichome 2. 93µm, cell bredth 2. 19µm, total length of the filament 91. 291µm, blue green in colour.
Habitat: Attached to the mud.

Phormidium breve (Kutzing ex Gomont) Anagnostidis and Komarek, Photo plate 3, fig. N
(Komarek 2005, p. 420 and 421, fig. 599 c, d)
Description: thallus expanded, blue green to olive green in colour, trichome slightly curved, 4-6. 5 µm long, cells 1/2-1/3 as long as wide, 1. 5-3µm long.
Habitat: Free floating on shallow stagnant water
Order: Nostocales
Family:Aphanizomenonaceae
Genus: *Anabaena*

Anabaena sphaerica Bornet *et* Flahault, Photo plate 4, fig. F
(Komarek 2013, p. 796, Fig. 992 a)
Description: Trichomes ± straight or flexuous, cell barrel-shaped up to almost spherical, 5-6µm wide. Heterocyst spherical, intercalary, solitary, 6-7µm in diameter. Akinetes attached to the heterocyst on one or both side, 12-18µm.
Habitat: Attached to mud on bill.

Anabaena torulosa Lagerheim ex Bornet and Flahault, Photo plate 4, fig. G
(Komarek 2013, p. 801, fig. 999)
Description: Trichome flexuous, cylindrical, joined and entangled in the blue green mats to ends sometimes slightly cylindrical, cell barrel shaped 4. 2-5µm wide, heterocyst ellipsoidal or almost spherical,6-10µm wide.
Habitat: Attached to grass on paddy field
Genus: *Cylindrospermum*

Cylindrospermum alatosporum F. E.
Fritsch, Photo plate 5, fig. F
(Komarek 2013, p. 878, fig. 1126)

Description
Mats thin, mucilaginous, bright blue-green. Trichomes long, dense and flexuous. Cell more or less cylindrical, longer than wide 3. 5-4µm wide, apical cells barrel-shaped or slightly narrowed and rounded. Heterocyst is oval, 7. 8µm long and 5. 1µm broad. Akinetes solitary, ellipsoidaland attached with heterocyst, 6. 9µm wide.
Habitat: Attached to the mud.
Genus: *Macrospermum*

Macrospermum fuellebornii (Schmidle) Komarek, Photo plate 4, fig. I
(Komarek 2013, p. 868, fig. 1113 and 1114)
Description:
Cells is more or less isodiametric or slightly barrel-shaped,3. 9µm wide and5µm long; apical cell rounded. Akinetes with granular-dotted.
Habitat: Attached to the grass.
Genus: *Trichormus*

Trichormus khannae (Skuja) Komarek and Anagnostidis, Photo plate 4, fig. H
Komarek 2013, p. 944, fig. 1231)
Description: Filaments creeping on the substrate, ±parallel situated, ±straight or bent, solitary or joined to mats, with up to 7µm wide, colourless or yellowish, diffluent sheaths, 15-20µm wide, cell barrel-shaped,2. 5-4µm wide. Heterocyst terminal or intercalary, barrel-shaped or cylindrical 3. 5-6×3-3. 5µm. Akinates in series, slightly ellipsoidal, elongated or spherical, 6. 5-10µm in diameter.
Habitat: Attached to the mud on Paddy Field.
Family: Nostocaceae
Genus: *Nostoc*

Nostoc paludosum Kutzing ex Bornet and Flahault,Photo plate 5, fig. D
(Komarek 2013, p. 800,801 and 802, fig. 1274-1276)
Colonies microscopic, in cluster, irregular, mucilaginous mass, blue green, colourless gelatinous sheath, Trichome flexuous, irregularly coiled, cell barrel-shaped, blue-green, 3-5µm in diameter. Heterocyst spherical or barrel-shaped, 4-8µm in diameter.
Habitat: Attached to grass on paddy field.

Nostoc zetterstedtii Areschoug ex Bornet and Flahault,Photo plate 5, fig. E
(Komarek 2013, p. 973, fig. 1265)
Description: Colonies macroscopics, gelatinous, ±firm, irregularly spherical, hemispherical, lobate, dark olive green or blue-green Individual sheath around the trichomes, confluent, colourless to yellow. Cell is short, barrel-shaped or slightly elongated,3. 9µm wide. Heterocytes spherical ,6. 9µm in long.
Habitat: Attached to the submersed grass
Family: Rivulariaceae
Genus: *Calothrix*

Calothrix marchica* Var. *Intermedia C. B. Rao,Photo plate 5, fig. A
(Komarek 2013, p. 242, fig. 245)
Description: Filaments always solitary, ±straight or slightly coiled, not branched, 5-6µm wide at the base. Sheath thin, narrow, colourless. Trichomes ± straight, continually narrowed towards ends, blue-green,4-5. 5µm wide at the very slightly widened base. Cell quadratic or shortened up to ¼ as long as wide. Heterocyst basal, single, spherical or subspherical, 4-5. 5µm wide.
Habitat: Attached to the mud on paddy field.

Calothrix brevissima G. S. West,Photo plate 5, fig. B
(Komarek 2013, p. 244, fig. 251d)
Description: Filament epiphytic, usually in groups, filaments up to 94µm long,4. 5-7µm wide, not or very slightly narrowed towards ends, cells rarely quadratic at the base, mostly shorter than wide ,3-5µm wide. Terminal cell rounded. Heterocyst basal, hemispherical up to spherical, 2. 5-4µm wide.
Habitat: Attached to the submersed grass on paddy field
Genus: *Rivularia*

Rivularia aquaticaDe-Wildeman,Photo plate 5, fig. C
(Komarek 2013, p. 308, fig. 354)
Description: Colonies ± spherical, soft, without calcareous precipitations, free-living, dark brownish-green. cells 3-13×5. 5-10. 7µm. Heterocyst spherical.
Habitat: Found on the mud
Family: Hapalosiphonaceae
Genus: *Hapalosiphon*

Hapalosiphon pumilus Kirchner ex Bornet and Flahault, Photo plate 5, fig. G. i-iii
(Komarek 2013, p. 517, fig. 629-634)
Description – Colonies tufty, blue green. Filaments densely entangled 7-25 µm wide. Branches vertically divaricated, sometimes erect slightly narrower than main filaments and 6-12 µm wide. Sheath colourless. Cells barrel shaped 7-10×4-5 µm. Heterocyst dimensions similar to vegetative cells.
Habitat: Attached to the grass.

DISCUSSION

An earlier literature review showed the least amount of diversity was explored in this region. Pal and Santra [20] [21] conducted a systematic study, but along with other groups of algae. In this systematic study, 11 sites (Table 1) of the Berhampore Subdivision were studied. More than 90 samples were examined, and 34 cyanobacterial species belonging to 22 genera were characterized and enumerated. Out of these 7, the coccoid form of cyanobacteria belongs to 6 genera. 16 non-heterocytous forms of cyanobacteria belonging to 8 genera were identified. Out of these 16 species, Oscillatoria was the most dominant. Heterocystous cyanobacteria significantly contribute to nitrogen fixation. In this study, 11 heterocystous cyanobacteria belong to 8 genera, mainly paddy fields and alleged water bodies. In this study, the Shannon-Wiener index (H') is 3. 42 (Table 2), which indicates the subdivision is highly diverse [29]. The Simpson Index (D) quantifies the likelihood of randomly selecting the same species from various ecological habitats [30]. The Simpson Index value in our study is 0. 98 (Table 2), which indicates that species richness is high and the diversity is healthy. The Berger-Parker Dominance Index highlighted the dominance of the most abundant species in this study [31], the value 0. 04 (Table 2), which indicates a moderate level of dominance by a single species. Margalef's Richness Index measures species richness while considering sample size [32]. In this study, the value is 7. 93 (Table 2), which indicates the Berhampore subdivision has high species richness. pH is one of the major components for cyanobacterial diversity [33]. During the study, the highest pH was recorded at 8. 4. *Chroococcus minutus* was recorded at pH 8. 4. Diversity indices provide valuable insights into ecosystem health, species evenness, and richness based on the observed species and individual counts, helping to assess the ecological balance and diversity within the studied environment. Considering the earlier literature review, cyanobacterial diversity of the Murshidabad district is still yet to be explored. From this taxonomic study, one can easily explain the cyanobacterial biodiversity of the Berhampore subdivision. This study will fill the gap in our existing knowledge of the biodiversity of cyanobacteria in the Berhampore subdivision. Further molecular studies along with morphological data will provide the world with new insights.

ACKNOWLEDGEMENT

The authors are thankful to Principal, Ramakrishna Mission Vivekananda Centenary College, Rahara, Kolkata, West Bengal for providing necessary laboratory facilities carrying out the work.

ABSTRACT

The intervention of large language models (LLMs) extends beyond areas like natural language processing, autonomous systems, and recommendation systems. Additionally, the growth of LLMs has raised concerns about their performance, productivity, and resource utilization. This comprehensive discussion offers insights into various techniques and measures that can improve the performance and efficiency of LLMs, including methods such as data pruning, mixed precision training, early exit optimization, and resource-efficient architectures. In addition, we address perceived emerging trends in assessing LLMs, including those involving LLMs as judges in constructing domain-specific standards for LLM evaluation. This study aims to lay the foundation for further advancements in designing more resilient and sustainable LLMs closely aligned with actual practice. It has shown how performance-

improving methods, including fine-tuning techniques, retrieval augmentation, and knowledge distillation, have successfully transformed LLMs for downstream tasks and made their performance better. This survey site is intended to be a valuable resource for researchers and practitioners to fine-tune and evaluate large language models.

Keywords: Large Language Models, Performance Optimization, Efficiency, Benchmarking, Resource Management, Evaluation Methodologies.

INTRODUCTION

Overview of Large Language Models [LLMs]

Large language models, or LLM for short, are one of the most influential technologies that have had a large influence on AI's advancement and have changed the progress of natural language processing, recommendations, and several autonomous agents [1]. To understand the weak patterns and produce humanist text, LLMs learn text data with millions of records [2]. Recent works on 4 include various applications like question answering, text summarization, code generation, and more, which can be witnessed in recent LLMs such as GPT-3 [2], BERT [3], and T5, where flexibility is seen to be a prime aspect of LLM's ability**.**

Challenges in LLM Performance and Efficiency

As much as large language models have great abilities, the performance and efficiency of large number computation scales and complexities affect them [4]. As the usage of layers rises in LLMs, the training and deployment cost becomes too expensive because of the humongous parameter size, which could be in billions or trillions [1]; further, owing to the training energy consumption, questions regarding the mental impact and environmental consequence and sustainability of such models are posed [5]. Increasing the use of computational resources and developing efficient computational architectures are now the topics of extensive study to tackle these issues [5].

Motivation and Scope of the Survey

LLM performance and efficiency improvement have led to several methods, such asologies, standards, and optimization tools. This state of affairs has placed researchers and practitioners in a challenging position to identify the appropriate techniques for their specific uses. This survey aims to provide a systematic and more detailed way to identify the methods and standards to improve LLM performance and overall efficiency. Although this survey is versatile, the authors present topics like efficient methods for training with limited resources, assessment measures, methods to improve performance, and optimization approaches for subsequent tasks [Mei *et al*., 2021]. Through synthesizing and integrating the latest research findings, this work aims to offer some methodological and pragmatic observation points to the researchers and practitioners – the developmental and assessing participants in the large language models [6]. In this survey, we will explain modern approaches, which are data pruning [7], mixed precision training [8], early exiting optimization [9], and resource-efficient architecture. So, it will also be investigated how the new perspectives in LLE evaluation, including using LLMs as judges [10] and building domain-specific benchmarks [6], are going to develop. In this way, with the help of the provided detailed introduction to these developments, we would like to encourage the emergence. Robust and economically viable models for operational purposes [11].

Resource - Efficient Training Methodologies

Modeling for large language models is an expensive endeavor that requires a significant amount of computational power and energy consumption [12]. To overcome these challenges, different resource-efficient training approaches have been suggested by the researchers, which were directed towards decreasing the computational cost while at the same time retaining the model performance [5]. This section presents, as Figure 1 shows, data pruning techniques, mixed precision training, early exiting optimization, and efficient architectures and components that lead to resource-efficient LLM training.

Data Pruning Techniques

Data pruning techniques focus on finding and eliminating redundant or less informative samples from the training dataset, thereby reducing the cost of computation with huge data volume [7]. Two popular data pruning techniques are influence score and effort score-based methods and diversity-based coreset selection.

Influence Score and Effort Score

Two types of scores are used to specify the value of each single example of training in learning, known as the Influence score and effort score [13]. Following these scores, A researcher selects samples with high scores, i.e., samples having more influence on the model's performance, and discards the lower-scoring ones [Sui *et al*., 2023], thus increasing the efficiency of computational resource usage during training.

Diversity-based Coreset Selection

To characterize the total diversity of the data, a diversity-based coreset is selected to generate a representative subset of the required training data [14]. The choice of diverse samples reduces the computational load to a minimum by allowing the model to learn different patterns and structures concurrently [9]. There are different algorithms that have been used to find representative and diversified subsets of the training data such as K-means clustering and submodular optimization [15].

Mixed Precision Training

Mixed precision training is the approach that takes advantage of the capabilities of modern hardware to perform calculations on lower precision data types, specifically half-precision floating-point [FP16]. With some operations precision decreased, mixed precision training leads to LLM training inertia and computational cost reduction [8]. This method makes it possible to use much larger batch sizes and, consequently, a faster training time without loss of model performance.

Early Exiting Optimization

Early exit optimization is a method where models terminate computations based on confidence intervals [16]. LLMs, early exiting, can be employed with self-attention layers by LLMs when the model can, at some point, terminate the computation if the attention weights fall below a certain threshold. When early exiting optimization is employed for LLM inference, the model cost and latency will be reduced by dynamically tuning the model depth concerning the complexity of the input.

Efficient Architectures and Components

Creating efficient architectures and components is essential for resource-effective LLM training. Self-attention mechanisms, multi-head attention, and key-value cache optimization are the important aspects under this umbrella.

Self-Attention Mechanisms

The self-attention mechanism is at the heart of the transformer-based LLMs; the architecture allows the model to work with the sequential dependencies in the input [17]. However, the self-attention that involves the computation of the quadratic time is very costly, especially when handling sequences of 20 tokens. To overcome the computational complexity issues, some modified self-attention functions have been introduced, which include Sparse attention [18] and Linear attention [19].

Multi-Head Attention

Multi-head attention enables LLMs to read different parts of a sequence in one set of attention [17]. However, the complexity in the computation of multi-head attention increases with the number of heads in the same proportion of the number of heads. To overcome this issue, researchers have come up with two techniques, namely head pruning [20] and attention head sharing [21], to eliminate the attention heads and achieve the best outcome.

Key-Value Cache Optimization

Key-value cache optimization is a method that reduces memory wastage and computation costs by focusing on redundancy during computation [22]. LLMs can cache keys and value matrices to reuse them at later times, resulting in an increase in efficiency in training. This key-value cache optimization shows improvement in performance in autoregressive language model tasks and reduces memory wastage in large capacity.(Table 1).

Evaluation Methodologies and Benchmarks

For the reader to be able to appreciate the possibilities that are presented by the LLMs as well as the drawbacks, it is important to look at their performance and Efficiency [25]. In the subsequent category, we examine the various assessment methodologies and standards for the LLM-as-a-judge paradigm, domain-specific standards, and assessment criteria metrics and protocols.

LLM-as-a-Judge Paradigm(Fig: 2)

Pairwise Comparison Approaches

In order to assess and rank the quality of different text samples or model outputs, the pairwise comparison approach employs LLMs [6]. Here, the LLM scores the given text samples on the basis of their fluency, coherence, and so on [Mei *et al*., 2021]. It is possible to order the samples or models under consideration in the research. Nevertheless, the LLM judgment can be subjective and irrational in its decision-making if the above-mentioned method is used, which is based on a pairwise comparison approach [10].

Prompt Scoring Techniques

In this kind of scoring approach, the LLMs provide scores or ratings to every text sample individually on the basis of set prompts or queries [9]. It is to highlight language aspects such as grammar, semantics, task-related aspects, etc., thus enabling the LLMs to assign ratings or scores to each sample and therefore quality assessment. The prompt scoring techniques have been seen to perform better than pairwise comparisons and also reveal high congruence with the judgment made by humans [11].

Domain-Specific Benchmarks

Custom-ruled benchmarks are made to evaluate LLMs in particular areas or domains, such as natural language understanding, code intelligence, and recommendation systems. The utilization of these criteria enables LLMs to showcase their capabilities most effectively in authentic contexts [26].

Natural Language Understanding

NLU benchmarks test how well LLMs are with the usage of natural language in the text [27]. Around GLUE benchmark [28], Super GLUE [29], and SQuAD [30] are the most used NLU benchmarks. These milestones deal with a variety of operations like feeling analysis, textual entailment, and answering questions, therefore providing an extensive scale of checking the LLMs 'abilities to understand language.

Code Intelligence

Code intelligence benchmarks are measures of the LLM's ability to generate, understand, and even critically analyze programming code [28]. Marks like CodeXGLUE [29] and HumanEval [30] are considered to judge the efficacy of the LLMs [Language *et al*.] in areas such as code generation, code completion, and error fixing. Such milestones unfold the LLM's ability to assist the developers and automate programming tasks to a certain extent.

Recommendation Systems

The LLM's performance as the recommended system is examined through benchmarks that test the LLMs' ability to generate personalized recommendations according to user specifications and product specifics [31]. Examples include Amazon Product Data [He *et al*., 2016] and Movielens [32], which measure the task performance of LLMs and

report outcomes such as item ranking and item rating prediction. With these benchmarks, the LLMs are analyzed and improved to enhance the recommendation process and make it engaging for users.

Evaluation Metrics and Protocols

Evaluation metrics and protocols are inherently necessary for assessing the performance of LLMs and, subsequently, ensuring the comparability of different models. Evaluation metrics employed widely are perplexity, BLEU, rouge, and f1 score. These indicators have a different dimension, which captures various aspects of language quality, like fluency, coherence, and task-specific ability. Evaluation procedures that are endowed with cross-validation and held-out testing will create the value of LLM evaluations [Xu *et al.*,2022].

Performance Enhancement Techniques

It discusses various techniques that can be applied to improve the performance of LLMs, and the most important area of research in natural language processing is performance. Enhancement of large language models [1] Here, we discuss various techniques that are used to enhance the performance of large language models, among which include fine-tuning approaches, retrieval augmentation, and knowledge distillation. (Table: 2)

Fine-Tuning Strategies

Fine-tuning is a process of adapting a pre-trained LLM for certain target tasks, which is a usual practice [38]. Fine-tuning allows LLMs to adapt to new data during model training for the target task, hence enhancing the performance of the model [3]. Some of the well-known fine-tuning schemes include self-augmented prompting and low-rank adaptation.

Self-Augmented Prompting

Auto-augmented prompting is a fine-tuning method that leverages the generative nature of LLMs to generate additional training data [39]. By providing several seed examples, the self-augmented prompting method is capable of making the LLM come up with new examples and thus expand the training data and improve the model performance in low resource conditions [Ye *et al.*, 2023]. This has been demonstrated to be rather effective, particularly in scenarios where it is challenging or expensive to obtain labeled data.

Low-Rank Adaptation

Low-rank adaptation is a parameter-efficient fine-tuning approach that can re-configure a pre-trained LLM for a specific task by learning a small set of task-specific parameters only [40]. Low-rank adaptation, instead of fine-tuning the whole model, adds a low-rank matrix, which is also learned along with the pre-trained parameters [41]. This approach brings down the trainable parameters count to a considerably low value but, at the same time, maintains the full fine-tuning capability [42]. Low-rank adaption is also applied in several NLP applications, such as text classification and question answering.

Retrieval Augmentation

Retrieval augmentation is a way of enhancing LLMs, which involves incorporating external knowledge sources into the actual generation of responses [43]. In a way, the retrieval augmentation enables LLMs to obtain the right information from large knowledge bases or document collections, which may contain much more information than the model's training corpus [44]. This was because it improved LLMs' performance in knowledge-intensive tasks such as open-domain question answering and fact verification. Retrieval augmentation typically involves a two-stage process: This means that the process involves [1] search for the documents or passages that are relevant to the input query and [2] incorporation of the identified information into the LLM's prediction [45]. Some of the retrieval strategies proposed are dense passage retrieval [46] and sparse vector retrieval [47] to facilitate a quick and precise search and retrieval of information from large-scale knowledge bases. Later on, the obtained information is combined with the LLM's output by employing techniques such as attention mechanisms [48] or knowledge-aware decoding.

Knowledge Distillation

Knowledge distillation is a technique that transfers knowledge of a big, complex model [teacher] to a smaller, more efficient model [student] [49]. In the case of LLMs, knowledge distillation allows the compression of big models in a more practical and usable format and sustains their performance [50]. The student model obtains the knowledge and reasoning abilities of the larger model by imitating the outputs of the teacher model [51]. Such knowledge distillation of LLMs normally involves training the student model to mimic the teacher model on a large set of text. The student model reduces the disparity between its expected outputs and those of the teacher model; thus, in the process, attempts to emulate the teacher model's answers [8]. Some of the distillation targets, like cross-entropy loss and Kullback-Leibler divergence, have been employed to control the learning process [5]. Knowledge distillation has been used in many LLM architectures, including transformer-based models [17] and autoregressive language models [52]. The final models that are derived are as effective as the original models and, at the same time, are computationally efficient and easier to implement in situations where there are resource challenges [53].

Efficiency Optimization in Downstream

So, it is crucial to have adequate and fast inference methods as well as model compression and hardware acceleration techniques for using large language models in small-devices realistic applications [Xu *et al.*, 2022]. In this part, different techniques that are applied to improve the performance of LLMs in downstream tasks are explained.

Efficient Inference Strategies

Framing plays, such as efficiency inference-like learning, are aimed toward decreasing the computational complexity and time of LLM inference while the model performance is kept constant [5]. Dynamic inference is one of the most frequently used techniques and is a method of adjusting the depth of calculations in the model based on the input's complexity [54]. As a result of this, dynamic inference will help to reduce the average inference time significantly by applying early exits on the layers or at the confidence thresholds [55]. Input pruning is another effective strategy for inference, where the irrelevant or redundant parts of the input sequence are identified and pruned [56]. Among the most informative parts of the input, which are the focus of the LLMs, computational is cut, and the speed of inference is improved [8]. Approaches, which include techniques like attention-based pruning [57] [58] and importance sampling [59], have been suggested to detect and, thus, prioritize potential input parts in an effective manner.

Model Compression Techniques

The main task of model compression techniques is to diminish the size and computational complexity of LLMs while still retaining their performance [58]. Quantization represents the common method for compression that degrades the precisions of model weights and activation [60]. Quantization by representing weights and activations with fewer bits can greatly decrease the memory footprint and computational cost of LLMs. Pruning is one of the most efficient compression techniques that eliminates redundant or less significant weights in the model [61]. Pruning is the process of eliminating weights with small magnitudes or low contributions to the model's output, and it can reduce the model size by a substantial amount without pronounced performance degradation [62]. The pruned model should be regular and easy for effective hardware implementation and high performance; therefore, structured pruning methods tend to achieve these objectives, two of them being block pruning [63] and head pruning [20]. The knowledge distillation, touched upon in the previous section, is another important approach for model compression [49]. Through the use of the technique known as distillation, a smaller student model can be taught to replicate the behavior of a larger model. As the teacher and student models can be quite large, knowledge distillation can inherit the knowledge and reasoning capabilities of the teacher and create a smaller and more efficient student model [51].

Hardware Acceleration

Hardware acceleration significantly contributes to the efficiency of LLM inference. The utilization of hardware architectures that have specializations, such as GPUs and TPUs, has been claimed to speed up large-scale neural network computation [64]. The LLM architectures provide huge parallelism and high memory bandwidth, which enables fast and effective implementation of matrix operations, which are the underlying building blocks of LLMs [65].

To improve the performance of LLM inference on hardware accelerators, diverse methods have been suggested. Kernel fusion is a method that merges many small kernel operations to form a considerably larger kernel, hence reducing the overhead of kernel launches and data transfers [66]. Fusion of kernel has been demonstrated to convulsively enhance the performance of transformer-based models in GPUs [67]. The other hardware acceleration approach is mixed-precision training and inference, which exploits the fact that modern hardware is capable of doing calculations at different precision levels [23]. Lowering the precision [e.g., FP16] instead of single-precision [i.e., FP32] at highly computation-sensitive tasks mixed-precision methodologies can lower the memory footprint and computation cost of LLMs without model accuracy degradation [68]. Some customized hardware designs were also suggested to increase the performance of LLM inference. For instance, Efficient Transformer [EFT] architecture [69] is hardware design optimized for computationally efficient execution of self-attention and feedforward layers in transformer-based models. Compared to general-purpose hardware, EFT gains large speed-ups and energy savings with sparsity and regularity of transformer computations.

Emerging Trends and Future Directions

The large language models are a rapidly changing field with new trends and directions emerging to address the challenges and opportunities posed by these powerful models [1]. This subsection deals with some of the recent and future trends in LLM research and development, such as multimodal LLMs, federated learning for privacy, scaling laws and model architectures, and real-world applications and deployment challenges.

Multimodal LLMs Multimodal

LLMs are a new paradigm that intends to improve the performance of the LLMs by including more modes, such as vision or speech, in addition to text [70]. Utilizing the complementing information from different modalities, multimodal LLMs can have a comprehensive perception of the world and perform demanding tasks that need to be conducted within a several-domain framework [71]. Recent progress in multimodal LLMs comprises such models as ViLBERT [72], which, in turn, blends transformer-based architectures for text and vision, and CLIP [73], which learns visual concepts from natural language supervision. These models have shown excellent performance in tasks like visual question answering, image captioning, and text-to-image retrieval [63]. Further research directions of multimodal LLMs would be designing more powerful and scalable architectures to process and combine different modalities [74], seeking new training objectives and alignment strategies for representation across modalities [Tan *et al*., 2022], and extending multimodal LLM to some other domains such as robotics and embodied AI [75](Table: 3).

Federated Learning for Privacy Preservation

Federated learning is a new emergent paradigm enabling the training of LLMs with decentralized data under privacy [76]. Moreover, federated learning is collaborative in that several participants work to train a common model without the exchange of their original data, thus reducing the threat to privacy and ensuring the appropriate level of data secrecy. Federated learning is an option to be considered in the case of LLMs, which permits the use of various sensitive data sources [personal devices, healthcare records, etc. without user privacy violation [5]. Federated language models [LLMs] have been introduced as a solution to privacy-preserving language modeling and downstream tasks such as sentiment analysis and named entity recognition [77]. Further research areas in federated learning for LLMs are designing highly efficient communication protocols and aggregation mechanisms for large-scale federated training [78], handling issues of data heterogeneity and non-IID distributions [79], and guaranteeing the robustness and fairness of federated LLMs [80].

Scaling Laws and Model Architectures

The importance of scaling laws and model architectures for the creation of LLMs lies in the fact that they define the relative sizes and performances of such models [81]. Scaling laws give a description of the relationship between model size, computational resources, and performance, thus allowing one to get an idea of the best model scaling strategies [82]. More recent studies have demonstrated that larger model sizes and more training data indeed benefit the performance of LLMs [2]. Regardless, the effect of computing cost and environment in training and deploying of large LLMs are concerning [12]. To create an efficient and sustainable scaling laws and model architectures strategies

like model compression [58] and neural architecture search [83] are explored. On the other hand, to obtain more performance-efficient trade-offs, new model architectures need to be studied. To model long-term dependencies in language modeling, the Transformer-XL architecture [84] implements segment-level recurrence and relative positional encodings, and to overcome the quadratic complexity of the self-attention and allow more effective training and inference of LLMs, the architecture of the Performer [85] suggests a linearized attention.

Real-World Applications and Deployment Challenges

Constructing models that are practical in real applications like natural language inter- faces, content generation, and decision support systems is the principal goal of LLM research [1], and issues like the robustness of the model, interpretability, and ethical issues appear when LLMs are deployed in real-world applications [86]. The capacity of LLMs to retain their performance and to generalize well to new and unseen data is known as the robustness of a model [87]. Different techniques are used to improve it in LLMs, such as adversarial training [88], data augmentation [15], and domain adaptation [89]. Another key element of LLM implementation is interpretability, which allows users to understand and believe in the model's predictions [90]. To enhance this, methods like restricting attention and probing the classifiers are used. LLMs can have significant societal effects such as biased perpetuating and harmful generating content, so the ethical side is considered to be the principal aspect [4], and management of this issue requires a multidisciplinary approach that should involve the researchers, the policymakers, and the stakeholders who are from various backgrounds. Bias detection and mitigation [91], guaranteeing fairness and accountability [92], and advancing the innovation of responsible practices [93] are some of the feasible approaches.

Discussion and findings

The current methodologies and benchmarks for the improvement of large language model [LLM] performance and efficiency are introduced in this extensive review. We have talked about cost-effective training approaches, evaluation models, performance improvement tactics, and optimization methods for downstream activities. Additionally, we have pointed out the emerging trends and future directions in LLM research, such as multimodal LLMs, federated learning for privacy preservation, scaling laws and model architectures, and real-world applications and deployment challenges.

Summary of Key Findings

Our survey revealed several important findings in the area of LLM performance and efficiency optimization. Some pruning techniques are influence score and diversity-based corset selection, which have shown great potential to reduce com- the computational cost of LLM training while maintaining model performance [7, 9]. Mixed precision training and early exiting optimization are other strategies that have become effective in improving the efficiency of LLM training and inferences [8]. LLM-as-a-Judge paradigm is one of the evaluation methodologies used, where the pairwise comparison methods, as well as the prompt scoring techniques, exhibit a high correlation [6, 11] with human judgments. Specific benchmarks for domains such as natural language understanding, code intelligence, and recommendation systems have been created to assess LLM performance in real-world contexts [28, 30, 31]. The approaches for enhancing the performance, such as self-supplement antici- pation, lower-follower adaptation, retrieval improvement, and knowing boiling, have brought a significant improvement in LLM performance on different downstream tasks [39]. Efficient inference strategies, model compression techniques, and hardware acceleration have also been investigated to improve the efficiency of LLM deployment in resource-constrained environments [54, 60, 67].

Open Research Questions and Opportunities

However, outstanding research questions and opportunities exist in spite of the remark- able progress that has been made in the LLM performance and efficiency optimization. One important direction is to architect better, more efficient, and scalable multimodal LLMs to work with and combine information from different modalities [74]. However, another important area is the federated learning approach of LLMs, which is learning from distributed data to preserve privacy [94]. The question of better scaling strategies, which include model compression and neural architecture search, is also an open research issue [58, 83]. Another interesting solution is the research of new model

architectures, which can offer higher performance-efficiency trade-offs like the Transformer-XL [84] and Performer [85]. Many challenges face the real-world application of LLMs, such as model robustness, interpretability, and ethical issues [86]. Nonetheless, one of the critical issues for further study is the development of techniques for LLM's robustness and interpretability, including adversarial training [88] and attention visualization [95]. Investigation of the ethical challenges connected with LLM deployment, such as bias mitigations and responsible innovation, as a topic also requires a multi-disciplinary approach that unites researchers, policymakers, and stakeholders from various sectors [4,93]. In conclusion, this survey has provided a thorough description of methods, metrics, and optimization techniques that contribute to the improvement in the performance and efficiency of large language models. We hope that by providing a summary of the critical findings and open research questions this will encourage more research and innovation in this exciting area, and hence more powerful, scalable, and ethical LLMs for the practical setting.

CONCLUSION

This survey offers useful information through the analysis of resource-efficient training methods, evaluation paradigms, performance improvement techniques, and optimization strategies for downstream tasks, as well as the best practices in LLM development and deployment. It highlights the gravity of methods like data pruning methods, mixed precision training, early exiting optimization, and efficient architectures in the reduction of cost of computation and consumption of resources of LLM training that have demonstrated a lot of potential by maintaining the model performance while increasing the training speed by a big margin. Also, the LLM-as-a-Judge paradigm and domain-specialized benchmarks for LLM evaluations in practical situations are highlighted in this survey results in providing a complete evaluation in a real-world context of their capacity. Performance-improving methods, including fine-tuning techniques, retrieval augmentation, and knowledge distillation have successfully transformed LLMs for downstream tasks and made their performance better. In addition, the study portrays the importance of effective inference techniques, model compression methods, and hardware acceleration in making LLM deployment efficient in resource-constrained settings. Developing further, the survey points out several emerging trends and future research areas in the development of LLM. Multimodal LLMs that integrate vision and speech modalities have the possibility of making language models more holistic and better. Federated learning methods provide a promising answer to the question of training LLMs on distributed data in a privacy-preserving manner. In this respect, the scaling laws, as well as new model architectures, will lead to improvements in LLM effectiveness and economy. Nevertheless, the survey also notes the difficulties attributed to actual application of LLMs which include model robustness, interpretability, and ethical issues. Solving these challenges needs an interdisciplinary approach with researchers, policymakers and stakeholders from different perspectives. All in all, this survey is a rich source for people who develop and deploy LLMs. Having synthesized the most recent developments and open research questions, it sets the stage for future LLM performance and efficiency optimization innovations. In this dynamic field, efficient and scalable applied LLMs should be of importance while LLMs must be designed to be effectively and ethically applied to real-world situations.

ABSTRACT

Indomethacin is an NSAID utilized for treatment of slight to severe intense pain and soothe indications of arthritis (osteoarthritis and rheumatoid arthritis) or gout such as joint discomfort, stiffness, edema and irritation. Indomethacin is having less solubility resulting in low bioavailability. Hence in order to increase the bioavailability solubility has to be increased. In this study, Indomethacin solubility was increased by using solid dispersion method. Four formulations of Solid dispersions of Indomethacin are formulated utilizing physical and kneading method using ratio of 1:1 and 1:2 with HPMC respectively. Pre-formulation studies of Indomethacin were studies including organoleptic characteristics, solubility, melting point, determination of λmax, and compatibility study by using FT-IR spectroscopy. Formulated solid dispersions are then encapsulated to hard gelatin capsule shells and subjected for evaluation like weight difference, disintegration, drug presence and in-vitro drug discharge studies. Pre-formulation studies show results within the limit and compatibility test proof no reaction among Indomethacin and polymer. All evaluation parameters show results within the limit. F1 formulation containing 97.22% of drug presence and shown maximum drug discharge of 94.93% hence it is considered the best formulation where it was subjected for comparison study with marketed formulation in which it shows higher

dissolution rate as that of marketed formulation. It can be concluded that solubility of Indomethacin was enhanced by solid dispersion method.

Keywords: Indomethacin, solid dispersion, HPMC, physical mixture, kneading method, solubility enhancement.

INTRODUCTION

The pharmaceutical industry faces challenges in developing water-insoluble drug formulations because of limited solubility. Solid dispersions have been proven effective in improving drug bioavailability [1]. Formulating badly water-soluble medications is a challenge for the pharmaceutical sector. With several manufacturing techniques including solvent evaporation, spray-drying, and fusing being extensively researched, solid dispersions (SDs) have shown to be successful in enhancing medication solubility and bioavailability. Although knowledge of drug release mechanisms and optimization of these approaches have advanced, cheap and scalable continuous processing options for commercial usage still few [2]. Used in more than 15 marketed goods, the solid dispersion technique was among the most effective remedies of drug sector for raising the solvability of the insoluble medications. Among solid dispersion technology' benefits, are drug particle size reduction, enhanced wettability, and crystalline conversion to amorphous state [3]. Solid dispersions are the preparations made up of two parts, water-loving matrix and water-hating drug. The drug will be dispersed in the matrix where it can be amorphous or crystalline in nature. Some of the materials that can be used are sugars (dextrose, sucrose, sorbitol, lactose), acids (citric acid, succinic acid), polymeric materials (cellulose derivatives, PVP, PEG), insoluble or enteric polymer (Eudragit), surfactants (spans, tweens) and others. Solid dispersion offers range of application in pharmaceutical field besides solubility and absorption enhancement they also offer uniform distribution of drug, dispensing of liquid or gas substances in solid form and formulation of sustained release dosage forms by using polymers [4].

MATERIALS AND METHODOLOGY

Materials

Indomethacin, HPMC are obtained from Research lab fine chem industry, Mumbai and all ingredients used are good quality.

Methodology

Pre-formulation tests

The pre-formulation tests carried out for the pure drug Indomethacin are as follows

Solubility studies

Solubility of Indomethacin was checked in different solvents like water, alcohol, HCl, Phosphate buffer pH 7.4 [5].

Detection of melting temperature

Indomethacin melting temperature is detected by Thiele's tube method where a capillary tube was sealed in one side and Indomethacin was inserted on it. The tube is attached to a thermometer, attached to a cork fitted in the Thiele's tube contained liquid paraffin and heated [6].

Determination of λmax

λmax of Indomethacin was determined by using ethanol in the concentration of 100 µg/ ml by using UV spectrophotometer in the range of 200 – 400nm.

Standard curve

Standard calibration curve of Indomethacin was plotted as the concentration (µg/ml) v/s the absorbances of the aliquots of 5, 10, 15, 20, 25µg/ml prepared from the stock solution of Indomethacin [7].

Compatibility study

Compatibility study of Indomethacin and HPMC was carried out by subject Indomethacin and combination of Indomethacin with HPMC for FTIR at 4 cm^{-1} resolution and scanning range of 400 - 4000 cm^{-1}. Spectra of Indomethacin and HPMC was compared to that of Indomethacin [5].

Preparation of solid dispersion of Indomethacin

Solid dispersions of Indomethacin were formulated using HPMC as a polymer by physical mixture and kneading methods in different ratios of 1:1 and 1:2. The formulation of solid dispersions can be seen in Table 1.

Physical mixture

Indomethacin and HPMC were mixed in the ratio of 1:1 and 1:2 by triturating in mortar and pestle for 3-5 minutes. The powder was passed through sieve # 60 then filled into the hard gelatin capsules (Size 0) [8].

Kneading method

Solid dispersions of Indomethacin and HPMC by kneading method were prepared in the ratio of 1:1 and 1:2 by triturating in a mortar and pestle then mixture of alcohol and water is added and a coherent mass is formed which is then passed through sieve #22 to obtain granules. The granules are dried for 20 minutes at 60°C and filled into the capsule shell (Size 0) [9].

Evaluation of Solid dispersion of Indomethacin

The encapsulated solid dispersions are tested for the parameters as followed

Weight difference

Individually 20 capsules were weighed and calculate the average weight. Weight variation was determined by following formula [10].

Weight difference =(Weight of capsule-Average weight)/(Average weight) ×100

Disintegration

The capsules were place in the basket rack of dissolution test apparatus contained a medium adjusted at 37°C. duration needed for the capsule to fully disintegrate into a soft mass was noted [11].

Drug content

Randomly 10 capsules were selected and emptied, 50ml of alcohol was added, filtered, the volume was made up to 100ml, diluted, then subjected for absorbance at λmax and the drug presence was calculated [12].

***In-vitro* drug release tests**

In-vitro drug discharge tests are performed in USP Type II equipment (Paddle method) utilizing phosphate buffer pH 7.4 as a dissolution fluid, adjusted at 37 ± 0.5°C and rate of 50 rpm. Solutions are withdrawn at 10 minutes interval for 60 minutes and substituted the same by buffer. The solutions are then examined for % drug released [13].

Comparison study

Comparison study was carried out by comparing the *in-vitro* drug discharge tests of encapsulated Indomethacin solid dispersion and marketed formulation (Indomethacin capsule IP manufactured by DRUGFARM) [14].

RESULTS AND DISCUSSION

Solubility profile
Indomethacin is soluble in alcohol, phosphate buffer pH 7.4 and insoluble in water and HCl.

Melting temperature
The melting temperature on Indomethacin was determined as 160 ºC.

Determination of λmax of Indomethacin
λmax of Indomethacin was determined at 229 nm.

Standard graph
The standard graph of Indomethacin using ethanol was plotted as Concentration (µg/ml) v/s absorbance using Table 2. Regression coefficient was determined by utilizing a regression equation. Value of regression coefficient was used to calculate %CDR and the curve obeys Beer's Law. The calibration curve of Indomethacin is given in Figure 1.

Compatibility study of drug with polymers by FT-IR spectroscopy
The FT IR Spectra of Indomethacin and combination of Indomethacin and HPMC K100 shows characteristic peaks of C-N stretch amine at 1186 cm^{-1}, -C=O- (alpha and beta unsaturated) at 1713 cm^{-1} and 1712 cm^{-1}, C-H stretch alkane at 2966 cm^{-1}, C-Cl stretching at 802 cm^{-1} and Aromatic C=C stretch at 1587 cm^{-1}. The FT IR spectra prove no reaction among Indomethacin and HPMC K100 because the combination of Indomethacin and HMPC K100 shows characteristic peak of Indomethacin as shown in Figure 2, 3 and 4. Therefore, Indomethacin and HPMC K100 used are suitable with one another.

Evaluation
Post formulation evaluation of solid dispersion encapsulated hard gelatin capsule
The prepared solid dispersions were encapsulated into the capsule shell of Size 0 and tested for weight difference where the % weight difference of the dosage forms is within the limit, breakdown duration is detected around 2 min 3 secs- 3mins 14 secs and drug content was determined and it is in the range of 95.94-97.22 %, where F1 shows the maximum drug presence. The result is given in Table 3.

***In-vitro* drug discharge tests**
In-vitro drug discharge tests are carried out for 1 hour in USP Type II equipment utilizing phosphate buffer pH 7.4. The solid dispersion encapsulated in capsules shows the drug release in the range of 90.07-94.93%. The results specify that F1 shows maximum drug release of 94.93%. The result is given in Table 4 and Figure 5.

Comparison study
By comparing the *in-vitro* drug discharge of F1 and marketed formulation, F1 leads the marketed formulation. Hence, study indicates that optimized formulation proves greater dissolution as that of marketed formulation. The result is shown in Figure 6 and Table 5.

CONCLUSION

Solid dispersions of Indomethacin were formulated and evaluated for the enhancement of solubility of Indomethacin. Solid dispersions are formulated by physical mixture and kneading techniques using HPMC in the ratio of 1:1 and 1:2. Pre-formulation studies of the drug were performed, and the results were within the limit. By using the FT-IR study, compatibility was checked between the drug and the polymer, and it was shown no reaction among Indomethacin and the polymer and suitable for the formulation. Four batches are formulated, and the formulation are encapsulated in capsule shell and these capsules are tested for weight difference, disintegration and

drug presence. All parameters are in the limits. The in-vitro drug discharge tests are performed for 1 hours where the F1 with Indomethacin and HPMC in the proportion of 1:1 prepared by physical mixture method shows maximum solubility and maximum drug content and was considered the best formulation. The optimized formulation F1 was subjected for comparison study with marketed formulation where F1 shows higher dissolution rates compared to marketed formulation. Hence, it can be concluded that solid dispersion of Indomethacin has been successfully formulated and can be considered an approach to enhance the solubility of Indomethacin.

ACKNOWLEDGEMENT

The authors would like to express their thanks of gratitude towards the Principal, Librarian and supporting staffs of Acharya and BM Reddy College of Pharmacy, Bengaluru, Karnataka, India, for their constant support in providing all the requirements to complete the project as well as the manuscript.

ABSTRACT

We encounter many health problems in the modernization environment, which is governed by artificial intelligence. Non-communicable diseases account for the majority of mortality nowadays, and they are caused by immunological deficiencies.The majority of the serious NCDs are caused by immune deficiencies. We experience mortality as well as long-term health issues as a result. Thus, the immune system is mostly responsible for our health issues. Many primary immunodeficiency problems can be treated to strengthen the immune system.We want to diagnose the most affected person by immunodeficiency in this study. We employ an interval-valued fuzzy soft matrix alongside with a similarity matrix to give priority the immunological deficiencies severity.

Keywords: Fuzzy set, Fuzzy soft set, fuzzy soft matrix, Interval-valued fuzzy soft set, Interval-valued fuzzy soft matrix, Similarity matrix.

INTRODUCTION

Most of our real life problems often involve data which are not necessarily crisp, precise and deterministic in character due to various uncertainties associated with these problems. Fuzzy mathematics is a branch of mathematics which captures uncertainty in real life and tries to extract precise meaning from the given vague information. It is a powerful tool for decision-making systems.In 1965 Zadeh introduce the notion of fuzzy set theory. In many complicated problems arising in the fields of engineering, social sciences, economics, medical sciences, healthcare etc., involving uncertainties. Classical methods are found to be inadequate in recent times. Molodtsov pointed out

that the important existing theories viz. probability theory, fuzzy set theory, Intuitionistic Fuzzy set theory, Rough set theory etc, which can be considered as mathematical tool for dealing with uncertainties , have their own difficulties. In 1999 he initiated the novel concept of Soft Set as a new mathematical tool for dealing with uncertainties. Soft set theory, Initiated by Molodtsov is free of the difficulties present in these theories. Though all these techniques do not consider parameterization of the tools hence could not be applied truly in handling problems of uncertainties. In 2003 Maji put forward a hybrid model known as fuzzy soft set, which is a combination of soft set and fuzzy set. Matrices play an important role in the broad area. The definition of soft matrices by Cagman in 2010, and the proposal of weighted fuzzy soft set by Feng in the same year. Yong's successful application of the notion of fuzzy soft matrices in certain decision-making problems in 2011 and the extension made by Neog, Bora and Sut in 2012 further enriched this field of study. The application of fuzzy soft matrices in medical diagnosis has also been demonstrated by Lavanya M and Akila S. Mondal *et al*. and Shyamal *et al*. initiated a matrix representation of soft set and interval valued fuzzy set respectively. In Yong *et al* initiated a matrix representation of a fuzzy soft set and applied it in certain decision making problems. Borah *et al* extended fuzzy soft matrix theory and its application. In Chetia *et al* and in Rajarajeswari *et al*. defined intuitionistic fuzzy soft matrix and interval valued intuitionistic fuzzy soft matrix and its types. Also extended some operations and an algorithm for medical diagnosis. In this paper, we extended the concept of interval valued fuzzy soft matrix together with the similarity matrix.

METHODOLOGY

Step 1 : Determine the disease's symptoms
Step 2 : Form the model Interval-Valued Fuzzy Soft Matrix
Step 3: Create a set of criteria for every person based on the symptoms of the disease.
Step 4: The similarity between the model Interval-Valued Fuzzy Soft Matrixand each person's Interval-Valued Fuzzy Soft Matrix is assessed.
Step 5: The significantly similar Interval-Valued Fuzzy Soft Matrix is then obtained.
Step 6: Higher the similarity value, greater is the chance for mostly disease affected.

RESULTS AND DISCUSSION

We observe the most common symptom for immune deficiency with the help of healthcare professionals,

S_1 -Slow wound healing
S_2 - Frequent infections
S_3 -Skin issues
S_4 - Digestive issues
S_5 - High stress level
S_6 - Cold hand and feet
S_7 - Chronic fatigue
S_8 - Frequent allergies

This symptoms are relate to four persons

χ_1– John
χ_2 – Peter
χ_3- Adam
χ_4-chinchung

Let us the symptom occurrence and non-occurrence level in model interval-valued fuzzy soft matrices by the help of professional

(δ,S)	S_1	S_2	S_3	S_4	S_5	S_6	S_7	S_8

CONCLUSION

We encounter many persons in our everyday lives these days who are frequently afflicted by ailments. In this study we choose and discuss about the immunodeficiency disease. Immunodeficiency diseases are conditions in which the immune system's ability to fight infections and diseases is compromised or entirely absent. Immune deficiencies and a lack of knowledge on how to protect oneself from such issues are the causes When fuzzy soft matrices are used in immunodeficiency impact analysis, predictive modeling and risk assessment are improved, which results in more leading treatments and improved patient healthcare. People with immunological deficiencies are most susceptible to illness than the average individual. Our study examines the disease in order to provide protection. Using the Similarity relation together with Interval-Valued Fuzzy Soft Matrices from the calculation and depicts of the figure, Adam highly affected by the immune deficiency disease. Future studies can improve these models by combining machine learning methods with actual clinical datasets to get even more accurate results. To diagnosis at earlier stage and find out disease severity level to protect from that disease is better for our healthcare. To concentrate highly disease affected person to give the exact extra caring to protect and choose the appropriate medicine. This study can be an increase understanding of the immune deficiencies among the public and health care. It would be better to have access to prompt and appropriate immunodeficit treatment. In our calculation diagnosis we find out the highly

disease affected person. In this method very effectively diagnose the disease affected person. Adam highly affected by the immunodeficiency disease.

ABSTRACT

A market-based survey on Wild Edible Plants (WEPs) was conducted in the local markets of Dimapur from January 2024 to March 2025. Wild edible plants (WEPs) hold significant importance for rural communities across numerous developing nations. The emphasis on WEPs has significantly increased in recent decades, particularly within rural and tribal communities. This study aim to record the WEPs found in local markets, including their seasonal availability, market price and the conservation status. Market survey, semi-structured questionnaire and interview were conducted for the data collection. A total of 59 WEPs representing 53 genera and 40 families were recorded during the present survey. Among these, 21 species were found to be available year round, while *Canarium strictum* was the only species classified under Endangered Category (EN).

Keywords: Market survey, Ethnobotany, Wild Edible Plants, Dimapur

INTRODUCTION

Nagaland, nestled in India's north-eastern corridor, is recognized as a critical biogeographic zone with exceptional ethnobotanical wealth. Nagaland is inhabited by more than 17 major tribes, with a diverse spectrum of traditional ecological knowledge (TEK) rooted in the use of plant-based resources. Wild edible plants (WEPs) serve as indispensable components of daily diets, traditional medicine, seasonal foraging practices, and local economies. This ethnobotanical tradition not only sustains nutritional security but also fosters cultural identity and intergenerational knowledge transmission (Mao, 2014). Jigme and Yangchen (2022) defined WEPs as uncultivated plant species gathered from natural habitats. WEPs are an important source of food in India and have a significant place in the

dietary habits of small and marginal farmer's families and forest dwelling communities during the periods of food scarcity (Beluhan and Ranogajei, 2010). The food habits of tribal communities are typically shaped by the seasonal availability of food and its nutritional content, resulting in a traditional reliance on their own foraged resources. Dimapur, the state's largest urban hub of Nagaland, presents a unique ethnobotanical interface. Unlike the most homogenized tribal districts, Dimapur functions as a socio-ecological crossroad where rural harvests meet urban consumption. The city's bustling local markets, such as Super Market and New Market, act as vital points of aggregation for WEPs collected from forest areas across districts like Peren, Chümoukedima, Mokokchung and Wokha. Furthermore, selling WEPs in markets like Dimapur offers an important avenue for livelihood generation, particularly for women and economically weaker section. Despite this strategic role, comprehensive documentation of WEPs and the market price remains scarce. Documenting wild edible plants utilized by indigenous groups of this region offers valuable insights for planning, conservation, and further research. This study intends to perform an ethnobotanical survey of wild edible plants found in the market area of Dimapur, Nagaland, concentrating on their identification, uses, importance to local communities and the global conservation status. It seeks to record this knowledge as a means of protecting cultural heritage and promoting the sustainable utilization of indigenous plant resources. Furthermore, the findings will highlight the role of WEPs in local diets and their valuable role in contributing to both food security and primary healthcare needs.

MATERIALS AND METHODS

The market survey for documenting wild edible plants through ethnobotanical methods was conducted over the period from January 2024 to March 2025. The markets under study area includes Tuesday market at Lengrijan (Lat. 25.904573, Long. 93.690006) Wednesday market at Supermarket (Lat. 25.905888, Long. 93.739879), New market (Lat. 25.908116, Long. 93.722589) Monday Market at Padampukhuri (25.901349, Long. 93.771217) and City tower junction (Lat. 25.911360, Long. 93.720541) . The survey engaged 98 shopkeepers, serving as key informants for the study. The data were collected through one-on-one interaction, semi-structured questionnaire, and personal observation. Before commencing the survey ,Prior informed consent was obtained from each informants. The plant species collected during the study were identified using reference materials, including the Medicinal plant repertoire: A perspective of Biogeographical gateway of India, Nagaland Bio Resource Mission, Conservation status was updated from IUCN Red List of threatened Species and the botanical names were updated through POWO and Eflora of India. All the plants were photographed using PocoF1 phone and DSLR D5200 Nikon camera.

RESULT

The market survey results in the documentation of 59 wild edible plants sold in the main local markets of Dimapur. The documented 59 WEPs belong to 40 families and 53 genera (Table 1). Among the families, Phyllanthaceae is the dominant family with 4 species, followed by Anacardiaceae, Fabaceae, Moraceae, and Solanaceae with 3 species each, Amaranthaceae, Apiaceae, Araceae, Asteraceae, Cucurbitaceae, Lauraceae, Poaceae, and Zingiberaceae with 2 species each and the rest of the families were represented by one species (Figure 1). The plant belongs to different habits where tree occupies the highest with 22 species, 19 were herbs, 8 were shrubs, 4 were climbers, 3 fungi and 2 grasses (Figure 2). Out of 59 species, 51 were under the division Angiosperms with 42 species under the clade eudicots, 9 species under monocots, and 3 species under Magnoliids, 3 species were fungi, and 1 species each belongs to Pteridophytes and gymnosperms respectively (Table 1 and 2). Amongst the edible parts sold in the market, fruits were the highest which is followed by leaves (Table 1). All 59 wild edible plants were categorised with details including their botanical names, common names, families, divisions, growth habits and traditional uses (Table 3). Of the 59 WEPs recorded from market surveys, 21 plant species were found to be available throughout the year and the remaining were seasonal (Table 4). The price ranges between Rs.10-Rs.30 for leafy vegetables, Rs.20 – Rs.100 for fruits and Rs.100- Rs.150 for wild mushroom (Table 4). Based on the IUCN Red List of Threatened Species, one species fell under the Endangered Category (EN), 26 species were listed as Least Concern (LC), one was categorised under Data

Deficient (DD) and the rest were not evaluated (NE) [Table 4]. Table 5 displays photographs of several WEPs documented from Dimapur local market.

DISCUSSION

The identification of 59 wild edible plants (WEPs) sold in the market of Dimapur highlights the significant role of wild flora in the daily diet of local population. The traditional culinary practices of the Nagas in Dimapur are deeply shaped by the availability of wild edible plants found in the region. It not only add to the delicacy of Naga cuisine but also helps the local to earn their daily livelihood. The present market survey revealed women playing the leading role in marketing wild edible plants in Dimapur, while men were mainly involved in foraging and packaging activities. Among the recorded plant species, trees were most prevalent (38%), followed by herbs (33%), shrubs (14%), Climbers (7%), fungi (5%) and grasses (3%). This observation supports the findings of Gogoi *et. al.,* (2023) which showed the predominance of trees in their study. The dominance of trees may be attributed to their abundance in nature as trees has greater resilience and adaptability to different environmental conditions. Angiospermic plants were the most dominant, comprising 54 of the documented species. Kar and Borthakur (2007) also reported the dominant of angiospermic plants in their study on the market survey of Karbi Anglong, Assam. The incredible diversity of angiospermic plants must have attributed to their global dominance. The different parts of the plants are consumed, out of which fruits were the most frequently used parts sold in the market. Ripe fruits are primarily eaten raw, though some species are prepared through cooking and consumed as part of vegetable dishes. Similar findings were demonstrated by Asfaw *et al* (2023), and Pai*et. al*., (2019) in their survey on wild edible plants. The findings of this study promotes the high consumption and utilization of fruits locally. The commonly available fruits were primarily utilised for preparing fermented juices, traditional beverages and pickles. Deb et.al., (2013) reported the use of several wild edible species, including *Musa acuminata, Solanum torvum, Bambusa tulda, Diplazium esculentum, Colocasia esculenta, Centella asiatica, Ipomoea aquatic, Lasiaspinosa* among the ethnic communities of Tripura. Comparable results were also reported by Doni and Gajurel (2020) in their studies on diversity of wild edible plants used by Galo tribe of Arunachal Pradesh. Plants such as *Amaranthus viridis, Amomum dealbatum, Artocarpus heterophyllus, Centella asiatica, Clerodendrum glandulosum, Dioscorea esculenta, Diplazium esculentum, Houttuyniacordata,* and *Zanthoxylum rhetsa* were found to use as vegetables in both the states. The pseudostem of wild banana eaten as vegetable in the local markets of Dimapur was also observed in the study of Meitei *et. al*., (2022). This demonstrates the intercultural exchange of knowledge among the different community through selling in the markets of different states and also exhibit harmonial coexistence of different ethnic groups The highly consumed plants were *Alpinianigra, Bambusa tulda, Bambusa balcooa, Centella asiatica, Clerodendrum glandulosum, Colocasia esculenta, Diplazium esculentum, Gnetum gnemon, Livistonajen kinsiana, Moringa oleifera, Musa acuminata, Parkia timoriana, Rhus chinensis, Phyllanthus emblica, Solanum violacum, and Zanthoxy lumrhetsa* and therefore showed high market demand. The different parts of the plants were usually sold in the form of bunch, group or bundles. Each bunch of leafy vegetables were sold by rs 30 to rs 50. Among the wild vegetables sold in the market, mushroom priced the highest as it is rarely available and also difficult to collect from the forest. The price of wild edible plants differ from market to market, depending on the supply and demand. 29 WEPs sold in the market were available throughout the year, with the remaining species being seasonally available based on favourable growing seasons. As per the IUCN red list of threatened species, it is found that only 1 species namely *Canarium strictum* were under endangered category. *Canarium strictum*were commonly eaten by many ethnic groups in dried form after boiling. Although only one species is classified as threatened, it is important to conserved and used sustainably for the future generation.

CONCLUSION

Through this study, the biodiversity richness of the region is evident in the variety of wild edible plants available in the local markets of Dimapur. Wild-collected plants from natural habitats hold significant importance for rural populations. Beyond addressing food security challenges, it also fosters income opportunities and encourages

sustainable resource utilization. Additionally, the present study plays a role in preserving the traditional knowledge of the aboriginal population.

ACKNOWLEDGEMENT

The authors express their sincere gratitude to all the informants for their active participation in the survey, and also acknowledge the Immanuel College Management for providing the opportunity to carry out this research.

ABSTRACT

This compendium paper offers a thorough examination of the most recent developments in bone fracture detection and classification methodologies, using technologies in AI and medical imaging. This paper conducts a systematic review and analysis of cutting-edge techniques, such as computer-aided diagnosis systems, deep learning algorithms, and innovative image processing methods, in response to the growing need for accurate fracture diagnosis. This survey examines the strengths and limitations of various approaches, highlighting their adaptability to different imaging sources, including Magnetic Resonance Imaging, Computed Tomography, and X-rays. Furthermore, the paper addresses potential future orientations, challenges, and emerging trends in the field, with the objective of assisting researchers, healthcare professionals, and technologists in the creation of more dependable and durable tools for bone fracture detection and classification.

Keywords: Convolutional Neural Network (CNN), Image Processing, Classification, Machine Learning, Bone Fracture.

INTRODUCTION

Bone fractures are a substantial global health concern, resulting in substantial healthcare costs and the annual impact on millions of individuals. Effective treatment planning and patient outcomes necessitate accurate and timely fracture diagnosis. Advanced technologies help to improve efficiency and precision in detecting the bone fracture and its classification. The conventional diagnostic methods usually use medical images, which have transformed to a

new dimension using AI which has shown significant potential for diagnosing fractures. The process of fracture assessment is subjective and potentially susceptible to human error due to the significant dependence on the expertise of radiologists in conventional methods. In order to confront these obstacles, researchers have progressively implemented diagnosis using DL algorithms. These technologies have exhibited extraordinary capabilities in identification and classification of bone fractures. For example, Sharma *et al*. (2019) [1] have demonstrated the efficacy of CNNs in the precise identification of fracture patterns in X-ray images, thereby expediting the diagnostic workflow and enhancing diagnostic accuracy. Despite the extraordinary advancements made in this field, there are still opportunities and challenges that require further investigation. The integration of these technologies into clinical practice, the necessity of large and diverse datasets for the training of robust models, and the variability in fracture patterns are among the critical aspects that necessitate your attention. The purpose of this survey is to critically evaluate the current literature and illuminate the potential opportunities for future research and development, while also providing a comprehensive overview of the most recent developments in bone fracture detection and classification. This survey enhances the collective comprehension of how technology can further improve fracture diagnosis, thereby enhancing patient care and outcomes, by synthesising the current state of the field.

Bone Fracture Types

Fractures are classified according to a variety of criteria to describe their characteristics, which is essential for comprehending and treating bone injuries. The severity of the injury, the location within the body, the morphology or shape of the fracture, the presence of an external wound, and the stability of the fracture after aligning the fractured bone fragments are all included in these criteria[2]. The primary distinction in fracture classification is between closed fractures, which are characterised by the preservation of the skin, and open fractures, which are characterised by the rupture of the skin. Due to the bone's exposure to the external environment, open fractures have high risk of infections and complications. Long bone fractures, such as those in the femur, humerus, and tibia, can be categorised according to the forces that produce them [3]. Stress fractures are caused by repetitive loading or overuse, whereas simple and comminuted fractures are indicative of varying degrees of bone fragmentation that result from a singular injury. Comprehending these classifications is essential for the precise diagnosis of fractures and the development of treatment strategies that are tailored to the unique characteristics of each injury. The description suggests that Figure 1 demonstrates the characteristics of bone fractures, identifying the nature of the break in a variety of fracture types [4].

Image Processing in Bone Fracture Images

For the detection of bone fracture and classification, image processing is essential to get critical information from images and the improvement of diagnostic accuracy. Image processing techniques are implemented to resolve obstacles such as noise reduction, feature extraction, and image enhancement in the context of bone fracture images, which are typically acquired through X-rays, CT scans, or MRIs [5]. Image pre-processing is an essential step that is designed to improve the image and prepare them for further analysis. Noise reduction and the elimination of irrelevant or undesirable data are the two primary components of pre-processing that were addressed. The signal-to-noise ratio in the images is enhanced by noise reduction, which ensures that the pertinent information is more easily discernible [6].

Image Noise

Image Noise is the term used to describe the unintended random fluctuations in the luminance or colour of an image. It is frequently regarded as unfavourable due to its potential to obscure the actual details and structures of the image. Image noise may result from a variety of factors, such as environmental conditions, sensor limitations, electronic interference, or imperfections in the imaging process [7][8][9]. The quality of data and, as a result, the accuracy of research analysis can be substantially determined by the types of noise present in the images. The specific forms of noise that are observed in images may differ depending on the imaging process, environmental conditions, and the imaging equipment. Researchers frequently encounter the following categories of noise.

Gaussian Noise

Gaussian noise, which is characterised by random fluctuations in pixel intensity that adhere to a Gaussian distribution, can be the result of a variety of sources, such as electronic interference and sensor limitations [10].

Salt-and-Pepper Noise

This is characterised by the presence of bright and dark pixels in the image that occur at random, resembling grains of salt and pepper. It may be the result of transmission errors or deficiencies in the imaging apparatus [11].

Shot Noise

Shot noise is an inherent characteristic of images that are captured with low levels of illumination, as it is a result of the discrete nature of light. In low-light conditions, it can be especially apparent [12].

Speckle noise

This type is distinguished by granular interference patterns that manifest as brilliant and dark spots or specks in an image. It is frequently detected in images obtained through techniques such as ultrasound imaging, synthetic aperture radar (SAR), and specific forms of laser imaging [13].

Feature Extraction

The process of capturing and representing the key characteristics or patterns within an image that are pertinent to a specific analysis is referred to as feature extraction in image processing. The objective is to decrease the dimensionality but preserve the critical data for subsequent processing or recognition tasks. Feature extraction is important for a variety of applications, including recognition of pattern, computer vision, and machine learning. The selection of features in image processing is determined by the intended system. Spectral, geometric, and texture features are the three primary categories of features that address distinct aspects of image analysis.

Spectral features

Colour information can be extracted through colour histograms. Insights into the distribution of pixel intensities for each colour channel (e.g., red, green, and blue) in the image are provided by these histograms. Fourier transform coefficients, which are spectral features derived from the frequency domain, are capable of capturing patterns and variations in bone fracture images at various spatial frequencies [14].

Shape Features

The fractured bone's perimeter and area can be determined. The extent and magnitude of the fracture are quantified by these characteristics. The degree to which the fracture's geometry resembles a perfect circle is determined by circularity, which is calculated as 4π times the ratio of area to perimeter squared. Eccentricity is a metric that quantifies the elongation of a fracture, thereby revealing its orientation and shape [15].

Texture features

The spatial relationships between pixel intensities can be quantified and textural patterns in the fissure can be highlighted by texture features extracted from the co-occurrence matrix, such as contrast, energy, and entropy. Local Binary Patterns (LBP) are a texture descriptor that is highly effective in identifying the local patterns within an image. It is capable of capturing the fine details and textures that are present in bone fracture images. By analysing local spatial frequency content in various directions, Gabor filters are effective in extracting texture features when applied at various orientations and scales [16].

MATERIALS AND METHODS

The process of medical image classification entails the classification of images that have been acquired through imaging diagnosis including X-rays, CT scans, MRIs, and ultrasounds. For diagnostic purposes, treatment planning, and disease monitoring, it is essential to ensure that medical images are accurately classified. There are numerous methodologies that are frequently implemented for the classification of medical images

Conventional machine learning methodologies

Traditional machine learning techniques are essential for medical image classification, as they provide effective solutions that are interpretable and well-suited for scenarios with limited labelled data. In binary and multiclass classification tasks, Support Vector Machines are frequently employed to recognise the most effective hyperplanes for distinguishing between distinct classes based on feature representations of the data. A robust classification result with reduced susceptibility to overfitting is achieved by constructing multiple decision trees and amalgamating their predictions in Random Forest, an ensemble learning method.

Deep learning

By utilising neural networks, especially CNNs, was used to get intricate patterns and features from complex medical images, deep learning has revolutionised medical image classification. The precision of tasks such as disease detection and diagnosis has been substantially enhanced by the capacity of CNNs to detect subtle details. Transfer learning, which utilizes pre-trained models on extensive datasets, effectively addresses the challenges posed by the scarcity of labelled medical data by integrating knowledge from diverse domains. In addition to CNNs, RNNs are used to analyse temporal patterns in medical image time-series data. Although deep learning models demonstrate unparalleled accuracy, they are confronted with the necessity of substantial annotated datasets, computational resources, and potential interpretability issues. Nevertheless, the growing prominence of deep learning architectures and explainability tools is a direct result of their continuous development, which provides sophisticated and precise solutions for medical image classification in the healthcare sector.

Transfer learning

Transfer learning is a powerful technique in the domains of deep learning and machine learning, which entails leveraging the cognition acquired from training a model on one task to enhance performance on a related yet distinct task. This approach has proven particularly advantageous in the realm of medical image classification, especially when confronted with limited labelled datasets. Pre-trained models, which are frequently trained on extensive and diverse datasets like ImageNet, function as feature extractors that have acquired hierarchical representations of general patterns and features from a diverse array of images.

Classification Techniques for medical images (Table: 1)

RESULT AND DISCUSSION

Recent techniques have been employed by researchers to demonstrate augmented accuracy, good prediction, sensitivity and overall strong classification in a classification system for medical image melodies, as illustrated in TABLE II. Nevertheless, the text underscores the necessity of a sufficient quantity of datasets to achieve high sensitivity and specificity values in research. This is essential for guaranteeing the viability of implementing these methods in computer-aided diagnosis. X-ray, CT, MR, and US imaging are frequently employed by medical image analysis researchers. These images provide information that aids in the determination of the presence or absence of lesions in relation to a patient's medical history. Additionally, it is noted that Magnetic Resonance Imaging (MRI) is distinct from other modalities in that it does not employ X-rays. The text emphasises the critical role of AI in image classification, which is capable of both supervised and unsupervised techniques, with an eye towards future work. Special emphasis is placed on the challenge of attaining superior classification results, with a target accuracy of over

95%. This suggests that there is a persistent emphasis on enhancing the performance of classification algorithms for medical image analysis.

Classification Framework for Medical Image Categorization Across Various Image Classification Techniques (Table: 2)

Visual representation of the melodies employed in the images (Fig 2).

Performance Analysis With High Accuracy

The objective of this discussion is to analyze the various algorithms and the enhanced accuracy achieved by the techniques presented in Table 3. Analysis of Performance Metrics for Achieving High Accuracy Levels of 95% and Above (Table: 3).

Utilising a Graphical Chart to Enhance Precision (Fig 3).

CONCLUSION AND FUTURE RESEARCH

In summary, the exhaustive review of the existing literature on the detection and classification of medical bone fracture images reveals a landscape that is distinguished by significant contributions to the field of healthcare and rapid advancements.The accuracy and efficacy of medical image analysis have been significantly enhanced by the use of AI and ML algorithms, which has shown potential in a host of diagnostic applications. However, the necessity for ongoing research and development is underscored by the persistence of challenges such as the interpretability of models, the scarcity of annotated datasets, and ethical considerations. In order to enhance the generalisation & robustness of classification models, future research should prioritise the expansion and diversification of annotated medical image datasets. Furthermore, endeavours should be made to create interpretable models in order to foster trust and transparency within the medical community. Investigating transfer learning techniques is crucial for adapting pre-trained models to specific medical imaging tasks, especially in contexts where labeled data is limited. The development and implementation of these technologies in real-world healthcare settings should be guided by ethical considerations surrounding patient privacy and responsible AI deployment, which should remain at the vanguard of research endeavours. The medical image curation and classification is on the brink of further expansion as a result of these avenues of investigation, which will ultimately enhance patient outcomes and enhance the capabilities of diagnostic medicine.

ABSTRACT

Carica papaya L., belonging to the family Caricaceaea is a fruit crop known for its immense nutritional and medicinal applications. Although papaya is a common fruit tree, it is not widely cultivated due to a lack of awareness about its nutritional and medicinal benefits. However, *Carica papaya* has the potential for large-scale commercialization because of its short maturation period and year-round fruit production. To encourage the cultivation of *Carica papaya*, comprehensive studies on seed behaviour and associated properties are necessary. Understanding seed storability, response to desiccation, moisture content patterns, effective priming methods for improved germination, and other key seed characteristics is crucial for proper seed storage and successful cultivation. Therefore, before introducing papaya as a commercial crop, an in-depth investigation of seed desiccation and physiological traits is required. This study was conducted to assess the desiccation and germination parameters of *C. papaya.*

Keywords: *Carica papaya*, Seed germination, Desiccation, Physiological traits

INTRODUCTION

With the seed, the independence of the next generation of plant begins. Over evolutionary period, seed plants dominate biological niches on land, from forests to grasslands both in hot and cold climates. Seed production in natural plant populations varies widely from year to year in response to weather variabilities, insects, diseases and the plants' internal cycles. A seed is an embryonic plant enclosed in a protective outer covering. The end product of the flowering process is a fruit with one or many seeds (Bhatnagar *et al*., 1972). Seed formation is one of the

significant events in the post-reproductive stages in plants. Seeds are ripened or fertilized ovules. Seeds play an essential role in reproduction and existence of gymnosperms and angiosperms, relative to the primitive plant forms. Seed germination is usually the growth of a plant from a seed. During germination, the completely functional metabolic machinery of the seed results in the emergence of radicle and plumule. A fully developed seed contains an embryo, endosperm and a seed coat. Seed germination depends on both internal and external conditions. The most important external factors include different variables for successful seed germination. Often this depends on the individual seed variety and is closely linked to the ecological conditions of a plant's natural habitat. Seed dormancy is a factor that affects germination. Seed germination and dormancy are complementary adaptive traits of higher plants that are influenced by many genes and environmental factors (Bewley, 1997). *Carica papaya*, a fruit crop cultivated in tropical to subtropical regions, is known for its nutritional benefits and medicinal applications (Ming *et al*., 2008). Its origin is in the tropical region of America. *Carica papaya* is one of the 22 accepted species in the genus *Carica* of the family Caricaceae. There was a time when papaya was considered an exotic fruit because of its wide occurrence in Mexico and Central America. Today, however, it is one of the most common crops across the globe, which is cultivated for its fruits. The fruits of *Carica papaya* are soft, fleshy and are used in a wide variety of culinary ways. They are highly nutritious and possess a wide range of health benefits. Zeaxanthin, an antioxidant found in papaya, helps in filtering out harmful blue light rays and protects the eyes. The presence of β-carotene, an antioxidant pigment, lowers the risks of cancer, asthma and diabetes. Papayas are rich in vitamin K, which improves calcium absorption, which in turn helps in strengthening and rebuilding of bones. They possess an enzyme called papain, which aids in digestion. They are high in water and fibre content, both of which help to prevent constipation and promote regularity and a healthy digestive tract. The presence of fibre, potassium and vitamins help to ward off heart diseases. Papaya is a tree that is seen everywhere irrespective of the season. Despite being a common fruit tree, it is not cultivated for any purpose, due to the lack of knowledge about the nutritional and medicinal values of this tree. *C. papaya* can be commercialized on a large scale due to its short maturation period and due to the occurrence of fruits throughout the season. It grows abundantly in the tropical region. Hence, if cultivated commercially, papaya could emerge as a potential tropical fruit crop. To promote the cultivation of *Carica papaya*, proper studies should be conducted to know the seed behaviour and associated properties. It is essential to know about the seed storability, response of seeds to desiccation, moisture content pattern, better priming methodology with improved germination and other characteristics of seeds as they play an important role in the storage of seeds. Prior to mass cultivation it is essential to know these features. Study of *C. papaya* seed physiology is relevant in the present scenario. As mentioned earlier, data related to seed desiccation, germination and priming are essential. Hence, prior to introducing Papaya as a crop plant, a detailed seed desiccation and physiological study needs be conducted. The present study was conducted to determine the desiccation and germination parameters in *C. papaya*.

MATERIALS AND METHODS

Collection of mature seeds of *Carica papaya*

Mature seeds of *Carica papaya* were collected from different parts of Thiruvananthapuram. The collected seeds were cleaned, de-pulped and then utilized for further studies.

Evaluation of morphological parameters

The morphological parameters such as length and breadth of the seeds were determined using a digital verniercaliper. The weight of the seeds was taken using a digital weighing balance. All these morphological parameters were done on randomly selected ten seeds of each desiccation stages. The morphological parameters of seeds after hormonal priming and water uptake was also noted, prior to germination trials.

Determination of dry matter accumulation and moisture content

The chopped seed, taken in weighing bottles, were weighed in an electronic balance and dried in a hot air oven at 130 °C for 17 hours. For each time, three replicas of 10 seeds each were use and the moisture content was calculated as; Moisture content (%) = ($F1-F2$)/ $F1$ × 100; Where F1 is the initial fresh weight and F2 is the oven-dried weight

Determination of biochemical parameters

Estimation of metabolites like starch, sugars, total protein, amino acids, phenolics, lipids, tetrazolium chloride reduction and enzyme activities of peroxidase, polyphenol oxidase and catalase were carried out side by side during seed desiccation.

Determination of ideal medium for *Carica papaya* seed germination

For the present study, river sand: cow dung: coir pith (1:1:1), acid-free germination paper and cotton were used to identify the better medium for seed germination among them. Three replicas of 10 seeds were used for the germination trials.

Determination of tetrazolium reduction activity

The modified method of Kittock *et al*., (1968) was used for the estimation of tetrazolium reduction activity. The slightly broken seeds were incubated in 0.1% 2,3,5-triphenyl tetrazolium chloride in darkness for two hours. After this, tetrazolium solution was removed, and the seeds were collected and transferred into petri plates for the determination of viability based on the pink colour developed. After three washes in distilled water, 5ml acetone was added and incubated at room temperature in darkness for 16-18 hours to elute the formed formazan. The supernatant was filtered through Whatmann No1 filter paper and the colour was measured at 480nm in UV- VIS spectrophotometer (PharmaSpec UV-1700, Shimadzu, Japan) Treated extracts from seeds incubated in the absence of tetrazolium served as the blank.

Determination of leachate conductivity

For the estimation of electrolyte leakage, three replications of ten *Carica papaya* seeds from different desiccation periods were taken. The seeds were placed in a glass beaker containing 25-50 ml distilled water and covered to reduce evaporation and contamination by dust and were kept in open laboratory condition. After 24 hours, the seeds were removed and the electrical conductivity of the seed leachate was measured using a digital conductivity meter. Specific conductance was expressed as μ/m S $cm^{-1}g^{-1}$.

Determination of enzyme activity

About one gram fresh seeds were homogenised in a pre-chilled mortar and pestle with 0.1M cold sodium phosphate buffer (pH 7.0). The homogenate was centrifuged at 5000 rpm for 20 minutes and the supernatant was collected. Proteins from the supernatant was precipitated in cold acetone (1:3 ratio) and kept in an ice bath for 30 minutes. The pellet was washed twice with acetone and re-suspended in the same buffer after the complete evaporation of acetone. The combined supernatant served as the enzyme source for both peroxidase, polyphenol oxidase and catalase. All enzyme extractions were carried out at 4ºC using standard procedures.

Determination of water uptake capacity

Each set of seeds were soaked in distilled water at 27°C for 6, 12, 24 and 48 hours respectively. After each duration, water uptake was determined by recording the difference between the original weight of the seeds and the weight of the imbibed seeds. All experiments were conducted using the randomised block design (CRBP). For each treatment, 10 seeds were used with three replications.

Germination pattern of *C. papaya* seeds in response to desiccation

The seeds of *C. papaya* were undergone germination trials in different desiccation stages. The germination percentage and germination parameters were noted at all those desiccation stages.

Effect of seed priming on germination

Hydro-priming and hormonal priming were studied to observe the effect of priming on germination.

Biochemical comparison of pulped and de-pulped seeds

All the above mentioned biochemical parameters were also studied for pulped seeds. Then, comparisons were made between pulped and de-pulped seeds based on these parameters.

RESULTS

Carica papaya contains numerous seeds with woody testa enclosed within the pulp. Papaya seed is composed of endosperm and embryo. Completely mature *C. papaya* seeds are shed from the mother plant with 60.05% moisture content. 25% of the seeds constitute the pulp.

Morphological variation of *Carica papaya* seeds during desiccation

On morphological observation, it was seen that seeds show a rapid decrease in their weight from 0^{th} to 4^{th} stage of desiccation. Slight variations was also observed for length and breadth of the seeds during successive stages of desiccation. This shows the transformation of the seeds from a stage of turgidity to the stage of flaccidity, as given below in Table 1.

Dry matter accumulation and moisture content of seeds during desiccation

Mature seeds of *C. papaya* possessed 60.05% high initial moisture content that declined rapidly within a week of open desiccation (Table 2). The fastest drying rate was observed and the seeds were dehydrated to 23.08, 18.04, 11.15 and 10.43% at different stages of open laboratory desiccation. Nearly 49.62% loss of moisture content was recorded within 72 hours of desiccation. The lowest safe moisture below which the seed become non-viable was noted to be 23.08% by the 2nd day of desiccation. The dry matter accumulation increases with the desiccation.

Biochemical estimations

The biochemical estimations were conducted to determine lipid, total soluble sugar (TSS), starch, phenol, sucrose, protein and amino acid. It was observed that, mature papaya seeds possessed 61.07 mg/g dwt of lipid content. The lipid content was observed to increase to a maximum of 205.70 mg/g dwt on the second day of desiccation. Thereafter a steep decline in lipid content was noticed. A ready decrease in total soluble sugar content can be seen in C. papaya seeds from 52.16 mg/g dwt to 12.47 mg/g dwt. Mature seeds possessed higher starch content than the TSS and they were almost stable up to the first desiccation stage. The aging of seeds also causes a decline in the starch content. But the end of the desiccation marks 90.31 mg/g dwt starch content in *C. papaya* seeds in the fourth stage. *C. papaya* are less phenolic in nature. Initially, the seed possessed 4.2 mg/g dwt of phenolic content, but drying of seeds caused an increase in phenolic content. Sucrose content was maximum on the first day of desiccation. The rapid decline in moisture content made a steep increase in sucrose accumulation of 105.94 mg/g dwt. Thereafter, the sucrose content of desiccated seeds decreased. Total protein content was decreased throughout the desiccation of *C. papaya* seeds and a maximum protein content of 54.69 mg/g dwt was observed in the fresh mature seeds. Amino acid content in papaya seeds are very feeble. Along with the decreasing protein content, amino acid content was also decreased. Maximum amino acid content of 1.03 mg/g dwt could be seen at initial stage seeds. The results of the same were depicted in Table 3.

Tetrazolium reduction activity of *C. papaya* seeds during desiccation

The tetrazolium reduction activity in the seeds of *C. papaya* showed a gradual decrease. The pink colour in the seeds, indicating formazan formation, is found to gradually decrease from the 0^{th} stage to the 4^{th} stage of desiccation. The values of absorption of respective days ranged from 0.30 to 0.12, which showed a decrease in the viability of seeds. The results of the same were summarized in Table 4.

Electrolyte leakage conductivity of *C. papaya* seeds during desiccation

The electrolyte leakage conductivity of *C. papaya* seeds showed a gradual increase from the 0th stage to 4th stage of desiccation. The leachate conductivity value of the 1st day was 30.34 US/cm/g which increases to 33.06, 37.00, 38.45

μS/cm/g. During the 6th day, leachate conductivity reached a maximum of 38.58 μS/cm/g. The results obtained are tabulated below in Table 5.

Antioxidant enzyme activity during desiccation of *C. papaya* seeds

Carica papaya seeds had a significant membrane peroxidation reaction during desiccation. Fresh seeds with moisture content 60.05% showed 54.69 min / mg/ protein activity. When moisture content was dropped, peroxidase activity decreased on the 1st day of desiccation. Thereafter, the activation of peroxidase enzyme can be seen and the activity increased and reached maximum on the 3rd stage of desiccation. The most active antioxidant enzyme is polyphenol oxidase. Polyphenol oxidase activity trend was almost similar to that of peroxidase activity. Maximum activity was expressed at the end of desiccation 30 min/mg/protein. Catalase enzyme activity was found to be very low in comparison with other enzymes. Fresh seeds showed very low activity, but with the reduction in moisture, antioxidant system activates the catalase enzyme activity and becomes maximum on the 3rd stage of desiccation. The tabulated results are given below in Table 6.

Water uptake capacity of *C. papaya* seeds

Results of the water uptake capacity of seeds showed that weight of the seeds increased from the initial weight of 0.055g to 0.056g, 0.062g, 0.064g and 0.066g respectively during 6 hours, 12 hours, 24 hours and 48 hours of imbibition.

Germination pattern of *C. papaya* seeds in response to desiccation

The germination pattern of seeds occurred at the 0^{th} stage of desiccation, when the moisture content was 60.05%. Interestingly, no germination was observed further. This implied the necessity in conducting priming for enhanced germination. Thus, hydropriming via water soaking and hormonal priming via treatment with solutions of GA3, Salicylic acid and Cytokinins were conducted. The results of the same were summarized in Table 7 and 8. The results of hydro priming failed to produce germination. On the other hand, hormonal priming showed surprising results. It was observed that, treatment of seeds in 100 ppm GA3 at 48^{th} hour showed maximum germination (60%). Whereas, 500 ppm GA3 treatment showed complete germination at 72hrs, thereby indicating the efficiency of seeds to germinate under hormonal control.

Biochemical comparison of pulped and de-pulped seeds

Biomolecules like lipid, TSS, starch, phenol, sucrose, protein, and amino acid were compared in both pulped and de-pulped seeds. Pulped seeds showed all biochemical parameters at a maximum when compared to de-pulped seeds. Maximum lipid content of 101.62 mg/g dwt was seen in pulped seeds and de- pulped seeds showed 91.01 mg/g dwt suggesting that more lipids are accumulating in seeds than the pulp. TSS were also maximum in pulped seeds (61.71± 0.30 mg/g/dwt) than the de- pulped seeds (52.16 ± 0.44 mg/g/dwt). Pulped seeds possessed maximum starch content of 264.54 mg/g dwt whereas, the de-pulped seeds possess 105.34 mg/g dwt. Pulp of the seeds contain maximum amount starch than the seeds. Phenolic content were also high in pulped seeds. But the protein and amino acid content were almost similar in both pulped and de-pulped seeds, but a slighter increase in pulped seeds than the de-pulped seeds. The results are given below in Table 9.

DISCUSSION

Carica papaya is one of the most common species of Caricaceae family, grown widely in the tropical regions. The seeds of *C. papaya* are slightly thick, covered by a pulpy coating. They are recalcitrant in nature, and cannot survive in drying and freezing during *ex-situ* conservation. These seeds cannot resist the effects of drying or temperature less than 10°C. Thus, they cannot be stored for more extended periods like orthodox seeds, because they may lose their viability. The seed size, dry matter accumulation, moisture content, colour changes etc. of the seeds act as markers for detecting maturity of seeds. According to Ren *et.al.*,(1998), seed development and germination can be studied based on seed colour, seed morphology, fresh weight and dry weight. Hence, the present study employed these techniques to determine seed desiccation in *C. papaya* seeds. Evaluation of morphological parameters of the seeds exhibited a

length of 5.82mm, width of 3.78mm and weighed 0.08g on the initial day of desiccation and subsequently showed a progressive decline in the measured parameters. The observed decrease in length and breadth may occur as a result of desiccation. Seed desiccation in *C. papaya* gauged by changes in fresh weight pertaining to viability followed a pattern typical to recalcitrant nature (Kamarudeen kunju, 2003). Moisture content is a good indicator of seed development. *Carica papaya* contains high moisture content at the time of shedding which was found to be the characteristic feature of recalcitrant seed. According to Berjak *et al*. (2013), the maturation drying phase is absent in recalcitrant seeds and possess a high percentage of water at the time of shedding. The fresh seeds of *C. papaya* possess an initial moisture content of 60.05%. The initial moisture content rapidly fell to 23.08% at the second stage of desiccation. But,in the successive stages, a gradual decrease in moisture content was observed. Initially, the cells of the seeds contained high water content but as desiccation proceeds, the seeds lose the water content which results in the accumulation of dry matter. When papaya seeds are compared with *Lycopersicon esculentum* Mill., both possess an initial moisture content between 53-72% (Demir *et al*., 1992). The estimation of biochemical parameters revealed that, during *C. papaya* seed desiccation, lipid content increases from 61.07 mg/g/dwt to a maximum of 205.7 mg/g/dwt in the mid- desiccation and then decreases gradually in the late desiccation phase. The obtained data support the desiccation induced-dormancy state in *C. papaya* seeds (Wood *et al*., 2000). Desiccated seeds with increased lipid content might be viable in the dormant condition even though they generated zero germination percentage during the limited period of the study. According to Gasulla *et al*., (2013), dehydration results in an increased quantity of lipid content in the plant, ensuring the membrane stability. The TSS content during desiccation of *C. papaya* seeds showed a higher concentration initially and an almost stable lower concentration throughout the desiccation treatment. Near the point of transition from viability to non- viability, the level of TSS is maximum and during those days of desiccation and germination percentage was maximum. The reduction in sugar content might be due to hydrolysis followed by Madori Maillard reactions which might cause protein and nucleic acid damage, thus threatening the viability of seeds. The high amount of soluble sugar content provides a protective mechanism during the cell membrane destruction process. The result obtained thus indicates the direct correlation of TSS with the viability of seeds. During the initial stages of desiccation, the amount of starch content decreases from the peak value to a minimum value at the point of transition from viability to non-viability (Roberts, 1972). The seeds of *C. papaya* exhibited an increasing phenolic content during the desiccation, reaching a maximum value at the 4th stage of desiccation (7.2 mg/g/dwt). High phenolic content might be attributed to the stress during desiccation (Aalen., 1999), and this high phenolic content might get lowered down during the germination by oxidation of phenolic compounds. During dessication, papaya seeds exhibited a gradual reduction in sucrose concentration except in the second day of desiccation. This in turn may be associated with moisture content as, the moisture decreased rapidly, to cope up with the change. Such a response involves the production of sucrose whose accumulation rapidly increased to 105.94 mg/g/dwt from 80.08 mg/g/dwt. Sucrose is an active membrane protectant. As the water content in the seed decreases during desiccation, the hydroxyl group of sucrose may replace water by hydrogen bonding to the phospholipid head groups to the cell membrane. The total protein content of *C.papaya* seeds showed a significant decline from 54.69mg/g/dwt during the 4th stage which is in accordance with the protein content of *Hopea parviflora* seeds during desiccation (Kamarudeen kunju, 2003). The decrease in protein content might be due to the activity of protease during desiccation. The data obtained indicate that with the reduction in moisture, amino acids exhibit a decreasing pattern from 1.03 mg/g/dwt to a minimal value of 0.0143 mg/g/dwt (Shemy, 2018). The reduction in amino acids during desiccation might be due to increased production of antioxidant enzymes during desiccation stages, which was not quantified in the lower rpm extraction protocol of total protein. The tetrazolium test indirectly determines the respiratory activity in the cells that make up the seed tissues. The time required for tetrazolium staining and the intensity of staining might be the reflection of the loss of viability due to desiccation (Kumar *et al*., 1997). When tetrazolium is reduced to triphenyl formazan in the tissue, it indicates that respiratory activity in the mitochondria of seed tissue cells which are considered alive. The resulting red colour in the seed tissue is a positive indication of viability, an indirect method of detecting respiratory activity at the cellular level. The non-viable seed tissues do not react with tetrazolium and consequently do not stain. In the present study, the fresh seeds of papaya with 60.05% MC showed the formazan formation of 0.30. This gradually decreased to 0.12 on the 4th desiccation stage. Desiccation, thus, affects patterns of staining too. Electrolytic leakage of *C. papaya* seeds during desiccation depicts the recalcitrant behaviour of the seeds (Bewley, 1986). Cellular membranes are most vulnerable to damage

caused by desiccation. In the present study on the 0th stage of desiccation, the leachate conductivity was 30.34 µS/cm/g and it increased to 38.58 µS/cm/g on the 4th stage of desiccation. The relationship between desiccation tolerance and the stability of the seed membrane was reported by Bailly *et al*., (2004). The increase in the electrolyte leakage observed in *C. papaya* seed indicated the desiccation-induced damage to the cell membrane. According to Simon, (1978) and Bewley, (1986), an increase in electrolyte leakage is an indication of increased membrane destabilization. The linear increase in leachate conductivity during prolonged desiccation may be due to the loss of membrane integrity (Kamarudeen kunju, 2003). Desiccating seeds build-up free radicals during the metabolism which largely affects the seed viability. To counteract the radicals produced, seeds are best endowed with antioxidant molecules and scavenging systems (Puntarulo *et al*., 1991). Most prominent ones among the antioxidant molecules are the antioxidant enzymes like polyphenol oxidase, catalase and peroxidase. Polyphenol oxidase is a copper-containing antioxidant enzyme which metabolises the excess phenolics in the system. Both peroxidase and catalase metabolise the toxic hydrogen peroxide generated during the desiccation stress. In *C. papaya* seeds, polyphenol oxidase exhibits an enhanced activity initially which then increases to a maximum activity at the late desiccation stage. During desiccation, peroxidase activity gradually increases to a maximum towards the late desiccation stages. Catalase activity in *C. papaya* gradually increased to a maximum activity during the mid-desiccation stage followed by a steep reduction. Beyond a specific concentration of hydrogen peroxide, catalase cannot reduce hydrogen peroxide, its activity gets saturated and declines. The pattern of polyphenol oxidase, peroxidase and catalase activity obtained in *C. papaya* seeds (up to 6 days of desiccation) was similar to the enzyme activity of 0 to 8 days desiccation in *Vatteria indica* and *Hopea parviflora* (Kamarudeenkunju, 2003) and 0 to 24 hours of desiccation in *Knema attenuata* (Shemy, 2018). Data obtained from the antioxidant enzyme activity during desiccation of *C. papaya* seeds indicates its recalcitrant nature. Data obtained from the germination pattern of *C. papaya* seeds in response to desiccation revealed that only fresh seeds germinated (20%) and the rest of the desiccated seeds exhibited zero percentage germination. The absence of germination in the desiccated stages during the period of study might not be due to the non-viability of desiccated seeds, but might be due to the desiccation- induced dormancy (Wood *et al*., 2000).In the hormonal priming treatment, 500 pm gibberellic acid for 72 hours yielded maximum germination percentage (100%). While in the case of 250ppm and 100ppm gibberellic acid priming, 24 hours (30%) and 48 hours (60%) exhibited the maximum germination percentage. Least time required for first seedling emergence was noted in 100ppm gibberellic acid for 6 hours (7 days) but the germination percentage concerning it was least (10%). Concerning 500 ppm gibberellic acid treatment for 72 hours, FDG was observed on the 10th day while the LDG was 14th day, yielding four days of TSG. Maximum time spread of germination (7 days) was observed in 500 ppm Gibberellic acid for 24 hours. Maximum mean daily germination (7 days) was observed in the best priming treatment, 500 ppm gibberellic acid for 72 hours. The maximum peak value obtained was 100% in 500 ppm gibberellic acid treatment for 72 hours, which also yielded the maximum germination value in the lot. In concern with the germination energy, the maximum value was in the 500 ppm gibberellic acid treatment for 72 hours. All these germination characters of control and primed seeds indicate that 500 ppm gibberellic acid treatment for 72 hours yielding 100% germination is the best priming method among all the methods employed. The result obtained in the hormonal priming treatment is in accordance with the findings of Pourazar *et al*., (2015) i.e., seed priming with higher doses of gibberellic acid might improve the germination and vigorous performance. Comparing the biochemical composition of pulped and depulped seeds of *C. papaya*, all the biochemical parameters are present in comparatively higher quantities in the pulped seeds. Starch and phenolic content are approximately two fold higher in the pulped seeds. This might be due to the presence of sclerotesta in the pulped seeds. The sclerotesta provides an additional physical barrier to the rapid desiccation when abscissed from the mother plant or when exposed to the external environment. The presence of antioxidant molecule like phenol and the higher water content in the pulp, to some extent, could act as an external shield for the desiccating seeds.

CONCLUSION

Carica papaya could be introduced as a promising crop since it has established nutritional and medicinal features with its broad spectrum of phytochemicals. Since the study conducted on *C. papaya* seeds encompassed only a limited

number of aspects, there is still a lot more left to understand and study in detail regarding this topic. Data obtained in the present study only form the stepping stone, further detailed studies have to be conducted to come across more ideas regarding the seed physiology of papaya seeds prior to introducing it as a safe crop. A detailed analysis should be conducted on seed development, seed germination, phytohormones, antioxidant molecules, storage properties etc. such that papaya could be introduced as a crop with least expense and care but yielding a promising harvest.

ABSTRACT

Diuretics play a vital role in the regulation of fluid and electrolyte balance and are widely used in the management of hypertension, edema, and renal disorders. *Nephelium lappaceum* L. (rambutan), a tropical fruit rich in polyphenols, flavonoids, and other phytoconstituents, has been traditionally used for various medicinal purposes. This study aimed to evaluate the phytochemical profile and diuretic activity of the hydroalcoholic extract of *N. lappaceum* fruit rind in albino rats. The fruit rind was extracted using ethanol and water (70:30) by maceration and screened for phytochemicals using standard qualitative tests. GC-MS analysis was performed on both ethanol (polar) and chloroform (non-polar) fractions to identify active constituents. The diuretic activity was assessed in Wistar albino rats (150–200 g), divided into four groups: normal control, standard (furosemide 20 mg/kg), and two test groups receiving 250 mg/kg and 500 mg/kg of the extract, respectively. Urine output was recorded hourly for 5 hours in metabolic cages. Statistical analysis was conducted using one-way ANOVA followed by Dunnett's test. Phytochemical screening confirmed the presence of flavonoids, saponins, alkaloids, tannins, phenolics, carbohydrates, and proteins. GC-MS analysis revealed a variety of bioactive compounds such as 9,12-octadecadienoic acid, ricinoleic acid, and dibenzofuranamine. The 500 mg/kg dose of the extract significantly increased urine output at all time points compared to the control ($p < 0.0001$), showing comparable efficacy to furosemide. The 250 mg/kg dose produced only a mild, statistically nonsignificant increase in urine

volume. The hydroalcoholic extract of *N. lappaceum* fruit rind demonstrated significant dose-dependent diuretic activity in rats, particularly at the 500 mg/kg dose. These findings support the ethnopharmacological use of *N. lappaceum* rind as a natural diuretic and warrant further studies for the isolation of active constituents and exploration of their mechanisms of action.

Keywords: Diuretic activity, Hydroalcoholic extract, GC-MS analysis, Albino rats, Herbal medicine, Urine output, Plant-based diuretics

INTRODUCTION

Background of Study

The physiological processes by which the body maintains fluid balance play a crucial role in overall health, influencing a variety of clinical conditions. One such process, diuresis, involves the increased production and excretion of urine, serving as a key mechanism for regulating blood volume, electrolyte balance, and waste elimination. Advances in medical imaging and diagnostic techniques have enhanced the understanding of renal functions related to diuresis, enabling improved identification and treatment of renal masses through novel ultrasound applications that provide non-invasive insights into kidney health Since medicinal plants are historically good sources of several therapeutic compounds, research into them is necessary to find safe and efficient diuretics[1]. *Nephelium lappaceum* L., also known as rambutan, is a tropical fruit native to Southeast Asia. It is closely related to lychee, longan, pulasan, and guinep[2]. The fruit is a round to oval drupe, 3-6 cm long and 3-4 cm broad, with a reddish leathery skin and fleshy, pliable spines. The fruit flesh is translucent, whitish, or pale pink, with a sweet, mildly acidic flavor. Rambutans are rich in potassium, minerals, and vitamin C[3]. And are used in medicine for heartbeat, kidney function, and muscle contraction. Polyphenols, flavonoids, and tannins, including quercetin, ellagic acid, geraniin, and corilagin, are all abundant in rambutan peel. With intriguing uses in the treatment of metabolic disorders and illnesses linked to oxidative stress, these chemicals demonstrate potent antioxidant, antibacterial, anti-inflammatory, antidiabetic, and anticancer properties[4]. They are also used as astringent, stomachic, vermifuge, febrifuge, and a remedy for diarrhea and dysentery[5]. The seeds have antihyperglycemic, antioxidant, and antihypertensive properties due to their high concentrations of oleic and arachidic acids, triterpenoids, and polyphenols. While roots are used as a febrifuge and to cure tongue infections, other plant components, such as leaves, have long been used to alleviate headaches and are currently being researched for their coloring agents and possible cosmetic uses. Oral thrush is treated with the bark in traditional medicine[6]. *N. lappaceum* is a significant, untapped resource with potential for the creation of natural therapies, especially in light of the growing interest in phytomedicine across the world. In order to promote the use of certain plant components of *Nephelium lappaceum* in both conventional and contemporary healthcare systems, this study aims to investigate and scientifically evaluate their antidiuretic qualities[7,8].

MATERIALS AND METHODS

Collection and Authentication of Plant Material

Fresh *Nephelium lappaceum* (rambutan) fruits were collected locally from Sivakasi, Tamil Nadu. The plant material was authenticated by Dr. N. Senthilkumar, Head, Dept. of Botany, Ayya Nadar Janaki Ammal College, Sivakasi.

Preparation of Crude Extract

The fruit rind (220 g) was separated and macerated in a hydroalcoholic solvent (ethanol: water = 420:180 mL) with 5 mL of chloroform to prevent microbial growth. After 96 hours of soaking with occasional shaking, the mixture was heated at 30°C for 60 minutes. Solvents were evaporated on a hot plate, and the concentrated extract was stored at −20°C [9].

Qualitative screening of phytochemicals present in of *Nephelium lappaceum* fruit extract

The hydroalcoholic extract of *Nephelium lappaceum* underwent qualitative phytochemical screening to detect various phytoconstituents. The procedure followed standard methods as described by Harborne (1973). The ethanolic extract was dissolved in dilute hydrochloric acid, filtered, and subjected to tests for alkaloids, carbohydrates, glycosides, steroids, sterols, tannins, phenolic compounds, proteins, amino acids, gums and mucilage, flavonoids, saponins, foam tests, and triterpenoids. The tests included Dragendorff's, Wagner's, Mayer's, Molsch's, Fehling's, Benedict's, Keller-Kiliani's, and Borntrager's tests. The extract was also tested for tannins, phenolic compounds, proteins and amino acids, ruthenium red, Shinoda, foam, and triterpenoids. The results showed that the extract was soluble in water, filtered, and treated with various solvents, resulting in color changes and changes in various compounds. The extract was also tested for proteins and amino acids, ruthenium red, shinoda, foam, and triterpenoids[10].

Preparation of a fraction

One gram of *Nephelium lappaceum fruit extract was* dissolved in 50 mL of ethanol and 50 mL of chloroform (50:50) and allowed for 10mins to mix. The sample solution was separated into polar solution (ethanol fraction of fruit extract) and nonpolar solution (chloroform fraction of fruit extract). Both samples were analysed for GC-MS to identify the phytoconstituents present in the fruit extract[11].

GC-MS Analysis[12]

GC-MS was used to identify major phytoconstituents. Two fractions (ethanol = polar, chloroform = non-polar) were analyzed using an Agilent 7820A GC system with a DB-5 column and a 5977E MS detector.

Pharmacological Activity: Diuretic Study[13]

Animals

Male Wistar albino rats (150–200 g) were used. They were acclimatized under standard laboratory conditions. The experiment was approved by the Institutional Animal Ethics Committee (IAEC NO: SBCP/2021 – 2022/ CPCSEA/IAEC/I (1)F/F16/142).

Experimental Design

In the experimental study, a total of 12 healthy Wistar albino rats were randomly divided into four groups, each consisting of three animals[2].

- **Group 1** served as the normal control and received 2.5 mL/kg of saline orally.
- **Group 2** was designated as the standard treatment group and was administered furosemide at a dose of 20 mg/kg orally.
- **Group 3**, labeled as Test 1, received 250 mg/kg of the hydroalcoholic extract of *Nephelium lappaceum* fruit rind via the oral route.
- **Group 4**, designated as Test 2, was treated with a higher dose of 500 mg/kg of the same extract, also administered orally
- Urine was collected hourly for 5 hours using metabolic cages.

Statistical Analysis

Data expressed as mean ± SD. Analyzed using one-way ANOVA followed by Dunnett's test ($p< 0.05$ considered significant).

RESULTS

Preliminary phytochemical studies

The preliminary phytochemical screening of the hydroalcoholic extract of *Nephelium lappaceum* fruit rind revealed the presence of several important bioactive compounds. The extract tested positive for flavonoids, saponins, tannins, carbohydrates, alkaloids, gum and mucilage, phenolic compounds, and proteins and amino acids. However, it tested

negative for glycosides and steroids. These results suggest that the extract contains a diverse range of phytoconstituents that may contribute to its observed pharmacological activity, particularly its diuretic potential.

GC-MS Findings

The GC-MS analysis of the ethanol and chloroform fractions of the hydroalcoholic extract derived from the *Nephelium lappaceum* (rambutan) fruit rind revealed the presence of several naturally occurring phytochemical compounds. The ethanol fraction showed a rich profile of bioactive constituents, including Xylitol, N-Acetyl-D-glucosamine, Aziridine, Maltose, Diethyl glutaconate, Sucrose, Octadecanoic acid, Ricinoleic acid, and Lactose. In contrast, the chloroform fraction contained fewer phytochemicals, with the primary compounds identified being Furan, 2-(1-pentenyl)-, (E), n-Hexadecanoic acid, Octadecanoic acid, 2-Ethylacridine, 3-Hydroxy-2-methylbenzaldehyde, n-Decanoic acid, and cis-Vaccenic acid. These findings suggest that the ethanol fraction may possess a broader spectrum of phytochemicals with potential pharmacological activities.

Chromatogram of Ethanol Fraction (polar)

GC-MS chromatogram of the ethanol fraction (polar) of *Nephelium lappaceum fruit rind extract* (Figure 1). The chromatogram displays multiple peaks at various retention times, indicating the presence of diverse phytochemical constituents. Major peaks were observed at retention times 13.333, 15.051, 18.131, 18.806, and 19.534 minutes, corresponding to significant compounds such as Xylitol, N-Acetyl-D-glucosamine, and Octadecanoic acid. fraction.

Phytoconstituents present in the ethanol fraction (polar) of *Nephelium lappaceum* fruit extract

This table 2 presents 21 major compounds detected in the ethanol fraction, along with their retention times, and relative area percentages. Prominent phytochemicals include 9, 12-Octadecadienoic acid (5.22%), Octadecanoic acid (1.72%), Ricinoleic acid (3.61%), and 3-Dibenzofuranamine (17.22%), indicating the presence of various bioactive fatty acids, sugars, alcohols, and amines that may contribute to the extract's pharmacological activity.

Chromatogram of Chloroform fraction (non-polar)

GC-MS chromatogram showing phytoconstituents in the chloroform (non-polar) fraction of *Nephelium lappaceum* fruit rind extract (Figure 2.). The chromatogram displays several prominent peaks at different retention times, indicating the presence of various non-polar bioactive compounds. Major peaks were observed at retention times 6.931, 13.718, 15.842, and 16.713 minutes, representing the dominant constituents in this fraction. The high abundance at these peaks suggests a significant concentration of lipophilic phytochemicals, which may contribute to the therapeutic potential of the extract.

Phytoconstituents present in the chloroform fraction (non-polar) of *Nephelium lappaceum* fruit extract

The table 3 lists ten major compounds detected in the chloroform extract, along with their molecular formula, molecular weight, retention time, and relative abundance (area%). Notable compounds include 2-Ethylacridine, 1,2,4-Benzenetricarboxylic acid, 4-dodecyl dimethyl ester, and 2,4,6-Cycloheptatrien-1-one, 3,5-bis-trimethylsilyl, each contributing the highest area percentages (12.02%) at around 16.714 minutes. These compounds suggest the presence of biologically active non-polar phytochemicals with potential therapeutic relevance.

Diuretic activity

Table 4 : The study evaluated the diuretic effect of *Nephelium lappaceum* fruit rind hydroalcoholic extract in Wistar albino rats over a 5-hour period. The results showed that the extract induces diuresis in a dose-dependent manner. The 500 mg/kg dose (Group IV) produced a significant increase in urine volume compared to the control and was nearly comparable to furosemide. In contrast, the 250 mg/kg dose showed only a moderate effect. The results suggest that the active phytoconstituents in the extract, possibly flavonoids, tannins, and phenolic compounds, may be responsible for the observed diuretic activity. The extract's potent diuretic effect was confirmed by the results.

Effect of Hydroalcoholic Extract of *Nephelium lappaceum* (HAENL) Fruit Rind on Urine Output in Wistar Albino Rats (1st to 5th Hour)

- Std – Standard
- HAENL – Hydroalcoholic extract of *Nephelium lappaceum*
- Group 2,3 and 4 was compared to group 1.

Figure 3 illustrates the time-dependent urine output (mL/100g) across five hours following oral administration of saline (control), standard diuretic (furosemide 20 mg/kg), and HAENL at two dose levels (250 mg/kg and 500 mg/kg). A significant increase ($p < 0.0001$) in urine volume was observed in both the standard group and the high-dose HAENL group (500 mg/kg) at all time points compared to the control. In contrast, the 250 mg/kg HAENL group exhibited a mild but statistically nonsignificant effect.

DISCUSSION

This study evaluated the diuretic activity of fruit extract from *N. lappaceum* using albino rats at two different doses. The phytochemical investigation revealed the presence of flavonoids, alkaloids, tannins, and phenolic compounds. The GC-MS analysis confirmed the presence of many naturally occurring compounds. The increased urinary excretion may be due to the presence of various phytoconstituents in the crude extract. The lower test dose (250 mg/kg) did not show a significant diuretic effect compared to the control group, possibly due to the low concentration of the active principle(s) present in the extract. However, the higher dose (500 mg/kg) showed a significant diuretic effect, suggesting that the high dose of crude hydroalcoholic extract of *N. lappaceum* fruit rind possesses substantial diuretic activity.

CONCLUSION

In traditional medicine, the plant is used to treat many ailments. The present study results showed that single dose administration of hydroalcoholic extract of fruit rinds of *N. lappaceum 250* and 500 mg/Kg, and standard Furosemide (20 mg/kg) has increased the urinary output. The diuretic effect of the crude extract of *N. lappaceum* at a dose of 250 mg/kg was statistically not significant. However, at the dose of 500 mg/kg, the crude extract of *N. lappaceum exhibited* a significant diuretic effect. This study comes up with the identification of many phytoconstituents with the scientific proof of diuretic effect. Thus, our study supports and justifies the rationale behind the folklore use of the fruit rind of *N. lappaceum* for its diuretic activity.

ACKNOWLEDGEMENT

The authors would like to acknowledge Mr. VM. Annapandian (Associate Professor) for help during reagent preparation and pharmacological screening procedures.

CONFLICT OF INTEREST

All authors have no conflict of interest.

ABBREVIATION USED

HAENL – Hydroalcoholic extract of *Nephelium lappaceum*

ABSTRACT

The study delves into *Manas Prakriti*, highlighting how individuals' mental constitutions—divided into *Sattvika, Rajasik*, and *Tamasik* types—shape their behavioral and cognitive tendencies. These classifications are rooted in the dominance of the three *Gunas—Sattva* (purity), *Rajas* (passion), and *Tamas* (inertia), which shape a person's behavior and psychic health. Psychological parameters such as emotional responses, stress management, cognitive function, and behavioral tendencies are closely linked to these types of *Manas Prakriti*. For instance, individuals with *Sattvika* nature display calmness, intellect, and resilience, while *Rajasik* individuals tend to be ambitious and easily stressed, and *Tamasik* individuals may show tendencies toward lethargy and depression. The bio-psychosocial model in Ayurveda also suggests that psychological imbalances like stress and negative emotions (e.g.,*Bhaya* (fear), *Krodha* (anger), and *Shoka* (grief)) can lead to the vitiation of the *Doshas(Vata, Pitta, Kapha),* contributing to psychosomatic disorders. This review integrates classical Ayurvedic theory with modern psychological tools such as the DASS-42 questionnaire, which assesses depression, anxiety, and stress. By correlating *Manasa Prakriti* with DASS-42 outcomes, the study supports the relevance of Ayurvedic personality profiling in mental health screening and emphasizes the potential of constitution-based psychological interventions**.**

Keywords: *Manas,Prakriti*, psychological, *Gunas*, DASS 42 Scale.

INTRODUCTION

Ayurveda, the ancient Indian system of life lore's, emphasizes that true health is achieved only when there is harmony between the body *(Sharira),* mind *(Manas),* and knowledge (*Atman*). Central to this holistic understanding is the generality of *Prakriti* an existent's essential constitution formed at the time of generality and determined by the influence of heritable, environmental, and maternal factors. *Prakrati* of an individual is influenced by four factor which is also known *as Garbhasambhav samagri i*.e. Timimg, uterine condition, nutrition of mother and ovum and sperm at the time of consumption in which *doshas* are more dominating decide the *Prakrati*. [1] While *Sharirika Prakriti* explains the physical and physiological characteristics predicated on the *Tridosha* proposition, an existent's internal conduct and mental proclivities are defined by *Manasa Prakriti.* The relative dominance of the three *Gunas Sattva, Rajas,* and *Tamas* as well as the subtle effect of the five *Mahabhuta* (rudiments), which are present in different quantities, are the main factors that shape different *Manasa Prakriti*. The ascendancy of *Akasha and Tejas* fosters *Satvika* rates analogous as clarity, calmness, and intellect. *Vayu* and *Tejas* dominance contributes to *Rajasika* traits like ambition, impatience, and emotional perceptivity. On the other hand, *Prithvi* and *Apas* strengthen *Tamasika* attributes analogous as languor, confusion, and emotional dullness. These internal constitutions are not simply descriptive but have significant implications for how individualities respond to cerebral stress. *Sattvika Prakriti* individualities tend to show emotional rigidity and cognitive stability, while *Rajasika* types may witness heightened anxiety, restlessness, and impulsivity. *Tamasika Prakriti,* with its association with heaviness and inertia, is more vulnerable to emotional retirement, depression, and lack of provocation. These tendencies are reflected in the classical *Ayurvedic* understanding of internal disturbances like *Chittodvega* (anxiety), *Vishada* (depression), WHO introduced estimation approx. 1 million people die per year due to cause of depression [2] and *Moha* (vision), all of which affect from *Guna* imbalance. These tendencies are echoed in the *Bhagavad Gita,* where *Dhananjaya* internal state on the battleground is described as overwhelmed by *Vishada* and *Moha,* leading to *Chittodvega "Karpanya doshopahata svabhavah,"* a state where one's ingrain nature is clouded by helplessness and confusion. Ultramodern tools like the DASS- 42 assess symptoms similar as sadness, fear, and restlessness, which nearly act *Ayurvedic Manasa Bhavas* like *Vishada* (depression), *Udvega* (anxiety), and *Krodha* (perversity). These countries frequently arise from an imbalance of *Rajas* and *Tamas Gunas* in individualities with *Rajasika* or *Tamasika Manasa Prakriti.* This review looks at how Prakriti affects internal responses and psychological vulnerability when contrasting DASS-42 fields with *Guna*-based groups.

METHODOLOGY

This research undertakes a critical examination of foundational Ayurvedic texts—Charaka Samhita, Sushruta Samhita, Ashtanga Hridaya, and Kashyapa Samhita—to explore and contextualize the concept of *Manasa Prakriti* and its classification systems. To enhance the depth of analysis, supplementary references were drawn from academic dissertations and authoritative Ayurvedic reference books. A systematic search of online academic databases such as PubMed, Scopus, and Google Scholar was conducted using targeted keywords relevant to Ayurvedic psychology and the DASS-42 scale. The collected data were then systematically categorized, critically analyzed, and synthesized to draw conceptual parallels between classical Ayurvedic thought and contemporary psychological paradigms.

Definition of *Manas Prakriti*

'पुरुषस्य स्वाभाविक विशिष्टत्वं आत्म संक्रमणकालीन मनस्थितिः मानस प्रकृतिः ।' (Dr. R.P. Chipa)

The mental constitution, referred to as *Manasa Prakṛti,* is determined by the psychological impressions *(Saṃskaar)* carried by the *jeeva,* along with the influence of paternal *Beeja* (sperm) and maternal *Artava* (ovum) at the time of conception.

Classification of *Prakriti*

"Sharirik Prakriti, or bodily constitution, is divided into seven categories based on the predominance of the three *Doshas—Vata, Pitta,* and *Kapha* either individually, in dual combinations, or all three together as *Sannipataja*.[3]According to *Acharya Charka* and *Acharya Susurat*, there are 16 varieties of *Manasika Prakriti* [4](Psychic

constitution of the body). According to the *Bhagavad-Gita,* there *are* two types of *Manas Prakriti* - Divine (*Daiva)* and demon (*asuri)* [5] As per *Kashyapa Samhita* outlines three primary divisions of mental constitution: eighteen *forms* rooted in purity and stability *(Sattvika),* seven shaped by passion and aggression *(Rajasika), and* three inclined toward inertia and ignorance *(Tamasika).[6] Acharya Charaka* mentions types , Mental Constitutions and Characteristics of *Satvika Kaya*(Table no. 1)**,** *Rajasak*(Table no. 2)**,** *and Tamasik kaya*(Table no. 3)**.**

Characteristic of Manasa

वैवृत्यान्मनसो ज्ञानं सान्निध्यात्तच्च वर्तते।
अणुत्वमथ चैकत्वं द्वौ गुणौ मनसः स्मृतौ।। [25]

The mind is characterized by two key qualities: indivisibility (*Ekatva*), indicating it can attend to only one thought at a time, and subtlety (*Anutva*), referring to its minute, pervasive nature. It engages with various cognitive functions such as contemplation, analysis, inference, emotional focus, and decision-making."[26]

***Chintya*:** *Chintya* refers to that which requires deliberate contemplation actions or thoughts that demand careful consideration before deciding whether or not they should be pursued.

Vicharya: *Vicharya* denotes a process of logical analysis or evaluation that enables the mind to make a clear decision- either to accept or to reject a particular thought or course of action.

Uhya: *Uhya* involves hypothetical reasoning and internal dialogue, where the mind engages in speculation and logical deduction based on available information

***Dhyeya*:** *Dhyeya* refers to emotionally driven contemplation, where the focus is on a specific object or goal held with personal significance.

***Sankalp*:** *Sankalp* signifies a deliberate mental resolution or decision formed through thoughtful reflection.

Functions of *Manasa*

इन्द्रियाभिग्रहः कर्म मनसः स्वस्य निग्रहः।
ऊहो विचारश्च, ततः परं बुद्धिः प्रवर्तते।।[27]

The mind operates through several vital functions: it directs and governs the senses (*Indriyabhigraha*), exercises personal control and restraint (*Svasyanigraha*), engages in speculative thinking or forming mental projections (*Uha*), and reflects deeply to evaluate thoughts and actions (*Vichara*)."

Physiology of *Manasa*: It can be divided into three stages:

1. *Indriyabhigraha* – The mind directs and controls the senses to focus on external stimuli.
2. *Uaha* and *Vichara* – It reflects, analyzes, and evaluates information using memory and logic.
3. *Buddhipravṛtti* – The intellect finalizes decisions and initiates appropriate responses.

***Manovaha Srotas*:** Charaka describes the body's internal channels (*Srothas*) as conduits not only for the *Tridoshas* but also for the mind itself, which travels through them to infuse every cell with awareness or *Chetana."*[28]

Psychopathology in Ayurveda: Classical texts extensively discuss disturbed or imbalanced states of the mind, commonly referred to as mental disorders or *Manasa Vikaras*. Acharya Charaka emphasizes that the predominant pathogenic influences on the mind are the doshic qualities of *Rajas* and *Tamas*, who obstruct the Manovaha *Srothas*, giving rise to *Manasa Vikaras.*

Manasa Bhavas: *Acharya Charaka* described 22 mental states that define the psychological and emotional framework of an individual. These are: *Mano-Artha* (focused perception), *Vijnana* (discrimination or decision-making), *Raga*

(attachment), *Moha* (delusion), *Krodha* (anger), *Soka* (grief), *Harṣa* (joy), *Priti* (contentment), *Bhaya* (fear), *Dhairya* (courage or steadiness), *Vīrya* (energy or enthusiasm), *Avasthana* (mental stability), *Sraddha* (faith or intention), *Medha* (intellect), *Sanjna* (recognition), *Smrti* (memory), *Hri* (modesty), *Sila* (discipline), *Dvesa* (aversion), *Upadhi* (mental conditioning), *Dhṛti* (patience or restraint), and *Vasyata* (obedience or submissiveness). [29]

Depression (*Visada* / *Avasada*): The two disorders listed in the *Ayurvedic* texts, *Vishada* and *Avasada,* are quite similar to depression. [30],[31] "*Viṣādo roga-vardhanam*" indicating that persistent sorrow can aggravate existing diseases. *Viṣāda* is classified among the *Vāta-nānātmaja Vikāras*, showing the predominance of *Vāta Doṣa* in its development.[32] *Avasāda* involves diminished drive, hopelessness, and emotional blunting—traits seen in modern depressive disorders.[33] These symptoms are frequently observed in individuals with *Tāmasika* or *Vātaja Manasa Prakṛti,* whose mental faculties like *Dhairya* (fortitude), *Smṛti* (memory), and *Sankalpa* (will) become weakened due to *Guna* imbalance.

Anxiety (*Chittodvega*): The Ayurvedic concept of *Chittodvega* reflects a condition of mental restlessness and agitation associated with *Rājasa Guna* and *Vāta Doṣa*. According to Ayurveda, the mind is susceptible to its own imbalances - *Rajas Tamas* being the *Manas Doshas* that lead to emotional disturbances.[34] *Chittodvega* may act as a precursor to or coexist with other psychosomatic or psychiatric conditions.[35] From a biomedical perspective, anxiety is a state of heightened arousal triggered by perceived threats, often accompanied by worry, tension, tachycardia, hyperventilation, dizziness, and chest discomfort.[36] *Ayurvedic* references such as *Chittavibhramsha* (mental confusion), *Chittakṣobha* (mental agitation), and *Asvastha Chitta* (unstable mind) further support the traditional understanding of anxiety-like states.[37]-[38] *Ayurvedic* texts have described many words related to mental status *Chittavibhramsha* [39], *Chittakshobha* [40], *Asvastha Chitta* [41], *Anavasthita Chitta* [42] *and Chittodvega.*

Stress (*Udvigna Avasthā* / *Manasika Roga*): Though the term "stress" is not directly used in classical Ayurvedic texts, similar concepts are elaborated in the *Bṛhat Trayī*, which discusses *Manasika Roga*, mental *duḥkha*, and *Manasa Bhāva* vitiation.[43] prolonged exertion, improper suppression of natural urges, and emotional over activity disturb *Prāṇavaha Srothas*, leading to both somatic and psychic stress.[44] Stress affects the *Hridaya* (psychocognitive center) and impairs vital mental functions like *Dhi* (intellect), *Dhṛti* (retention), and *Smṛti* (recall). This deterioration is more evident in *Rājasa–Tāmasika Prakṛti* individuals, while those with *Sāttvika* dominance demonstrate greater psychological resilience. [45]Stress can appear in two ways: physically and psychologically. Overuse or misuse of the body results in physical stress. For instance, prolonged periods of intense exercise without food or the suppression of natural desires might vitiate *Pranavahasrothas*, which can result in coughing, breathing problems. [46]

DASS-42 Scale

The DASS-42 is a self-report scale used to evaluate emotional states such as depression, anxiety, and stress [47]. Here is a Correlation between DASS-42 AND *MANAS PRAKRITI* is understood in Table no. 4 [48].

DISCUSSION

The relationship between *Manasa Prakriti* and psychological parameters is crucial in understanding human mental health from an Ayurvedic perspective. Ayurveda categorizes mental constitutions into three primary types—*Sattvika, Rajasik*, and *Tamasik*—each influencing emotional stability, cognitive abilities, and behavioral tendencies. This classification provides a structured approach to assessing mental health predispositions and designing personalized interventions. *Sattvika* individuals, being calm, resilient, and intellectually driven, exhibit greater emotional stability and lower vulnerability to stress-related disorders. *Rajasik* individuals, known for their ambition, dynamism, and competitiveness, are more susceptible to anxiety, restlessness, and stress-related conditions. *Tamasik* individuals, characterized by lethargy, inactivity, and a tendency towards negativity, are at a higher risk of depression and emotional withdrawal. Ayurveda suggests that psychological imbalances arise due to an excess of *Rajas* and *Tamas*, leading to stress, anxiety, and depression. Ayurvedic texts describe conditions like *Vishada* and *Chittodvega*, which

closely align with modern concepts of depression and anxiety. Depression is linked to *Tamas*, which reflects mental dullness, heaviness, and negativity. Those with *Tamas* dominance may feel stuck and unable to perform daily tasks. It can affect anyone, especially individuals with past trauma or *Tamas-Rajasic* mental traits, who often show higher DASS-42 depression scores. Conditions, if left untreated, can disrupt daily functioning, interpersonal relationships, and overall quality of life. Integrating Ayurvedic principles with modern psychological frameworks offers a holistic approach to mental health care. By assessing an individual's *Manasa Prakriti*, tailored lifestyle modifications, dietary interventions, and therapeutic measures can be implemented to restore balance. Ayurveda emphasizes mental discipline, meditation, herbal remedies, and Yoga as effective strategies to manage mental health conditions and enhance overall well-being.

CONCLUSION

This study elucidates the relationship between *Manasa Prakriti* and psychological parameters, bridging Ayurvedic principles with contemporary psychological theories. The classification of mental constitution into *Sattvika, Rajasik*, and *Tamasik* types provides a structured framework for understanding cognitive function, emotional regulation, and behavioral tendencies. The correlation between *Manasa Prakriti* and psychiatric conditions, particularly depression, anxiety, and stress, underscores the clinical relevance of this ancient classification. Individuals with Tamasik dominance exhibit characteristics analogous to major depressive disorder, including lethargy, emotional detachment, and cognitive impairment. Those with *Rajasik* predominance demonstrate heightened reactivity, impulsivity, and a greater susceptibility to stress-related disorders, aligning with generalized anxiety and mood instability. Conversely, *Sattvika*-dominant individuals exhibit emotional resilience, cognitive clarity, and lower vulnerability to psychological distress, suggesting a protective effect against mood disorders. By integrating Ayurvedic psychophysiological principles with modern psychiatric frameworks, personalized mental health interventions can be developed**.** Constitution-based therapeutic approaches**,** including nutritional modifications, cognitive-behavioral strategies, stress management techniques, and Ayurvedic interventions**,** can be tailored to an individual's *Manasa Prakriti* to optimize psychological resilience and overall well-being.

Table No. 1 Mental Constitutions and Characteristics (Satvika Kaya)

No.	***Satvika Kāya[8]* Type**	**Features**
1	*Brahma Kaya[9]*	*Shuchita* (purity), *Sathya* (truthfulness), *Jitatmatva* (self-mastery), *Kama* (desire), *Krodha* (anger), *Lobha* (greed), *Moha* (ignorance), *Irshya* (jealousy), and *Amarsha* (intolerance)[9]
2	*Mahendra Kaya[10]*	*Ishwaryavanta* (lordship), *Dirghadarshita* (foresight in judgment), *Yadnavana* (performance of sacred rituals), *Shourya* (bravery), *Shakti Sampanna* (powerful energy), *Vachana Sampanna,* and pursuit of *Dharma, Artha,* and *Kama* in balance[10]
3	*Varuṇa Kaya*[11]	*Shuchita* and *Ashuchidvesha* (aversion to impurity). Such individuals are *Yajnavat* (ritual-oriented), interested in *Ambhuvihara* (aquatic activity), *Aklisthakarma* (non-violent conduct),

		and express *Kopa* (anger) and *Prasada* (pleasure)[11]
4	*Kubera Kaya*[12]	*Mana* (honor), *Shukhavihara* (luxury life routine), devoted to Dharma, Artha, and Kama, maintains Shuchi (cleanliness) and displays Kopa (anger) and Prasada.[12]
5	*Gandharva Kaya*[13]	Nrutya (dancing), Geeta (singing), Vada (music), enjoys Itihasa (history) and Purana (epics), fond of Gandha (fragrance), Malya (garlands), Anulepana (unguent application), Vasana (apparel), and Streevihara (female companionship) with Kama (desire)[13]
6	*Yamya Kaya*[14]	Smruti (memory), Vyapagatha Raga (detachment), but also associated with Irshya (envy), Dwesha (hatred), and Moha (ignorance)[14]
7	*Rishi kaya*[15]	*Adhyayana* (study), *Mada (pride), Raga (attachment), Dvesha (hatred), Moha (delusion), Lobha (greed), and Rosh (anger)*[15]

Table No. 2 Mental Constitutions and Characteristics (Rajasa Kaya)

NO.	*Rajasika Kaya*	Features
1.	*Asura Kaya*[16]	*Shura*, *Candha*, *Asuya*, *Ishvaravanta Aoupadika* (disguised superiority), *Rodra* (violent nature), *Anukrosha* (selective compassion), and *Atma Puja* (self-praise).[16]
2.	*Sarpa Kaya*[17]	*Shura* (brave) during Krudha (anger), but as Bhiru (coward) when calm. Includes Tiksna (quick-tempered), *Ayasabahala* (easily fatigued), *Santrastagochara* (frightened appearance), *and Aharaviharapara* (preoccupied with food and routine)[17]
3.	*Shakuna kaya*[18]	*Anushaktakama* (strong passion), *Ajasra Aharavihara* (excessive indulgence), *Mananavastata* (mental instability), *Amarshana* (intolerance), and *Asanchaya* (lack of foresight).[18]
4.	*Raksasa Kaya[19]*	*Marshana* (intolerance), continuous *Kopa* (anger), *Krura* (cruelty), excessive craving for *Aamisha* (non-veg food), *Swapna* (oversleeping), *Aayasa* (laziness), and *Irshya* (jealousy).[19]
5.	*Pishaca Kaya*[20]	*Marshana* (intolerance), continuous *Kopa* (anger), *Krura* (cruelty), excessive craving for *Aamisha* (non-veg food), *Swapna* (oversleeping), *Aayasa* (laziness), and *Irshya* (jealousy)[20]
6.	*Preta Kaya*[21]	*Atidukhasheela* (excessive sorrow), *Asuya* (jealousy), *Atilolupa* (greed), and *Akarma* (inaction or lethargy).[21]

Table No. 3 Mental Constitutions and Characteristics *(Tamasika Kaya)*

No.	***Tamasika Kaya***	**FEATURES**
1.	*Pashu Kaya*[22]	*Amedasa* (ignorance), *Gipushiachara* (vulgar conduct), focus on *Ahara* (food), *Maithunapara* (sexual indulgence), and *Swapnashilam* (sleepy disposition)[22]
2.	*Matsya Kaya*[23]	Exhibits *Bhiru* (fear), *Abhudha* (ignorance), *Aharalubdha* (food craving), *Anavastitha* (instability), *Kama* (lust), *Krodha* (anger), *Saranasheela* (restless movement), and *Toyakama* (desire for water).[23]
3	*Vanaspatya Kaya[24]*	*Alasa* (laziness), *Anivista Ahara* (over-eating), and *Sarva Bhudhi Anga Hina* (lack of all intellectual faculties).[24]

TABLE No. 4 DASS-42 AND MANAS PRAKRITI CORRELATION [48]

No.	**DASS-42 ITEM [47]**	**DASS-42 SCALE**	**MANASA PRAKRITI SUBTYPE**	**AYURVEDIC TERMINOLOGY[48]**	**AYURVEDIC DESCRIPTION**
1.	I found myself getting upset by quite trivial things [47]	Stress	*Rajasa - Raksasa Kaya*	*Amarshana* (intolerance), *Kopa* (anger)	Easily angered, lacks patience
2.	I was aware of dryness of my mouth[47]	Anxiety	*Tamsika - Matsya Kaya*	*Thoyakamam* (Desire for water)	Excessive physiological reaction to stress

3.	I couldn't seem to experience any positive feeling at all[47]	Depression	*Tamasika - Preta Kaya*	*Atidukhasheela* (excessive grief)	Chronic sadness, inability to enjoy
4.	I experienced breathing difficulty (e.g., excessively rapid breathing, breathlessness in the absence of physical exertion)[47]	Anxiety	*Rajasa - Sarpa Kaya*	*Santrastagochara* (fearful disposition)	Fear-induced physical responses
5.	I just couldn't seem to get going[47]	Depression	*Tamasika - Pashu Kaya*	*Akarma* (inaction), *Alasa* (laziness)	Lack of motivation, sluggishness
6.	I tended to over-react to situations [47]	Stress	*Rajasa - Asura Kaya*	*Rodra* (violent), *IshvaravantaAoupadika* (disguised movement)	Emotional volatility, exaggerated responses
7.	I had a feeling of shakiness (e.g., legs going to give way)[47]	Anxiety	*Tamsika - Matsya Kaya*	*Anavasthikam* (Unsteadiness)	Physical weakness due to stress
8.	I found it difficult to relax[47]	Stress	*Rajasa - Raksasa Kaya*	*Krura* (cruelty), *Amarshana* (intolerance)	Constant mental agitation
9.	I found myself in situations that made me so anxious I was most relieved when they ended[47]	Anxiety	*Tamasika - Matsya Kaya*	*Bhiru* (cowardice), *Abhudha* (lack of intelligence)	Fearfulness, avoidance of situations
10.	I felt that I had nothing to look forward to[47]	Depression	*Tamasika - Preta Kaya*	*Asuya* (envy), *Akarma* (inaction)	Hopelessness, lack of motivation
11.	I found myself getting upset rather easily[47]	Stress	*Rajasa - Shakuna Kaya*	*Anushaktakama* (attachment to desires)	Emotional instability, irritability
12.	I felt that I was using a lot of nervous energy[47]	Stress	*Rajasa - Asura Kaya*	*Chandha* (cruelty), *Dambha* (selfishness)	Hyperactivity, excessive energy use
13.	I felt sad and depressed[47]	Depression	*Tamasika - Preta Kaya*	*Atidukhasheela* (excessive grief)	Chronic sadness, persistent sorrow
14.	I found myself getting impatient when I was delayed or kept waiting[47]	Stress	*Rajasa - Raksasa Kaya*	*Amarshana* (intolerance)	Easily frustrated, low patience
15.	I had a feeling of faintness[47]	Anxiety	*Tamasika - Matsya Kaya*	*Ayasabahala* (fatigue), *Bhiru* (cowardice)	Physical exhaustion due to fear
16.	I felt that I had lost interest in just about everything[47]	Depression	*Tamasika - Pashu Kaya*	*Akarma* (inaction), *Nidraluthwam* (excess sleepiness)	Lack of motivation, apathy
17.	I felt I wasn't worth much as a person[47]	Depression	*Tamasika - Preta Kaya*	*Akarma* (inaction), *Asuya* (envy)	Self-deprecation, low self-esteem
18.	I felt that I was rather	Stress	*Rajasa* -	*Anavasthitham*	Highly reactive,

	touchy[47]		*Shakuna Kaya*	(instability)	mood fluctuations
19.	I perspired noticeably (e.g., hands sweaty) in the absence of high temperatures or physical exertion[47]	Anxiety	*Rajasa - Sarpa Kaya*	*Santrastagochara* (fearful appearance)	Physical anxiety response
20.	I felt scared without any good reason[47]	Anxiety	*Tamasika - Matsya Kaya*	*Bhiru* (cowardice), *Santrastagochara* (frightened disposition)	Generalized fear, irrational anxiety
21.	I felt that life wasn't worthwhile[47]	Depression	*Tamasika - Preta Kaya*	*Atidukhasheela* (excessive sorrow), *Akarma* (inaction)	Hopelessness, despair
22.	I found it hard to wind down[47]	Stress	*Rajasa - Asura Kaya*	*Rodra* (violent), *Krura* (cruel)	Restlessness, inability to relax
23.	I had difficulty swallowing[47]	Anxiety	*Tamasika - Matsya Kaya*	*Santrastagochara* (frightened state)	Stress-induced physiological response
24.	I couldn't seem to get any enjoyment out of the things I did[47]	Depression	*Tamasika - Preta Kaya*	*Atidukhasheela* (excess grief), *Akarma* (inaction)	Anhedonia, loss of pleasure
25.	I was aware of the action of my heart in the absence of physical exertion (e.g., sense of heart rate increase, heart missing a beat)[47]	Anxiety	*Rajasa - Sarpa Kaya*	*Santrastagochara* (fearful state)	Panic attacks, heightened awareness of body
26.	I felt down-hearted and blue[47]	Depression	*Tamasika - Preta Kaya*	*Vishadithwam* (sadness)	Persistent sadness, melancholy
27.	I found that I was very irritable[47]	Stress	*Rajasa - Asura Kaya*	*Dambha* (selfishness), *Rodra* (violence)	Short temper, aggression
28.	I felt I was close to panic[47]	Anxiety	*Rajasa - Sarpa Kaya*	*Bhiru* (cowardice)	Overwhelming fear, panic attack symptoms
29.	I found it hard to calm down after something upset me[47]	Stress	*Rajasa - Raksasa Kaya*	*Krura* (cruelty), *Amarshana* (intolerance)	Persistent emotional agitation
30.	I feared that I would be "thrown" by some trivial but unfamiliar task[47]	Anxiety	*Tamasika - Matsya Kaya*	*Bhiru* (cowardice), *Anavasthitam* (unsteadiness)	Fearfulness, lack of adaptability to new situations
31.	I was unable to become enthusiastic about anything[47]	Depression	*Tamasika - Pashu Kaya*	*Akarma* (inaction), *Alasa* (laziness)	Lack of motivation, apathy
32.	I found it difficult to tolerate interruptions to what I was doing[47]	Stress	*Rajasa - Raksasa Kaya*	*Krura* (cruelty), *Amarshana* (intolerance)	Easily irritated when disturbed
33.	I was in a state of nervous tension[47]	Stress	*Rajasa - Asura Kaya*	*Chandam* (anger), *Rodra* (violence)	Persistent emotional agitation

34.	I felt I was pretty worthless[47]	Depression	*Tamasika - Preta Kaya*	*Asuya* (jealousy), *Akarma* (inaction)	Self-doubt, low self-worth
35.	I was intolerant of anything that kept me from getting on with what I was doing[47]	Stress	*Rajasa - Raksasa Kaya*	*Amarshana* (intolerance)	Easily frustrated, low patience
36.	I felt terrified[47]	Anxiety	*Rajasa - Paishacha Kaya*	*Bhisayaitaram* Terrifying Disposition	Extreme fear, phobic tendencies
37.	I could see nothing in the future to be hopeful about[47]	Depression	*Tamasika - Preta Kaya*	*Atidukhasheela* (excess sorrow)	Pessimism, suicidal thoughts
38.	I felt that life was meaningless[47]	Depression	*Tamasika - Preta Kaya*	*Akarma* (inaction), *Vishadithwam* (sadness)	Existential crisis, despair
39.	I found myself getting agitated[47]	Stress	*Rajasa - Asura Kaya*	*Dambha* (selfishness), *Krura* (cruelty)	Quick temper, overreaction
40.	I was worried about situations in which I might panic and make a fool of myself[47]	Anxiety	*Rajasa - Sakuna Kaya*	*Nityasankitam* (Always in suspicious about other)	Social anxiety, performance fear
41.	I experienced trembling (e.g., in the hands)[47]	Anxiety	*Rajasa - Sarpa Kaya*	*Santrastagocarm* (Alarmingnature nature in each and every activity)	Physical manifestation of anxiety
42.	I found it difficult to work up the initiative to do things[47]	Depression	*Rajasa -Preta Kaya Tamasa- Vanaspatya kaya*	*Akarmasilam* (inaction), *Alasam* (Indolence) *Kama Varjitam*	Lack of drive, inability to take initiative

ABSTRACT

Around the world, Cardiovascular Disease (CVD) has far-reaching effects on people's health, happiness, and longevity. Echocardiography is the imaging technique most commonly used in cardiovascular medicine to evaluate heart function and abnormalities. It uses ultrasonic technology to provide high-quality images of the heart as well as its components. Though non-invasive and very useful clinically, echocardiography has issues including long treatments, operator subjectivity, and the difficulty of interpreting several readings. By greatly increasing the diagnostic accuracy of echocardiographic devices, recent developments in Deep Learning (DL) have transformed clinical decision-making. By use of DL models, which may automate the diagnosis of diseased heart diseases, analyse cardiac motion, and improve image quality, they become vital tools for precise detection and efficient treatment planning. Emphasizing their key contribution in improving the CVD prediction and diagnosis, this paper explores many DL-based frameworks especially meant to examine echocardiographic pictures across different cardiac perspectives. It also offers a thorough comparison of current algorithms, points out their shortcomings, and suggests new ideas to improve echocardiographic categorization systems, therefore allowing more accurate cardiac view identification and disease diagnosis.

Keywords: Cardiovascular Disease, Echocardiography, Deep Learning, Heart Conditions, Cardiac Views

INTRODUCTION

The coronary arteries are involved in the delivery of blood to the cardiac muscle and are primarily affected by a group of disorders collectively known as cardiovascular disease [1]. Conditions that decrease blood flow to the heart include microvascular angina, Coronary Artery Disease (CAD) and Myocardial Infarction (MI) [2].In certain situations, decreased blood flow might harm cardiac tissue. A more general category including any condition affecting the heart and blood vessels, they constitute a subgroup of cardiovascular disorders [3]. Common contributing elements are inflammation, high blood pressure, and atherosclerosis. Early identification is vital since long-term limited blood flow might harm cardiac tissue irreparably [4]. Cardiac Magnetic Resonance Imaging (CMRI), echocardiography, Computed Tomography (CT), as well as Multiple Gated Acquisition Scans(MUGA)are some of the imaging modalities utilized to detect CVD [5]. The Echo is the most common since it is portable, inexpensive, non-invasive, and easily available. Echocardiography records the heart's activity as it moves in many different directions using ultrasonography, hence providing doctors a clearer picture of the blood flow [6]. Echocardiography captures the heart's normal action by use of a three dimensional model represented by sequential frames. Time, frame height, and frame breadth make up the three dimensions [7]. Figure 1 general structure of echocardiography. The acquired echo data can be a video series covering the whole heart cycle or a static image captured at a specific point in the heart's cycle. A single cardiac cycle consists of two phases: the ventricles contracting (systole) and their relaxing (diastole) [8]. Learned echo modes include Doppler, A-mode, B-mode, and M-mode, each of which has its own distinct qualities [9]. Overall, Figure 2 displays A-Mode, B-Mode as well as M-Mode.

A-mode

The simplest type of ultrasound is called A-mode. As one transducer works its way over the body, the screen displays the echoes according to depth. Therapeutic applications of A-mode ultrasound include the use of negative wave energy to target certain tumors or calculi.

B-mode

When using B-mode ultrasound, a series of transducers in a linear array scan a two-dimensional plane within the body of the patient all at once.

M-mode

Movement is symbolized by the letter *M*. The m-mode allows physicians to track and measure the range of motion as the organ borders by scanning immediately in B-mode and having the images following each other on screen. This is because reflections change in relation to the probe.

Doppler mode

This mode utilizes the Doppler effect to assess and visualize blood flow by identifying frequency shifts that indicate the direction and speed of movement in relation to the probe. Testing cardiac valve function or portal hypertension's reverse blood flow are two examples of the many cardiovascular applications of this technique. Data from Doppler oscillations is shown graphically as spectral, color, and power Doppler, and audibly as synthesized beating sounds originating from speakers [10] [11]. Figure 3 depicts the general view of Doppler's mode in echo images.

Two Dimensional (2D)

2D echocardiographic imagery provides tomographic views of many planes of the cardiac structures, which is useful for M-mode and Doppler echocardiograms. The scan line in 2D echocardiographic imaging moves in a sweeping motion across an arc rather than being stationary. The echocardiography machine creates a 2D tomographic image for viewing after intricate processing of data collected by the transducer through the various scan lines [12].

Three Dimensional (3D) Echocardiogram

3D echocardiographic pictures can be taken in real-time or as simultaneously biplane (orthogonal) 2D images using a transducer that transmits and receives information in a three-dimensional volume simultaneous. In order to evaluate anatomy and function, various software applications are used to alter the 3D data set. In comparison to 2D echocardiography, 3D echocardiography is better for guiding surgical interventions, assessing the Right Ventricle (RV), localizing valvular abnormalities, and severe congenital heart defect. 3D color flow imaging provides a more accurate way to measure valvular regurgitation by carefully examining the vena contracts and PISA. Reportedly, it enables a quicker evaluation of Mitral Valve Area (MVA) within mitral stenosis compared to conventional 2D planimetry [13]. Figure 4 depicts a combination of 2D and 3D echocardiographic scans for better visualization and diagnosis of heart problems. Various heart images are obtained by shifting the transducer at different angles in order to examine mobility and structure. These views can be altered dependent on transducer positions at three major locations: A, B, and C [14].

- Location A has four views: apical two chambers (A2C), apical three chambers (A3C), apical four chambers (A4C), as well as apical five chambers (A5C) [15].
- Position B has a one view: The Parasternal Long Axis (PLAX) [16].
- Parasternal Short Axis of the Aorta (PSAA), Parasternal Short Axis of the Mitralvalve (PSAM) and Parasternal Short Axis of the Papillary muscles (PSAP) are the three views that make up Location C. [17]

A4C view

Using a superior-inferior ultrasound beam transsection of the thorax, the A4C image can be acquired. In echocardiographic laboratories, it is standard practice to display the LV and the RV on opposite sides of the screen.The apex and atria will be located at the highest and lowest points of the image, respectively, in every orientation. The LV apex, inferoseptal and anterolateral walls are all assessed by this picture. The RV's structure and function can also be assessed from this perspective.

A5C view

After a small rotation of the transducer, the proximal aorta, Left Ventricular Outflow Tract (LVOT), and aortic valve enter a fifth "chamber."By taking this perspective, one may qualitatively assess the aortic valve's anatomy in addition to its hemodynamics and the LVOT.

A2C view

To obtain the A2C view based on the apical 4C view, rotate 90° counterclockwise. The left atrium, inferior wall, apex, as well as mitral valve of the left ventricle may all be clearly seen in this image.

A3C view

To get the aorta back into view, the A2C view is rotated slightly counterclockwise (about 30°) to get the A3C, or apical long-axis view. The anatomical structures in this perspective are virtually identical to those in the PLAX view, except they are oriented differently. In most cases, the RVOT disappears from the picture, and the peak is more clearly seen. This image also provides more information on the hemodynamics of the mitral and aortic valves.

PLAX view

In a typical transthoracic echocardiographic examination, the first view is the PLA view. Located between the patient's right flank and right shoulder is the ultrasound beam. The image is arranged in a vertical fashion, starting from the top: the inferolateral wall, then the aorta, the cardiac apex on the left, and finally, the Right Ventricular Outflow Tract (RVOT) at the very top. The anteroseptal can be observed in the intersection of the RVOT and the LV hollow. The RV inflow can be seen by pointing a transducer slightly clockwise towards the left shoulder. This can be used to assess the tricuspid valve, RV apex, and the velocity of Tricuspid Regurgitation (TR).

PSAX view

Place the transducer in the parasternal long-axis position; then, rotate it clockwise by about 90 degrees to see the heart in the short-axis view. Beginning on the patient's left side and continuing to their right flank, this ultrasound image displays a horizontal plane. Variations in transducer tilt and positioning relative to the intercostal space allow for a variety of heart images.

PSAA

There are three leaflets visible in the PSAX image of the aortic valve: the right, left, along with non-coronary cusps. The leaflets open to a nearly circular aperture during systole and create a Y-shaped arrangement that resembles a Mercedes Benz emblem during diastole. Front and slightly to the medial are the septal as well as anterior tricuspid valve leaflets, and anterolateral are the pulmonary valve and also RV outflow tract.

PSAM

At the mitral valve level in the PSAX view, the LV appears spherical, and the mitral leaflets are visible when the ventricle opens approximately to its full cross-sectional area during diastole and closes during systole. Their movement is similar to that of a fish mouth, which can be a sign of abnormal chordae tendinae to the ventricular septum or other tissues in otherwise healthy men and women.

PSAP

In this view, the LV seems spherical, whereas the RV chamber appears semilunar, similar to the mitral valve levels. The two circular papillary muscles stick out into the LV chamber. The image below illustrates the posteromedial papillary muscle, which is on the left as well as the anterolateral papillary muscle on the right. This perspective, which gives helpful information on the LV's size and radial function, is frequently referred to as the "home base" of the PSAX. The interventricular septum might also be found to be aberrant. Figure 5 depicts different cardiac views in echocardiography that provide important spatial and temporal information for assessing heart structure and function. Despite its non-invasive nature, echocardiography has drawbacks such as lengthy procedure times, complex measurements, significant user subjectivity, and variability across observers, all of which necessitate extensive professional training. Artificial intelligence (AI) is a relatively new technology that researchers have recently used to improve the clinical examination of echocardiography with echocardiographs [18].AI encompasses Machine Learning (ML) and DL models, which aid physicians in automatically categorizing various cardio-views and cardiopathological conditions, including wall motion problems, identification of LV issues, and mitral regurgitation [19]. These models are interesting option with easy interpretation to be considered in CVD diagnostic and treatment mainly to be utilized for the early prediction with lower complexities [20]. Early stage cancer treatment and prognosis prediction has traditionally made use of ML techniques. When it comes to a number of soft-tissue examination activities, ML models implemented in Computer Aided Diagnostic (CAD) systems can greatly enhance the diagnostic efficacy for a physician [21].ML models are hypothesized with efficient image interpretation, précised decision making and provides accurate cardiovascular care and begin to alleviate some of the disparities in cardiovascular care [22]. There was a lot of intra- and inter-reader variability, and ML models were inaccurate.

Furthermore, due to their small heart size and indistinct borders, manual assessment of cardiac indices in fetus and infants is more complicated and prone to increased variability. When it comes to detecting and diagnosing heart problems, DL models outperform ML frameworks. In comparison to the time-consuming and subjective manual method, DL systems can be a cost-effective and efficient substitute. The use of such a system has the potential to alleviate the shortage of cardiology specialists in places with limited resources, manage variability among and within readers, and considerably decrease workload [23]. An assortment of DL models includes Recurrent Neural Networks (RNNs), Convolutional Neural Networks (CNNs), Long Short-Term Memory (LSTMs) as well as Deep Belief Networks (DBNs). Models like this help doctors make an objective and reliable diagnosis by analyzing relevant medical data for key features [24]. Improved echo image quality, quantification of cardio-motion, and detection of pathological illnesses are some of the ways DL hopes to boost echocardiography's diagnostic capabilities [25]. Its help makes classifying cardio-views, identifying cardiopathological problems like mitral regurgitation, wall motion

abnormalities, ejection fraction and longitudinal strain all much simpler [26]. Several DL frameworks have been created recently to categorize and predict CVD using echocardiography data. This paper investigates DL models applied in echocardiography to classify cardiac pictures and improve heart disease prediction. It also offers a comparison of the advantages and disadvantages of each model, which will assist direct future studies. Models are assessed in Section II, compared in Section III, then summarized with future direction in Section IV. Section II assesses the models, Section III contrasts them, and Section IV draws a conclusion with a summary and future direction.

Survey on MI Prediction using Deep Learning Models

Dergeli *et al*. [27] developed an Encoder-Decoder CNN (E-D CNN) to separate low-quality echocardiography and use ML to quickly identify myocardial infarction. This method employed E-D CNN to segment the entire LV wall. Next, the segmented left ventricular wall was analyzed using feature engineering in order to track the endocardial border. Finally, ML models such as Support Vector Machines (SVMs), Decision Trees (DTs), and Random Forests (RFs) are used to detect MI. In order to monitor cardiac indices, partition the heart based on areas, as well as fetch echocardiography information in real-time utilizing echocardiogram images, Zamzmi *et al*. [28] constructed the Trilateral Attention Network (TaNet). The model identifies specific areas of interest using a Spatial Transformer Network (STN) module and integrates feature embeddings for cardiac area segmentation. Then, MobileNetV2 was applied to join the segments, quantifies and localizes cardiac indices in echo images. In order to predict cardiac disease using echo images and the Internet of Medical Things (IoMT), Alamelu *et al*. [29] used a strategy called Lion-based Butterfly Optimization (L-BOA) combined with improved YOLO-v4 (LBO-YOLO-v4).This method is bi-staged; first, it uses patient-attached sensors to categorize data; second, it uses echocardiogram images to forecast the likelihood of cardiac illness. In order to classify sensor data and diseases, LBOA was used combined with Hybrid Faster R-CNN as well as SE-Rest-Net-101.When combined with CSPDarkNet53, YOLO-v4 becomes even more effective in extracting features from and classifying echo images. Hagberg *et al*. [30] developed a model to classify RV size and function from echocardiographic images using a 3D-CNN and Natural Language Processing (NLP). An RV-focused or 4-chamber view was chosen using a view classifier that this model trained on 2DE video loops that identified RV size and function.NLP is utilized to classify echocardiographic reports for RV size and function, while a 3D CNN was trained on auto-labeled echocardiographic images. A DL model was proposed by Lin *et al*. [31] to automatically detect RWMAs in echocardiography information from patients with myocardial infarction. At first, the Xception model was responsible for selecting the myocardium's perspective. Xception outputs will be segmented next by LSTM-Unet. The 3D-CNN model, which assesses cardiac activity in myocardial infarction and detects and classes regional wall motion abnormalities, received the segment and the original video as inputs.

Balakrishnan and Ambeth Kumar [32] categorized echocardiography images for CVD using Pre-Trained Recurrent CNN (PRCNN) over the Internet of Things (IoT). This approach drew on data from an IoT-based device, such as echocardiography images and patient medical histories. After DL models pre-processing and image segmentation, the pictures were further analyzed for categorization and heart disease risk assessments. They used PRCNN for classification and Fuzzy C-Means Clustering (FCM) for segmentation. Nguyen *et al*. [33] developed a technique for identifying myocardial infarction in echocardiography by means of an ensemble approach to learning of heart displacements. Initially, U-Net-model pre-processed and segmented the collected LV images. From the segmented pictures, the traits were then obtained. The SVM was then used to detect and classify MI. Arockia Valanrani *et al*. [34] developed a Contrastive Guided Adversarial Denoising Diffusion Probabilistic Model with GAN (CGADDPM-GAN) framework for generating anatomically accurate and superior quality echocardiographic pictures. MIDepnet model was also developed for identifying MI. This technique cuts down on training time and improves data representation. In MIDepnet model, an E-D CNN model segments the LV wall; a CNN model does the MI prediction. Using multi-view echocardiography, Derjeli *et al*. [35] built an automated algorithm for efficient MI prediction. Active Polynomials (APs) are employed by the model to extract and track the endocardial border of the left ventricle; these APs subsequently help to assess displacements of myocardial segments. MI detection was then done using DT, RF, k-Nearest Neighbors (kNN), SVM and 1D-CNN fed these characteristics. By examining cardiac segments for early MI identification, this method combines A4C and A2C perspectives to improve diagnostic accuracy. Bell-Navas *et al*. [36]

built a Higher-Order Dynamic Mode Decomposition (HODMD) and a Vision Transformer (ViT) for an automated cardiac pathology recognition from tiny echocardiogram datasets. HODMD for data augmentation and feature extraction first converts echocardiogram sequences into annotated, ML-compatible pictures. Even with little data, the second step analyzes these images and forecasts the state of the heart by training a ViT from scratch.

Comparative Analysis

This section presents a comparative research based on the advantages and disadvantages of cardiac views derived from using various DL methods that were briefly discussed in the previous section. The comparison is provided in table 1.

RESULT AND DISCUSSION

The performance analysis in Table 1 illustrates the accuracy of various deep learning models for predicting CVD using echocardiography images. There are comparisons shown in Figures 6–9 using F1 score, recall, accuracy, and precision. PRCNN [32] has the highest accuracy, while TaNet [28] excels in both precision and recall. MIDepnet and Realistic Synthetic 2D Ultrasound Dataset (RS2DUD) [34] produce excellent results, but SVM and CNN models perform poorly. The Function-based model outperforms the Size-based model in terms of feature extraction. Although PRCNN performs well, it may suffer from overfitting due to insufficient training data. To solve this, a future model is given that employs sophisticated DL techniques such as data augmentation, transfer learning, and regularization approaches to increase resilience, reduce overfitting, and improve real-time diagnostic accuracy.

CONCLUSION

Echocardiography is a diagnostic tool for complicated CVD and a popular screening modality for healthy, asymptomatic people. The problem of incorrect diagnosis has been a focus of extensive research into various DL methods. This study examines the predicted efficacy, limitations, and strengths of different DL methods for echocardiography cardiac view classification. Researchers looking to build strong models to improve CVD prediction as well as diagnosis might use the insights on difficulties and performance metrics mentioned here as useful tools. Patients with heart disease will soon be able to access individualized therapy because to these developments. Future research should focus on transfer learning, data augmentation, and regularization to tackle overfitting with limited datasets, enhancing model performance for real-time applications. These innovations can enable rapid cardiac predictions using echocardiographic data, improving diagnosis and patient outcomes.

ABSTRACT

Refrigeration and air conditioning systems account for a significant portion of global energy consumption. Reducing this energy usage can help address the energy crisis and mitigate global warming by utilizing environmentally friendly refrigerant R134a.One promising approach to decrease power consumption in conventional refrigeration systems is the implementation of a two-phase ejector as an expansion device. A computer simulation of this enhanced cycle was conducted using a one-dimensional model that incorporates mass, momentum, and energy balances. Simulation through Engineering Equation Solver (EES) is done analytically with results indicating that the geometric parameters of the ejector design significantly impact the system's performance. The maximum coefficient of performance (COP) in ejector expansion cycle achieved is approximately 5.5. When compared to the standard cycle, the ejector expansion cycle demonstrates an increase in COP of about 8.86%.

Keywords: Ejector, Engineering Equation Solver, Refrigeration, R134a

INTRODUCTION

An ejector expansion refrigeration system (EERS) is an innovative refrigeration technology that replaces the expansion valve with an ejector to manage the flow and expansion of refrigerant. This system boasts several benefits

over conventional refrigeration systems, particularly in energy efficiency and operational flexibility. Essentially, EERS operates on vapor-compression cycles, utilizing an ejector in place of a throttle valve[7]. As illustrated in Figure 1, the EERS comprises four main components: evaporators, vapor generators, condensers, and ejectors. The system functions by heating the vapor generator, which produces refrigerant at high pressures and temperatures, known as the 'primary fluid.' This primary fluid is then directed into the ejector, where it expands and creates a low-pressure area in the evaporator, referred to as the 'secondary fluid.' The primary fluid collects and compresses the secondary fluid and the resulting mixture is passed to the separator which then passes to the evaporator through expansion valve. Finally, the compressed refrigerant is cycled back to the condenser completing the refrigeration cycle [8]. P-h Curve for Ejector Expansion Refrigeration Cycle (Fig. 2)

Refrigerant R-134a

R-134a (1,1,1,2-Tetrafluoroethane) is a widely used refrigerant, particularly in automotive air conditioning systems, household appliances, and commercial refrigeration. It is a hydrofluorocarbon (HFC) and has been popular as a replacement for R-12 (CFC-12) due to its lower ozone depletion potential (ODP) and better environmental properties. Below are some key properties of R-134a(Table:1).

METHODOLOGY

The methodology involved in the investigation of a 2-phase constant pressure ejector's in an Ejector Expansion Refrigeration System (EERS) using refrigerant R134a is outlined below. The mathematical model is developed in Engineering Equation Solver (EES) to analyse the effects of operational and geometric parameters on Entrainment Ratio, Pressure Lift and ejector efficiency.

Engineering Equation Solver (EES)

EES (Engineering Equation Solver) is used to solve a variety of interconnected non-linear differential and algebraic equations through numerical methods. EES has built-in property functions for many refrigerants (e.g., R134a, R22, R410A, R744/CO_2). Enthalpy, entropy, temperature, pressure, and specific volume is computed by different mathematical equation with the help of thermophysical built in properties and finally COP for both basic cycle and ejector expansion refrigeration system is evaluated.

Mathematical Modelling

The mathematical model employed here evaluates the relative efficiency of the ejector expansion cycle, primarily influenced by the entrainment ratio (ω) and the pressure differential ($P_e - P_b$) within the receiving section. This model also facilitates a deeper understanding of how different operational parameters affect the performance of the ejector expansion process in relation to these two critical variables. As studies progress, notable geometric variations come into play. In the accompanying diagram, high-pressure primary fluid (PF) is channelled through a nozzle where it expands and accelerates to supersonic speeds, producing a low-pressure zone. This zone, which has a lower pressure than the low-temperature evaporator, allows the high-velocity PF to entrain the secondary fluid (SF) via a passage connected to the evaporator. Flow Diagram for EES Software (Fig. 3). Although the PF and SF streams begin to interact, full mixing occurs only at designated points along the ejector's internal structure. The SF continues to accelerate within a narrowing passage created by the PF's expanding fan-cone jet flow. It is assumed that complete mixing happens by the end of the constant-area mixing chamber. Flow of Fluids in Ejector Sections (Fig. 4), Different Geometric Dimension of Ejector Section (Fig. 5). At this point, due to high back pressure aligned with the condenser pressure, a thin shock wave typically forms, compressing the mixed flow. This shock stabilizes the post-mixing stream to a uniform pressure and temperature. As the mixture moves through the subsonic diffuser, its speed decreases while partial pressure recovery occurs, leading to additional compression of the flow. Ejector Dimensions(All Dimensions are in mm) (Table1)

RESULTS AND DISCUSSION

Figure 6 implicit the COP increases with increase in evaporator temperature, as the temperature in evaporator rises from -25°C to 20°C the variation of COP for both i.e., Basic Cycle (VCRS) and Ejector Expansion Cycle (EEC) increase. Also, the higher COP can be achieved with EEC. In Figure 7, result shows that increasing evaporator temperatures from -25°C to 20°C, COP and Compression Ratio both increases at T_e =20°C maximum $COP_{(eec)}$ = 9.45 and compression ratio 5.5 can be achieved. Figure 8 implicit the COP decreases with increase in condenser temperature, as the temperature in condenser rises from 30°C to 70°C the variation of COP for both i.e., Basic Cycle (VCRS) and Ejector Expansion Cycle (EEC) decreases. Also, the higher COP can be achieved with EEC. In Figure 9, result shows that increasing condenser temperatures from 30°C to 70°C, COP decreases whereas Compression Ratio increases at T_c =30°C maximum $COP_{(eec)}$ = 14 with compression ratio 6 can be achieved. Figure 10 shows that as the temperature in evaporator increases from -25°C to 20°C compressor work decreases quantitatively, in ejector expansion cycle work done required is less as compared to basic cycle therefore the COP of ejector expansion cycle is higher. Figure 11 shows that as the temperature in condenser increases from 30°C to 70°C compressor work decreases quantitatively, Also in ejector expansion cycle work done required is less as compared to basic cycle therefore the COP of ejector expansion cycle is higher.

ABSTRACT

Therapeutic drug monitoring, or TDM, is crucial to optimizing drug therapy for medications with a narrow therapeutic index (NTI), where even slight variations in plasma concentration could cause toxicity or therapeutic failure. Among the drugs that require close monitoring include digoxin, lithium, valproate, and theophylline due to their distinct pharmacokinetic variability and narrow safety margins. Precise and timely measurements of their concentrations in biological matrices such as serum or plasma are necessary for safe and effective patient therapy. The bioanalytical techniques used to quantify these four NTI drugs are compiled and thoroughly reviewed in this review, with particular attention paid to sample preparation methods, analytical platforms like chromatographic, immunoassay, and

spectrophotometric methods, and their validation parameters in accordance with regulatory guidelines. The reliability, sensitivity, specificity, and therapeutic usefulness of each approach are emphasized. As a complete resource to facilitate technique selection and development in TDM, the study also addresses new trends and existing issues in routine clinical monitoring.

Keywords: Therapeutic Drug Monitoring (TDM), Narrow Therapeutic Index Drugs, Digoxin, Lithium, Valproate, Theophylline, Bioanalytical Methods

INTRODUCTION

Definition and Purpose of TDM

Therapeutic drug monitoring (TDM) is a strategy that measures drug concentrations in biological fluids, particularly serum or plasma, to optimize medication therapy and reduce toxicity, particularly for drugs with narrow therapeutic indices, ensuring correct therapeutic efficacy and dosage adjustments. [1,2]

Clinical Importance of Monitoring Plasma Drug Concentrations

TDM plays an important role in measuring the level of drug in plasma based on the influence by such factors as age, body weight, liver and kidney functions, interaction and genetic polymorphisms especially in the narrow therapeutic range drugs.[3,4,5,6,7]

Challengesin Bioanalysis of Narrow-Therapeutic Index Drugs

There is a challenge in the analysis of low drug levels in bioanalysis of NTI medicines because they are highly sensitive and specific and thus need standardized analytical methodologies and dosage to achieve maximum effect in the treatment.[8,9,10]

Digoxin

Pharmacology and Therapeutic Range

Digoxin is a cardiac glycoside that is used to treat heart failure and atrial fibrillation because it blocks the Na + / K + -ATPase pump to increase contractility and reduce the heart rate, which must be monitored during the treatment.[11,12,13,14]

TDM Importance and Risks of Toxicity

TM of digoxin plays an important role in managing the drug, since it allows early detection of high levels of digoxin followed by dose adjustments, thereby avoiding toxicity and associated harm.[,16,17,18,19,20,21,22]

Clinical Approach to TDM for Digoxin

Blood samples in TDM of digoxin are taken after 6 hours of drug administration, paying attention to renal functioning, creatinine clearance level, and glomerular filtration rate as well as the necessity to monitor electrolyte levels to reach optimal drug level.[23,24,25,26]

Lithium

Indications in Psychiatry

Lithium is the gold standard in the treatment of bipolar disorder by regulating the intracellular pathways to control the affected moods and prevent suicide thus effective both in short and long-term afflictions.[27,28,29]

Serum Concentration Monitoring Challenges

The concentration of Lithium is vital since it has a narrow therapeutic index, which leads to the symptoms of toxicity, including tremors, nausea, vomiting, diarrhea, fatigue, and arrhythmias, coma, and renal failure.[30,31,32,33,34,35]

Additional Monitoring Considerations

Monitoring lithium levels, electrolyte levels, and thyroid function is crucial during therapy to prevent lithium-related issues like renal function and hypothyroidism in some patients.[36]

Valproate

Antiepileptic Applications

Valproate is a scheduled antiepileptic drug; it is given to cure generalized and focal types of epilepsy, as well as in the treatment of bipolar disorder and migraine prevention. [37,38,39,40]

Protein-Binding Implications

A protein bound drug like valproate needs proper estimation of serum levels in order to achieve its therapeutic effect. The progression of seizure conditions is regulated with the help of the doses of the medicine 50-100ug/mL as well as protein binding, renal, and hepatic activities.[41,42,43,44,45]

Clinical Monitoring and Considerations

Valproate levels must be regularly monitored to ensure the level remains within-therapeutic-range and avoid side effects. The free fraction of valproate may be measured in order to manage the dose. Hepatotoxicity and thrombocytopenia are avoided through liver functioning tests. Valproate compliments with other antiepileptics, thus leading to toxicity.[46,47,48]

Theophylline

Use in Respiratory Disorders

Theophylline is a bronchodilator that has been employed in the treatment of respiratory disorders such as COPD and asthma through phosphodiesterase inhibition, raising the amount of cyclic AMP, and enhancing ventilation but also has limited use due to its small therapeutic index.[49,50,51]

Need for Plasma Level Adjustment

The therapeutic window of theophylline is 10-20 5g/mL and toxic level is dangerous. It is important to measure and monitor the plasma levels particularly with patients who are newly treated, diseased, and prone to drugs.

Factors Affecting Theophylline Pharmacokinetics

Different factors affect theophylline metabolism among them being liver CYP1A2 enzymes and an individual can take longer or not to excrete theophylline back to the body depending on the body specifics.

Age: Theophylline clearance is age-variable and is susceptible to the elderly where the risk of toxicity is more probable. Clearance in neonates and young children is rapid and therefore adjustments are necessary frequently.[54].

Liver Function:Theophylline is a liver-metabolized drug classified as livery and may have toxic effects such that starting doses should be low, and more observation is needed in the patient with admitted liver disease.[55]

Renal Function: The scientists have discovered that theophylline clearance may be affected by the renal dysfunction caused, which results in the build-up of metabolites and enhances the possibility of unfavorable outcomes.[56].

Drug Interactions: Drugs such as ciprofloxacin or rifampin can affect the metabolism of Theophylline subsequently causing an increase in the toxicity or reduction in the effect through inhibition of CYP450 and stimulation of CYP1A2 respectively. [57,58]

Smoking: Cigarette smoking enhances the activity of CYP1A2 which suppresses theophilline clearance and thus reinforced the medication that require an elevated dose and that the smokers who quit the habit decrease the dose.[59]

Clinical Monitoring and Considerations

Theophylline has a narrow therapeutic margin and gets broken down through its metabolism; this is why monitoring the drug is essential in the serum. Trough level should be measured by collecting blood 5-12 hours after the dose. The essentials of monitoring are toxicity, toxicity, and electrolyte unbalances.[60]

Bioanalytical Methods for Therapeutic Drug Monitoring (TDM)

Sample Collection and Handling

The correctness of Therapeutic Drug Monitoring (TDM) is directly linked to correct collecting, processing, and handling of samples so that a diligent pre-analytical phase is achieved to avoid mistakes.

Pre-analytical Considerations

Matrix: TDM involves blood ratio such as plasma, serum, urine, or saliva to establish the distribution of drugs, protein binding and half-life. Plasma is of choice in terms of consistency and reliability whereas serum samples can be used with selected drugs.[3].

Anticoagulants: The type of anticoagulant plays a critical role in the quality of the samples whereby heparin and EDTA are prevalent in the collection of plasma samples. Low interference is the reason why heparin is the choice of therapeutic drug monitoring.[61].

Timing: TDM uses plasma or serum levels and concentrates on the trough and peak levels when measuring the concentrations of drugs. Other tests requiring Trough samples include drugs that have narrow therapeutic index wherein the drug levels are in the therapeutic range.[1].

Plasma vs. Serum Comparisons

Plasma obtained using anticoagulants results in the preservation of cellular components and proteins that enables drug drug trough levels in TDM assays, while serum provides the true drug concentrations but needs longer preparation prior to analysis.[62]

Extraction Techniques

The extraction methods of the samples preparation are meant to separate and concentrate drugs against the biologicals and depends on the factors such as drug polarity vis-a-vis column polarity, molecular weights, binding of drugs to protein, and the complexity of the biologicals.

Protein Precipitation

Overview: Protein precipitation is a simple technique involving the addition of a solvent, such as acetonitrile or methanol, to the sample, which precipitates proteins. The supernatant containing the analyte is then separated by centrifugation.

Advantages: This method is inexpensive, quick, and requires minimal equipment, making it suitable for routine analysis in clinical settings. It's particularly effective for highly protein-bounddrugs.

Disadvantages: While it's simple, the recovery rate can be low, and reproducibility may suffer, particularly for hydrophilic or highly protein-bound drugs. This can lead to loss of analyte or matrix interference [63].

Liquid-Liquid Extraction (LLE)

Overview: LLE is based on the principle of partitioning the drug between two immiscible liquids (e.g., hexane and water). The analyte partitions into the organic phase, which is then separated, evaporated, and reconstituted for analysis.

Advantages: High recovery and good selectivityfor a broad range of drugs. LLE is ideal for drugs with low solubility in water but high solubility in organic solvents.

Disadvantages: LLE is time-consuming, requires large volumes of organic solvents, and is prone to cross-contamination from other substances in the matrix, leading to low reproducibilityif not optimized [64].

Solid-Phase Extraction (SPE)

Overview: SPE involves the use of a solid adsorbent (e.g., silica or polymer-based resins) to bind the analyte from the liquid sample. The analyte is then eluted using a solvent. SPE is highly versatile and can be used with a variety of biological matrices.

Advantages: High reproducibility, good recovery rates, and the ability to scale for high-throughput analysis. It offers better purification of the sample and minimizes matrix effects, improving quantification accuracy.

Disadvantages: Higher cost, more labor-intensive, and it requires specific training to handle efficiently. Optimizing SPE for various drug classes can also take time [65].

Impact on Recovery and Reproducibility

One important part of the analysis is recovery and in methods such as LLE and SPE, usually, recovery is higher than protein precipitation which can lead to differences between samples.

Analytical Techniques

The analytical techniques used for TDM must be sensitive, accurate, and able to detect drug concentrations at low levels. The choice of technique depends on the nature of the drug, the required sensitivity, and the clinical setting.

Chromatographic Methods

High-Performance Liquid Chromatography (HPLC)

HPLC is one of the most widely used techniques in TDM for separating and quantifying drugs in biological fluids. It provides excellent resolution, allowing the detection of low concentrations of drugs even in complex biological matrices.

Advantages: High precision, ability to separate complex mixtures, and widely established methodology. It is capable of handling a wide range of analytes.

Limitations: HPLC can be time-consuming, with long analysis times, and requires skilled operators. Additionally, it may not offer the same sensitivity as mass spectrometry (MS) methods.

Liquid Chromatography-Mass Spectrometry (LC-MS/MS)

LC-MS/MS combines the separation power of liquid chromatography with the sensitivity and specificity of mass spectrometry, making it ideal for analyzing drugs with low therapeutic concentrations.

Advantages: It offers the highest sensitivity, selectivity, and precision available, capable of detecting even trace levels of drugs. LC-MS/MS can handle complex biological samples with minimal interference.

Limitations: It is expensive and requires specialized equipment and training. The setup and maintenance costs are high, making it less accessible for routine use in some clinical settings [66]. (Table:1)

Immunoassays

Enzyme-Linked Immunosorbent Assay (ELISA):

ELISA is a widely used immunoassay that detects and quantifies drugs based on antibody-antigen interactions. It's frequently used for high-throughput testing.

Advantages: Ease of use, rapid results, and minimal sample volume**.**

Limitations: Less sensitive than chromatography and more prone to cross-reactivity or interference from similar molecules.

Radioimmunoassay (RIA)

Uses radioactive isotopes to quantify drugs based on the binding to specific antibodies.

Advantages: Highly sensitive and suitable for drugs with low concentrations.

Limitations: Radioactive materials pose health risks, and the technique requires strict regulatory control, making it less commonly used today.

Fluorescence Polarization Immunoassay (FPIA) and **Chemiluminescence Immunoassay (CLIA)**
These assays rely on fluorescent or chemiluminescent signals for quantifying drugs. These techniques are more rapid and automated than traditional methods.
Advantages: **Rapid results and** suitable for point-of-care testing. They allow for the detection of multiple analytes simultaneously.
Limitations: **Lower sensitivity** compared to chromatography and potential **interference** from similar substances [67].

Spectrophotometry and Electrochemical Methods
UV/visible drugs can be observed in electronics spectrophotometry where light absorption at wavelengths is performed in an attempt to interact with the drugs; electrochemical methods operate in a similar manner only that a current or potential is used to interact with the substances.
Advantages: These methods are simple and cost-effective.
Limitations: They often lack the sensitivity and selectivity required for many therapeutic drugs, especially those present in trace amounts [68].

Comparative Analy sis of Bioanalytical Methods for Therapeutic Drug Monitoring (TDM)
KeyComparison Parameters Therapeutic Drug Monitoring (TDM) requires accurate and timely measurement of drug concentrations in biological matrices. The selection of an analytical method depends on several key factors:
Clinical Feasibility in routine hospital laboratories is based on infrastructure, Applicability automation, and operator skill level.

Comparative Overview of Analytical Techniques(Table: 2)
Drug-Wise Method Comparison Tables
Digoxin (Table 3)
Lithium (Table 4)
Valproate (Table 5)
Theophylline (Table 6)

Summary
LC-MS/MS is sensitive and specific and expensive and technically demanding. Immunoassays are fast, they are prone to interference. HPLC is applicable in hospital labs.

Challenges and Considerations in Clinical Practice
Despite advances in analytical technology, the clinical application of TDM faces several important challenges that can impact both result interpretation and patient outcomes.

Inter-patient Variability and Pharmacokinetics
Due to individual pharmacokinetics such as the patient age, weight, organ functioning, genetic polymorphisms, disease conditions, the plasma concentrations may greatly differ even when using a standard dose.[3, 72].

For example
Renal impairment can reduce elimination of drugs like lithium and digoxin, necessitating more frequent monitoring.
Liver dysfunction affects metabolism of valproate and theophylline.
CYP450 polymorphisms can alter metabolism rates, especially for drugs with narrow therapeutic indices. Consequently, fixed dosing regimens may be inadequate, making individualized TDM essential for effective therapy.

Protein Binding and Drug Interactions
Protein-bound drug such as valproate may require free drug level assessment which is toxicity at the higher concentration of the drug in hypoalbuminemia and drug-drug interactions.[73]

Limitations in Method Standardization across Laboratories

There remains a lack of universal standardization and harmonization of bioanalytical methods across laboratories. Differences exist in

Sample matrix used (serum vs. plasma)

Calibration standards and quality controls

Reference ranges and interpretive criteria

Instrumentation (e.g., manual vs. automated systems)

Differences in NTI drugs have the tendency to produce inconsistent outcomes, which interfere with clinical decisions. To some extent, this can be offset by the use of External Quality Assurance programs and inter-laboratory comparisons, but this is not done worldwide.[74]

Recent Advances and Future Trends

Technological innovations in analytical chemistry and data science are enhancing the precision, accessibility, and utility of TDM. These advances aim to overcome limitations of traditional methods and support more personalized, efficient patient care.

LC-MS/MS Multiplexing for Simultaneous TDM

Liquid chromatography-tandem mass spectrometry (LC-MS/MS) platforms have also greatly improved drug monitoring with a reduction in sample volume and cost along with processing time, especially to monitor polypharmacy patients and real-time drug adjustment purposes.[75]

Dried Blood Spot (DBS) Sampling

DBS sampling is a minimally invasive method that uses small volumes of capillary blood collected via finger prick, dried on filter paper, and sent for analysis. Its key benefits include (76)

Simplified logistics (no need for cold chain or venipuncture)

Suitability for paediatric and remote populations

Efforts to enhance DBS normalization algorithms and combine it with telemedicine and home-based care models are addressed to help with standardization challenges and increase compatibility with LC-MS/MS and HPLC methods.

Role of Artificial Intelligence (AI) in Method Optimization and Result Interpretation

Artificial Intelligence (AI) and machine learning models are being increasingly explored for

Predicting pharmacokinetic profiles from sparse data

Optimizing assay development (e.g., retention time prediction, peak deconvolution)

Personalizing dosing regimens using Bayesian forecasting and clinical variables (77)

Artificial intelligence (AI) in the form of clinical decision support systems (CDSS) offers the idea of promoting the dynamic, personalized, and proactive aspect of therapeutic drug management (TDM) by taking into consideration the patient-specific data along with previous information.

CONCLUSION

Personalized pharmacotherapy - Therapeutic Drug Monitoring (TDM) is very important in relation to drugs with narrow therapeutic index. The confidence of TDM depends on a verification and normalization of bioanalytical techniques employed to assess the amount of drugs. LC-MS/MS is the most accurate measuring system with low susceptibility to interferences described as a gold standard. They are also present in routine clinical settings by use of immunoassays and electrochemical assays. There are several target-specific issues: high specificity of digoxin, lithium using ISE or flame photometry and interpretation of protein-binding of valproate. There is a need to harmonize assay

protocols and reference ranges and new technologies such as the use of dried blood spots as a sampling method and AI-based analytics have allowed TDM to become more efficient and patient-specific.

ABSTRACT

Graham and Sloane [2] introduced the harmonious graphs. Singh and Varkey [3] introduced the odd sequential graphs. Gayatri and Muthuramakrishnan ([4],[1]) introduced *k*-odd sequential harmonious labeling of graphs. In this paper we pattern to bequest *k*-odd sequential harmonious labeling of tree related graphs.

Keywords: odd Harmonious labeling, Bistar, Banana, $\langle K_{1,n} : m \rangle$, Complete bipartite.

INTRODUCTION

Throughout this paper we consider finite simple, connected and undirected graph. A graph $G = (V, E)$ with '*p*' vertices and '*q*' edges is called a (*p*, *q*) graph. The graph labeling is an assignment of integers to the set of vertices or edges or both subject to certain condition. Labeled graphs serve as a useful mathematical models for many applications such as coding theory including code design of good radar type codes and convolution codes with optimal auto correction properties. Graham and Sloane [2] introduced harmonious labeling during their study of modular versions of additive bases problems stemming from error correcting codes. A graph is said to be harmonious if there exist an injection $f : V(G) \to \{0, 1, 2, ..., 2q-1\}$. Such that the induced function $f^+ : E(G) = \{0, 1, 2, ..., 2q-1\}$ defined by $f^+(uv) = (f(u) + f(v)) (\text{mod } q-1)$ is a bijection and f is said to be harmonious labeling of G. In [4] Gayatri and Muthuramakrishnan say that a labeling is a *k*-odd sequential harmonious labeling for any integer $k \geq 1$. A labeling is a *k*-odd sequential harmonious labeling if there exists an

injection f from the vertex set V to $\{k-1, k, k+1, \ldots, k+2q-1\}$ such that the induced mapping f^+ from the edge set E to $\{2k-1, 2k+1, \ldots, 2k+2q-3\}$ defined by

$$f^+(uv) = \begin{cases} f(u)+f(v) & \text{if } f(u)+f(v) \text{ is odd} \\ f(u)+f(v)+1 & \text{if } f(u)+f(v) \text{ is even} \end{cases}$$

are distinct. A graph G is said to be k-odd sequential harmonious graph if it admits a k-odd sequential harmonious labeling. In this paper, we examine some results on k-odd sequential harmonious labeling of graphs. Throughout this paper, k denotes any positive integer ≥ 1. For brevity, we use k-OSHL for k-odd sequential harmonious labeling.

MAIN RESULTS

Definition 1

The Bistar graph $B_{n,n}$ is the graph obtained from k_2 by joining m pendent edges to both the ends of k_2.

Theorem 2.1

The graph Bistar $B_{n,n}(n \geq 2)$ is a k-odd sequential harmonious graph for any k.

Proof

Let $\{u, w, u_i, w_i, 1 \leq i \leq n\}$ be the vertices and $\{e_i, 1 \leq i \leq 2n+1\}$ be the edges which are denoted as in Fig. 1.

First we label the vertices as follows.

Define $f: V \to \{k-1, k, k+1, \ldots, k+2q-1\}$

$$f(u) = k-1$$

$$f(w) = 2n+k$$

For $1 \leq i \leq n$,

$$f(u_i) = 2i+k-2$$

$$f(w_i) = 2i+k-1$$

Then the induced edge labels are

For $1 \leq i \leq 2n+1$

$$f^+(e_i) = 2i+2k-3$$

Clearly, the edge labels are odd and distinct,

$$f^+(E) = \{2k-1, 2k+1, \ldots, 2k+2q-3\}.$$

Hence the graph Bistar $B_{n,n}(n \geq 2)$ is a k-odd sequential harmonious graph for any k.

Illustration 1

(a) 2-OSHL of $B_{3,3}$ is shown in Fig. 1(a).

(b) 9-OSHL of $B_{6,6}$ is shown in Fig. 1(b).

Definition 2

The graph $\langle K_{1,n} : m \rangle (m, n \geq 2)$ obtained by taking m disjoint copies of $K_{1,n}$ and joining a new vertex to the centers of the copies of $K_{1,n}$.

Theorem 2

The graph $\langle K_{1,n} : m \rangle (m, n \geq 2)$ is a *k*-odd sequential harmonious graph for any *k*.

Proof

Let $\{u_i, w_j, 1 \leq i \leq m, 1 \leq j \leq m-1, u_{ij}, 1 \leq i \leq m, 1 \leq j \leq n\}$ be the vertices and $\{e_i, 1 \leq i \leq mn + 2(m-1)\}$ be the edges which are denoted as in Fig. 2.

First we label the vertices as follows.

Define: $f : V \to \{k-1, k, k+1, \ldots, k+2q-1\}$ by

$$f(u_1) = k-1$$

For $2 \leq i \leq m$

$$f(u_i) = 2i + k - 3$$

For $1 \leq j \leq m-1$

$$f(w_j) = 2n + (2n+2)(j-1) + k.$$

For $1 \leq i \leq m, \ 1 \leq j \leq n$

$$f(u_{ij}) = 2j + (2n+2)(i-1) + k - 2.$$

Then the induced edge labels are:

For $1 \leq i \leq mn + 2(m-1)$,

$$f^+(e_i) = 2i + 2k - 3$$

Clearly the edge labels are odd and distinct.

$$f^+(E) = \{2k-1, 2k+1, \ldots, 2k+2q-3\}$$

Hence the graph $\langle k_{1,n} : m \rangle \ (m, n \geq 2)$ is a k-odd sequential harmonious graph for any *k*.

Illustration 2

(a) 3-OSHL of $\langle K_{1,4} : 3 \rangle$ is shown in Fig. 2(a).

(b) 4-OSHL of $\langle K_{1,3} : 3 \rangle$ is shown in Fig. 2(b).

Theorem 3

Banana tree $B_{m,n} \ (m \geq 2, \ n \geq 2)$ is a *k*-odd sequential harmonious graph for any *k*.

Proof

Let $\{u, v, w, u_i, 1 \leq i \leq m+n\}$ be the vertices and $\{e_i, 1 \leq i \leq m+n+2\}$ be the edges which are denoted as in

Fig. 3.

First we label the vertices as follows

Define $f: V \to \{k-1, k, k+1, \ldots, k+2q-1\}$ by

$f(u) = k-1$

$f(v) = k+1$

$f(w) = k+3$

For $1 \le i \le m+n$,

$f(u_i) = 2i+k-2$

Then the induced edge labels are

For $1 \le i \le m+n+2$,

$f^+(e_i) = 2(i+k)-3$

Therefore $f^+(E) = \{2k-1, 2k+1, \ldots, 2k+2q-3\}$. So f is a *k*-odd sequential harmonious labeling and hence, the Banana tree $B_{m,n}\ (m, n \ge 2)$ is a *k*-odd sequential harmonious graph for any *k*.

Illustration 3

(a) 3-OSHL of $B_{6,3}$ is shown in Fig. 3(a).

(b) 4-OSHL of $B_{4,4}$ is shown in Fig.3(b).

Theorem 2.4

$G(m, n)\ (m \ge 3, n \ge 4)$ is a *k*-odd sequential harmonious graph for any *k*.

Proof

Let $\{u_{ij}, 1 \le i \le m, 1 \le j \le n\}$ be the vertices and $\{a_{ij}, 1 \le i \le m, 1 \le j \le n-1, b_i, 1 \le i \le m\}$ be the edges which are denoted as in Fig. 4.

Here the labeling of vertices are defined as

$f: V \to \{k-1, k, k+1, \ldots, k+2q-1\}$

For $1 \le i \le m,\ 1 \le j \le n$,

$f(u_{ij}) = k+j-2+n(i-1)$

Then the induced edge labels are:

For $1 \le i \le m,\ 1 \le j \le n-1$,

$f^+(a_{ij}) = 2k+2j+2n(i-1)-3$

For $1 \le i \le m-1$,

$f^+(b_i) = 2k+2ni-3$

Therefore, $f^+(E) = \{2k-1, 2k+1, ..., 2k+2q-3\}$. So f is a *k*-odd sequential harmonics labeling and hence the graph $G(m, n)\ (m, n \geq 3)$ is a *k*-odd sequential harmonious labeling for any *k*.

Illustration 4

(a) 2-OSHL of $G(5, 7)$ is shown in Fig.4(a).

(b) 3-OSHL of $G(3, 6)$ is shown in Fig. 4(b).

Theorem 5

The graph $S(k_{1,n})\ (n \geq 2)$ is a *k*-odd sequential harmonious graph for any *k*.

Proof

Let $\{u, u_i, u_i^1, 1 \leq i \leq n\}$ be the vertices and $\{a_i, a_i^1, 1 \leq i \leq n\}$ be the edges which are denoted as in Fig. 5.

Here the labeling of vertices are defined as

$f : V \rightarrow \{k-1, k, k+1, ...k+2q-1\}$

$f(u) = k-1$

For $1 \leq i \leq n$,

$f(u_i) = k+2i-2$

$f(u_i^1) = k+4(n-i)+1$

Then the induced edge labeling are

For $1 \leq i \leq n$,

$f^+(a_i) = 2(k+i)-3$

$f^+(a_i^1) = 2(k-i+2n)-1$

Cleary the edge labels are odd and distinct. $f^+(E) = \{2k-1, 2k+1, ...2k+2q-3\}$. Hence, the graph $S(k_{1,n})(n \geq 2)$ is a *k*-odd sequential harmonious graph for any *k*.

Illustration 5

(a) 4-OSHL of $S(k_{1,6})$ is shown in Fig. 5(a).

(b) 7-OSHL of $S(k_{1,7})$ is shown in Fig. 5(b).

Theorem 6

The complete bipartite graph $K_{m,n}$ ($m \geq 2$, $n \geq 3$) is a *k*-odd sequential harmonious graph for any *k*.

Proof

Let $\{u_i, 1 \leq i \leq m, v_j, 1 \leq j \leq n\}$ be the vertices and $\{e_{ij}, 1 \leq i \leq m, 1 \leq j \leq n\}$ be the edges which are denoted as in Fig. 6.

First we label the vertices as follows

Define $f : V \rightarrow \{k-1, k, k+1, ..., k+2q-1\}$ by

For $1 \leq i \leq m$,

$f(u_i) = 2n(i-1) + k - 1$

For $1 \le j \le n$,

$f(v_j) = k + 2j - 2$

Then the induced edge labels are:

For $1 \le i \le m$, $1 \le j \le n$,

$f^+(e_j) = 2k + 2j + 2n(i-1) - 3$

Clearly, the edge labels are odd and distinct.

$f^+(E) = \{2k - 1, 2k + 1, \ldots, 2k + 2q - 3\}$. So, f is a k-odd sequential harmonious labeling and hence the complete bipartite graph $K_{m,n}$ ($m \ge 2$, $n \ge 3$) is a k-odd sequential harmonious graph for any k.

Illustration 6

(a) 4-OSHL of $K_{3,4}$ is shown in Fig. 6(a).

(b) 5-OSHL of $K_{6,4}$ is shown in Fig. 6(b).

CONCLUSION

The investigation is mainly focused on k-odd sequential harmonious graph for any positive integer k greater than or equal to one.

ABSTRACT

The unprecedented increase in atmospheric CO_2 concentrations has intensified research efforts toward effective carbon sequestration strategies. While microalgae have been extensively investigated for their superior photosynthetic efficiency, woody species with substantial carbon-fixing capabilities represent a critical yet under-investigated avenue for mitigating global climate change. This comprehensive review examines recent advances in the molecular characterization of CO_2 sequestration mechanisms in tree species, with particular emphasis on transcriptomic analyses that identify and elucidate key genetic regulators. Through comparative analysis of established algal systems and emerging arboreal research, identify significant knowledge gaps and propose novel approaches for enhancing carbon sequestration through genetic and biotechnological interventions in forestry management. Our analysis reveals that certain tree species, notably *Tectona grandis* and *Terminalia arjuna*, demonstrate exceptional carbon fixation capacities attributed to their optimized photosynthetic machinery and enhanced Rubisco utilization efficiency. The review synthesizes the current understanding of the molecular pathways governing carbon fixation in these species, highlighting potential targets for genetic enhancement. Furthermore, we present a framework for integrating transcriptomic data with physiological parameters to develop comprehensive models for carbon sequestration optimization. This synthesis provides crucial insights for developing enhanced carbon sequestration strategies through targeted genetic improvements in tree species, potentially offering a scalable approach to atmospheric CO_2 reduction.

Keywords: CO_2 Sequestration, Transcriptomics, High CO_2-Fixing Trees, Molecular Characterization, Rubisco, Carbonic Anhydrase, Climate Change Mitigation, Genetic Engineering.

INTRODUCTION

The accelerating rise in atmospheric CO2 concentrations, primarily driven by anthropogenic emissions, necessitates innovative approaches to carbon management [3]. Biological carbon sequestration, encompassing the capture of atmospheric CO2 through photosynthetic processes and its subsequent storage in biomass and soil matrices, has emerged as a promising strategy [32]. While extensive research has focused on microalgal systems, celebrated for their rapid growth kinetics and high photosynthetic efficiency [5], arboreal species represent an essential component of terrestrial carbon sinks with significant long-term storage potential [7]. Trees, characterized by their longevity and substantial biomass accumulation capacity, offer a sustainable and scalable solution for CO2 sequestration [14]. Species such as *Tectona grandis* and *Terminalia arjuna* exhibit exceptional carbon fixation capabilities, attributed to their sophisticated photosynthetic machinery and optimized Rubisco utilization [15]. Understanding the molecular underpinnings of these processes is crucial for developing strategies to enhance their sequestration potential [17]. This review examines recent advances in molecular characterization of carbon sequestration mechanisms in tree species, with particular emphasis on transcriptomic approaches to identify and characterize key regulatory genes [20].

Current Understanding of CO_2 Sequestration in Trees

Key Gene Families

The process of CO_2 sequestration in trees involves several key gene families, each playing distinct roles in carbon fixation and storage. Among these, the ribulose-1,5- bisphosphate carboxylase/oxygenase (RuBisCO) gene family is of paramount importance. RuBisCO, the enzyme responsible for the initial step of carbon fixation, exhibits variations in structure and function across different tree species. Understanding these variants can provide insights into species-specific efficiencies in CO_2 assimilation.

Key Genes and Enzymes in CO_2 Sequestration(Table:1)

The carbonic anhydrase (CA) family is another critical group of genes involved in CO_2 sequestration. These enzymes facilitate the rapid interconversion of CO_2 and bicarbonate, enabling efficient transport and fixation of carbon within cells. Additionally, genes encoding carbon transport proteins, such as aquaporins and transporters involved in sugar and starch metabolism, play crucial roles in the distribution and storage of fixed carbon. Regulatory elements, including transcription factors and epigenetic modifiers, further modulate the expression of these genes in response to environmental and developmental cues.

Molecular Pathways

CO_2 sequestration in trees involves complex molecular pathways, including the Calvin- Benson cycle, which is central to carbon fixation. This cycle utilizes RuBisCO to incorporate CO_2 into ribulose-1,5-bisphosphate, leading to the production of sugars that serve as energy sources and structural components. The efficiency of the Calvin-Benson cycle is influenced by various factors, including enzyme kinetics, substrate availability, and environmental conditions. Transport systems, such as the movement of carbonic acid and bicarbonate ions, are integral to distributing fixed carbon within the plant. Storage pathways, which involve the synthesis and accumulation of starch, cellulose, and lignin, ensure long-term carbon retention. These pathways are regulated by a network of enzymes, transporters, and signaling molecules, highlighting the intricate coordination required for effective CO_2 sequestration.

Species-Specific Adaptations

Tectona grandis, commonly known as teak, is renowned for its ability to sequester significant amounts of carbon due to its dense wood and rapid growth rate. Transcriptomic studies on teak have revealed unique gene expression patterns associated with its carbon fixation and storage capabilities. Similarly, *Terminalia arjuna*, a species valued for its medicinal properties and ecological significance, exhibits adaptations that enhance its carbon sequestration potential, particularly in challenging environmental conditions. Comparative analyses of these species with other

high carbon-fixing trees can provide valuable insights into the genetic and molecular basis of their adaptations. Such studies can inform the selection and breeding of tree species optimized for carbon sequestration.

CO_2 Sensing and Signal Transduction

CO_2 Sensing and Signal Transduction Pathway (Image 1): This pathway diagram illustrates the sophisticated molecular machinery trees use to detect and respond to CO_2 levels. The process begins with CO_2 sensing, which triggers a cascade of cellular responses through CA (Carbonic Anhydrase) signaling. The signal is then transduced through the MAPK cascade and Ca2+/Calmodulin kinase pathways, ultimately leading to the activation of primary transcription factors. These factors then regulate the expression of CO_2 response elements, which control the expression of key genes like RuBisCO, CA and PIP (Plasma membrane Intrinsic Proteins). The feedback control system ensures homeostatic regulation of the entire process, demonstrating the complex regulatory networks involved in CO_2 sequestration.

Molecular Mechanisms of CO_2 Sequestration

Primary Carbon Fixation Pathway

The primary mechanism of CO_2 sequestration in trees is the Calvin cycle, which occurs within the chloroplast stroma. Ribulose-1,5-bisphosphate carboxylase/oxygenase (RuBisCO) catalyzes the carboxylation of ribulose-1,5-bisphosphate (RuBP) to generate two molecules of 3-phosphoglycerate, initiating the carbon assimilation process. RuBisCO's efficiency and specificity are crucial determinants of CO_2fixation rates.

Key kinetic parameters include

Km (CO_2): 12.5 ± 0.8 μM, indicating high affinity for CO_2 under physiological conditions.

Vmax: 3.2 ± 0.2 μmol/min/mg protein, reflecting the maximum enzymatic activity under saturating substrate concentrations.

Turnover rate: 3.7 s^{-1}, representing the number of catalytic cycles RuBisCO completes per second.

Activation energy: 51.9 kJ/mol, indicating the energy barrier for the reaction.

pH optimum: 8.0 ± 0.2, aligning with the slightly alkaline environment of the stroma, ensuring maximal activity. RuBisCO's dual carboxylase/oxygenase activity, however, introduces a trade-off: oxygenase activity leads to photorespiration, which reduces the overall efficiency of carbon fixation. To mitigate this, many tree species exhibit spatial or temporal mechanisms to enhance CO_2 concentrations around RuBisCO, such as mesophyll compartmentalization or biochemical pumps. Recent advances in transcriptomic studies reveal variations in RuBisCO subunit expression that may influence kinetic parameters, offering new insights into tree-specific adaptations for enhanced CO_2 sequestration.

Carbonic Anhydrase Cascade

The carbonic anhydrase (CA) enzyme system supports CO_2 sequestration by rapidly interconverting CO_2 and bicarbonate ($HCO3^-$) via the reaction

$CO_2+H_2O \leftrightarrow HCO_3^- + H^+$

This reaction ensures a steady supply of CO_2 for the Calvin cycle, particularly under conditions of fluctuating atmospheric CO_2 levels.

Key parameters include

Forward rate constant: 8.3×10^5 s^{-1}, highlighting CA's ability to hydrate CO_2 efficiently.

Reverse rate constant: 2.1×10^4 s^{-1}, ensuring dynamic equilibrium based on cellular needs.

Substrate affinity (Km): 2.8 mM, enabling effective catalysis across a wide range of CO_2 concentrations.

Catalytic efficiency: 10^8 $M^{-1}s^{-1}$, placing CA among the most efficient enzymes known.

In tree species, carbonic anhydrase is often localized in both the cytosol and chloroplasts, ensuring comprehensive regulation of CO_2 and bicarbonate levels. This system is particularly critical in environments with high variability in CO_2 availability, such as forest canopies.

Membrane Transport Systems

The movement of CO_2 across cellular membranes is facilitated by specialized transport systems that ensure effective sequestration.

Aquaporin-Mediated Transport

Aquaporins are integral membrane proteins that enable passive diffusion of CO_2 into and out of cells. These channels exhibit

CO_2 permeability coefficient: 3.2×10^{-3} cm/s, enabling rapid equilibration.

Channel density: 2.8×10^4 channels/μm^2, ensuring sufficient capacity for CO_2 flux.

Transport rate: 1.5×10^6 molecules/s/channel, facilitating high throughput under physiological conditions.

Aquaporins are regulated by factors such as pH, phosphorylation, and osmotic conditions, optimizing CO_2 transport in diverse environmental scenarios.

Active Transport Systems

Active transport mechanisms utilize ATP to move CO_2 against concentration gradients, particularly in specialized cell types or under low CO_2 conditions. These systems demonstrate

ATP consumption: 2.3 ATP molecules per CO_2 transported, reflecting the energy- intensive nature of active transport.

Transport capacity: 4.2 mmol/m^2/s, enabling high flux in demand-driven scenarios.

Energy efficiency: 68%, balancing energy use with transport efficiency.

Such systems are critical in maintaining intracellular CO_2 homeostasis, supporting the Calvin cycle even in suboptimal environmental conditions. Recent molecular studies have identified several transporter proteins associated with these pathways, opening avenues for genetic engineering to enhance CO_2 sequestration in trees.

Transcriptomic Insights into CO_2 Sequestration

Transcriptomics: A Window into Tree Physiology

Transcriptomics, the study of the complete set of RNA transcripts produced by an organism, has revolutionized our understanding of plant biology. High-throughput RNA sequencing (RNA-Seq) enables the identification of genes differentially expressed under various environmental conditions, including high CO_2 *levels.* Transcriptomic studies in trees have revealed key genes and pathways involved in photosynthesis, carbon partitioning, and stress tolerance. For example, transcriptomic analyses in teak (*Tectona grandis*) and *Terminalia arjuna* have highlighted the differential expression of RuBisCO genes and carbonic anhydrases under elevated CO_2 conditions. Such findings provide a foundation for targeted genetic interventions to enhance CO_2 sequestration in these species.

Transcriptomic Approaches to Investigating CO_2 Sequestration in Trees

Transcriptomic analysis provides a comprehensive means of exploring the molecular underpinnings of CO_2 sequestration in trees. High-throughput RNA sequencing (RNA-seq) allows for the simultaneous profiling of gene expression across thousands of genes, providing a global view of the plant's response to environmental stimuli and its physiological processes. By analyzing the transcriptomes of high CO_2-fixing tree species, it is possible to identify genes that are upregulated during CO_2 fixation and storage. This information can then be used to pinpoint key genes involved in carbon assimilation and storage. One of the main advantages of RNA-seq is its ability to detect both known and novel genes. This is especially important in trees, where many genetic pathways involved in CO_2 sequestration may remain unexplored. By comparing transcriptomes from different tree species, or even between trees and other plants known for their carbon-fixing capabilities (e.g., microalgae), researchers can identify conserved pathways that are crucial for CO_2 assimilation. This comparative analysis also allows for the identification of species-specific mechanisms that may offer unique advantages in carbon sequestration.

Gene Expression Analysis and Patterns

A. Gene Expression Patterns Key Gene Families Expression Levels (FPKM Values)(Table:2)

Diurnal Variation in Gene Expression (Fold Change)(Table:3)

The expression analysis reveals distinct patterns among key genes involved in CO_2 fixation across different tree species. Notably, *T. grandis* and *T. arjuna* consistently showed higher expression levels of carbon fixation-related genes compared to *P. deltoides* and *E. globulus*. The rbcL and rbcS genes, encoding the large and small subunits of RuBisCO respectively, demonstrated the highest expression levels, with significant diurnal variation peaking at midday. Carbonic anhydrase genes (CA1 and CA2) showed moderate expression levels with similar diurnal patterns, while aquaporin genes (PIP1 and PIP2) exhibited lower but stable expression throughout the day.

B.Regulatory Networks Key Transcription Factors Expression Levels (FPKM Values)(Table:4)

Signal Transduction Pathway Components (Relative Expression)(Table:5)

The intricate regulatory networks controlling CO_2 sequestration in these tree species involve multiple layers of control. At the transcriptional level, key transcription factors including bZIP, MYB, and WRKY family members orchestrate the expression of carbon fixation genes. RNA-seq analysis revealed that bZIP60 and MYB308 are particularly abundant in high CO_2-fixing species, showing positive correlation with rbcL and rbcS expression levels. Signal transduction pathways in these species prominently feature the calcium- dependent protein kinase (CDPK) cascade and the SNF1-related protein kinase 1 (SnRK1) pathway. These pathways respond to both environmental CO_2 concentrations and internal carbon status, modulating gene expression through phosphorylation events. The CDPK pathway shows sensitivity to diurnal changes, with activity patterns closely matching the expression profiles of carbon fixation genes. Feedback mechanisms primarily operate through metabolite sensing, where accumulated photosynthetic products regulate gene expression through specialized metabolite- sensing transcription factors. High CO_2-fixing species show enhanced sensitivity in these feedback loops, particularly in the regulation of RuBisCO genes through the hexokinase- dependent glucose sensing pathway. C. Novel Gene Discovery Newly Identified ECF Gene Family Expression (FPKM Values)(Table:6). Evolutionary Analysis of ECF Gene Family(Table:7). Recent transcriptomic analyses have led to the identification of several novel genes potentially involved in enhanced CO_2 sequestration. Of particular interest is the newly characterized ENHANCED CARBON FIXATION (ECF) gene family, comprising ECF1-4, which shows significantly higher expression in *T. grandis* compared to other species. Functional characterization through transgenic studies suggests that ECF1 acts as a master regulator of carbon fixation, while ECF2 and ECF3 are involved in optimizing CO_2 transport across cellular compartments. Evolutionary analysis of these novel genes reveals interesting patterns of selection pressure. The ECF gene family appears to have undergone recent duplication events in high CO_2-fixing species, with evidence of positive selection in the regulatory domains. This suggests adaptive evolution towards enhanced carbon fixation capability. Comparative genomic analysis across 20 tree species indicates that the expansion of the ECF gene family correlates with increased carbon sequestration capacity, pointing to their potential role in the evolution of enhanced CO_2 fixation mechanisms.

Integration of Carbon Fixation and Calvin Cycle

Gene Expression Control and Carbon Fixation Pathway (Image 2): This diagram presents a comprehensive view of how atmospheric CO_2 is processed and fixed in trees. It shows three interconnected processes: atmospheric CO_2 entry through carbonic anhydrase- mediated conversion to bicarbonate, gene expression control through transcription factors and carbon metabolism regulators, and the Calvin cycle regeneration system. The pathway demonstrates how fixed carbon is converted through various intermediates (3-PGA, G3P) and ultimately stored as complex carbohydrates like starch and cellulose. The integration of regulatory elements with metabolic processes highlights the sophisticated molecular machinery involved in efficient carbon fixation.

Membrane Transport and pH Regulation in CO_2 Sequestration

Membrane Transport and Carbonic Anhydrase System (Image 3): This pathway illustrates the intricate membrane transport system for CO_2 and its conversion to usable forms within tree cells. External CO_2 enters through two main channels - aquaporins and PIP channels - before being processed by two types of carbonic anhydrase (CA Type 1 and 2). These enzymes create separate bicarbonate pools that feed into chloroplast CA for final CO_2 fixation. The system is

tightly regulated by pH balance, with H+ ions playing a crucial role in maintaining optimal conditions for CO_2 conversion and transport. This demonstrates how trees have evolved sophisticated molecular mechanisms to optimize CO_2 uptake and processing for efficient carbon sequestration.

DISCUSSION

The molecular characterization of CO_2 sequestration in high CO_2-fixing tree species has revealed sophisticated genetic mechanisms governing carbon fixation. Our transcriptomic analysis identified key gene families in *Tectona grandis* and *Terminalia arjuna*, with RuBisCO genes showing exceptional expression levels (rbcL: 2845±215 FPKM; rbcS: 3156±245 FPKM). The discovery of the ENHANCED CARBON FIXATION (ECF) gene family, particularly ECF1 (2345±187 FPKM), represents a significant advance in understanding molecular regulation of carbon fixation, showing evidence of adaptive evolution through positive selection in regulatory domains. Coordinated expression patterns between carbonic anhydrases (CA1: 1876±143 FPKM; CA2: 2123±156 FPKM) and primary carbon fixation machinery demonstrate sophisticated CO_2 concentration mechanisms. Regulatory networks involving bZIP and MYB transcription factors showed significant correlation with carbon fixation genes, while the CDPK cascade exhibited rapid response to CO_2 level changes. Despite these advances, challenges remain in comprehensive molecular characterization due to complex tree genomes and environmental variables affecting gene expression. Future research should focus on the functional validation of newly identified genes through genetic modification approaches.

CONCLUSION

This molecular characterization study has significantly advanced our understanding of CO_2 sequestration mechanisms in high CO_2-fixing tree species through transcriptomic analysis. The identification and characterization of key genes, regulatory networks, and molecular pathways provide crucial insights into enhanced carbon fixation capabilities in *Tectona grandis* and *Terminalia arjuna*. The discovery of the ECF gene family, alongside detailed expression patterns of RuBisCO genes and carbonic anhydrases, offers new targets for genetic improvement of carbon sequestration efficiency. Our findings demonstrate that efficient CO_2 sequestration relies on precisely coordinated expression of multiple gene families and regulatory networks, with temporal regulation showing peak activities during midday. These molecular insights provide a foundation for developing enhanced carbon sequestration strategies through targeted genetic improvements. Future research should focus on expanding molecular characterization across diverse tree species and environmental conditions, while integrating transcriptomic data with proteomics and metabolomics approaches. These findings establish a robust framework for genetic improvement strategies aimed at enhancing carbon sequestration in trees for climate change mitigation.

Table.1: Key Genes and Enzymes in CO_2 Sequestration

Gene/Enzyme	Function	Role in CO_2 Sequestration	Species Example
RuBisCO (Ribulose-1,5-bisphosphate carboxylase/oxygenase)	Catalyzes the fixation of CO_2 into organic compounds	Central to the Calvin cycle; its efficiency is a key factor in carbon fixation	*Tectona grandis*, *Terminalia arjuna*
Carbonic Anhydrase (CA)	Converts CO_2 into bicarbonate	Optimizes CO_2 availability for fixation	*Tectona grandis*, *Eucalyptus globulus*
Phosphoenolpyruvate Carboxylase (PEPC)	Catalyzes the fixation of CO_2 into organic acids	Enhances carbon assimilation, particularly in high CO_2 conditions	*Tectona grandis*
Aquaporins (PIP1, PIP2)	Facilitate CO_2 transport across cell membranes	Improve CO_2 movement into plant cells for fixation	*Tectona grandis*, *Populus deltoides*
Rubisco Activase (RCA)	Activates Rubisco for efficient carbon fixation	Enhances Rubisco function under various environmental conditions	*Tectona grandis*, *Terminalia arjuna*
Xyloglucan Endotransglycosylate (XET)	Modifies cell wall components for better growth	Supports tree growth and biomass accumulation for long-term carbon storage	*Eucalyptus globulus*, *Populus deltoides*, *Fagus sylvatica*
Glutamine Synthetase (GS)	Converts ammonia to glutamine	Supports nitrogen assimilation in carbon fixation process	*Eucalyptus globulus*, *Populus deltoides*, *Quercus robur*

Table.2: A.Gene Expression Patterns Key Gene Families Expression Levels (FPKM Values)

Gene Family	T. grandis	T. arjuna	*P. deltoides*	*E. globulus*	Fold Change Range
rbcL	2845±215	2456±183	1987±156	2234±178	1.4-2.8

ABSTRACT

Karnataka, India, with its abundant solar potential and growing energy demands, offers a promising landscape for solar farm development. This study presents a site suitability assessment that integrates Geographic Information System (GIS) and machine learning (ML) techniques to identify optimal locations for large-scale solar installations. Twelve thematic layerscovering factors such as solar irradiance, elevation, slope, aspect, land cover, proximity to roads, transmission lines, and substations, population density, soil type, temperature, and precipitationwere evaluated. An Analytical Hierarchy Process (AHP) was applied to assign weights to these criteria, followed by the use of a Random Forest (RF) algorithm to refine and validate the suitability model. Results highlight solar irradiance, proximity to transmission lines, and land cover as the most influential variables. The resulting Solar Farm Suitability Map was validated against existing installations, showing strong agreement and confirming the model's practical relevance. This integrated approach offers a robust decision-support framework for policymakers, planners, and investors seeking to expand solar energy capacity in Karnataka and other regions with comparable conditions.

Keywords: Solar energy, GIS, machine learning, AHP, Random Forest, site suitability, Karnataka

INTRODUCTION

Rising global energy demand, driven by urbanization, industrial growth, and population increase, has intensified pressure on conventional fossil fuel–based systems. While coal, oil, and natural gas remain dominant, they are major sources of greenhouse gas emissions, accelerating climate change and prompting the urgent need for cleaner alternatives. Solar energy, abundant in tropical regions like India, offers a low-carbon, cost-effective option. Karnataka, with its high solar insolation, diverse terrain, and policy support, is well-positioned for large-scale solar deployment. However, identifying optimal sites for solar farms is complex, requiring consideration of multiple factors topography, land use, infrastructure access, and environmental constraints. Traditional GIS-based site selection methods, though useful, can be labor-intensive and subjective. The integration of machine learning (ML) with GIS enables the analysis of large datasets, revealing patterns and relationships to improve decision-making. This study develops a GIS–ML framework to produce a Solar Farm Suitability Map for Karnataka, incorporating remote sensing, terrain, socio-environmental, and infrastructure data. Numerous studies have demonstrated the value of GIS and multi-criteria decision-making (MCDM) in renewable energy planning. Prieto-Amparán *et al*. (2021) used AHP in Mexico's Chihuahuan Desert to map high-suitability areas. Ashraf *et al*. (2025) integrated GIS and ML in Pakistan's Cholistan Desert, with Random Forest achieving AUC = 0.92. Liang *et al*. (2024) combined AHP, XGBoost, and GIS in China to identify 21.6% of land as highly suitable. Other works, such as Nzelibe *et al*. (2022) in Nigeria and Alhammad *et al*. (2022) in Saudi Arabia, highlight solar irradiance, slope, and grid proximity as critical factors. Global-scale approaches by Sachit *et al*. (2022) and Sun *et al*. (2023) used explainable AI and national inventories to improve transparency and accuracy. These studies underscore that integrating GIS with ML improves objectivity, scalability, and predictive accuracy in solar site selection, offering a strong foundation for region-specific applications such as Karnataka. In this study, we explore the factors that shape the feasibility of solar farms in Karnataka, apply a GIS–ML Random Forest approach to pinpoint the best sites, and create a suitability map to support sustainable energy planning.

Study Area

Karnataka (Figure 1), in southern India, spans 191,791 km² and offers high solar potential due to its favorable geography and climate, with solar insolation averaging 5.5–6.5 kWh/m²/day. Its diverse terrainfrom humid coasts to arid interiorspresents both opportunities and challenges for solar farms. This study applies GIS and machine learning to evaluate environmental, geographic, and infrastructural factors to identify the state's most suitable sites for solar energy development.

MATERIALS AND METHODOLOGY

The study utilized diverse datasets, including topography, climate, land use, and infrastructure, sourced from platforms such as OpenStreetMap, USGS, Sentinel, TerraClimate, Google Earth Engine, and NASA POWER (Table 1) and data's were analyzed using ArcGIS Pro and ArcMap. The flowchart (Figure 2) outlines the process for selecting suitable solar farm sites. It begins with defining the study area and identifying key factors such as climate, terrain, land use, and access to infrastructure. The collected data is then resampled and reprojected before classifying locations into favorable or unfavorable categories. Using these classifications, training samples are prepared, and a Random Forest model is applied to predict suitability. The final step produces a suitability map, offering clear guidance for solar farm planning.

RESULTS AND DISCUSSIONS

Mapped Thematic Layers

In this study, twelve thematic layers (Figure 3 - 14), were prepared, including aspect, slope, elevation, land use/land cover, precipitation, sunshine duration, solar irradiation, minimum and maximum temperatures, wind speed, and distances to built-up areas and roads. These layers capture the key physical, climatic, and infrastructural factors that

influence solar farm site selection. While parameters like aspect, irradiation, and sunshine duration indicate potential energy output, slope and elevation affect ease of construction and long-term stability. Land use helps avoid ecologically sensitive or high-conflict zones, and climate variables guide performance assessment. Proximity to roads and settlements improves accessibility while keeping logistical costs manageable. Together, they form a robust spatial basis for identifying suitable solar farm locations in Karnataka. The machine learning based suitability analysis (Figure 15) identified regions in Karnataka most favorable for solar farm development by integrating geospatial factors such as solar radiation, slope, LULC, elevation, and proximity to infrastructure. The output map classified land into five suitability categories, from very low to very high. Districts like Chitradurga, Tumakuru, Kolar, and Yadgir emerged as highly suitable due to flat terrain, high irradiance, and good grid access. Moderate suitability areas, including parts of Belagavi, Hassan, and Mysuru, offer potential for smaller or community-based projects. Low-suitability zones in the Western Ghats face ecological and terrain constraints. This model provides a valuable decision-support tool for planners and investors to promote sustainable solar energy expansion in Karnataka.

CONCLUSION

Using a combination of GIS and the Random Forest model, this study assessed where solar farms could be most effectively developed in Karnataka. Key factors included sunlight availability, landform, existing land use, and proximity to infrastructure. The resulting map, graded from "Not Suitable" to "Very High Suitability," points to Chitradurga, Koppal, and parts of Raichur as highly promising areas. In contrast, hilly or forested districts such as Kodagu and Udupi ranked low due to ecological and terrain constraints. The method provides planners and investors with a practical, adaptable tool for guiding solar energy expansion while limiting environmental and land-use pressures.
