It was observed that fluorescence value obtained with 2 ppm dye concentration in 4 hours was comparatively higher than that obtained with 1.5 ppm in 6 hours. This indicates that there was faster reduction of resazurin at higher dye concentrations. Further higher dye concentrations were not checked because sharp colour change will not be visualized easily in shorter time period. Hence, resazurin dye concentration of 2 ppm was found appropriate for

further studies. Resazurin dye concentration of 2 ppm was used to check the effect of different cell number of *Escherichia coli*, *Enterobacter* sp. and *Salmonella typhii* on reduction of resazurin dye. For this, bacterial cells were inoculated in concentrations of 10 to 50 cells/100ml into sterile nutrient broth containing 2 ppm resazurin dye concentration. Tubes were incubated at 37°C and resorufin production was checked after every hour. The experiment was carried out in triplicates and fluorescence obtained was quantified using ImageJ software as mentioned in section 2.4.2.

In case of *Escherichia coli*, tube with bacterial load of 50 cells/100 ml showed resazurin reduction within 3½ hours. On further incubation at 37°C, reduction was observed in tubes containing lower load of *E. coli*. After 5 hours of incubation, resazurin reduction was observed in tube with bacterial concentration of 30 cells/100 ml (Figure 9). Further incubation did not show reduction of resazurin dye. Hence, 2 ppm of resazurin dye can detect minimum *Escherichia coli* concentration of 30 cells/100 ml within 4 hours. In case of *Enterobacter* sp., tube with bacterial load of 50 cells/100 ml showed resazurin reduction within 6 hours (Figure 9). Further incubation did not show reduction of resazurin dye. Hence, resazurin dye can detect minimum *Enterobacter* sp. concentration of 50 cells/100 ml within 4 hours. In case of *Salmonella typhii*, tube with bacterial load of 50 cells/100 ml showed resazurin reduction within 3 hours. On further incubation at 37°C, reduction was observed in tubes containing lower load of *S. typhii*. After 4 hours of incubation, very less reduction of resazurin was observed in tube with bacterial concentration of 40 50 cells/100 ml (Figure 9). Further incubation did not show reduction of resazurin dye. Hence, 2 ppm resazurin dye can detect minimum *S. typhii* concentration of 40 cells/100 ml within 4 hours.

Resorufin fluorescence was quantified for lower bacterial cell concentration as shown in Table 8. In this case, fluorescence of resorufin produced was lower as compared to results obtained from optimization. This is because of lower concentration of bacterial cells. Hence, it can be observed a strong relationship between load of bacterial cells and fluorescence of resorufin. '-' indicates resazurin reduction was not observed. Resazurin dye of 2 ppm concentration works successfully for detection of lower microbial load in shorter time. This was possible due to incorporation of nutrient broth in resazurin dye.

Heavy metal toxicity on bacteria:

Using microbes for bioremediation purpose usually requires acytotoxic analysis for checking of tolerance of microbes towards substance to be removed. Hence, cell viability was checked in the presence of heavy metals using resazurin dye. For present study, three heavy metals were selected based on their availability and solubility in water i.e. chromium, lead and mercury.

Chromium toxicity on bacteria:

Potassium dichromate ($K_2Cr_2O_7$) was used as chromium source. Initially, chromium toxicity on bacteria was checked by inoculating bacterial cultures with different concentrations of chromium ranging from 10 to 50 ppm. Growth of bacteria was checked by taking O.D. at 600 nm. It was observed that with increase in chromium concentration, significant decrease of growth of *E. coli*, *Enterobacter* sp. and *S. typhii*was observed (Figure 10). This is because higher concentrations were not tolerated by all three bacteria. It was observed that *E. coli* has more tolerance towards chromium as compared to *S. typhii* and *Enterobacter* sp. Resazurin dye of 2 ppm was used for chromium toxicity on *E. coli*, *Enterobacter* sp. and *S. typhii*. After 5 hours, resazurin reduction was observed in tube containing chromium concentrations of 10 and 20 ppm along with control (absence of chromium) thus indicating the presence of viable *E. coli* (Figure 11). The tubes were further incubated but resazurin reduction was not observed with higher concentrations of chromium. This indicates *E. coli* can tolerate upto 20 ppm of chromium.

After 5 hours, resazurin reduction was observed in tube containing chromium concentration of 10 ppm along with control (absence of chromium) thus indicating the presence of viable *Enterobacter* sp. (Figure 11). The tubes were further incubated but resazurin reduction was not observed with higher concentrations of chromium. This indicates *Enterobacter* sp. can tolerate up to 10 ppm of chromium. After 5 hours, resazurin reduction was observed in tube containing chromium concentrations of 10 and 20 ppm along with control (absence of chromium) thus indicating

presence of viable *S. typhii* (Figure 11). The tubes were further incubated but resazurin reduction was not observed with higher concentrations of chromium. This indicates *S. typhii* can tolerate up to 20 ppm of chromium.

Lead toxicity on bacteria:

Lead (II) nitrate ($Pb(NO_3)_2$) was used as the lead source. Initially, lead toxicity on bacteria was checked by inoculating bacterial cultures with different concentrations of lead ranging from 10 to 50 ppm. Growth of bacteria was checked by measuring absorbance at 600nm. It was observed that with increase in lead concentration, significant decrease of growth of *E. coli*, *Enterobacter* sp. and *S. typhii* was observed (Figure 12). This is because higher concentrations of lead were not tolerated by all three bacteria. It was observed that *E. coli*has more tolerance towards lead as compared to *Enterobacter* sp. and *S. typhii*.

Resazurin dye of 2 ppm was used for lead toxicity on *E. coli*, *Enterobacter* sp. and *S. typhii*. After 5 hours, resazurin reduction was observed in tube containing lead concentration of 10 ppm along with control (absence of lead) thus indicating presence of viable *E. coli* (Figure 13). The tubes were further incubated but resazurin reduction was not observed with higher concentrations of lead. This indicates *E. coli* can tolerate up to 10 ppm of lead. After 5 hours, resazurin reduction was observed in tube containing lead concentrations of 10 ppm along with control (absence of lead) thus indicating presence of viable *Enterobacter* sp. (Figure 13). The tubes were further incubated but resazurin reduction was not observed with higher concentrations of lead. This indicates *Enterobacter* sp. can tolerate up to 10 ppm of lead. After 4 hours, resazurin reduction was observed in tube containing lead concentrations of 10 ppm along with control (absence of lead) thus indicating presence of viable *S. typhii* (Figure 13). The tubes were further incubated but resazurin reduction was not observed with higher concentrations of lead. This indicates *S. typhii* can tolerate up to 10 ppm of lead.

Mercury toxicity on bacteria:

Mercury (II) chloride ($HgCl_2$) was used as mercury source. Initially, mercury toxicity on bacteria was checked by inoculating bacterial cultures with different concentrations of mercury ranging from 10 to 50 ppm. Growth of bacteria was checked by measuring absorbance at 600 nm. It was observed that with increase in mercury concentration, significant decrease of growth of *E. coli*, *Enterobacter* sp. and *S. typhii* was observed (Figure 14). This was because higher concentrations were not tolerated by all three bacteria. It was observed that *Enterobacter* sp. has more tolerance towards mercury as compared to *E. coli* and *S. typhii*.

After 5 hours, resazurin reduction was observed in tube containing mercury concentrations of 10 ppm along with control (absence of mercury) thus indicating presence of viable *E. coli* (Figure 15). The tubes were further incubated but resazurin reduction was not observed with higher concentrations of mercury. This indicates *E. coli* can tolerate up to 10 ppm of mercury. After 6 hours, resazurin reduction was observed in tube containing mercury concentrations of 10 ppm along with control (absence of mercury) thus indicating presence of viable *Enterobacter* sp. (Figure 15). Resazurin reduction was not observed with higher concentrations of mercury. This indicates *Enterobacter* sp. can tolerate up to 10 ppm of mercury. After 5 hours, resazurin reduction was observed in tube containing mercury concentrations of 10 ppm along with control (absence of mercury) thus indicating presence of viable *S. typhii* (Figure 16). The tubes were further incubated but resazurin reduction was not observed with higher concentrations of mercury. This indicates *S. typhii* can tolerate up to 10 ppm of mercury. Mercury toxicity was rapidly detected in *E. coli* as compared to *Enterobacter* sp. and *S. typhii*. However, tolerance capacity towards mercury was higher in *Enterobacter* sp. than *E. coli* and *S. typhii*. Since resorufin production was observed to be maximum in *Enterobacter* sp., it is most preferred for bioremediation of mercury contaminated water or sites.

Soil Dehydrogenase Activity:

There are numerous bacteria present in soil. Soil microorganisms and their activities are essential components of the biotic community and are largely responsible for ecosystem functioning. Dehydrogenase enzyme is present in microorganisms and it reflects oxidative activity of soil microorganisms thus indicating microbial activity of soil [40].

Soil dehydrogenase activity was checked using various resazurin concentrations. Since dehydrogenase enzyme is present in microorganisms, soil DHA assay reflects the viability of cells present in soil. Soil contains variety of microorganisms, reduction of resazurin dye may get faster so resazurin dye was optimized for soil dehydrogenase assay. Dye concentration of 0.1, 0.2, 0.3, 0.4, 0.5, 1, 1.5 and 2 ppm were considered to check presence of viable bacteria. After 20 hours, resazurin reduction was observed in the dye with 1, 1.5 and 2 ppm (Figure 17). Thus, 1, 1.5 and 2 ppm dye were selected for further optimization. After 20 hours, resazurin reduction was observed with dye concentration of 2 ppm (Figure 18). Thus, dye concentration of 2 ppm were found appropriate for checking soil dehydrogenase activity and ultimately, the presence of viable cells in soil.

DISCUSSION

Coliforms in water or food increases the probability of presence of pathogenic micro-organisms [28] thus, causing food-borne and water-borne diseases like diarrhoea, typhoid, dysentery etc. Hence, coliforms have been tested as preliminary step in health care departments to check a sanitary conditions of food and water. Enumeration of bacterial cultures (*E. coli*, *Enterobacter* sp., *S. typhii* was carried out using Most Probable Number method, which is used to quantify lactose fermenting bacteria such as coliforms and members of *Enterobacteriaceae* family and by Spread Plate Count method. For all three bacteria, cell count with both the methods didn't show remarkable variation in cell count. Wohlsen *et al*. [29] reported SPC as most appropriate method for enumeration of coliform bacteria. Thus, results of SPC were considered for further studies. With both dye concentrations, resazurin dye gets reduced to highly fluorescent pink coloured resorufin. Similar study was carried out by Patel [20] who concluded that resazurin dye concentration of 200 ppm along with modified *Escherichia coli* broth is suitable for checking of bacterial cell viability.

The indication of very less reduction of resazurin taken place after 4 hours could have been attributed because, oxygen which is loosely attached to resazurin was consumed in the metabolic activities of viable cells and maximum resazurin was reduced to resorufin [17]. Thus, with increase in the dye concentration, amount of resorufin increases and thus there is increase in fluorescence (Figure 4). Detection of viable *Escherichia coli* can be carried out within 6 hours using resazurin dye. Reduction of resazurin by viable cells was detected within 7 hours using 96-well plate reader [30]. In both the dye concentration of 1.5 ppm and 2 ppm, fluorescence slowed down after 6 hours. This is because, oxygen which is loosely attached to resazurin was consumed in the metabolic activities of viable cells and maximum resazurin was reduced to resorufin thus, very less change in fluorescence is observed [17]. Thus, with increase in the dye concentration, amount of resorufin increases and thus there is increase in fluorescence (Figure 5). Detection of viable *Enterobacter* sp. can be carried out within 6 hours using resazurin dye. Reduction of resazurin by viable cells was detected within 7 hours using 96-well plate reader [30].

There the gradual increase in fluorescence with time was seen increasing in the dye concentration and the amount of resorufin increases and thus there was increase in fluorescence. Detection of viable *Salmonella typhii* can be carried out within 6 hours using resazurin dye. Reduction of resazurin by viable cells was detected within 7 hours using 96-well plate reader [30]. Resazurin dye of 2 ppm was able to check viability of bacterial cells when present in lower numbers. This indicates presence of coliforms and pathogenic bacteria can be carried out with resazurin dye. According to previous studies detection of coliforms and pathogenic bacteria were carried out within 8 to 9 hours [20]. This is because resazurin dye of 200 ppm was used and due to higher resazurin concentration, it took more time to impart visible pink colour against blue. Members of *Enterobacteriaceae* family along with other bacteria have their application in bioremediation [31]. For example, bioremediation of chromium from tannery effluents by *Enterobacter aerogenes* and *Acinetobacter* sp. [32], bioremediation of heavy metal contaminated soil [33], bio-removal of lead using *Enterobacter cloacae* [34] and bioremediation of mercury by *Enterobacter* sp. [35]. Chromium toxicity was rapidly detected in *S. typhii* as compared to *E. coli* and *Enterobacter* sp. However, tolerance capacity towards chromium was higher in *E. coli* and *S. typhii* than *Enterobacter* sp. Resazurin reduction with 20 ppm chromium was faster in the presence of *S. typhii* but due to its pathogenicity, it is not recommended for bioremediation purpose. Hence, *E. coli*

can be used for bio-removal of chromium from contaminated sites. Experiment was carried out by Wohlsen *et al.* [36] which concludes that chromium concentration of 30 ppm and higher is toxic to dehydrogenase enzyme activity. Zare *et al*. [37] concluded that members of *Enterobacteriaceae* family have ability to tolerate 20 ppm of chromium.

Lead toxicity was rapidly detected in *S. typhii* as compared to *E. coli* and *Enterobacter* sp. However, tolerance capacity towards lead was higher in *E. coli* than *S. typhii* and *Enterobacter* sp. Since resorufin production was observed maximum in *E. coli*, it is most preferred for bioremediation of lead contaminated sites. Garhwal *et al.* [38] concluded that members of *Enterobacteriaceae* family have ability to tolerate 30 ppm of lead. However, such difference in tolerance capacity is observed as it varies within species. Mathema *et al*. [39] concluded that members of *Enterobacteriaceae* family can tolerate up to 20 ppm of mercury. From above results, it was confirmed that resazurin concentration of 2 ppm was found appropriate to check toxicity of heavy metals on bacterial cells. The results obtained by using 2 ppm resazurin dye are rapid and weresimilar to the results obtained by conventional microbiological methods. Thus, resazurin dye can be used to check heavy metal toxicity on bacterial cells within short time. As compared to pure bacterial cultures, detection of viable cells in soil took longer time period. This is due to the fact that soil contains consortium of various bacteria where antagonistic microbial activities occurs. Some other factors which affects the detection are optimum temperature of microbial enzyme, humidity, moiture content of soil [41,42]. Similar experiment was carried out by using using triphenyltetrazolium chloride (TTC), a colourless dye which is reduced to red colour triphenylformazan (TPF) by dehydrogenases present in soil environment. Poor results were observed when TTC dye was used to check soil dehydrogenase activity [24].

CONCLUSION

The present study demonstrated that resazurin dye is a rapid, sensitive, and reliable indicator of bacterial viability for *Escherichia coli*, *Enterobacter* sp., and *Salmonella typhii*. Enumeration by MPN and Spread Plate Count methods produced comparable results, while optimization identified 2 ppm resazurin as the most suitable concentration for rapid detection. The assay successfully detected low bacterial loads within 4–6 hours, with fluorescence intensity showing a direct relationship with bacterial cell concentration, making it an efficient alternative to conventional microbiological methods. The optimized resazurin assay was also effective in assessing heavy metal toxicity and soil microbial activity. *E. coli* exhibited greater tolerance to chromium and lead, whereas *Enterobacter* sp. showed higher tolerance to mercury, highlighting their potential for bioremediation applications. Additionally, the assay successfully detected soil dehydrogenase activity, demonstrating its applicability for environmental monitoring. Overall, the study establishes the 2 ppm resazurin assay as a simple, rapid, cost-effective, and reliable tool for microbial viability assessment, environmental analysis, water quality monitoring, food safety, and bioremediation studies.

ACKNOWLEDGEMENT

We would like to thank Mr. Sheetal Patel, Secretary (SPEC), for encouragement in the present study.

Conflict of Interest

The authors declare that they have no conflict of interest.

Author Contributions

MCT conceptualised the work, supervised and contributed for manuscript draft, editing and finalising. PK carried out the statistical analysis using the One-way ANOVA (Analysis of Variance) and did formal analysis and SSB and AP did all calculation and helped in drafting of the manuscript.

ABSTRACT

Kiwi (*Actinidia deliciosa*) belongs to the family Actinidiaceae and genus *Actinidia*. It is one of the most commercialized fruits on the international front and islocated with many nutrients such as vitamins, minerals and phytochemicals and its parts are well recognized for their medicinal and therapeutic properties against diseases.

Keywords: *Actinidia deliciosa,* Biological activities, Pharmacological activities, Therapeutic properties.

INTRODUCTION

There are 76 species in the genus *Actinidia* but only two species which is commercially cultivated which is *Actinidia deliciosa* (Green Kiwi) and *Actinidia chinesis* (Gold Kiwi). Different types of the variety Actinidia incorporate *Actinidia arguta* (Child Kiwi), *Actinidia purpurea* (Purple Kiwi), *Actinidia kolomikta* (Icy Kiwi), *Actinidia eriantha* (Velvet plant), *Actinidia polygama* (Silver Kiwi) and *Actinidia melanandra* (Red Kiwi)(Guroo I, 2017).

Morphology

The plant thrives in either full sun or partial shade, preferring slightly acidic soil with a pH of 6.0 to 6.5(Guroo I, 2017). According to (Lim T. , 2012), Large, lamellate, woody, deciduous, dioecious vine with yellowish to brown pith. Petioles and young branchlets are strigose and brownish. The leaves are arranged in an alternating pattern and measure 6-17 × 7-15 cm. Their base is subcordatal, their edge is setose-serrulate and their apex is truncate to

emarginate to abruptly cuspidate. The leaves are typically glabrous adaxially but they can also occasionally become puberulent especially on the midvein and lateral veins. Cymose, 1-3 flowered, white, velutinous inflorescences that are either yellowish brown or silky-tomentose are present. Brown-villus pedicels with orange-yellow blooms indicate unisexuality. Five persistent, widely oval to oblong-ovate sepals with dense, yellowish tomentose development on both surfaces are the norm. the superior and styles free. Usually there are five widely obovate petals that are rounded at the apex and short clawed at the vase. There are also numerous stamens with yellow oblong anthers, superior ovary which is globose, golden-strigose and styles free.(13). Kiwi fruit is nearly three inches long and has a brown, hairy peel with green flesh, white pulp in the middle and numerous tiny edible black seeds.

Production

The production of kiwi is dominated by China followed by Italy and New Zealand. (Satpal et al.,2021) New Zealand and Italy are the most significant kiwi exporters worldwide. In India Arunachal Pradesh produces 8.5 thousand tons which is 56.5% of India's kiwi fruit production. 4.18 million metric tonnes of kiwifruit were produced worldwide in 2016. Of the 2.39 million metric tonnes of kiwis produced worldwide, 2.39 million came from China alone. Italy, New Zealand, and Iran are the other three main kiwi-producing countries. Only one-third of the world's kiwifruit production originates from the southern hemisphere, but the majority of kiwifruit cultivation is focused in the northern hemisphere, accounting for two-thirds of total production. Kiwifruit is considered a minor crop globally, making up approximately 0.2–0.3% of the world's total fruit production. India also produces a negligible quantity of kiwis for the market. The first Indian state which show the commercial production of kiwifruit was Himachal Pradesh.(13). Sikkim, Meghalaya, Andhra Pradesh, Karnataka, Uttarakhand, Kerala, Uttar Pradesh, Arunachal Pradesh, and HP all contribute to the nation's kiwi production (Nishiyama et al., 2007). It has recently been grown commercially in Jammu and Kashmir. In the state of J&K, kiwifruit is grown on 3 hectares of land.

Phytochemical Constituents

Kiwi fruits are a good source of few essential trace minerals including manganese, chromium, zinc, selenium, calcium, iron, potassium, magnesium, copper and phosphorus. Kiwi contains Vitamin C, β-carotene, lutein, α-tocophenol, γ-tocophenol, γ-tocotrienol. Kiwi fruit is a contains several bioactive compounds which includes Protocatechuic acid ($C_7H_6O_4$), 4-Hydroxybenzoic acid ($C_7H_6O_3$), Vanillic acid ($C_8H_8O_4$), Caffeic acid ($C_9H_8O_4$), Syringic acid ($C_9H_{10}O$), (E)-p-coumaric acid ($C_9H_8O_3$), Ferulic acid ($C_{10}H_{10}$), Anisic Acid ($C_8H_8O_3$), Naringin ($C_{27}H_{32}O_{14}$), 4-Hydroxybenzoic acid ($C_7H_6O_3$), Gallic acid ($C_7H_6O_5$), Salicylic acid ($C_7H_6O_3$), Kaempferol ($C_{15}H_{10}O_6$), Quercetin ($C_{15}H_{12}O_8$), Ascorbic acid ($C_6H_8O_6$), Chlorogenic acid ($C_{16}H_{18}O_9$), Sinapinic acid ($C_{11}H_{12}O_5$), Cinnamic acid ($C_9H_8O_2$), D-(+)-Catechin ($C_{15}H_{14}O_6$), (−)-Epicatechin ($C_{15}H_{14}O_6$) and Rutin ($C_{27}H_{30}O_{16}$).(Satpal et al., 2021) These bioactive components contribute to the pharmacological properties of kiwi (Satpal et al., 2021).

Health Benefits

Kiwi is good source of actinidin which is proteolytic enzyme that helps the stomach and small intestine digest complex protein structure.Vitamin C which works as an antioxidant and improves skin texture is abundantly stored in kiwi. Additionally it aids in the synthesis of collagen protein which protects skin from UV damage and promotes youthful, flexible skin (Richardson et al., 2018). The bioactive compounds present in kiwi natural product achieves a promising change in the human colonic microorganisms, changes waste consistency, lessens stomach dis-solace and frees The side effects from blockage by diminishing digestive travel time. (Satpal et al., 2021)Furthermore Xanthophylls and Lutein which is present in kiwi helps with keeping up with eye wellbeing and forestalls macular degeneration (Tyagi et al., 2015). Kiwi is associated with a number of well-known health benefits including support for cardiovascular health , improved sleep, aid in blood clotting, absorption of Vitamin D, facilitation of iron absorption , reduction in kidney stone formation and cytotoxic and antimicrobial activity. (Satpal et al., 2021)

According (Singh et al., 2018)It is used to treat and prevent a variety of cancers including liver, lung and stomach cancer.It has been shown to have a variety of biological properties including being Anti-oxidant, Anti-asthmatic, Hepatoprotective, Anti-carcinogenic, Anti-fungal, Antiviral, Antimicrobial , Anti-constipation, Anti-inflammatory,

Anti-hypertensive, Anti-platelet, Anti-nociceptive, Anti-HIV, Cytotoxic, Anti-tumor, and it has different medical advantages attributable to its rich pharmaco-legitimate profile.

Extraction Methods

Cold extraction an orbital shaker (REMI) was used to shake 30g od dried kiwi powder in 300ml of different solvents for 50 hours at room temperature. Whatman No.1 filter paper was used to separate the concentratesn from the buildups. At 50° C, the concentrates were concentrated and evaporated to dryness under reduced tension (El et al., 2015; Zhang et al., 2018; Ewansiha et al., 2012). The complete *Actinidia deliciosa* fruit was ground into small pieces by using a mixer grinder. This material was then soaked in a solvent combination that contained a 70% ethanol solution and second sample was made by simultaneously grinding and soaking fruit in a 70% methanol solution. All sample were soaked for 48 hours after which they were filtered using musilin cloth and Whatman No. 1 filter paper. A rotary evaporater was used to concentrate the obtained filterate. After that the extracts were refrigerated at 8° C to test for antioxidant activity and to analyse phytochemicals.(Zhang et al.,2018 ;Azwanida et al.,2015).

According to (Peter et al., 2015), in order to prepare cold extract, 450 g of the plant were weighed combined with 1 liter of deionized water and vigorously shaken in an electrical shaker for an hour. Using filter paper the solution was filtered and the filtrate was stored in the refrigerator for later use. In order to extract 30 g of the fruit peel and pulp, 300 ml of 80% ethanol and water were used in a Soxhlet extractor over the course of eight hours. The fruit peel and pulp were separated, utilized fresh and allowed to air dry for three day. For three days, the resultant extracts were evaporated at 37° C in an oven. After that, DMSO was used to dissolve each extract. Five milliliters of DMSO were used to dissolve one gram of each extract. As a result the standard extract concentration was 200 mg/ml of stock. All samples were kept at -4° C until they were needed and extracts were sterilized using 0.22 m membrane filters (Abeysinghe et al., 2011).

Qualitative Analysis

An examination of flavonoids using ferric chloride has been carried out qualitatively. when two to three drops of ferric chloride solution are added to a test sample, the precipitate turns green or blackish which is suggesting the presence of flavonoids. (Audu *et al*., 2007). According to (Sadia et al., 2018) research, flavonoids were present in *Actinidia deliciosa* extract. According to (Bhandary *et al*., 2012), The DNPH test has been used to measure vitamin C. 2,4- Dinitro phenyl hydrazine should be dissolved with strong sulfuric acid. This reference combination was applied to each test solution independently, and it was shaken hard. The presence of vitamin C would be shown by the formation of yellow precipitate. The DNPH test confirms that vitamin C is present in *Actinidia deliciosa* extract. The purpose of the Hager's test is to detect the presence of alkaloids by using 3-4 drops od Hager's reagent (saturated picric acid solution) on each test solution individually. Alkaloids are present if shaking causes a yellow precipitate to form(Bhandary *et al*., 2012). Glycosides have undergone a bromine test, test tubes were filled with an equal amount of the solution and bromine water and they were shaken thoroughly then favorable reaction would be elicited by the emergence of yellow precipitate(De *et al*., 2010).

According to (Edeoga *et al*., 2005), The Keller-Killani test is used to test for glycosides. In two test tubes, the glacial acetic acid droplets were combined with the ferric chloride solution and the mixture was then combined in a single test tube. Two layers were seen to form when 2-3 drops of strong sulfuric acid were introduced. A layer of acetic acid would form at the top and transform to bluish green to show the presence of glycosides, while a reddish brown layer would appear at the bottom. An amino acid test using ninhydrin was conducted. With 0.2% Ninhydrin solution bring the test solution to a boil. Boiling anything purple would indicate the presence of free amino acids (Lee *et al*., 1966). Benedict's test was used for determine carbohydrates. Benedict's solution consists of an alkaline solution and a cupric citrate complex. After adding 2 ml of this reagent to a test solution it is boiled for a short while in a water bath. Carbohydrates are present if a reddish- brown precipitate forms(Yadav *et a*l., 2011).

The biuret test is used to detect proteins. Apply a solution containing two drops of sodium hydroxide solution (10%) and copper sulphate solution (0.1%) to the test sample. Protein might be indicated by the presence of violet or pink

color. (Bhandary *et al*., 2012)According to (De *et al*., 2010), The Liebmann Burchard test was used for triterpenoids and steroids. Add 3-4 drops of acetic anhydride to the test sample and bring the mixture to a boil. Then let it cool then pour strong sulfuric acid into the test tube from the sides. If a brown ring forms where two layers meet. Steroids and triterpenoids may be present, as indicated by the upper layer's green hue and the lower layer's deep red color. A test sample would show a positive result for tannins if a small amount of gelatin solution was added and white precipitate would form at the test tube's bottom (Samatha *et al*., 2012).A foam test is used to determine saponins. When the test sample is combined with purified water and vigorously shaken for 5 minutes. Saponins are present if foam forms and stays that way for 15 minutes(Ayoola *et al*., 2008).

Quantitative Analysis

According to (Nazami *et al*., 2016),To determine total phenolic contents take 50 µl of the sample and 50 µl of the Folin-Coicalteu reagent and combine it with 750 µl of purified water and allow the mixture to sit at room temperature for 10 minutes then add 150 µl of 20% Na_2CO_3 to the entire mixture and heated it for 20 minutes at 40°C in a water bath and then chilled in an ice bath. Using a spectrophotometer absorbance was measured at 755 nm. The total phenolic content in *Actinidia deliciosa* extract was 116.43 mg GAE/g extract and the absorbance was at 0.821 nm (Sadia *et al*., 2018).To determine total flavonoid content take 0.5 ml was combined with 0.5 ml of a 2% $AlCl_3$ methanol solution and incubated it for 10 minutes at room temperature then 368 nm was used to quantify absorbance by using spectrophotometer. (Patel *et al*., 2015). The total flavonoid content in *Actinidia deliciosa* extract was 61.91 mg QE/g extract (Sadia *et al*., 2018).According to (Saeed *et al*., 2019), Folin-ciocalteu method was used to determine total phenolic contents as (Guo *et at*., 2012) reported. The findings were given in mg GAE/100 g FW. To summarize, 0.25 M of Folin-ciocalteu reagent was combined with either the extract sample or the gallic acid standards. After six minutes of homogenization 7% (w/v) sodium carbonate was added to neutralize the mixture of homogenization 7% (w/v) sodium carbonate was added to neutralize the mixture. Using and ultraviolet-visible spectrophotometer the absorbance reaction was measured at 760 nm following a 90 minutes incubation period at room temperature. The examination of high-performance liquid chromatography (HPLC) was used to determine the free phenolic extract which is reported by (Ti *et al*., 2015).

The aroma profile and aroma active components of kiwi fruit were investigated using Gas chromatography-mass spectrophotometry (GC-MS) and Multidimensional gas chromatography olfactometry (GC/GC-O) (Shastri *et al*., 2012). Ten components including 3-penten-2-ol, 3-hydroxy-2-butan`2one, 3-methyl-2-butenal, 2-hexanol, nonanal, 3-methyl-1-butanol, 2-methyl-1-butanol, 3-met4zzazzzhyl-2-butanone, 3-methyl 3-buten-2-one and octane were quantified as constituents of the kiwi fruit using Gas chromatography-mass spectrometry(GC-MS) and Multidimensional gas chromatography olfactometry (GC/GC-O) (Jordaa *et al*., 2002).β-carotene and lutein were extracted using the SEY-BOLD et al. (2004) method and quantified by HPLC.α-tocophenol, γ-tocophenol, γ-tocotrienol were extracted and quantified using HPLC/ flurore scence detector as described by (BALTZ *et al*.,1992). Absolute ethanol in an equivalent amount precipitates proteins. An aliquot of the upper layer is mixed with α,α-dipyridly to identify the main component interfering at 460 nm. In order to after the color of the solution which is measured at 520 nm, ferric chloride was introduced to the system at this point. A test tube containing 500 µl of each extract and juice was filled with 500 µl of ethanol and 500 µl of xylene. After 10 minutes of mixing each tube was centrifuged for 10 minutes at 450 xg. 800 µl of xylene were added to the solution followed by 800 µl of α,α-dipyridly (1.2 g in one litre of n-propanol). Removed to use spectronic 21 D measure the sample's absorbance at 460 nm. After that 200 µl of $FeCl_3.6H_2O$ (1.2 gm in a litre of ethanol) was added to the mixture. All tubes' absorbance were then measured at 520 nm using spectronic 21 D(Hashim *et al*., 1996).

Pharmacological Activities

Antimicrobial Activity

Kiwifruit peels has both cytotoxic activity and multidrug resistance reversal activity were found in the less polar fractions of kiwifruit peel extracts. (Motohashi et al., 2001). The Antibacterial activity was distributed in various

fractions and none of them showed any activity against Helicobacter pylori and *Candida albicans*. Methanol extracts exhibited anti-human immunodeficiency virus activity in just 70% caces. These fractions also demonstrated a bimodal (pro-oxidant ant antioxidant) action by efficiently scavenging O^2 generated by the xanthine-xanthine oxidase interaction. (Lim T. , 2012) The 80% ethanol and 80% acetone extract of kiwifruit peels exhibit a broad zone of inhibition against gram-positive bacteria strains (19.82 mm for *Bacillus subtilis* in acetone extract and 17.65 mm for *Staphylococcus aureus* in ethanolic extract), gram-negative bacterial strains (19..52 mm for *Escherichia coli* and 19.50 mm for *Pseudomonas aeruginosa*) and fungi (17.85 mm for *Candida albicans*) according to an antimicrobial study at 400-500 ppm. (Satpal et al., 2021). Furthermore, it was discovered that the acetone extract outperformed the ethanolic fruit peel extract against these bacterial and fungal species. (Salama *et al*., 2018).

Furthermore,It was shown that the acetone extract outperformed the ethanolic fruit peel extract against these bacterial and fungal species. Ultimately the research findings indicated that kiwi peels possess significant nutritional value and can be employed as a key component in the creation of functional food products. Moreover, it is strongly advised to isolate the components with significant biological value. (Salama *et al*., 2018)

Compared to gram-negative bacterial strains, gram-positive bacteria were found to be more susceptible to the polyphenolic chemicals contained in kiwis. (Satpal et al., 2021).The reason for this is because the hydrophilic outer membrane contains lipopolysaccharide molecules, which operate as a barrier to substances that are known to be hydrophobic in nature. (Alim *et al*., 2019) Kiwifruit has been shown to modulate people's immune systems, which helps to provide immunity. (Skinner *et al*., 2011). Through their studies on mice, (Shu et al., 2008) and (Hunter *et al*., 2008) among others hypothesized that supplementing with kiwi fruit extract improves lymphocyte transformation, supports phagocytic activity, increase serum antibody or immunoglobulin production (IgA, IgG and IgM) and improves biomarkers of both innate and acquired immunity. These elements support the kiwi fruit's immune modulatory properties aid in reducing cold and flu symptoms and demonstrate the fruit's effectiveness against viruses.

Antioxidant Activity

Strong antioxidant components like lutein, vitamin C, phenolics, carotenoids, chlorophyll and flavonoids were found to be abundant in kiwi fruit, which is why it has been shown to have antioxidant potential. (Satpal et al., 2021). These results were obtained from the antioxidant activity of kiwi fruit peel extracts in aqueous, acetone, methanolic and ethanolic extracts. (Salama *et al*., 2018).

Anti-inflammatory Activity

Kiwifruit aqueous extracts were shown to have potential anti-inflammatory effect in vitro by reducing the production of interleukin(I-1B) and tumor necrosis factor (TNF) a produced by lipopolysaccharide. (Farr *et al*., 2008)Human THP-1 (human acute monocytic leukemia cell line) monocytes and peripheral whole blood were subjected to aqueous extracts from *Actinidia deliciosa* and *Actinidia chinensis* kiwifruit cultivators, which demonstrated encouraging activity, however individual donors showed different effects. (Lim T. , 2012)

Anticancer

Actinidia deliciosa root ethanol extracts have been shown to have anticancer effects both in vitro and animals. (Liang *et al*., 2007).*Actinidia deliciosa* root extracts in ethanol and butanol shown anti-tumor effects in hepatoma mice and hepatoma H22-mice had extended survival times.(13). It was discovered that both extracts enhanced the tumor bearing mice's immune system. (Lim T. , 2012). The h0 induced inhibition of gap-junction intercellular communication was prevented in WB-F344 rat liver epithelial cells by both green and gold kiwifruit. (Lee *et al*., 2010)

Immuno modulatory

According to (Lim T. , 2012)Kiwifruit extracts *Actinidia chinesis* and *Actinidia deliciosa* significantly improved the intestinal mucosal and serum antibody responses to the vaccines and promoted interferon-γ and natural killer cell activities in BALB/c mice. Proliferative responses, phagocytic activity and interleukin-4 production did not

significantly improve.(13). This study demonstrated the ability of kiwi extract to enhance markers of innate and adaptive immunity in the tested murine modal. (Shu *et al.*, 2008)

Rationale

Actinidia deliciosa has several reasons for being valuable, including its substantial nutritional, agronomic, and financial advantages. Packed with antioxidants, fiber, vitamin C, and vital minerals like potassium, kiwis promote heart, digestive, and immunological health. It is beneficial for gut health because its enzyme actinidin facilitates digestion, and its antioxidant qualities help to lower inflammation and shield cells from oxidative damage. Because of its adaptability and low environmental impact, kiwis are a valuable crop for global agriculture, especially in places like Chile, Italy, and New Zealand. Its rising market worth is highlighted by its growing demand as a functional food and its potential in health-conscious products. Its long-term significance is further increased by research into bettering its types and uses in food processing and biotechnology.

CONCLUSION

The value of *Actinidia deliciosa*is found in its many benefits to agriculture, the environment, human health, and the economy. It is a significant fruit both a nutrient-dense food item and as a crop that farmers may make money from. Its importance in contemporary society is only increased by the continuous research into its potential as a functional food, sustainable agriculture, and health advantages.

ABSTRACT

Primary infertility is a multifactorial reproductive health condition that may involve female, male, or combined factors. Ayurveda describes infertility in relation to the proper functioning of *Ritu, Kshetra, Ambu,* and *Beeja* and emphasizes individualized management based on the underlying *Dosha* and *Samprapti*. Uttara Basti is a specialized Ayurvedic therapeutic procedure traditionally indicated in disorders involving the female reproductive and genitourinary system. The present case report describes the outcome of an individualized Ayurvedic management protocol with particular emphasis on Uttara Basti in a 30-year-old woman presenting with primary infertility, with a history of genital tuberculosis, endometriosis, and previous unsuccessful intrauterine insemination (IUI). The patient's menstrual cycle was regular at approximately 28 days, with menstrual bleeding for 2–3 days and relatively low menstrual flow. Her AMH was reported as 1.960 ng/mL, while her husband's semen analysis showed reported sperm motility of 40% and total sperm count of 18.8 million/ML. A single three-day Uttara Basti regimen was administered beginning on the eighth day of the menstrual cycle. On Day 1, Kshara Taila 1 mL and Kshirabala Taila 2 mL were administered; on Day 2, Kasis Taila and Shatavari–Shatapushpa Taila were administered in a total volume of 3 mL; and on Day 3, Phala Ghrita 2 mL and Mahanarayana Taila 1 mL were administered. Yoni Pichu with Jatyadi Taila was performed following each procedure, along with supportive oral Ayurvedic medications. Following the

treatment protocol, the patient subsequently achieved conception, evidenced by a positive urine pregnancy test. This case highlights the potential clinical relevance of a single-cycle sequential Uttara Basti protocol as part of individualized Ayurvedic management of primary infertility. However, the temporal association between treatment and conception cannot establish causality, and further systematic clinical studies are required to evaluate the efficacy and safety of Uttara Basti in infertility management.

Key words: Primary infertility; Uttara Basti; Ayurveda; Apatyakankshini; Endometriosis; Genital tuberculosis; IUI failure; Conception.

INTRODUCTION

Infertility is an important reproductive health problem affecting individuals and couples worldwide and is defined by the World Health Organization (WHO) as a disease of the male or female reproductive system characterized by the failure to achieve pregnancy after 12 months or more of regular unprotected sexual intercourse[1]. Approximately one in six people of reproductive age experience infertility during their lifetime, making it a significant medical, psychological, social, and economic concern. Infertility may result from female factors, male factors, a combination of both, or remain unexplained[2]. In females, reproductive dysfunction may be associated with abnormalities of ovulation, ovarian reserve, uterine or endometrial factors, tubal pathology, endometriosis, or other pelvic and systemic conditions3. Endometriosis is particularly relevant to infertility because pelvic inflammation, adhesions, altered pelvic anatomy, and other reproductive disturbances may adversely affect fecundity. Previous genital or pelvic infections may further compromise reproductive tract function and contribute to infertility. In contemporary practice, couples with infertility may undergo various medical and assisted reproductive interventions, including intrauterine insemination (IUI) [4] and in-vitro fertilization (IVF)[5], depending upon the underlying etiology and clinical circumstances. In Ayurveda, successful conception is described as dependent upon the appropriate functioning of *Ritu*, *Kshetra, Ambu,* and *Beeja[6]*, while disorders affecting these factors may manifest as *Vandhyatva* or failure to achieve conception. Ayurvedic management emphasizes individualized assessment of *Dosha, Dushya, Srotas,* and *Samprapti*, followed by appropriate therapeutic interventions aimed at restoring physiological balance and supporting reproductive function.

Among the specialized procedures described in Ayurveda, Uttara Basti[7] is traditionally utilized in disorders involving the female reproductive and genitourinary system and has been described in Ayurvedic clinical practice as a localized therapeutic intervention. Although emerging clinical reports have described the use of Uttara Basti in reproductive disorders, contemporary evidence regarding its role in infertility remains limited, necessitating further systematic clinical investigation. The present case is noteworthy because a 30-year-old woman with primary infertility visited us at Dr. Mahesh Birla`s OJUS AYURVED Super speciality Hospital, Jalgaon, Maharashtra.A history of genital tuberculosis and endometriosis, and previous unsuccessful IUI subsequently achieved conception following an individualized Ayurvedic treatment protocol in which a single three-day sequential Uttara Basti regimen constituted the principal local therapeutic intervention. The present case report aims to describe the clinical presentation, Ayurvedic assessment, therapeutic rationale, detailed Uttara Basti protocol, associated management, and subsequent reproductive outcome, thereby contributing to the clinical literature and providing a basis for further investigation into the potential role of Uttara Basti in the management of primary infertility.

Case Presentation

A 30-year-old married woman presented with a history of primary infertility and inability to conceive despite regular marital life. The patient had a history of genital tuberculosis and endometriosis, both of which were considered relevant to her reproductive history. Prior to presenting for Ayurvedic management, she had undergone intrauterine insemination (IUI) on 24 January 2026, which was unsuccessful. At presentation, her menstrual cycles were regular, occurring approximately every 28 days, with menstrual bleeding lasting for 2–3 days; however, the patient reported relatively reduced menstrual flow. An additional complaint documented during the clinical assessment was a history

of night-time *Angataapa* for approximately three years. Based on the clinical presentation and Ayurvedic assessment, the condition was considered under the Ayurvedic diagnosis of *Apatyakankshini9*, with *Rajahkshinatā10* considered among the relevant clinical features. The patient's reproductive evaluation included assessment of ovarian reserve and evaluation of the male partner. Her serum anti-Mullerian hormone (AMH) level, assessed on 20 May 2026, was reported as 1.960 ng/mL. Semen analysis of her husband, performed on 21 May 2026, reported sperm motility of 40% and a total sperm count of 18.8 million/ML. On clinical examination, her blood pressure was 110/80 mmHg. The remaining general and Ayurvedic examination findings were recorded as part of the clinical assessment and will be presented in detail after confirmation of the recorded abbreviations and terminology.

Following assessment, an individualized Ayurvedic treatment protocol was planned. In addition to internal Ayurvedic medications and supportive management prescribed during the treatment period, Uttara Basti was selected as the principal localized therapeutic intervention. A single three-day course of Uttara Basti was administered beginning on the eighth day of the menstrual cycle. On tChief consultant at Ojus Ayurved Super Speciality Hospital, Jalgaon. he first day, Kshara Taila 1 mL followed by Kshirabala Taila 2 mL was administered. On the second day, Kasis Taila and Shatavari–Shatapushpa Taila were administered in a total volume of 3 mL. On the third day, Phala Ghrita 2 mL followed by Mahanarayana Taila 1 mL was administered, giving a total volume of 3 mL. Following each Uttara Basti procedure, Yoni Pichu[8] was performed using a cotton swab soaked in Jatyadi Taila. The Uttara Basti protocol was administered for only one menstrual cycle and was not repeated subsequently. The patient was followed after completion of the treatment protocol. During the subsequent reproductive follow-up, she reported a positive urine pregnancy test, indicating conception. The temporal sequence of treatment followed by conception was documented as the principal clinical outcome of interest in this case. Further objective confirmation of pregnancy, including serum β-hCG and ultrasono graphic findings, will be incorporated into the case report when available. The clinical course, including the patient's pre-treatment infertility history, previous failed IUI, Ayurvedic assessment, detailed Uttara Basti protocol, concomitant medications, follow-up, and subsequent conception, is presented to document the clinical outcome associated with this individualized treatment approach. As this is a single case, the observed conception is reported as a clinical outcome following treatment and does not establish a direct causal relationship between Uttara Basti and pregnancy

RESULTS

Following a single three-day course of sequential Uttara Basti initiated on the eighth day of the menstrual cycle, along with the prescribed supportive Ayurvedic treatment, the patient subsequently achieved conception. Pregnancy was initially confirmed by a positive urine pregnancy test during follow-up. No further Uttara Basti cycle was administered after this treatment. The successful conception following a single therapeutic cycle represents the principal clinical outcome of this case, particularly in view of the patient's history of primary infertility, endometriosis, genital tuberculosis, and previous unsuccessful IUI. Further pregnancy confirmation and follow-up findings, including serum β-hCG and ultra sonography, may be incorporated as they become available. As this is a single case involving multiple therapeutic interventions, the observed conception should be considered a clinical outcome following the overall treatment protocol rather than evidence of a direct causal effect of Uttara Basti.

DISCUSSION

The present case describes successful conception in a 30-year-old woman with primary infertility, a history of endometriosis and genital tuberculosis, and previous unsuccessful IUI, following an individualized Ayurvedic treatment protocol incorporating a single three-day course of Uttara Basti. In Ayurveda, infertility is understood in relation to the proper functioning of *Ritu, Kshetra, Ambu,* and *Beeja*, with treatment planned according to the underlying *Dosha* and *Samprapti*. Uttara Basti is traditionally described as a specialized local therapeutic procedure for disorders of the female reproductive and genitourinary system. In this case, a sequential protocol using Kshara

Taila, Kshirabala Taila, Kasis Taila, Shatavari–Shatapushpa Taila, Phala Ghrita, and Mahanarayana Taila was administered from the eighth day of the menstrual cycle, with Yoni Pichu using Jatyadi Taila following each procedure. The subsequent positive UPT following only one therapeutic cycle represents a noteworthy clinical outcome, particularly given the patient's complex infertility history and previous failed IUI. However, as the patient also received supportive Ayurvedic medications and the case represents a single observation, conception cannot be attributed independently to Uttara Basti. The case nevertheless highlights the potential role of a carefully planned, individualized Uttara Basti protocol in Ayurvedic infertility management and provides a basis for further systematic clinical research evaluating its efficacy, safety, and reproductive outcomes.

CONCLUSION

This case highlights the potential role of a single three-day sequential Uttara Basti protocol as part of an individualized Ayurvedic approach to primary infertility. Successful conception following the intervention, despite a complex reproductive history and previous failed IUI, represents a noteworthy clinical outcome. However, this single case cannot establish a direct causal relationship between Uttara Basti and conception. Further well-designed clinical studies are required to evaluate its efficacy, safety, and reproducibility in infertility management.

ABSTRACT

Embelia basaal (Roxb.) A. DC., a medicinal plant belonging to the family Primulaceae, is traditionally used in various systems of folk medicine for the treatment of several ailments. The present study investigated the phytochemical composition and quantified major bioactive constituents in the acetone extracts of leaves and bark of *Embelia basaal* using thin-layer chromatography (TLC), high-performance thin-layer chromatography (HPTLC), high-performance liquid chromatography (HPLC) and gas chromatography-mass spectrometry (GC-MS). TLC analysis confirmed the presence of flavonoids and phenolic compounds in both extracts using quercetin and gallic acid as reference standards. HPTLC densitometric analysis at 254 nm revealed distinct chromatographic profiles for leaf and bark extracts. Calibration curves for quercetin and gallic acid exhibited excellent linearity within the concentration range of 0.00–0.10 µg/spot. The leaf extract showed a higher flavonoid content, whereas the bark extract exhibited comparatively greater phenolic accumulation. HPLC analysis further confirmed the occurrence of flavonoid and phenolic constituents through characteristic retention-time profiles. GC-MS analysis identified 32 phytocomponents in the leaf extract and 40 phytocomponents in the bark extract. Major compounds detected in the leaf extract included dl-α-tocopherol, squalene, 1-hexadecanol and n-tetracosanol-1, whereas the bark extract was rich in 10(E),12(Z)-conjugated linoleic acid, decanedioic acid bis(2-ethylhexyl) ester, stigmasterol and dl-α-tocopherol. Both extracts contained 6,3′-dimethoxy-3-(trimethylsilyl)oxyflavone, indicating the presence of methoxylated flavonoids. The findings demonstrate that *E. basaal* is a rich source of bioactive phytochemicals with potential therapeutic significance and provide valuable quality-control parameters for the standardisation of herbal preparations and future pharmacological investigations.

Keywords: *Embelia basaal*; HPTLC; HPLC; GC-MS; flavonoids; phenolic compounds; phytochemical profiling.

INTRODUCTION

The genus *Embelia*, belonging to the family Primulaceae (formerly Myrsinaceae), comprises approximately 130 species of climbing shrubs distributed across tropical and subtropical regions of Asia, Africa and Madagascar. Among these, *Embelia basaal* (Roem. & Schult.) A. DC., commonly known as "Basaal" or "Babrang", holds significant ethno medicinal importance in the Indian subcontinent [1]. The plant is a woody climbing shrub characterised by elliptic-lanceolate leaves, small greenish-white flowers and globose fruits that turn black upon ripening. It is predominantly found in the deciduous forests of the Western Ghats, Eastern Ghats and Himalayan foothills up to an altitude of 1500 m [2]. Traditionally, various parts of *E. basaal* have been employed in Ayurvedic, Siddha and folk medicine systems for the management of rheumatism, inflammation, skin disorders, gastrointestinal disturbances and helminthic infections [3]. The therapeutic potential of medicinal plants is intrinsically linked to their phytochemical constituents, particularly secondary metabolites such as flavonoids, phenols, tannins, alkaloids and terpenoids [4]. These bioactive compounds exhibit diverse pharmacological activities including antioxidant, anti-inflammatory, antimicrobial, anticancer and hepatoprotective effects. Flavonoids and phenolic compounds have attracted considerable attention because of their ability to modulate oxidative stress and scavenge free radicals. Therefore, the characterisation and quantification of these phytoconstituents are important for validating traditional medicinal uses and developing standardised herbal formulations [5].

Despite the documented ethnopharmacological significance of *Embelia* species, comprehensive phytochemical investigations on *E. basaal* remain limited. Previous studies have focused predominantly on *Embelia ribes*, a medicinally important species known for its embelin content and anthelmintic activity. Since *E. basaal* is often used as a substitute for *E. ribes* in traditional medicine, detailed phytochemical evaluation is necessary to establish its therapeutic significance and quality standards [6]. The development of modern analytical techniques has greatly enhanced phytochemical investigations by enabling rapid, sensitive and accurate identification of plant constituents [7]. Thin-layer chromatography (TLC) serves as a simple and economical technique for preliminary phytochemical screening, whereas high-performance thin-layer chromatography (HPTLC) provides enhanced resolution and reproducibility for qualitative and quantitative analysis. High-performance liquid chromatography (HPLC) and gas chromatography-mass spectrometry (GC-MS) are widely employed for the separation, quantification and identification of phytoconstituents. The combined application of these analytical techniques provides comprehensive phytochemical information essential for quality control and pharmacological evaluation of medicinal plants [8]. Therefore, the present study was undertaken to perform phytochemical profiling of acetone leaf and bark extracts of *E. basaal* using TLC, HPTLC, HPLC and GC-MS techniques. Particular emphasis was placed on the detection and quantification of flavonoids and phenolic compounds and the identification of major phytoconstituents present in both extracts [9].

MATERIALS AND METHODS

Plant material collection and extraction:

Fresh leaves and bark of *Embelia basaal* (Roxb.) A. DC. were collected from Manjoor Village, Nilgiris District, Tamil Nadu, India, during the flowering season (September-November). A taxonomist authenticated the plant material, and a voucher specimen (BSI/SRC/5/23/2024/Tech-234) was deposited in the departmental herbarium for future reference. The collected materials were washed, shade-dried, powdered and stored in airtight containers. Extraction was carried out using acetone in a Soxhlet apparatus as described previously [10].

Thin-layer chromatography analysis:

TLC analysis was performed on silica gel 60 F254 plates (Merck, Germany). Flavonoids and phenolic compounds were detected using appropriate solvent systems and reference standards. The developed plates were visualised under ultraviolet light and derivatised using specific reagents [11].

High-performance thin-layer chromatography analysis:
HPTLC analysis was performed using a CAMAG HPTLC system equipped with Linomat 5 applicator, TLC Scanner 4 and visionCATS software. Densitometric scanning was carried out at 254 nm [12].

Preparation of calibration curves:
Calibration curves for quercetin and gallic acid were prepared using standard solutions of different concentrations. Linear regression analysis was performed to determine the correlation coefficients [12].

High-performance liquid chromatography analysis:
HPLC analysis was performed using a Shimadzu Prominence-i LC-2030C 3D Plus system equipped with a photodiode array detector. Separation was achieved using a C18 reversed-phase column under gradient elution conditions [13].

Gas chromatography-mass spectrometry analysis:
GC-MS analysis was carried out using a Thermo Scientific Trace 1300 gas chromatograph coupled with an ISQ 7000 mass spectrometer. Identification of phyto components was performed by comparison with NIST and Wiley spectral databases [14].

Data analysis:
All experiments were performed in triplicate and results were expressed as mean ± standard deviation. Calibration curves were analysed using linear regression, and statistical significance was determined at $P < 0.05$.

RESULTS AND DISCUSSION

Phytochemical screening by TLC:
Preliminary phytochemical screening of *Embelia basaal* leaf and bark acetone extracts was carried out using thin-layer chromatography (TLC). TLC analysis confirmed the presence of flavonoids and phenolic compounds in both extracts. Under ultraviolet light at 254 nm, distinct quenching bands corresponding to conjugated phytoconstituents were observed. Following derivatisation with aluminium chloride reagent, characteristic fluorescent bands were visualised at 366 nm, confirming the occurrence of flavonoids. The leaf extract exhibited multiple bands with Rf values comparable to those of quercetin standard, suggesting the presence of flavonoid derivatives. The bark extract also showed prominent flavonoid bands, although differences in intensity indicated variation in phytochemical composition. Ferric chloride derivatisation revealed the occurrence of phenolic compounds in both extracts, with greater band intensity observed in the bark extract. Similar chromatographic observations have been reported in medicinal plants rich in flavonoids and phenolic compounds [15,16].

HPTLC fingerprinting and quantification:
HPTLC analysis generated characteristic chromatographic fingerprints for both leaf and bark acetone extracts of *E. basaal*. Densitometric scanning at 254 nm revealed distinct peak patterns corresponding to various phytoconstituents. The chromatographic profile of the leaf extract showed several peaks corresponding to flavonoid compounds, whereas the bark extract displayed dominant peaks associated with phenolic constituents. Calibration curves prepared using quercetin and gallic acid standards exhibited excellent linearity within the concentration range studied, with correlation coefficients (R^2) greater than 0.99. Quantitative estimation indicated that the leaf extract contained a higher concentration of flavonoids, whereas the bark extract showed comparatively higher phenolic content. These findings are in agreement with previous studies demonstrating tissue-specific accumulation of secondary metabolites in medicinal plants [17,18].

HPLC analysis:
HPLC chromatographic profiling further confirmed the occurrence of flavonoid and phenolic constituents in both extracts. Several peaks were detected in the chromatograms, reflecting the chemical complexity of the extracts. Peaks

corresponding to the retention times of quercetin and gallic acid standards were observed, confirming the presence of these bioactive compounds. The leaf extract exhibited comparatively greater flavonoid-associated peaks, while the bark extract displayed prominent phenolic peaks. The consistency between HPTLC and HPLC findings validates the reliability of the analytical methods employed and confirms the abundance of antioxidant phytoconstituents in *E. basaal* [19,20].

GC-MS analysis:

GC-MS analysis enabled the identification of volatile and semi-volatile phytoconstituents present in the acetone extracts. A total of 32 compounds were identified in the leaf extract, whereas 40 compounds were detected in the bark extract. The leaf extract was characterised by the predominance of dl-α-tocopherol, squalene, 1-hexadecanol and n-tetracosanol-1. Tocopherols are recognised as potent antioxidants capable of protecting cellular membranes against oxidative damage [21]. Squalene has been reported to possess antioxidant, immunomodulatory and chemoprotective activities [22]. Long-chain alcohols such as 1-hexadecanol and n-tetracosanol-1 have been associated with anti-inflammatory and antimicrobial properties [23]. The bark extract exhibited a comparatively diverse phytochemical profile and was rich in 10(E),12(Z)-conjugated linoleic acid, decanedioic acid bis(2-ethylhexyl) ester, stigmasterol and dl-α-tocopherol. Conjugated linoleic acid has been reported to exhibit antioxidant and anticancer activities, while stigmasterol possesses anti-inflammatory and cholesterol-lowering effects [24,25]. Several compounds including phorone, neophytadiene and fatty acid esters were detected exclusively in the bark extract. The presence of aspidinol and 2-methoxyphenol further supports the higher phenolic content observed in chromatographic analyses. Both extracts contained 6,3′-dimethoxy-3-(trimethylsilyl)oxyflavone, indicating the occurrence of methoxylated flavonoids throughout the plant [26].

Comparative phytochemical profile:

Comparative evaluation of leaf and bark extracts revealed notable differences in phytochemical composition. The leaf extract was rich in flavonoids, tocopherols and long-chain alcohols, whereas the bark extract exhibited greater phytochemical diversity and higher phenolic accumulation. These differences may be attributed to tissue-specific biosynthetic pathways and ecological functions of secondary metabolites. The presence of compounds possessing antioxidant, anti-inflammatory, antimicrobial and chemoprotective activities provides scientific support for the traditional medicinal use of *E. basaal* [27]. The combined application of TLC, HPTLC, HPLC and GC-MS techniques established a comprehensive phytochemical profile of the species and generated valuable quality-control parameters for future standardisation, pharmacological validation and herbal drug development. Furthermore, the observed phytochemical variations between leaf and bark extracts highlight the importance of selecting appropriate plant parts for therapeutic applications and future phyto pharmaceutical investigations [28**].**

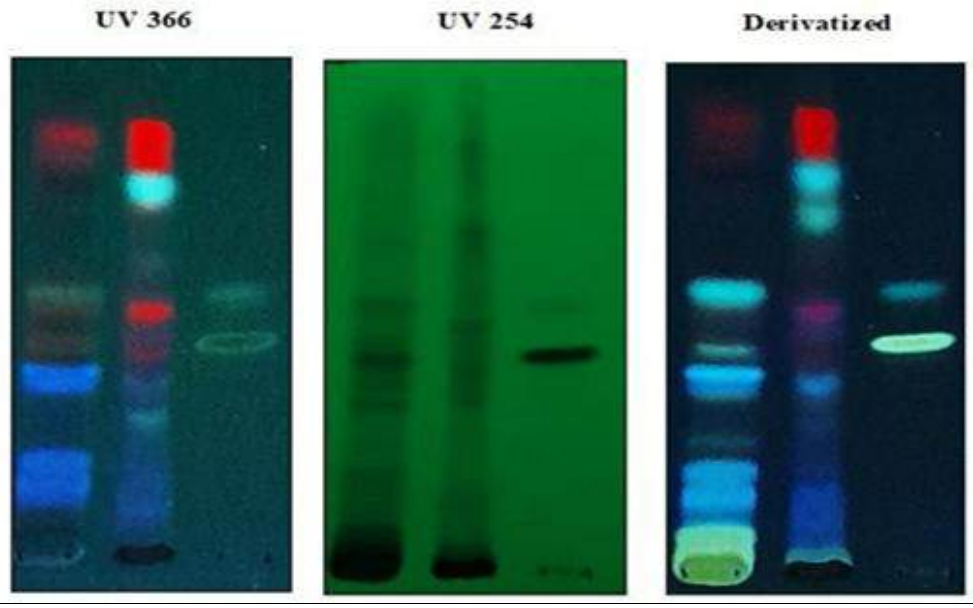

Figure 1: Detection of flavonoids using Thin Layer Chromatography (TLC). Plates were developed using a mobile phase of Toluene:Ethyl acetate:Formic acid:Methanol (5:5:0.4:0.1 v/v). Visualization was achieved by spraying with 1% Aluminium chloride in ethanol, followed by observation under UV light at 254 nm, 366 nm, and after derivatization. Track 1: Acetone extract of Leaf; Track 2: Acetone extract of Bark; Track 3: Marker - Quercetin.

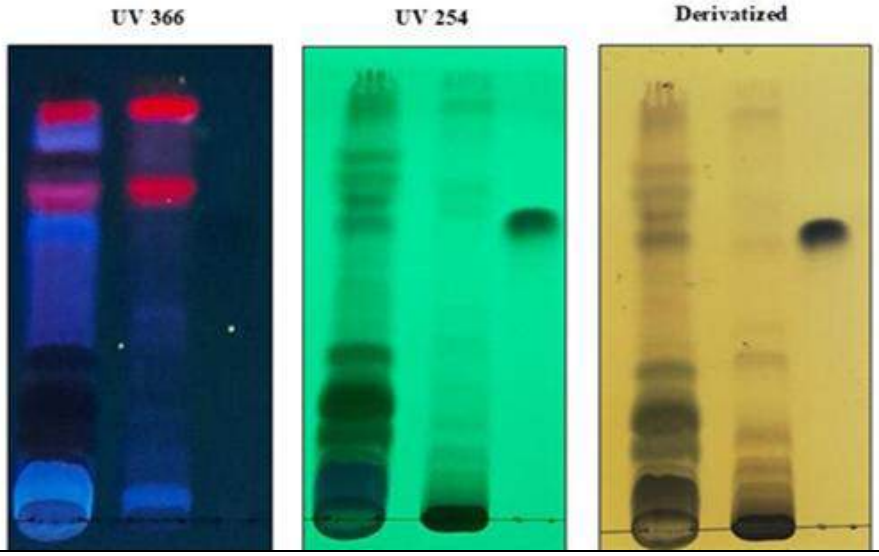

Figure 2. Detection of phenols and tannins using Thin Layer Chromatography (TLC). Plates were developed using a mobile phase of Ethyl acetate:Acetic acid:Water (10:0.5:0.2 v/v). Visualization was achieved by spraying with 0.5% Ferric chloride in ethanol, followed by observation under UV light at 254 nm, 366 nm, and after derivatization. Track 1: Acetone extract of Leaf; Track 2: Acetone extract of Bark; Track 3: Marker - Gallic acid.

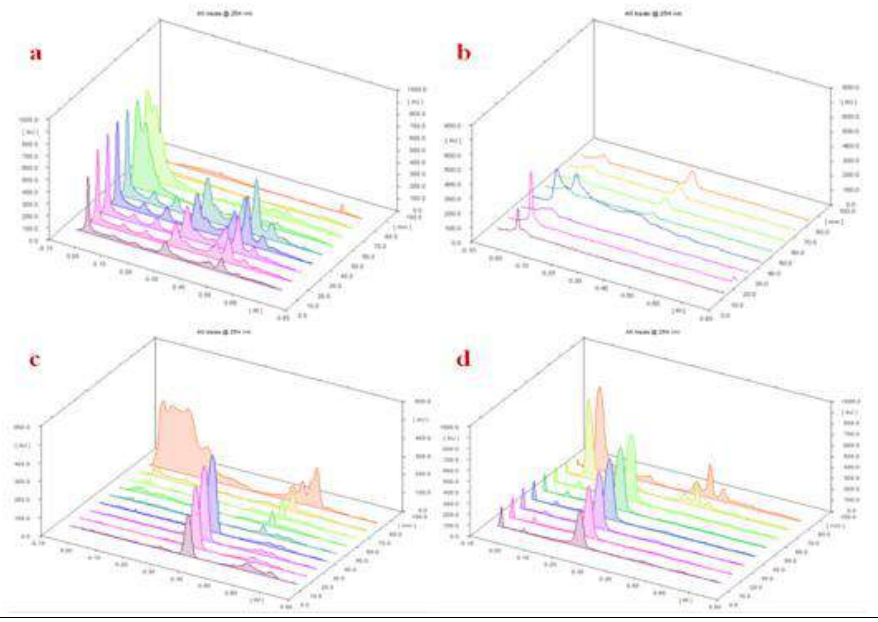

Figure 3. HPTLC 3D densitometric chromatogram of *E. basaal* acetone extracts for the quantification of flavonoids and phenols. Overlay of sample tracks against standard markers scanned at 254 nm. The X-axis represents the migration distance (0.00–1000.0 AU) and the Y-axis represents the absorbance (0.00–800.0 AU). (a) Leaf acetone extract vs. Quercetin (flavonoid standard); (b) Bark acetone extract vs. Quercetin; (c) Leaf acetone extract vs. Gallic acid (phenolic standard); (d) Bark acetone extract vs. Gallic acid

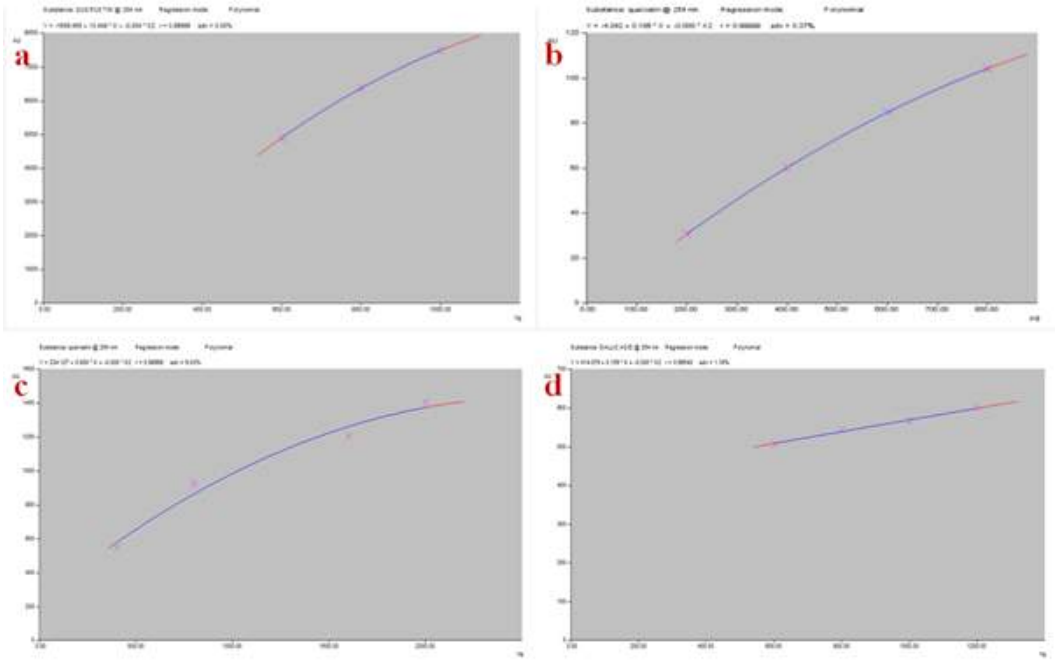

Figure 4. Calibration curves for the quantification of flavonoids and phenols in *E. basaal* acetone extracts. Spectral analysis was performed at 254 nm with corresponding insets showing expanded views or percentage purity/area calculations. (a) Leaf acetone extract vs. Quercetin standard; (b) Bark acetone extract vs. Quercetin (inset: 0.37%); (c) Leaf acetone extract vs. Gallic acid (inset: 1.18%); (d) Bark acetone extract vs. Gallic acid. Minimum and maximum absorbance values are indicated for each track at 254 nm

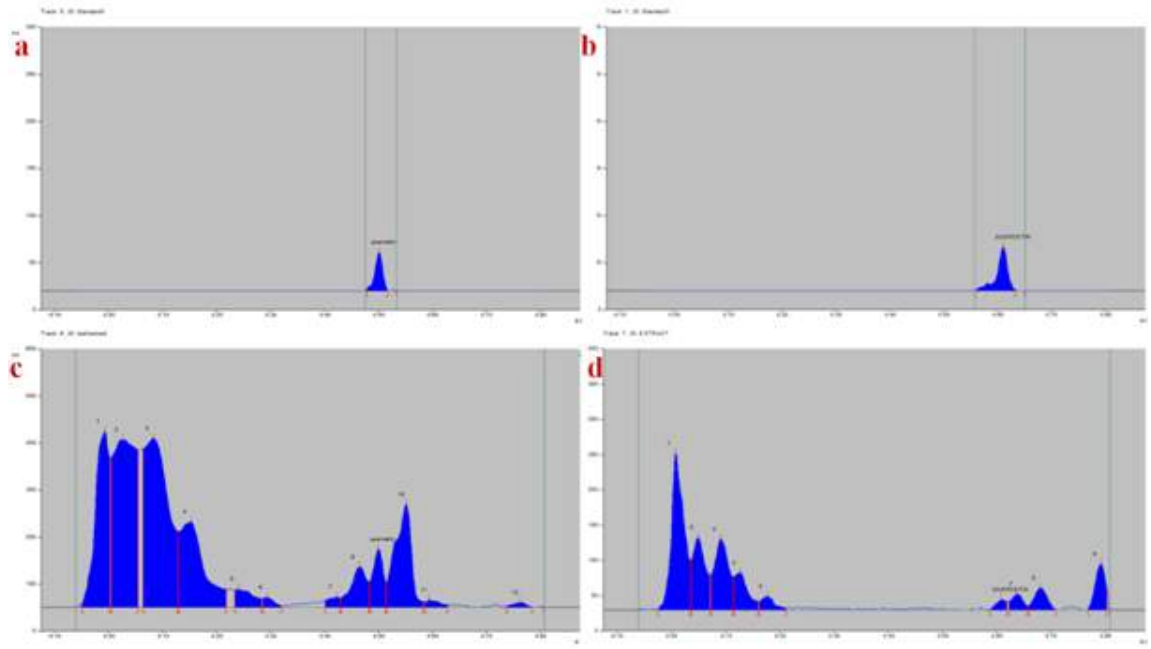

Figure 5: Calibration curves for the quantification of flavonoids in *E. basaal* acetone extracts using Quercetin as a reference standard. The X-axis represents concentration (µg/spot) and the Y-axis represents peak area (AU). (a) Quercetin standard (leaf quantification); (b) Quercetin standard (bark quantification); (c) Leaf acetone extract; (d) Bark acetone extract. Linear regression ranges are indicated for each curve (0.00–0.10 µg/spot for a–d; additional ranges of 0.00–0.15 and 0.00–0.20 µg/spot shown for e and f, respectively, representing replicate or extended calibration models).

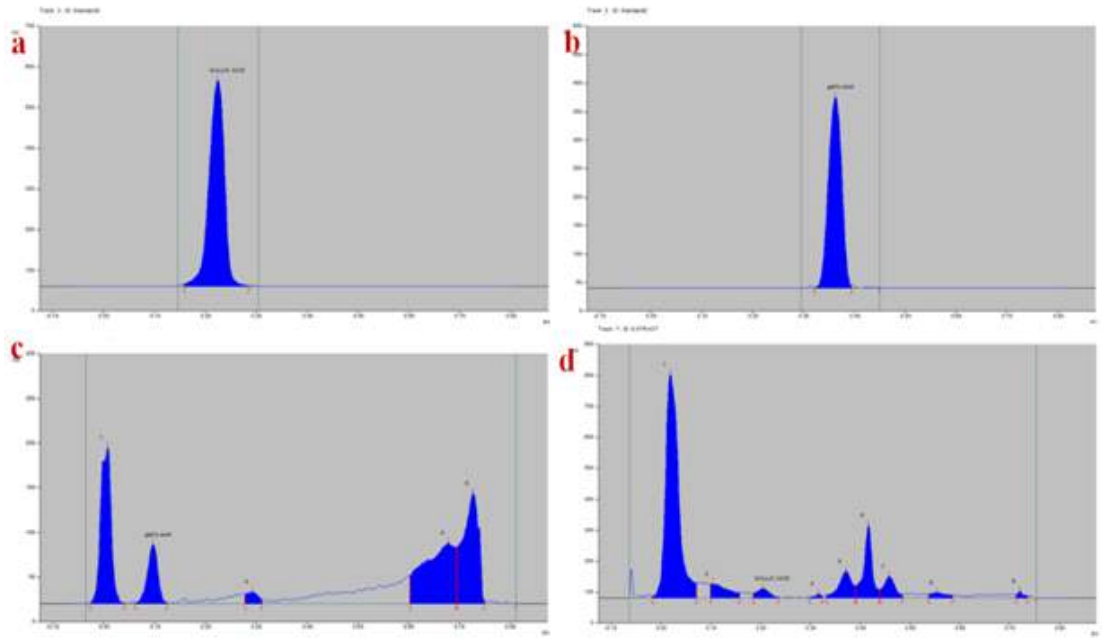

Figure 6. Calibration curves for the quantification of phenols in *E. basaal* acetone extracts using Gallic acid as a reference standard. The X-axis represents concentration (µg/spot) and the Y-axis represents peak area (AU). (a) Gallic acid standard (leaf quantification); (b) Gallic acid standard (bark quantification); (c) Leaf acetone extract; (d) Bark acetone extract. Linear regression ranges are indicated for each curve (0.00–0.10 µg/spot), with panel (b) showing extended calibration data points.

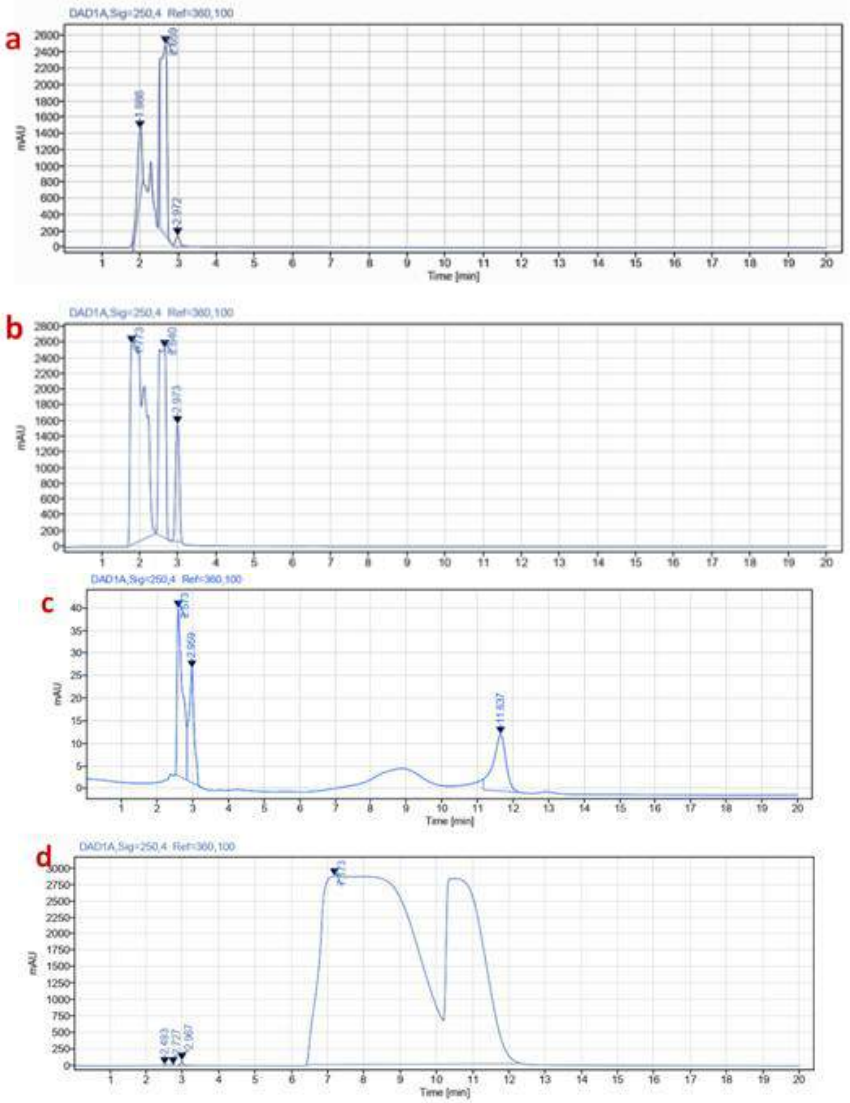

Figure 7. HPLC chromatograms of *E. basaal* acetone extracts and reference standards recorded at [λ, e.g., 254 nm]. The X-axis represents retention time (min) and the Y-axis represents absorbance (mAU). (a) Leaf acetone extract; (b) Bark acetone extract; (c) Quercetin standard; (d) Gallic acid standard. Major peaks corresponding to flavonoids and phenols are identified based on retention time matching with reference standards

ABSTRACT

The rapid advancement of digital technologies has significantly transformed traditional education systems into intelligent and technology-enabled learning environments. Smart education systems integrate advanced technologies such as artificial intelligence, Internet of Things, cloud computing, big data analytics, and immersive technologies to improve teaching efficiency and enhance student learning experiences. This study explores the role of innovative teaching and learning applications in the development of smart education systems from a technology-driven perspective. The research adopts a conceptual and secondary data–based approach to analyze the evolution of smart education technologies and their impact on educational outcomes. Secondary data from global educational technology reports and research publications were analyzed to understand the trends in the adoption of digital learning platforms and intelligent educational systems. The findings indicate that smart education technologies enable personalized learning, collaborative learning environments, and interactive educational experiences that significantly improve student engagement and learning efficiency. The study further proposes a conceptual framework that links technological enablers, smart teaching applications, smart learning applications, and educational outcomes. The framework provides a structured understanding of how advanced digital technologies contribute to the development of intelligent educational ecosystems. The study concludes that smart education systems have the potential to reshape modern education by providing flexible, adaptive, and data-driven learning environments. The findings offer useful insights for educators, policymakers, and technology developers interested in implementing smart education solutions in contemporary educational institutions.

Keywords: Smart Education Systems, Artificial Intelligence in Education, Internet of Things, Digital Learning Technologies, Smart Learning Applications, Educational Technology, Learning Analytics

INTRODUCTION

The rapid advancement of digital technologies has significantly transformed the landscape of education across the world. Traditional teaching and learning approaches are increasingly being complemented and enhanced by technology-driven systems that support interactive, flexible, and personalized learning experiences. In this context, the concept of smart education systems has emerged as a key paradigm for modern educational environments[1]. Smart education integrates advanced technologies such as artificial intelligence (AI), Internet of Things (IoT), cloud computing, big data analytics, and immersive technologies to create intelligent and adaptive learning ecosystems that improve both teaching effectiveness and learning outcomes. Smart education systems are designed to provide a learner-centered educational environment where technology supports personalized learning pathways, real-time feedback, and data-driven decision making. Unlike conventional e-learning platforms, smart education systems enable dynamic interaction between teachers, students, and digital learning resources through intelligent platforms and smart devices[2]. These systems facilitate innovative teaching methods such as intelligent tutoring systems, automated assessment tools, collaborative learning platforms, and adaptive learning environments. As a result, they play an important role in improving student engagement, learning efficiency, and knowledge retention[3]. In recent years, educational institutions worldwide have increasingly adopted smart education technologies to respond to the growing demand for flexible and technology-enabled learning. The integration of artificial intelligence and learning analytics enables educators to analyze student learning patterns and design personalized instructional strategies. Similarly, IoT-based smart classrooms provide real-time monitoring and interactive learning environments, while cloud-based educational platforms ensure accessibility and scalability of learning resources[4].

These technological innovations collectively contribute to the development of a more efficient and sustainable education system. Despite the growing importance of smart education systems, the integration of innovative teaching and learning applications remains a complex challenge for many educational institutions[5]. Issues such as technological infrastructure limitations, lack of digital skills among educators, data privacy concerns, and uneven technology adoption across institutions can hinder the effective implementation of smart education initiatives. Furthermore, existing research on smart education often focuses on individual technologies rather than examining the integrated role of multiple technologies in supporting both teaching and learning processes[6], [7].Therefore, there is a need for a comprehensive analysis that examines how technology-driven applications contribute to the development of smart education systems. This study aims to analyze innovative teaching and learning applications within smart education systems by synthesizing existing literature and analyzing secondary data from educational technology reports and academic studies[8]. The research explores the technological enablers of smart education, evaluates their role in transforming teaching and learning practices, and presents a conceptual framework illustrating the integration of digital technologies in modern educational environments[9]. The findings of this study contribute to the growing body of knowledge on technology-enhanced education by providing insights into the role of innovative applications in improving educational outcomes[10]. The study also offers implications for educators, policymakers, and educational institutions seeking to adopt smart education technologies to enhance teaching quality and learning effectiveness.

LITERATURE REVIEW

Concept of Smart Education Systems

Smart education systems represent a transformative shift in the delivery and management of education through the integration of advanced digital technologies and intelligent learning environments. The concept of smart education has emerged as a response to the increasing demand for flexible, personalized, and technology-enabled learning systems that can improve teaching effectiveness and student learning outcomes. Unlike traditional educational systems, smart education integrates multiple technologies to create an adaptive, interactive, and data-driven learning ecosystem that supports both instructors and learners. The concept of smart education is closely related to the

broader development of smart environments and smart cities, where digital technologies are utilized to enhance efficiency, connectivity, and decision-making processes. In the educational context, smart education systems combine digital infrastructure, intelligent learning platforms, and real-time data analytics to provide an optimized learning experience for students. According to Zhu et al., smart education systems aim to build intelligent learning environments that enable personalized learning, continuous feedback, and adaptive educational services through advanced information technologies [11]. These systems leverage data collected from learners and educational platforms to support more effective teaching strategies and learning processes. One of the defining characteristics of smart education systems is their ability to provide personalized and adaptive learning experiences. Artificial intelligence and learning analytics play a crucial role in enabling these capabilities by analyzing learner behavior, performance patterns, and engagement levels. Through these technologies, educational platforms can deliver customized learning content and recommendations that suit individual student needs and learning styles. Research by Holmes et al. highlights that AI-driven learning systems can significantly enhance educational efficiency by providing intelligent tutoring, automated feedback, and adaptive assessment mechanisms [12].

Such innovations allow educators to focus more on mentoring and facilitating learning rather than solely delivering instructional content. Another important component of smart education systems is the integration of Internet of Things (IoT) technologies within educational environments. IoT-based smart classrooms utilize interconnected devices such as sensors, smart boards, and mobile learning tools to create an interactive and responsive learning environment. These technologies enable real-time monitoring of classroom activities and support collaborative learning experiences. IoT technologies can enhance the learning environment by enabling seamless connectivity between educational devices, students, and instructors, thereby improving communication and engagement within smart learning environments [13]Cloud computing also plays a critical role in supporting smart education systems by providing scalable and accessible digital learning platforms. Cloud-based educational systems allow institutions to store and distribute learning resources efficiently while enabling students to access educational content from anywhere at any time. Studies indicate that cloud-based learning management systems significantly improve the accessibility and flexibility of educational services, making education more inclusive and adaptable to diverse learner needs [14] In addition to AI, IoT, and cloud technologies, big data analytics is increasingly being used to enhance the effectiveness of smart education systems. Learning analytics enables educational institutions to analyze large volumes of student data to identify learning patterns, predict academic performance, and improve decision-making processes in education management. Siemens and Baker emphasize that learning analytics can provide valuable insights into student engagement and performance, allowing educators to design more effective learning strategies and interventions [15], [16].

Technological Enablers of Smart Education Systems

The development of smart education systems is largely driven by the rapid advancement of digital technologies that enable intelligent, connected, and adaptive learning environments. These technological enablers play a crucial role in transforming traditional education systems into dynamic ecosystems capable of supporting personalized learning, real-time feedback, and data-driven educational decision-making. Among the most significant technologies supporting smart education systems are artificial intelligence, Internet of Things (IoT), cloud computing, big data analytics, and immersive technologies such as virtual and augmented reality. The integration of these technologies enhances both teaching efficiency and student learning outcomes.

Artificial Intelligence in Education

Artificial Intelligence (AI) has emerged as one of the most influential technologies in the development of smart education systems. AI-based educational tools enable intelligent tutoring systems, automated grading, personalized learning pathways, and predictive analytics that support improved learning outcomes. Through machine learning algorithms, AI systems can analyze student performance data and provide tailored recommendations to improve learning efficiency. Research indicates that AI-driven learning environments enable adaptive learning by identifying students' strengths and weaknesses and providing customized instructional content. According to Luckin et al., AI technologies can significantly enhance educational processes by supporting personalized learning experiences and

improving instructional decision-making for educators [17]. Similarly, AI-based chat bots and virtual assistants are increasingly being used to provide real-time academic support and guidance to students in digital learning environments [18].

Internet of Things in Smart Classrooms

The Internet of Things (IoT) is another important technological enabler that supports the development of smart education environments. IoT refers to the network of interconnected devices that collect and exchange data through sensors and wireless communication technologies. In educational settings, IoT devices such as smart boards, wearable devices, environmental sensors, and connected classroom equipment help create interactive and responsive learning environments. IoT-enabled smart classrooms facilitate real-time monitoring of classroom conditions, student participation, and learning activities. According to Al-Emran et al., IoT technologies enhance educational environments by enabling seamless communication between students, instructors, and digital learning resources [19]. These technologies also support collaborative learning and remote education by connecting various learning devices through cloud-based networks.

Cloud Computing for Educational Platforms

Cloud computing provides the infrastructure necessary to support scalable and accessible smart education systems. Cloud-based learning platforms allow educational institutions to store, manage, and distribute large volumes of digital learning content efficiently. Students and instructors can access learning materials, assignments, and interactive learning tools from any location using internet-enabled devices. Cloud computing also supports the development of learning management systems (LMS), virtual classrooms, and collaborative learning environments. Studies show that cloud-based educational platforms enhance the flexibility and accessibility of educational services while reducing infrastructure costs for educational institutions [20]. As a result, cloud technologies have become a critical component of modern smart education ecosystems.

Big Data and Learning Analytics

Big data analytics plays a significant role in improving the effectiveness of smart education systems by enabling data-driven insights into student learning behaviors and academic performance. Educational institutions generate large amounts of data through online learning platforms, digital assessments, and student interaction with educational technologies. Learning analytics tools analyze these data to identify learning patterns, predict academic outcomes, and support personalized instructional strategies. According to Siemens and Long, learning analytics enables educators to gain deeper insights into student engagement and learning progress, thereby facilitating more informed educational decision-making [21]. By utilizing predictive analytics and data mining techniques, smart education systems can identify students at risk of academic failure and provide timely interventions to improve learning outcomes.

Immersive Technologies: Virtual and Augmented Reality

Immersive technologies such as Virtual Reality (VR) and Augmented Reality (AR) are increasingly being integrated into smart education systems to enhance experiential learning. VR and AR technologies allow students to interact with simulated environments and complex concepts in a highly engaging and visual manner. These technologies are particularly useful in disciplines such as engineering, medicine, and science where practical demonstrations and simulations play a crucial role in the learning process. Research indicates that immersive learning technologies can significantly improve student motivation, engagement, and knowledge retention. Radianti et al. emphasize that VR-based learning environments provide students with interactive and experiential learning opportunities that are difficult to achieve through traditional teaching methods [22]. Consequently, VR and AR technologies are becoming important tools in the development of next-generation smart education systems.

RESEARCH METHODOLOGY

This study adopts a descriptive and analytical research approach to examine the role of technological innovations in enabling smart education systems and their applications in teaching and learning processes. The research is primarily based on secondary data sources, including peer-reviewed journal articles, conference proceedings, institutional reports, and global educational technology publications. The objective of the methodology is to synthesize existing knowledge and analyze trends in the adoption of technology-driven educational systems.

Research Design

The study employs a literature-based analytical research design to explore the technological enablers and applications of smart education systems. This approach allows the integration of insights from existing academic research and technology reports to identify major developments, technological trends, and emerging practices in smart education environments. The research design focuses on evaluating how advanced technologies such as artificial intelligence, Internet of Things, cloud computing, big data analytics, and immersive technologies contribute to the transformation of teaching and learning systems.

Data Sources

The data used in this study were collected from secondary sources, including academic databases and international educational reports. Major sources include:

- IEEE Xplore Digital Library
- Scopus-indexed journals
- Web of Science databases
- UNESCO and OECD educational technology reports
- Government and institutional publications on digital education

The selected sources provide reliable and peer-reviewed information on the development, adoption, and impact of smart education technologies.

Literature Selection Criteria

To ensure the relevance and quality of the analyzed studies, a set of inclusion criteria was applied during the literature selection process. Publications were selected based on the following criteria:

- Studies related to smart education systems, digital learning technologies, and educational innovation.
- Articles published in peer-reviewed journals or conference proceedings.
- Studies focusing on technological applications in teaching and learning environments.
- Publications from recent years to capture current developments in educational technology.

Through this selection process, a collection of relevant academic literature and technology reports was identified and systematically reviewed.

Data Analysis Method

The collected secondary data were analyzed using comparative analysis and thematic analysis techniques. Comparative analysis was used to examine the roles and impacts of different technologies used in smart education systems, while thematic analysis helped identify major research themes related to teaching innovation, learning applications, and technological integration. Additionally, trend analysis was applied to examine the growth of technology adoption in education and the increasing integration of digital tools within learning environments. The findings derived from the literature and secondary datasets were organized into thematic categories, including technological enablers, innovative teaching applications, and smart learning systems.

Conceptual Framework Development

Based on the insights obtained from the literature review and secondary data analysis, a conceptual framework for smart education systems was developed. The framework illustrates the relationship between technological enablers and innovative teaching and learning applications in smart educational environments. It highlights how digital technologies support the creation of intelligent learning ecosystems that enhance student engagement, instructional efficiency, and educational outcomes.

RESULTS AND ANALYSIS

To understand the growing importance of technology-driven smart education systems, this study analyzes secondary data obtained from international education technology reports, academic studies, and global digital education statistics. The analysis focuses on the adoption of digital learning technologies, the growth of artificial intelligence in education, and the impact of smart technologies on learning engagement and educational efficiency.

Growth of Digital Education Adoption

The rapid expansion of digital infrastructure and internet connectivity has significantly increased the adoption of digital learning platforms in educational institutions worldwide. The COVID-19 pandemic further accelerated the shift toward technology-enabled learning environments, prompting universities and schools to adopt online learning systems and smart education technologies. Table I presents the growth of digital education adoption globally over recent years. The data indicate a consistent upward trend in digital education adoption. The adoption rate increased significantly between 2019 and 2021, largely due to the widespread implementation of remote learning systems. This trend demonstrates that digital technologies have become an essential component of modern education systems. The increasing reliance on digital platforms highlights the need for advanced smart education systems that integrate intelligent technologies to improve learning effectiveness.

Growth of Artificial Intelligence in Education

Artificial intelligence is becoming a key driver of innovation in smart education systems. AI-based learning platforms support adaptive learning, automated grading, and intelligent tutoring systems that personalize educational experiences for students. Table II illustrates the growth of the global AI in education market. The results show that the AI in education market has experienced rapid growth in recent years, reflecting the increasing adoption of intelligent learning technologies. Educational institutions are increasingly integrating AI-driven systems to provide personalized learning support and enhance student engagement. The growth of AI technologies indicates that smart education systems are becoming more data-driven and adaptive.

Impact of Smart Technologies on Learning Outcomes

Smart education technologies have also demonstrated significant potential in improving student engagement and learning outcomes. Technologies such as intelligent tutoring systems, learning analytics, and gamified learning platforms provide interactive learning environments that encourage active participation. Table III presents the impact of selected smart technologies on learning performance and engagement based on findings reported in previous studies. The findings indicate that interactive and intelligent learning technologies significantly enhance student engagement and participation. Gamified learning platforms show the highest improvement in engagement levels, highlighting the importance of interactive learning approaches. Similarly, AI-based tutoring systems provide personalized learning support, which improves knowledge retention and learning efficiency.

Comparative Analysis of Smart Education Approaches

A comparative analysis was conducted to evaluate the effectiveness of different education systems and technological approaches used in modern learning environments. The comparison focuses on three major learning systems: traditional classroom learning, conventional e-learning platforms, and technology-driven smart education systems.

The analysis considers several performance indicators such as learning flexibility, personalization, student engagement, accessibility, and technological integration.

Comparison of Learning System Characteristics

Table IV presents a comparison of the fundamental characteristics of traditional learning systems, e-learning systems, and smart education systems. The results indicate that smart education systems outperform traditional learning approaches in terms of personalization, accessibility, and engagement. The integration of artificial intelligence and learning analytics allows smart education platforms to adapt learning content according to the individual needs of students.

Comparative Evaluation of Educational Technologies

The effectiveness of various educational technologies used within smart education systems was also analyzed. Table V presents a comparative evaluation of major technologies used in modern education systems. The analysis shows that each technology contributes unique advantages to smart education environments. AI enhances adaptive learning capabilities, while IoT enables interactive classroom experiences. Cloud computing ensures the accessibility of educational resources, and immersive technologies provide engaging learning experiences.

Performance Comparison of Learning Approaches

To further evaluate the effectiveness of smart education technologies, performance indicators reported in previous educational technology studies were analyzed. Table VII presents the comparative performance of different learning approaches based on student engagement and learning efficiency. The comparative results indicate that smart education systems significantly improve student engagement and learning efficiency compared to traditional and conventional e-learning systems. The integration of intelligent technologies enables personalized learning pathways, real-time feedback, and interactive educational environments, which collectively enhance the overall learning experience.

Conceptual Framework for Smart Education Systems

The rapid development of digital technologies has created new opportunities for transforming traditional education systems into intelligent and adaptive learning environments. Based on the literature review, technological analysis, and comparative evaluation of existing learning approaches, this study proposes a conceptual framework for smart education systems that integrates advanced technologies with innovative teaching and learning applications. The proposed framework highlights the relationship between technological enablers, smart teaching applications, smart learning applications, and educational outcomes. The framework illustrates how modern digital technologies support the development of intelligent educational environments that enhance both teaching efficiency and student learning experiences.

Technological Enablers

At the foundation of the smart education ecosystem are several key technologies that enable intelligent and connected learning environments. These technologies include artificial intelligence (AI), Internet of Things (IoT), cloud computing, big data analytics, and immersive technologies such as virtual reality (VR) and augmented reality (AR). These technological enablers provide the digital infrastructure necessary to support interactive learning platforms, intelligent tutoring systems, and data-driven educational decision-making[23]. Artificial intelligence enables adaptive learning systems and personalized instruction, while IoT technologies facilitate smart classroom environments through connected devices and sensors. Cloud computing supports scalable and accessible learning platforms, allowing students and educators to access educational resources from any location. Additionally, big data analytics and learning analytics help institutions analyze student learning behavior and improve educational strategies.

Smart Teaching Applications

The second component of the framework focuses on innovative teaching applications that utilize technological capabilities to enhance instructional practices. Smart teaching applications include intelligent tutoring systems, automated assessment tools, digital content management systems, and collaborative teaching platforms. These applications assist educators in delivering more effective and personalized instruction by providing real-time feedback and adaptive learning resources[24]. For example, AI-powered tutoring systems can analyze student performance and provide customized learning materials based on individual learning needs. Similarly, smart assessment systems can automate grading processes and provide instant feedback to students, enabling instructors to focus more on mentoring and facilitating learning.

Smart Learning Applications

The third component of the framework focuses on smart learning applications, which emphasize the role of technology in enhancing the student learning experience. Smart learning applications include personalized learning platforms, collaborative learning tools, gamified learning environments, and immersive learning systems based on VR and AR technologies[25]. These technologies enable students to actively engage with educational content through interactive and experiential learning methods. Personalized learning systems allow students to progress at their own pace, while collaborative platforms support peer-to-peer learning and knowledge sharing. Gamified learning systems also increase student motivation by incorporating game-based elements into the learning process[26].

Educational Outcomes

The final component of the framework focuses on the educational outcomes generated by smart education systems. The integration of advanced technologies and innovative applications leads to several positive outcomes, including improved student engagement, enhanced learning efficiency, better knowledge retention, and more effective teaching practices[27]. Smart education systems also support data-driven decision-making in educational institutions by providing insights into student learning patterns and performance trends. These insights enable educators and administrators to design more effective educational strategies and policies[28].

Framework Structure

The conceptual framework proposed in this study can be represented as a layered model that connects technological infrastructure with educational applications and outcomes. This framework demonstrates that technological innovations serve as the foundation for developing intelligent teaching and learning systems, which ultimately lead to improved educational outcomes. Overall, the proposed conceptual framework provides a structured understanding of how technology-driven innovations contribute to the development of smart education systems. It highlights the interconnected relationship between technological infrastructure, teaching practices, learning applications, and educational performance. The framework can serve as a guide for educational institutions and policymakers seeking to implement smart education strategies and improve the quality of modern education systems.

DISCUSSION

The findings of this study highlight the growing significance of technology-driven innovations in transforming traditional education systems into intelligent and adaptive smart education environments. The secondary data analysis demonstrates a substantial increase in the adoption of digital learning technologies and the integration of advanced technological tools within educational institutions worldwide[29]. The results indicate that smart education systems are becoming an essential component of modern educational infrastructure due to their ability to provide flexible, personalized, and interactive learning experiences. One of the key observations from the analysis is the rapid expansion of digital learning platforms and educational technologies over the past few years[30]. The increasing adoption of online learning systems and digital education platforms reflects the growing demand for flexible learning environments that can support remote and hybrid educational models. This shift has been

accelerated by global technological advancements and the increasing availability of internet connectivity and digital devices. As a result, educational institutions are increasingly investing in smart learning technologies to enhance the accessibility and efficiency of educational services[31].

Another important finding relates to the role of artificial intelligence and learning analytics in improving educational outcomes. AI-driven educational tools enable adaptive learning systems that provide personalized instructional content based on individual student performance and learning behavior. The integration of learning analytics allows educators to monitor student engagement and identify learning patterns that can be used to improve teaching strategies. These technologies support data-driven decision-making and enable educators to design more effective learning interventions[31].The comparative analysis conducted in this study further highlights the advantages of smart education systems compared to traditional classroom learning and conventional e-learning systems. While traditional learning environments provide direct teacher–student interaction, they often lack flexibility and technological support. Conventional e-learning platforms improve accessibility but may still provide limited personalization and interactive capabilities. In contrast, smart education systems integrate multiple technologies such as artificial intelligence, Internet of Things, cloud computing, and learning analytics to create adaptive and interactive learning environments that significantly improve student engagement and learning efficiency.

The proposed conceptual framework developed in this study further demonstrates how technological enablers support innovative teaching and learning applications within smart education systems. The framework illustrates that advanced technologies serve as the foundation for intelligent teaching tools and interactive learning platforms, which ultimately contribute to improved educational outcomes. The integration of smart teaching applications and smart learning applications enables a more learner-centered educational environment that emphasizes collaboration, personalization, and continuous feedback. Despite the significant benefits of smart education technologies, the successful implementation of these systems requires addressing several challenges. Educational institutions must invest in adequate technological infrastructure, including reliable internet connectivity, digital learning platforms, and smart classroom technologies. In addition, educators must develop the necessary digital skills to effectively integrate these technologies into their teaching practices. Data privacy and security concerns also represent important issues that must be carefully managed when implementing data-driven learning systems.

Future Research Directions

Although smart education systems have demonstrated significant potential in transforming teaching and learning processes, several areas require further research to enhance their effectiveness and scalability. Future research should focus on developing more advanced and integrated technological solutions that can support intelligent and adaptive learning environments. One important area for future research is the development of advanced artificial intelligence–based educational systems. AI technologies such as machine learning, natural language processing, and intelligent tutoring systems have the potential to further personalize learning experiences by analyzing student behavior, learning patterns, and performance data. Future studies could explore how AI-driven educational platforms can improve adaptive learning models and provide more accurate learning recommendations for students.

Another promising research direction involves the integration of immersive technologies such as virtual reality (VR) and augmented reality (AR) into smart education systems. These technologies can create highly interactive and experiential learning environments that enhance student engagement and improve the understanding of complex concepts. Future research may examine the effectiveness of immersive learning technologies across different academic disciplines and educational levels. The application of big data analytics and learning analytics also presents significant opportunities for future research. As educational institutions increasingly adopt digital learning platforms, large volumes of educational data are generated through student interactions with online learning systems. Future research could focus on developing advanced analytical models that can utilize these datasets to predict student performance, identify learning difficulties, and support early intervention strategies. Another important area for further investigation is the integration of smart education systems within broader smart campus and smart city initiatives. The development of interconnected educational environments that utilize IoT devices,

intelligent infrastructure, and cloud-based platforms can support seamless learning experiences and improve educational resource management. Future research may explore how smart campuses can enhance collaboration between educational institutions, technology providers, and government organizations. Finally, future studies should examine the ethical and policy implications of smart education technologies, particularly with regard to data privacy, digital equity, and the responsible use of artificial intelligence in education. Addressing these issues will be essential for ensuring the sustainable and inclusive implementation of smart education systems worldwide.

CONCLUSION

This study examined the role of innovative teaching and learning applications in the development of smart education systems from a technology-driven perspective. By analyzing existing literature and secondary data sources, the research explored how advanced digital technologies contribute to the transformation of modern educational environments. The findings indicate that technologies such as artificial intelligence, Internet of Things, cloud computing, big data analytics, and immersive learning technologies play a crucial role in enabling smart education systems. These technological enablers support the development of intelligent teaching applications and interactive learning platforms that enhance student engagement, improve learning efficiency, and enable personalized educational experiences. The secondary data analysis demonstrated the increasing adoption of digital learning platforms and the rapid growth of AI-based educational technologies across educational institutions worldwide. The comparative analysis further revealed that smart education systems provide significant advantages over traditional and conventional e-learning systems by offering more flexible, personalized, and adaptive learning environments. In addition, the conceptual framework proposed in this study illustrates the relationship between technological enablers, innovative teaching applications, smart learning applications, and educational outcomes. The framework provides a structured understanding of how advanced technologies can be integrated into educational systems to create intelligent and efficient learning ecosystems. Despite the significant benefits of smart education technologies, the successful implementation of these systems requires addressing challenges such as technological infrastructure limitations, digital skill gaps among educators, and data privacy concerns. Educational institutions must adopt appropriate strategies and policies to ensure the effective integration of digital technologies into teaching and learning processes

ABSTRACT

The main aim of the study is to evaluate the antiurolithiatic activity of *Andrographis paniculata* (Burm.f.) Nees *leaves* in ethylene glycol induced renal calculi in rats. The powdered leaf material is extracted by continuous hot percolation method for 36 hours. Initially, the phytochemical investigations Ethanolic Extract of *Andrographispaniculata* (EEAP) leaves were performed. The study involved five groups, Group I (Normal control group), Group II (ethylene glycol induced urolithiasis), Group III (Cystone), Group IV and Group V (test drug 1 and test drug 2) were treated upto 21 days, on 21st day animals of each group were placed in metabolic cage to collect the urine samples, the next day rats from the each of the group were anesthetized; blood collected in a sterile centrifuge tube by intra cardiac puncture method. The EEAP leaves Demonstrated the presence of flavonoids, alkaloids, saponins, tannins, glycosides, phenolic compounds, terpenoids. The results showed that EEAP leaves significantly reduced elevated serum parameters and improved histopathological damage. The extract prevented urolithiasis induced by the toxicity of ethylene glycol. The results of this study strongly indicate the preventive effect of EEAP leaves against urolithiasis. Overall, the study provides scientific evidence for the traditional use of *Andrographis paniculata*leaves in the treatment of urolithiasis.

Keywords: *Andrographis paniculata,* urolithiasis, ethylene glycol, Cystone.

INTRODUCTION

The kidneys are a pair of vital excretory organs located retroperitoneally on the posterior abdominal wall, flanking the vertebral column. These bean-shaped structures, each roughly 11 cm long and weighing between 135–150 g depending on sex, play a multifaceted role in maintaining the body's internal equilibrium. Their primary function involves filtering blood to remove metabolic waste products, excess fluids, and salts, while regulating pH, electrolyte balance, and systemic blood pressure. Additionally, they serve an endocrine role by secreting critical hormones such as renin, which modulates blood pressure; erythropoietin, which stimulates red blood cell production; and the active form of vitamin D3 that aids in bone health. Anatomically, each kidney consists of an outer capsule, a cortex rich in convoluted tubules and corpuscles, and a medulla made up of renal pyramids whose apexes converge into minor calyces, forming a channel for urine to pass through major calyces and ultimately into the funnel-shaped renal pelvis. The blood supply intricately branches from the renal arteries into glomerular and peritubular capillaries, ensuring precise filtration and reabsorption processes. Among the most prevalent disorders affecting renal function is urolithiasis the formation of stones within the kidneys, bladder, or urinary tract triggered by decreased urine volume or increased concentration of stone-forming substances like calcium, oxalate, phosphate, and uric acid.(Andrew, 2010)These stones, known as renal calculi, can vary in size from grain like fragments to large staghorn formations occupying the entire renal pelvis.[5] The condition manifests with sudden, severe, radiating pain, often accompanied by nausea and vomiting, and is most commonly observed in men between the ages of 20 and 49. Globally, it affects nearly 12% of the population, with recurrence rates reaching as high as 75% over two decades without proper metaphylaxis or preventive care.(Strohmaier et al., 2016)

Urolithiasis is not only a medical concern but also a significant public health issue linked to modern lifestyle factors such as poor hydration, reduced physical activity, and unhealthy dietary patterns.[2] The incidence is markedly rising in both developed and developing nations, and climate change, especially global warming, exacerbates the risk due to increased dehydration during high-temperature periods. Geographic patterns have revealed "stone belts" in regions like the southeastern United States and northern India, where socio-demographic factors, environmental stress, and dietary customs including the absence or presence of certain foods like tamarind further influence stone formation.(Walter, 2016) Medicinal plants possess significant potential in the management of kidney, gall, and urinary stones through diuretic, lithotriptic, antioxidant, and anti-inflammatory actions. (Ankur C*et al.,* 2010; Kamil M*et al.,* 2015) Several herbs such as *Phyllanthusniruri, Solanumvirginianum,* (Chinnala KM *et al.,* 2013)*Bergenialigulata,*(Sulaiman CT*et al.,* 2022) *Tragiainvolucrate,* (Velu V*et al.,* 2017)and *Crataevanurvala* are widely used in traditional systems of medicine for anti-urolithiatic activity. Further scientific validation and clinical studies are necessary for the development of standardized herbal formulations. *Andrographis paniculata*is an important source for the development of herbal formulations and modern phytopharmaceuticals. The plant possesses broad therapeutic potential due to its hepatoprotective, antimicrobial, anti-inflammatory, antidiabetic, (Premanath R*et al.,* 2015; Hidayat R*et al.,* 2021) immunomodulatory, and anti-urolithiatic properties. *Andrographis paniculata* exhibits promising antiurolithiatic activity against calcium oxalate crystals *in vitro*. (Dulanjali SS, Srikaran R, 2020)The aim of the research is to identify and confirm the antiurolithiatic activity through further *in vivo* studies.

MATERIALS AND METHODS

Plant collection

Fresh *Andrographis paniculata* (Burm.f.)Nees *leaves* were gathered from the Chidambaram area in the Cuddalore district of Tamilnadu, India. The authenticity of the plant material was confirmed by Prof. Dr. L. Mullainathan at the Department of Botany, Annamalai University, Annamalai Nagar. The plant material has an authentication reference number: 619.

Preparation and Extraction of the plant material

The collected leaves are cleaned, washed with distilled water, dried under sunshade in dark room, and course powdered by using mechanical mixer. (Borgohain and Kakoti, 2019)Coarse powder of *Andrographis paniculata leaves* was extracted with ethanol by hot percolation method using Soxhlet apparatus. The extraction was carried out for 36 hours. After extraction, the solvent was distilled out to obtain a concentrated extract. Then the concentrated extract was vacuum dried and the dry extract was stored in an air tight container in 20°C for further phytochemical and pharmacological studies. (Jayakumar et al., 2013)

Experimental animals:

Male albino Wistar rats weighing 150–250 g were used for the study. The animals were obtained from MASS BIOTECH private limited, Chengalpattu(REG. NO: 2084/PO/RcBt/S/19/CPCSEA). All the animals were housed and maintained by central animal house, Cuddalore Medical College and Hospital. The animals were placed at random and allocated to treatment groups in polypropylene cages with paddy husk as bedding. Animals will be housed at a temperature of 24±20C and relative humidity of 30 – 70 %. A 12:12 light: day cycle was followed.(Makasana*et al.*, 2014)All animals were allowed to free access to water and fed with standard commercial rat pellets. The animalswere acclimatized to the laboratory condition for a week before starting the experiment. Paddy husk were used as bedding and it were changed twice in a week. (Velu*et al.*, 2017)The study protocol received approval from the Institutional Animal Ethics Committee (IAEC) (Proposal No: GMCHC –IAEC/1401/4/25), which is registered with the Committee for the Control and Supervision of Experiments on Animals (CCSEA).

Experimental Study Design

Methodology

The animals were divided into five groups of six animals each. The grouping of animals is shown in table 1. On 21st day animals of each group were placed in metabolic cage to collect the urine samples; the next day urine samples were collectedand rats from the each of the group were anesthetized; blood collected in a sterile centrifuge tube by intra cardiac puncture method. serum was separated by centrifugation at 10,000 rpm for 10 min and analysed forserum parameters.(Chinnala*et al.*, 2013)

Effects on Biochemical parameters

Biochemical parameters such as serum analysis (creatinine, uric acid, blood urea nitrogen) and urine analysis (urine volume, calcium, oxalate, phosphate, magnesium) were analysed.(Kamil*et al.*, 2015; Saranya and Geetha, 2014 and Siddiqui*et al.*, 2018)

Histopathological studies

Before histopathological examination and for the preservation of isolated kidneys of rats of different groups,10% neutral buffered formalin, processed in a series of graded alcohol and xylene, embedded in paraffin wax, sectioned at 5 μm and stained with haematoxylin (H) and eosin (E) for histopathological examination. The slides were examined under light microscope (magnification 10×) to study the structure of the kidney and calcium oxalate deposits.[1]

Statistical analysis

Data were expressed as Mean ±SEM. Comparison between different groups was performed using One-way ANOVA, followed by Dunnett's multiple comparison tests [GraphPad Prism 10.4.2 (633)]. $P<0.05$ was considered to be statistically significant. (Sulaiman*et al.*, 2022)

RESULTS

Effects on Biochemical parameters

Serum analysis: In this experiment, the EEAP leaves appears to be effective in reducing the ethylene glycol caused urolithiasis as observed from a significant reduction of ethylene glycol induced elevated serum parameters.

Administration of ethylene glycol (Group II) led to a marked increase in serum creatinine, uric acid, and BUN levels compared to the control group (Group I), indicating substantial renal impairment. Notably, EEAP at both 200 mg/kg and 400 mg/kg doses (Groups IV and V) also produced a significant, dose-dependent reduction in these renal biomarkers, suggesting that EEAP confers protective effects against ethylene glycol-induced urolithiasis, comparable to the standard treatment.

Urine analysis

In this experiment, the EEAPleaves appears to be effective in reducing the ethylene glycol caused urolithiasis as observed from a significant changes in urine parameters. Administration of ethylene glycol in rats (Group II) resulted in a significant reduction of urine volume and marked elevations in urinary calcium, oxalate, and phosphate levels, along with a decrease in magnesium levels, compared to the control group (Group I), indicating compromised renal function and altered mineral balance.Notably, EEAP at doses of 200 mg/kg and 400 mg/kg (Groups IV and V) demonstrated a significant reversal of ethylene glycol-induced changes by increasing urine volume, decreasing urinary calcium, oxalate, and phosphate levels, and restoring magnesium levels in a dose-dependent manner, suggesting that EEAP possesses promising nephroprotective and antiurolithiatic activity, comparable to the standard treatment.

Histopathological studies

The histopathological study was performed using light microscopy, 40 X resolution using hematoxylin-eosin stain. Normal control group (Figure 3) showed normal glomerular structures (red arrow) with intact bowman's capsule(white arrow) normal tubules (black arrow). Negative control group (Figure 4) showed normal glomerular structures (red arrow) with intact bowman'scapsule (white arrow). There noted are extensive calcium oxalate deposits (black circle) within the renal tubules, accompanied by dilation of the proximal tubules (yellow arrow) and interstitial inflammation in the renal tissue (blue arrow). In between the normal tubules are marked as black arrow. Standard drug group (Figure 5) showed normal glomerular structures (red arrow) with intact bowman's capsule(white arrow) normal tubules(black arrow). Test drug 1 treated group (Figure 6) showednormal glomerular structures(red arrow) with intact bowman's capsule(white arrow). There noted are occasional tubules with calcium oxalate deposits (black circle), accompanied by dilation of the proximal tubules(yellow arrow) and inflammation is much reduced or absent.In between the normal tubules are marked as black arrow. Test drug 2 treated group(Figure 7) showed normal glomerular structures(red arrow) with intact bowman's capsule(white arrow) normal tubules(black arrow). Also seen are occasional dilated proximal tubules(yellow arrow).

DISCUSSION

The current study successfully employed an ethylene glycol-induced urolithiasis rat model to mimic human calcium oxalate kidney stone formation, enabling an effective evaluation of the antiurolithiatic activity of *Andrographis paniculata*. Preliminary phytochemical analysis confirmed the presence of bioactive compounds such as alkaloids, flavonoids, tannins, phenols, and terpenoidsseveral of which are known to possess antioxidant, anti-inflammatory, and nephroprotective properties. The acute toxicity assessment further validated the safety profile of the ethanolic extract, allowing for its administration at therapeutic doses without observed adverse effects. The extract exhibited strong potential in mitigating the biochemical disruptions caused by ethylene glycol. Elevated urinary levels of calcium, oxalate, and phosphate in the lithiatic rats pointed to crystal nucleation and retention processes characteristic of stone formation. Treatment with EEAP, especially at 400 mg/kg, resulted in a significant decrease in these stone forming constituents and promoted increased urine output. These outcomes collectively suggest an inhibitory effect on crystal aggregation and enhanced diuresis two crucial factors in the management of urolithiasis. Additionally, serum markers of renal dysfunction such as urea, creatinine, and uric acid were markedly reduced post-treatment, indicating restored kidney filtration efficiency. Histopathological examination supported the biochemical findings, revealing minimal structural damage in EEAP-treated kidneys compared to the extensive damage observed in the lithiatic group. Particularly at the 400 mg/kg dose, renal architecture approached

nearnormal, with reversal of tubular dilation and reduction in calcium oxalate deposits. These observations highlight the extract's dual protective and curative roles, not only preventing stone formation but also preserving kidney integrity at both microscopic and physiological levels.

CONCLUSION

The study underscores the therapeutic efficacy of the ethanolic extract of *Andrographis paniculata* in combating ethylene glycol-induced urolithiasis in rats. Through its phytochemical constituents, the extract exhibited significant antiurolithiatic, nephroprotective, and diuretic activities. The higher dose of 400 mg/kg consistently demonstrated superior benefits, suggesting that EEAP holds promise as a natural alternative for managing kidney stones with minimal side effects.

ABSTRACT

Traumatic Brain Injury is one of the leading causes of death and long-term disability worldwide. It commonly results from road traffic accidents, falls, sports injuries, and physical assaults. Early diagnosis is essential because delays in treatment can lead to severe complications, including permanent neurological damage or even death. Computed Tomography, or CT, is considered the first-line imaging modality for evaluating patients with suspected TBI. It is fast, widely available, and highly effective in detecting skull fractures, intracranial hemorrhage, brain contusions, cerebral edema, and midline shift. These findings help clinicians make rapid decisions regarding emergency treatment and neurosurgical intervention. This study evaluated 72 patients with suspected traumatic brain injury over a six-month period. CT findings were correlated with clinical presentations to assess their diagnostic value. The results showed that contusions, hematomas, and intracranial hemorrhages were among the most common abnormalities. The majority of patients were older adults, highlighting the increasing burden of TBI in the elderly population. The study also emphasizes recent advancements such as multi detector CT and artificial intelligence, which improve image quality, reduce reporting time, and enhance diagnostic accuracy. Although CT has limitations, including radiation exposure and reduced sensitivity for diffuse axonal injury, it remains the cornerstone of emergency neuro imaging. In conclusion, CT plays a vital role in the timely diagnosis, management, and prognosis of traumatic brain injury. Future research integrating CT with MRI, artificial intelligence, and advanced imaging biomarkers has the potential to further improve patient outcomes and support personalized treatment strategies.

Keywords: Computed Tomography, neuroimaging, intracranial hemorrhage

INTRODUCTION

Traumatic Brain Injury (TBI) is a major global health concern, with millions of cases reported annually, significantly impacting healthcare systems worldwide. It represents one of the leading causes of death and disability, particularly among young adults and older populations (1). TBI results from diverse causes, including motor vehicle accidents, falls, assaults, and sports-related injuries. Its outcomes vary widely, ranging from mild, transient neurological deficits to severe, life-threatening conditions. The complexity of TBI lies in its dual nature: primary injuries, caused directly by the initial impact, and secondary injuries, which occur as a result of subsequent physiological responses such as cerebral edema, intracranial hemorrhage, or brain herniation (2). Computed Tomography (CT) has emerged as the gold standard for the initial evaluation of TBI due to its speed, accuracy, and widespread availability in emergency settings (3). As a non-invasive imaging modality, CT provides detailed cross-sectional views of the brain, enabling clinicians to rapidly identify critical conditions such as skull fractures, intracranial hemorrhages, brain contusions, and midline shifts (4). This ability to quickly and reliably detect life-threatening injuries makes CT indispensable for triaging patients and determining the need for urgent neurosurgical interventions (5). Beyond its role in acute diagnostics, CT imaging also plays a pivotal part in monitoring the progression of TBI and guiding long-term management strategies. For instance, delayed complications such as hydrocephalus or subacute hematomas, which can manifest days or weeks after the initial injury, are effectively identified through follow-up CT scans (6). CT's capacity to assess secondary injuries caused by mass effects and herniation patterns is equally critical (7). These secondary injuries, often more damaging than the primary ones, have a profound impact on clinical outcomes, underscoring the need for timely therapeutic interventions guided by imaging findings (8).

The practicality of CT imaging extends its utility even further. Its rapid scan time minimizes delays in the care of critically injured patients, ensuring that life-saving interventions are not postponed (9). Additionally, CT is cost-effective compared to other imaging modalities, such as Magnetic Resonance Imaging (MRI), making it accessible in both high-resource environments and resource-limited settings (10). This accessibility is particularly vital in underserved regions, where timely imaging can significantly reduce mortality rates by aiding early diagnosis and intervention (11). CT technology has continued to evolve, with modern advancements such as multi detector CT (MDCT) systems and artificial intelligence (AI) applications enhancing its diagnostic capabilities (12). MDCT systems provide higher resolution images and enable three-dimensional reconstructions, which are invaluable for detecting complex injuries and planning surgical interventions (13). The integration of AI into CT imaging has further improved its utility by enabling rapid identification of intracranial pathologies, reducing interpretation time, and enhancing diagnostic precision, especially in emergency settings (14).

However, despite its many strengths, CT imaging is not without limitations. One major concern is the exposure to ionizing radiation, which is particularly significant in pediatric populations or patients requiring multiple follow-up scans (15). Efforts to address this issue have led to the development of low-dose CT protocols, aimed at minimizing radiation exposure without compromising diagnostic quality (16). Another limitation is CT's reduced sensitivity in detecting certain types of brain injuries, such as diffuse axonal injuries or subtle parenchymal changes. In such cases, MRI, with its superior soft tissue contrast and sensitivity, serves as a complementary imaging modality, particularly in the subacute or chronic phases of TBI (17). Furthermore, CT's role in the forensic investigation of TBI should not be overlooked. In cases involving blunt force trauma or other mechanisms of injury, CT scans provide critical insights into injury patterns, aiding in both medical management and legal proceedings (18). The advent of portable CT units has also expanded its applicability, particularly in resource-limited or remote areas, where access to traditional imaging facilities may be restricted (19).

Additionally, novel techniques such as spectral CT imaging and AI-powered automated analysis are transforming the landscape of TBI diagnostics (20). These emerging technologies facilitate improved tissue characterization, allowing for the differentiation between various hemorrhagic and ischemic changes in the brain (21). Real-time data processing through AI-driven algorithms has further enhanced decision-making, supporting clinicians in assessing

prognosis and tailoring personalized treatment strategies (22). Recent studies have also suggested that multimodal imaging approaches integrating CT and MRI findings may offer a more comprehensive understanding of TBI pathology, leading to improved clinical outcomes (23). Another area of innovation is the development of neuroimaging biomarkers derived from advanced CT analytics, which may play a critical role in predicting long-term cognitive and functional impairments (24). These advancements underscore the ongoing evolution of CT imaging as a cornerstone in the management of TBI, ensuring better diagnostic accuracy, timely interventions, and ultimately, improved patient care (25).

METHODOLOGY

Study Type
This will be a prospective study designed to evaluate the role of Computed Tomography (CT) in the diagnosis and management of traumatic brain injuries (TBI).

Study Design
A prospective study will be conducted with informed consent forms, incorporating cross-examination of CT reports and clinical findings to evaluate primary and secondary injuries in TBI patients.

Sample Size
The study will include 72 patients who will undergo CT examination for suspected traumatic brain injuries. Participants will be selected randomly from patients admitted with head trauma.

Study Area
This study will be conducted in the Radiology Department

Study Duration
The study will be carried out over a period of 6 months, from 1st October 2024 to 30th March 2025.

Selection Criteria
Inclusion Criteria
- Patients of any age presenting with head trauma RTA.
- Patients undergoing CT for acute head injuries.

Exclusion Criteria
- Patients unwilling to participate in the study.
- Patients with contraindications for CT imaging pregnancy.

Data Collection
Data will be collected through the following methods:
- **CT Imaging Findings:** Evaluation of CT reports for detecting skull fractures, intracranial haemorrhages, contusions, and mass effects.
- **Clinical Correlation:** Cross-referencing CT findings with clinical symptoms and outcomes.
- **Patient Records:** Reviewing medical records for demographics, clinical history, and treatment details.

This study adopts a quantitative, retrospective cross-sectional research design to assess the role of computed tomography (CT) in the diagnosis and management of patients presenting with traumatic brain injury (TBI). The quantitative approach enables objective measurement and statistical analysis of CT findings in correlation with clinical outcomes. A retrospective review allows the inclusion of a large sample size from existing medical records, minimizing bias and ensuring real-world applicability. The aim is to evaluate patterns of CT findings, their

diagnostic relevance, and how they influence clinical decision-making such as surgical intervention or ICU admission.

RESULT

The analysis of patient demographics and pathology distribution reveals that the majority of patients fall within the 61–80 age group, indicating a predominantly elderly population, followed by the 41–60 age bracket. This suggests a higher prevalence of age-related chronic conditions such as cardiovascular, neurological, and general medical issues. The gender distribution is relatively balanced, with a slight male predominance, indicating the need for gender-inclusive healthcare planning. Pathology data highlights cardiology as the most common specialty, followed by general medicine and neurology, further reinforcing the focus on chronic disease management in an aging population. Departments like dermatology, ENT, and urology show lower patient volumes, potentially due to lower referral rates or lower severity. Overall, these trends emphasize the importance of strengthening geriatric care, enhancing chronic illness services, and maintaining a gender-equitable healthcare approach while using this data to guide strategic resource allocation and service planning

DISCUSSION

Traumatic Brain Injury (TBI) is a critical public health issue that necessitates prompt diagnosis and effective management, especially in vulnerable populations. Computed Tomography (CT) has emerged as an essential imaging modality in the acute evaluation of TBI due to its rapid acquisition time, ability to detect life-threatening hemorrhages, fractures, and brain swelling, and its widespread availability in emergency settings. The results of our study indicate a higher prevalence of TBI among the elderly, with the majority of patients falling within the 61–80 age group, followed by those aged 41–60. This demographic distribution is consistent with findings from previous studies emphasizing that age is a significant predictor of poor outcomes following TBI as per the table **4.2** Our inclusion criteria focused on patients who presented with signs and symptoms of head trauma and underwent CT imaging within the acute phase. Exclusion criteria included individuals with pre-existing chronic neurological disorders, prior cranial surgeries, or incomplete CT data. These criteria helped ensure a representative sample focused on acute trauma assessment without confounding by prior conditions.

The gender distribution in our study was relatively balanced, with a slight male predominance, which is also in agreement with existing literature. According to Mushkudiani et al. (2016), demographic factors such as age, sex, and pupillary response are critical for predicting outcomes in TBI. Their analysis from the IMPACT study concluded that older age and abnormal pupil reactions were strongly associated with un favorable outcomes, underscoring the need to consider these factors when interpreting CT results and planning interventions. The pathology distribution in our study revealed cardiology, general medicine, and neurology as the most frequent specialties involved, highlighting the overlap between TBI and chronic health conditions common in aging populations. This reinforces the necessity for integrated care models where radiological findings are interpreted in conjunction with comorbidities to devise comprehensive management strategies. Maas et al. (2014) offered a detailed comparison between the Marshall and Rotterdam CT scoring systems, concluding that the Rotterdam score provides superior prognostic utility by incorporating features such as traumatic subarachnoid hemorrhage and basal cistern status. Given our study's high percentage of elderly patients with potential cerebral atrophy and vascular pathology, such refined scoring systems can significantly aid in outcome prediction and guide therapeutic decisions.[1]

Stiell et al. (2015) developed the Canadian CT Head Rule (CCHR), a tool designed to identify patients with minor head injuries who genuinely require CT scanning. The CCHR demonstrated excellent sensitivity and improved imaging efficiency, which is especially relevant in resource-limited settings or in healthcare systems burdened by high patient volumes. Applying such decision rules can enhance clinical judgment and ensure judicious use of CT resources without compromising patient safety. Bigler and Maxwell (2016) discussed the importance of integrating

neuroimaging findings with neuropathological knowledge to improve diagnosis and prognosis in TBI. They stressed the role of MRI in identifying injuries that may be occult on CT, such as diffuse axonal injury and microbleeds, thus supporting a multi-modal imaging approach, especially in cases with persistent symptoms despite normal CT scans.[2] In a study by Lee et al. (2019), the characteristics of focal lesions, including type, volume, and location, were shown to significantly influence outcomes in moderate to severe TBI. Lesions in the frontal and temporal lobes were particularly impactful, affecting cognitive and behavioral functions. Such information is crucial for tailoring rehabilitation strategies and providing realistic prognostic information to patients and caregivers.[3] From a strategic standpoint, the lower patient volumes in departments such as dermatology, ENT, and urology, as observed in our study, may reflect the urgency and severity associated with neurotrauma cases that demand prioritization in imaging and care pathways. These findings should inform hospital resource allocation and highlight the need for specialized neuroimaging units within emergency departments.[4]

CONCLUSION

In conclusion, CT plays a foundational role in the diagnostic and management pathways of TBI, particularly in elderly populations where timely detection of critical findings can significantly alter outcomes. Our results, supported by a review of key literature, advocate for the use of structured CT scoring systems, evidence-based imaging rules like the CCHR, and integration of patient demographics in clinical decision-making. Further, while CT remains the first-line imaging modality, incorporating advanced neuroimaging techniques such as MRI in complex cases can enhance diagnostic accuracy. Strengthening geriatric neurotrauma care, promoting interdisciplinary management, and optimizing imaging protocols are essential steps toward improving outcomes in TBI care.[5]

Future Prospects

Building upon these insights, future work should focus on longitudinal studies integrating CT findings with long-term clinical outcomes to establish more robust prognostic models. Incorporating multimodal imaging, such as CT perfusion and MRI, alongside machine learning tools may enhance the diagnostic accuracy and predictive capacity of imaging. Furthermore, the development of standardized CT scoring systems specific to demographic subgroups (e.g., elderly vs. young adults) could aid in more individualized treatment planning. Finally, integrating radiological data with biomarkers of neuronal injury may usher in a new era of precision diagnostics in TBI care, improving both survival and quality of life outcomes.

ABSTRACT

Chronic Kidney Disease Stage 3, marked by a moderate reduction in glomerular filtration rate, represents a crucial phase for early intervention to delay progression. This study evaluated the impact of individualized homeopathic treatment as an adjunct to standard care on renal function and quality of life in Stage 3 CKD patients.To evaluate the clinical efficacy of individualized homeopathic medicines as an add-on to standard conventional care compared to standard care alone in improving renal parameters and quality of life (KDQOL-SF) among patients diagnosed with Stage 3 CKD. A six-month, prospective, open-label, non-randomized, controlled clinical trial was conducted with 35 patients. Participants were assigned via systematic allocation to an experimental group (n=21) receiving individualized homeopathy plus standard care, or a control group (n=14) receiving standard care alone. Homeopathic remedies were selected through constitutional and miasmatic analysis and administered in 30C or 200C potencies. Primary outcomes were changes in serum creatinine and eGFR (CKD-EPI 2021); secondary outcomes included HRQoL scores. The experimental group showed significant creatinine reduction (−0.47 ± 0.35 mg/dL, $p<0.001$) and eGFR gain (+14.95 ± 13.37 mL/min/1.73 m², $p<0.001$); controls remained unchanged ($p=0.692$). Inter-group eGFR superiority was significant ($p=0.002$, Cohen's $d=1.15$). SF-12 PCS/MCS improved significantly ($p<0.001$). *Lycopodium clavatum*(28.57%), *Pulsatilla nigricans* (19.05%), and *Sepia officinalis* (14.28%) predominated for sycosis miasm (52%), administered via standardized step-wise potency escalation (30C to 200C). Zero disease progression occurred vs. 21.4% in controls ($p=0.042$, Fisher's exact test). No adverse events were reported. Add-on individualized homeopathy significantly

stabilized renal function and improved quality of life in Stage 3 CKD, showing a large effect size (d=1.15). These pilot results suggest a synergistic therapeutic potential, warranting further validation through large-scale randomized controlled trials.

Keywords: Chronic Kidney Disease, eGFR, Individualized Homeopathy, KDQOL-SF, Miasm, Sycosis.

INTRODUCTION

Chronic Kidney Disease (CKD) Stage 3 (eGFR 30–59 mL/min/1.73 m²) represents a critical pathophysiological threshold where 50% of renal function is lost[2] [3], marking a vital window for intervention to delay progression to end-stage renal disease. This stage marks a vital window for intervention to delay progression toward end-stage renal disease. While conventional management remains primarily focused on secondary systemic comorbidities, a notable therapeutic gap exists for adjunctive strategies that may directly preserve nephron function and improve health-related quality of life. This study investigates the potential of individualized homeopathic medicine as a complementary approach to standard care. We hypothesize that homeopathic protocols, selected through constitutional and miasmatic analysis, may offer synergistic benefits in renal stabilization and patient well-being.

MATERIAL AND METHOD

Study design

The study was conducted at the Outpatient Department (OPD) of a tertiary care homeopathic teaching hospital in collaboration with a consultant nephrologist from September 2023 to July 2024. Although the primary setting was an outpatient facility, a formal emergency referral protocol was established with an affiliated multi-specialty center for access to haemoidalysis and intensive care services. All biochemical outcome measures (serum creatinine and eGFR) were processed using an ISO-certified clinical laboratory to ensure data reproducibility. While not prospectively registered in a public database, the study adhered to a pre-defined protocol approved by the Institutional Ethics Committee (IEC Ref No: HNS/HR/EC/001/2023) to ensure transparency, with written informed consent obtained from all 35 participants prior to enrollment.

Participant Eligibility

Inclusion criteria : To ensure a homogenous study population and maintain high internal validity, the inclusion criteria included participants were adults aged 18–70 years diagnosed with Stage 3 Chronic Kidney Disease (eGFR 30–59 mL/min/1.73m2) according to KDIGO guidelines, who had maintained a stable conventional treatment regimen for at least three months.

Exclusion criteria: To minimize confounding variables and ensure patient safety, the exclusion criteria included advanced pathology (CKD Stage 4 or 5), dependency on dialysis, or the presence of severe systemic illnesses such as malignancy. To prevent therapeutic interference and ensure a clear assessment of the homeopathic intervention, patients currently receiving Ayurvedic treatment or participating in other clinical trials were also excluded. All participants provided written informed consent and demonstrated a commitment to the six-month follow-up schedule.

Objective

The primary objective is to evaluate the clinical efficacy of individualized homeopathic medicines as an add-on to standard conventional care, compared to standard care alone, in improving renal parameters and quality of life(assessed via KDQOL-SF) among patients diagnosed with Stage 3 Chronic Kidney Disease (CKD).

Hypothesis: The study hypothesizes that homeopathic protocols selected through constitutional and miasmatic analysis may offer synergistic benefits in renal stabilization and overall patient well-being when used as a complementary approach to standard care.

Sample size calculation and justification: This exploratory pilot study enrolled a convenience sample of 35 CKD Stage 3 patients (Experimental n=21; Control n=14) from 70 screened CKD patients. The sample size was dictated by resource constraints and strict eligibility criteria common in specialized homeopathic trials. A POST-HOC power analysis indicated that for detecting a 2 mL/min/1.73m²difference in eGFR decline (SD=5 mL/min, α=0.05, 80%), the current cohort achieved approximately 30% power, suitable for exploratory analysis of clinical trends rather than definitive superiority, per CKD trial guidelines and future confirmatory RCTs should target n = 85 per arm [15] [16] [17] [18] .

Group Allocation: This study utilized a non-randomized, open-label, controlled clinical trial design. Participants were assigned to the experimental or control group via systematic allocation based on their clinical registration numbers (Odd = Experimental; Even = Control). This method was chosen to maintain an objective, sequential enrollment process in the OPD setting. The resulting 21:14 split was a natural outcome of the time limited enrollment phase, and baseline statistical equivalence between the groups was confirmed to ensure study validity.

Measure To Minimise Bias: To minimize intervention bias, both the experimental and control groups received identical standard conventional nephrological care and followed a uniform monthly monitoring schedule for all parameters. This standardized approach ensured that any observed therapeutic improvements in the experimental arm could be attributed specifically to the individualized homeopathic intervention, rather than differences in auxiliary care, dietary advice, or the frequency of clinical oversight.

Outcome measures

- **Primary Outcomes:**

The primary objective was to evaluate renal functional stability through longitudinal biochemical monitoring. Blood samples were analysed using Mindray BS 200 and BS 250 fully automatic analysers. Serum Creatinine was measured via the Jaffe's reaction method, and the estimated Glomerular Filtration Rate (eGFR) was calculated using the CKD-EPI 2021 formula, representing the current clinical standard for non-dialysis CKD staging. Additional safety and metabolic parameters, including Blood Urea, Sodium, Potassium, and Thyroid profile (T3, T4, TSH), were monitored to ensure systemic stability throughout the six-month intervention.

- **Secondary Outcomes:**

The secondary outcome was the improvement in Health-Related Quality of Life (HRQOL), assessed via the KDQOL-SF Version 1.3 instrument. This 36-item multidimensional tool profiles eight broad domains, including Physical Functioning (PF), Role Physical (RP), Bodily Pain (BP), General Health (GH), Vitality (VT), Social Functioning (SF), Role Emotional (RE), and Mind Health (MH). These domains were consolidated into two major summary scores: the Physical Component Summary (PCS) and the Mental Component Summary (MCS) [8]. All data were processed using the Scoring Program 2.0, where scores were standardized (Mean = 50, SD = 10) on a 0–100 scale, with higher values indicating superior quality of life [9].

Variables definition: CKD stages were defined based on GFR using the guidelines from KDIGO.[5]

Statistical Analysis: Statistical analysis was performed using IBM SPSS Statistics for Windows, Version 26.0 (IBM Corp., Armonk, N.Y., USA). Descriptive statistics were used to summarize socio-demographic data, with continuous variables expressed as Mean ± Standard Deviation (SD) and categorical variables as frequencies (n) and percentages (%).

Primary Outcome Analysis: To evaluate the internal efficacy of the treatments, a Paired Sample t-test was utilized for the experimental group to compare baseline and post-treatment values, providing specific t-statistics and degrees

of freedom. For the control group, which exhibited non-normal distribution and higher variance, the Wilcoxon Signed-Rank Test (reported via the Z-statistic) was employed.

Inter-group Comparisons: For the comparison between the Add-on Homeopathic Intervention (n = 21) and Standard Care (n = 14), a Welch's t-test (unequal variances t-test) was employed. This specific model was selected to account for the unequal sample sizes and the variance heterogeneity observed in both primary outcomes. The Serum Creatinine data exhibited unequal variances (s^2 = 0.147 vs. 0.179), while the eGFR data similarly demonstrated a variance disparity (s^2 = 436.3 vs. 531.8) as confirmed by the F-test. Given that the clinical data showed a moderate positive skew ness, Welch's t-test was utilized to provide a robust analysis that maintains statistical power and controls for Type I error under these non-normal distribution and unequal variance conditions.

Significance Threshold: The Pearson Correlation Coefficient was calculated to determine the strength of the relationship between the pre- and post-treatment observations. For all statistical tests, a p-value of less than 0.05 ($p < 0.05$) was considered to indicate statistical significance. Two-tailed p-values were reported to ensure a conservative estimation of the treatment effect.

Safety Monitoring and Adverse Event Reporting: Safety was actively assessed at each monthly follow-up through clinical examination and structured inquiry regarding untoward medical occurrences or homeopathic aggravations. Adverse events (AEs) were predefined as any significant clinical or renal parameter deterioration, including a >25 % increase in baseline Serum Creatinine or severe electrolyte imbalances. Throughout the six-month study period, no serious adverse events (SAEs) or treatment-related complications were observed or recorded in either the experimental or control groups.

Ethics and Consent: Informed written consent was obtained directly from the patient for the utilization of clinical data, timeline parameters, and anonymized diagnostic records for scientific publication.

RESULT

Calculated using Independent Samples t-test for age and Fisher's Exact test for categorical data. SD = Standard Deviation; DM = Diabetes Mellitus. As demonstrated in Table 5, there were no statistically significant differences between the experimental and control groups regarding age ($p = 0.153$), gender distribution ($p = 0.110$), or the prevalence of associated comorbidities ($p = 0.718$). Although the experimental group showed a slightly higher frequency of combined diabetes and hypertension (33.3 %), and the control group exhibited a stronger family history of DM (42.8 %), these variations did not reach statistical significance. The inclusion of the two participants lost to follow-up in the baseline analysis follows the Intention-to-Treat (ITT) principle, ensuring that the two study arms were well-matched and comparable at the point of enrollment. The experimental group demonstrated a highly significant internal improvement in renal markers, with a mean creatinine reduction of −0.48 ± 0.35 mg/dL ($t(20) = 6.18$, $p < 0.001$) and an eGFR increase of +14.95 ± 13.37 mL/min/1.73 m² ($t(20) = 5.12$, $p < 0.001$). In contrast, the control group exhibited non-significant changes when analyzed via the Wilcoxon Signed-Rank test, showing a creatinine Z-score of −0.34 ($p = 0.787$) and an eGFR Z-score of −1.18 ($p = 0.203$). To account for unequal sample sizes and variance heterogeneity between the cohorts, Welch's t-test was employed for inter-group comparison. This analysis confirmed that the experimental group achieved a significantly greater reduction in serum creatinine compared to the control group ($t(33) = 2.163$, $p = 0.033$), representing a large effect size (Cohen's $d = 0.81$). While the between-group difference for eGFR improvement did not reach the threshold for statistical significance ($p = 0.224$), the moderate effect size (Cohen's $d = 0.44$).

To control Type I error (α), a 0.05 threshold was used. Post-hoc analysis yielded a power of 0.86 ($1-\beta$), indicating low Type II error risk for the primary outcome, while the eGFR comparison suggests a higher Type II risk due to the pilot sample size. Individualized homeopathic intervention demonstrated a statistically significant benefit in

stabilizing renal function and enhancing filtration markers in CKD Stage 3 patients compared to standard care alone. Mean and standard deviation (SD) results of KDQOL-36 domains. Pre was before treatment and Post was after treatment in both experimental and control groups. SF 36 means Short Form-36 Health Survey. SF-12 means Short Form-12 Health Survey for PCS- physical component system and MCS means mind component system. PCS reflects physical functioning, bodily pain, general health, and role limitations due to physical health. MCS reflects emotional well-being, social functioning, energy/fatigue, and role limitations due to emotional problems. Within-group: t = Paired t-test; W = Wilcoxon Signed-Rank Test. Inter-group comparison performed via Mann-Whitney U test. Statistical analysis, including Shapiro-Wilk normality screening, was utilized to evaluate health-related quality of life. The experimental group (n = 21) demonstrated highly significant within-group improvements across all KDQOL-36 and SF-12 domains ($p < 0.001$), with a Wilcoxon statistic of W = 0 in domains such as Symptom/problem and Role-emotional, indicating a unanimous positive clinical shift. Specifically, the SF-12 Physical Composite Score (PCS) rose from 37.21 ± 4.32 to 49.86 ± 6.64 and the Mental Composite Score (MCS) from 35.14 ± 4.04 to 47.50 ± 5.45. While the control group (n=14) showed significant general gains in PCS ($p = 0.023$) and MCS ($p = 0.029$), they failed to reach significance in disease-specific areas like Effects of Kidney Disease ($p = 0.289$). Inter-group analysis confirmed the intervention achieved a significantly higher magnitude of improvement in PCS ($p = 0.042$), Symptom/problem ($p = 0.003$), and Effects of Kidney Disease ($p = 0.008$), supporting the intervention as a preferable approach for enhancing both physical and psychological health in kidney disease patients.

The categorical analysis of clinical outcomes demonstrated a statistically significant difference in favour of the experimental group ($p=0.042$, Fisher's Exact Test). While 90.36% of patients in the experimental arm achieved clinical improvement, only 71.40% in the control arm reached similar benchmarks. The p-value confirms that the higher success rate and the complete absence of disease worsening (0%) in the experimental group are statistically significant compared to the control group, where 21.40% of patients deteriorated. This provides evidence that the individualized homeopathic intervention is preferable to standard care alone in managing CKD Stage 3. Dominant miasmatic analysis identified Sycosis as the most prevalent influence in both the experimental (52%) and control (42%) groups. The experimental group showed a secondary Psora trend (29%), while the control group exhibited a higher Syphilitic baseline (30%). Regarding hereditary factors, Syphilis was the most frequent family history trait in the experimental group (29%), whereas the control group was characterized by a Syco-Syphilitic background (30%). These findings provided the clinical basis for individualized anti-miasmatic prescribing throughout the study period.

Most selected rubrics

Kidney; inflammation; nephritis; chronic, Anger ; easily, Anger ; suppressed controlled, Anger; contradiction from, Mildness, Disappointment; deception, Industrious; mania for work, Anxiety; about health, Offended easily, Injustice; cannot support, Hopefulness, Courageous, Egotism; self-esteem, Fear of disease. Individualized remedy selection was based on the totality of symptoms and repertorization, with *Lycopodium clavatum* (28.57 %, n = 6), *Pulsatilla nigricans* (19.05 %, n = 4), and *Sepia officinalis* (14.28 %, n = 3) emerging as the most frequently indicated medicines. These polychrest remedies, along *with Nux vomica* and *Aurum metallicum* (each 9.52 %, n = 2), were selected to address the specific constitutional and miasmatic needs of the experimental group. The remaining cases required a diverse range of medicines including *China*, *Sulphur*, and *Arsenicum album* (each 4.76 %, n = 1), reflecting the highly individualized nature of the homeopathic intervention in managing CKD Stage 3. A standardized, stepwise escalation protocol was employed to manage potency and posology based on clinical and biochemical response. All patients in the experimental group (n = 21) initiated treatment with a 30C dynamization (2 drops in 30 ml distilled water). Following the second follow-up (Month 2), 52.38% (n = 11) of patients remained stable and improved after the dosage was increased to 4 drops of 30 C in 30 ml distilled water. For the remaining 47.62 % (n = 10) who experienced a plateau in renal markers, the potency was escalated to 200 C (2 drops in 30 ml distilled water) by the third follow-up.This structured approach follows the classical methodology of altered doses and gradual escalation in chronic pathology as defined in the 6th Edition of the *Organon of Medicine* by Hahnemann. By initiating treatment with a lower dynamization (30 C) in cases of structural renal damage, as advocated in *The Genius of Homoeopathy* by Stuart Close and *The Principles and Art of Cure* by H.A. Roberts, the study ensured patient safety while providing

reproducible criteria for potency changes based on objective renal parameters. No medicinal aggravations were recorded, confirming the safety of this stepwise posology in CKD Stage 3.

Safety and Adverse Events: Safety was a primary secondary endpoint. No unexpected Adverse Events or Serious Adverse Events occurred during the 6-month study. While 21.40 % (n = 3) of the control group showed clinical worsening, this was attributed to the natural pathophysiology of CKD Stage 3 rather than an intervention-related event. No patients in the experimental group withdrew due to medicinal aggravations, and the individualized homeopathic protocols demonstrated a high safety profile with zero reported toxicities or side effects.

DISCUSSION

The demographic and clinical baseline characteristics (Table 5) demonstrated no statistically significant differences between the experimental (homeopathy + standard care) and control (standard care only) cohorts regarding age ($p = 0.153$), Gender ($p = 0.110$), or comorbidity prevalence ($p = 0.718$). While a male predominance was observed (52 % experimental; 79 % control), this distribution aligns with international outpatient trends reported [11], where men are more frequently under active nephrological care despite a higher global prevalence of CKD in women. Adhering to the Intention to Treat (ITT) principle minimized attrition bias, though the open-label, non-randomized design (N = 35) positions these findings as exploratory, consistent with established guidelines for pilot clinical research[15]. The experimental group exhibited marked longitudinal improvements in renal markers: serum creatinine declined by −0.48 ± 0.35 mg/dL ($p < 0.001$) and eGFR rose by +14.95 ± 13.37 mL/min/1.73 m² ($p < 0.001$). Inter-group analysis via Welch's t-test confirmed superior creatinine reduction in the experimental arm compared to the control ($p = 0.033$), yielding a large effect size (Cohen's $d = 0.81$). Notably, these clinical gains were achieved despite a slightly higher baseline comorbidity burden in the experimental group (e.g., 76% hypertension and 33% diabetes mellitus) compared to the control group (64% and 21%, respectively), as detailed in Table 1 ($p = 0.718$) [12][1][4]. These outcomes align with prior homeopathic trials in CKD[14], where symptom-matched remedies stabilized renal function and regarding remedy-induced renal stabilization[25]. The identified predominance of the Sycotic miasm (52%) reflects the progressive structural and degenerative nature of Stage 3 CKD. This clinical observation aligns with the anti-miasmatic frameworks described by H.A. Roberts[24], where chronic degenerative conditions represent a complex Syco-Syphilitic graft onto a base of functional decline (Psora). Clinical research corroborates this, linking renal pathology to Syco-Syphilitic dominance during the functional-to-structural transition[22], with sycosis specifically driving interstitial changes[21].The reportorial strategy, anchored by the Complete Repertory rubric *Kidney; inflammation; nephritis; chronic*, addressed the pathological foundation while individualized mind rubrics—targeting anger, anxiety, and fear—facilitated a constitutional match. By synthesizing these subjective states with structural "Sycotic" markers of Stage 3 CKD, the prescribing process targeted the Syco-Syphilitic complex to arrest miasmatic decline. However, a primary limitation of this repertorization is the subjective interpretation of mind symptoms and the potential for rubric selection, which may introduce practitioner bias. These constraints emphasize the need for continuous clinical verification of modern repertories to ensure that selected rubrics consistently translate into reproducible renal stabilization.

The frequent indication of polychrest such as *Lycopodium clavatum* (28.57 %), *Pulsatilla nigricans* (19.05 %), and *Sepia officinalis* (14.28 %) addressed the totality of symptoms to stimulate the vital force and arrest miasmatic progression[20](§ 246–248) via a standardised step wise potency escalation (30 to 200) and frequent repetition, preventing homeopathic aggravation while maintaining therapeutic momentum. This split dose methodology, suited for chronic structural diseases with preserved organ reserve, yielded 0 % disease worsening rate in the experimental group compared to 21.40 % in the control arm ($p = 0.042$, Fisher's Exact Test). This suggests that individualized anti-miasmatic prescribing halts vital force suppression and provides a protective effect against natural destructive progression, as evidenced in CKD research[23][14]. The experimental group demonstrated robust HRQoL gains, with the SF-12 Physical Composite Score (PCS) improving from 37.21 ± 4.32 to 49.86 ± 6.64 ($p < 0.001$). The observed improvement (mean = +12.65) significantly exceeds the established Minimal Clinically Important Difference

(MCID) thresholds of 3–5 points for renal populations. Inter-group analysis confirmed superior PCS gains ($p = 0.042$) and significant improvements in KDQoL-SF domains such as Symptom/Problem ($p = 0.003$), Effects of Kidney Disease ($p = 0.021$), and Role-Emotional (Wilcoxon $W = 0$, indicating a unanimous positive shift).

These gains directly address Stage 3 CKD's profound impairments—including fatigue, emotional distress, and social limitations—documented in global cohorts[13]. Control scores remained stagnant ($p = 0.289$ for kidney effects), highlighting standard care's limited holistic impact. Individualized homeopathy likely stimulated the vital force, yielding functional restoration absent in controls. This aligns with clinical research showing uplift via constitutional remedies [25][10] and RCTs demonstrating physical domain gains (+10.5points) at six months[19]. Despite potential performance bias from the open-label design, the objective PCS divergence suggests a substantial supportive value in functional restoration. Despite promising signals, several limitations temper the interpretation of these results. The non-randomized, open-label design and brief six-month follow-up period preclude definitive causal claims regarding long-term outcomes, such as the prevention of End-Stage Renal Disease (ESRD). Furthermore, the small sample size (N=35) renders these results hypothesis-generating rather than broadly generalizable. This research serves as a feasibility foundation for future high-powered, multi-center Randomized Controlled Trials (RCTs) required to validate these miasmatic-constitutional effects in broader CKD populations.

CONCLUSION

This pilot study provides promising clinical signals for the use of individualized homeopathic intervention as an adjunct to standard care in Stage 3 CKD. The integration of homeopathy was associated with significant improvements in renal function—specifically through serum creatinine reduction ($p=0.033$) and eGFR gains ($p<0.001$)—alongside a zero percent disease progression rate and robust HRQoL enhancement. The observed predominance of Sycotic-Syphilitic miasms and the efficacy of polychrest remedies like *Lycopodium clavatum*, *Pulsatilla nigricans*, and *Sepia officinalis* selected through the Complete Repertory, align with classical principles suggesting that vital force stimulation can effectively arrest degenerative tendencies. While methodological limitations (N=35, non-randomized) preclude definitive causal inferences, these findings serve as a hypothesis-generating foundation for future multicentre Randomized Controlled Trials (RCTs).

Table 1: Baseline Demographic and Clinical Characteristics of Study Participants

	Experimental (n = 21)	Control (n = 14)	t-statistic
Age (Years)	58.00 ± 9.39	52.57 ± 11.42	1.48
Serum Creatinine (mg/dL)	2.14 ± 0.83	1.92 ± 0.38	1.06

Data presented as Mean ± Standard Deviation. p-values calculated using Welch's t-test ($p>0.05$ indicates no significant difference)

Table 2: Interventions

Group		
Participants in both the experimental and control groups (N=35) continued their baseline conventional treatment as managed by their respective nephrologists		
	Standard care (control group) (n = 14)	Add on homeopathic intervention (n = 21) (Experimental group)
Intervention	No standard care of treatment were	Received individualized homeopathic medicines

	altered or withdrawn for the purpose of this study.	as an add-on to the standard care
Case taking / Clinical assessment and Quality Of Life measurement	Each participant underwent a comprehensive homeopathic consultation following the classical principles of the *Organon of Medicine*, 6th Edition. The Totality Of Symptoms" was constructed by evaluating mind-emotional states, physical generals (such as thermal preferences and thirst), and specific renal characteristics, including the nature of oedema and urinary changes. To evaluate the humanistic impact of the intervention, health-related quality of life was assessed using the KDQOL-SF Version 1.3 questionnaire. Raw data from these assessments were processed and validated using the KDQOL-SF Scoring Program 2.0, ensuring an objective calculation of the disease-specific burden and the physical/mind health components at both baseline and the six-month follow-up.	
Repertorisation	Not done	Most of the rubrics selected were related to mind symptoms, along with pathological rubrics for kidney inflammation; chronic conditions. Hompath zomeo version 13.8.0 of Complete repertory, was used as a repertorisation.
Remedy selection	Standard Care treatment followed the KDIGO 2012 guidelines, focusing on blood pressure regulation (typically via ACE inhibitors or ARBs), glycaemic control for diabetic patients, and renal-specific dietary counselling by Nephrologist in both group.	
Individualisation process	N/A	Symptoms were systematically repertorised using the Complete Repertory to identify remedies with high numerical affinity, focusing on the pathological rubric *Kidney; inflammation; nephritis; chronic*. This was refined through a miasmatic lens, synthesizing mind rubrics—such as anger and anxiety—with structural "Sycotic" markers to target the Syco-Syphilitic complex. Finally, a comparative study of classical literature ensured the prescription matched the specific medicinal energy and pathological stage of the individual's CKD.
Dose, Potency, Frequency	The control group followed the same KDIGO 2012 guidelines for conventional management of Stage 3 CKD but received only standard medical care without the adjunctive homeopathic intervention. Clinical and biochemical parameters were monitored at the same monthly intervals to provide a baseline for comparative analysis.	Following KDIGO 2012 guidelines, the experimental group received individualized homeopathic remedies (GMP certified, Schwabe India) in 30C or 200C potency, selected based on susceptibility and pathological stage. Utilizing a modified water-dose method, two drops of the remedy were added to 30 ml of distilled water. Patients administered four drops twice daily (morning and night), performing ten succussions before each dose to maintain dynamic quality. This frequency was maintained over the six-month study, with monthly reviews to evaluate potency escalation or dosage adjustments.
Follow up	The study was conducted over six months, with monthly clinical follow-ups to monitor renal stability. Each visit included biochemical assessments of Serum Creatinine, eGFR, Blood Urea, Sodium, and Potassium, alongside systemic monitoring of Blood Pressure and Random Blood Sugar. At the six-month conclusion, health-related quality of life was re-evaluated using	

	the KDQOL-SF Version 1.3 instrument, with final scores objectively calculated via the Scoring Program 2.0 to quantify the therapeutic impact.

Table 3: Variables definition

Hypertension	*Diabetes*
Either a systolic blood pressure (SBP) and diastolic blood pressure (DBP) ≥140/90 mmHg[6] or if the patient was on medication for hypertension.	Fasting blood sugar FPG ≥126 mg/dl (7.0 mmol/l), 2-h PG ≥200 mg/dl (11.1 mmol/l)[7] or any medication of Diabetes.

Table 4: Assessment criteria

Mark improvement	Moderate improvement	Mild improvement	No improvement	Worse	Not reported
When the patient has symptomatic and all parameters are normal. Relief at general level.	When the patient has symptomatic relief and parameters with more than 50% reduction.	When the patient has symptomatic relief and parameters with less than 50% reduction.	No response after treatment for sufficient period.	Aggravation of subjective and objective symptoms.	The patient does not report back after first, second and third visit.

Assessment done through creatinine, GFR and symptoms

Table 5: Baseline Socio-Demographic and Clinical Characteristics

Characteristic	Experimental Group (n=21)	Control Group (n=14)	p-value
Age (Years), Mean ± SD	58.00 ± 9.39	52.57 ± 11.42	0.153
Gender, n (%)			0.11
Male	11 (52.4 %)	11 (78.6 %)	
Female	10 (47.6 %)	3 (21.4 %)	
Associated Diseases, n (%)			0.718
DM + Hypertension	7 (33.3 %)	3 (21.4 %)	
Hypertension alone	8 (38.1 %)	5 (35.7 %)	
DM alone	2 (9.5 %)	1 (7.1 %)	
Family History, n (%)			0.31
CKD	4 (19.1 %)	3 (21.4 %)	
DM + Hypertension	3 (14.3 %)	2 (14.3 %)	
DM alone	3 (14.3 %)	6 (42.8 %)	
Hypertension alone	3 (14.3 %)	3 (21.4 %)	

Table 6: Normality Testing (Shapiro-Wilk Test)

Group	Parameter	Shapiro-Wilk (W)	p-value	Distribution
Experimental	Creatinine	0.942	0.235	Normal ($p > 0.05$)
	eGFR	0.928	0.124	Normal ($p > 0.05$)
Control	Creatinine	0.812	0.007	Non-Normal ($p < 0.05$)
	eGFR	0.845	0.021	Non-Normal ($p < 0.05$)

The Experimental group data follows a normal distribution. However, the Control group data for both Creatinine and eGFR is significantly skewed (Non-Normal)

Table 7: Renal parameter Outcomes and Comparative Effectiveness

Parameter	Group	Baseline Mean ± SD	6-Month Mean ± SD	Difference Mean ± SD	Within-Group (t / Z)	Between-Group t (p)	Cohen's d
Creatinine (mg/dL)	Experimental (n=21)	2.14 ± 0.83	1.66 ± 0.86	−0.48 ± 0.35	t(20) = 6.18 (<0.001)	2.163 (0.033*)	0.81

ABSTRACT

The literature on shift work, especially night shifts, is becoming more and more abundant. It has been shown that shift work can disrupt the sleep-wake cycle, which can cause insomnia or makeshift nurses sleepier during the day. Recent research has also linked shift work sleep disorders to workplace stress, accidents, poor job performance, and ultimately, lower standards of care and health service quality. To assess the prevalence of symptoms associated with shift work sleep disorder among Nursing Officers. To intricately develop a customized module for the effective management of shift work sleep disorder in nursing officers, taking into account the distinctive aspects of the selected hospital. To systematically investigate the association of shift work sleep disorder with socio demographic variables among nursing officers. This research utilizes a quantitative approach, selected for its ability to measure data and identify trends effectively**.** The quantitative method allows for the statistical analysis of data, providing insights into the prevalence and characteristics of shift work disorder symptoms among the participants. The sample consists of 100 nursing officers from SGT Hospital. These participants were selected based on their availability and willingness to engage during the data collection phase. Sample size is 100. The only demographic factor with a significant association with PSI Scores is the age group, with a p-value of 0.07. The analysis indicates that among the demographic factors studied, age has a significant association with sleep quality as measured by the PSI Score, while others factors such as gender, marital status, educational status, work experience, current department, work shift, number of night shifts per month, duration of sleep, and use of caffeine or other stimulants do not show a significant association. A vast majority (97%) of the participants have poor sleep quality as indicated by PSI Scores ranging from 6-21. Only a small fraction (3%) of the participants have good sleep quality with PSI Scores ranging from 0-5. This indicate the sleep quality is predominantly poor among the participants, highlighting a

potential area of concern that may require intervention or further investigations. The present study concludes that sleep disturbance is a significant occupational health concern among nursing officers working in shifts**.** The findings revealed that a vast majority (**97%**) of the participants had poor sleep quality as measured by the Pittsburgh Sleep Quality Index (PSQI), while only **3%** demonstrated good sleep quality. These findings indicate that nursing officers working in shifts are highly vulnerable to disturbed sleep patterns, which may potentially affect their physical well-being, psychological health, work performance, and quality of patient care.

Keywords: Pittsburgh Sleep Quality Index, psychological health, PSI Score

INTRODUCTION

Night shift workers often face challenges in maintaining a regular sleep pattern due to their work schedules conflicting with the body's natural circadian rhythms. This disruption can result in substantial health problems, given that these workers represent a large portion of the workforce. Research has shown a correlation between night shift work and the development of metabolic syndrome, which includes conditions such as obesity, dyslipidaemia, hypertension, and insulin resistance. Exposure to artificial light at night can disrupt biological processes, especially the production of melatonin, a hormone vital for regulating insulin levels. A thorough review of existing studies was conducted to explore the relationship between night shift work and metabolic syndrome, as well as the specific components of this syndrome, to guide future research efforts. This review adheres to the guidelines set by the Preferred Reporting Items for Systematic Reviews. Working night shifts can significantly disrupt the body's natural circadian rhythm, causing irregular sleep patterns and increased fatigue during work hours. There is a notable gap in research specifically exploring the effects of these disruptions on healthcare workers in Ethiopia. This study aims to explore the prevalence and potential causes of sleep disturbances among healthcare professionals in public hospitals in the Sideman National Regional State, Southern Ethiopia.

Need of the Study:
Approximately six million Americans work night shifts, either regularly or on a rotating basis. Shift work is linked to numerous negative health outcomes, with SWSD being a significant concern for these workers. SWSD is often overlooked, despite its considerable impact on health, social interactions, economic stability, and overall quality of life. Individuals with SWSD not only face higher risks of gastrointestinal and cardiovascular diseases but also struggle with severe sleep disturbances due to working during regular sleep hours, posing significant safety concerns. Various studies have explored different approaches to mitigate these issues, including interventions that target the body's internal clock, such as light exposure, melatonin, sedatives, caffeine, and CNS stimulants like amphetamine. The review covered 38 studies and found that fatigue was a factor in 82% of medical errors (MAEs) and near misses (NMs). Fatigue is linked to decreased cognitive performance, reduced concentration, and lower alertness, which negatively impacts nursing performance and patient safety. Various aspects of shift work, including circadian rhythm disruption and overtime, were identified as contributing factors. However, the methods for assessing fatigue varied significantly across the studies.

Aim of the Study: A study to assess the prevalence of symptoms of shift work sleep disorder among nursing officers and to develop a module on its management in a selected hospital, Gurugram.

RESEARCH METHODOLOGY

This study employed a non-experimental descriptive study design and an approach to quantitative research. The current investigation was carried out in Gurugram's SGT Hospital, Budhera. The study's samples were the staff

nurses frequently work non-traditional hours, making them an ideal sample for studying shift work disorder symptoms from SGT Hospital. Based on sample availability, a goal of 100 samples was chosen. The data for this study were gathered using a purposive sampling method.

Data Collection Procedure

The data collection process was carried out over a period of two weeks, from March 18 to March 31, 2024, with a total of 100 staff nurses participating in the study. The procedure was conducted systematically to ensure accuracy, ethical compliance, and confidentiality. Before initiating the study, formal approval was obtained from the Dean of the Faculty of Nursing and the Medical Superintendent of SGT Hospital to ensure institutional support and adherence to ethical guidelines. All participants were provided with a detailed explanation of the study's objectives, procedures, potential benefits, and confidentiality measures. Written informed consent was obtained from each participant to ensure voluntary participation. A purposive sampling technique was employed to select participants who met the inclusion criteria and were available during the study period. The Pittsburgh Sleep Quality Index (PSQI) scale and a demographic questionnaire were administered to all participants. Data collection was conducted in a confidential manner, ensuring participant privacy and data security.

RESULT

Section I: Socio demographic variables of staff nurse working in SGT Hospital

Most participants (67%) are aged 20–29, while only 9% are more than 40. Females (63%) outnumber males (37%). Singles are the largest group (57%), followed by married individuals (39%), with 4% divorced or widowed. A bachelor's degree is most common (48%), with 20% holding postgraduate degrees and 26% diplomas. Most (53%) have 1–5 years of experience, with fewer having over 10 years. The General department employs 70%, while Emergency and ICU each have 14%. Night shifts (36%) are most common, followed by rotating (29%), evening (20%), and day shifts (15%). Most (61%) sleep 5–7 hours, but 25% get less than 5. Caffeine or stimulant use is high (61%).

Section –2: Frequency & Percentage distribution level of PSQI among staff nurses working at SGT Hospital

A vast majority (97%) of the participants have poor sleep quality as indicated by PSQI scores ranging from 6 to 21. Only a small fraction (3%) of the participants have good sleep quality with PSQI scores ranging from 0 to 5.

Section-3 Association of Scores and Demographic Variables;

The chi-square test was used to assess the relationship between score levels and these factors. The only demographic factor with a significant association with PSQI scores is the age group, with a p-value of 0.007. This analysis indicates that among the demographic factors studied, age has a significant association with sleep quality as measured by the PSQI score, while other factors such as gender, marital status, educational status, work experience, current department, work shift, number of night shifts per month, duration of sleep, and use of caffeine or other stimulants do not show a significant association.

DISCUSSION

Objective 1-To assess the prevalence of symptoms associated with shift work disorder among nursing officers. A vast majority 97% of the participants have poor sleep quality as indicated by PSQI Scores. Only a small fraction 3% of the participants have good sleep quality with PSQI Scores ranging from 0 to 5. This data suggests that sleep quality is predominantly poor among the participants, highlighting a potential area of concern that may require intervention or further investigations. Similarly, a cross-sectional study among 513 shift-working nurses in Shanghai found that nurses who were currently performing shift work were significantly more likely to have poor sleep quality (PSQI >5) than nurses without shift-work experience. Current shift workers had almost four times the odds of poor sleep quality, demonstrating the strong relationship between shift work and impaired sleep. A recent systematic review

and meta-analysis by Zhao et al. (2026), involving 15,479 nurses, estimated the pooled prevalence of shift work disorder at 45.5%, with an even higher prevalence of 61.7% among nurses working in a three-shift system. The authors identified night-shift frequency, rapid shift changes, stress, anxiety, depression and fatigue as important risk factors.

Objective 2: To intricately develop a customized module for the effective management of shift work disorder in nursing officers, taking into account the distinctive aspects of the selected hospital. Developed module including assessment tool for SWSD, sleep management strategies for shift workers, sleep environment optimization, work schedule design, diet and nutrition. Furthermore, Zhao et al. (2026) specifically recommended reducing rapid shifts and night-shift frequency, improving scheduling stability, providing mental-health support and using standardized assessment tools **fo**r reducing shift work disorder among nurses. These recommendations support the inclusion of assessment, sleep hygiene, work-schedule modification and lifestyle-related components in the customized module developed in the present study.

Objective 3: To systematically investigate the association of shift work with socio demographic variables among nursing officers. Participants between 20–29-year-old reported the highest mean PSQI Scores and indicating the most severe sleep difficulties. A recent study among nursing officers in Bhubaneswar also demonstrates the relevance of examining demographic characteristics in relation to sleep quality. The study used the PSQI among 236 nursing officers and reported that the majority were young adults, with 66.5% aged 25–30 years.

Summary

The aim of this study is to assess the prevalence of symptoms of sleep disorders related to shift work among nurses in SGT Hospital. Quantitative research is considered appropriate to conduct this study. The research design of this study is a non- experimental descriptive study. The study sample consisted of 100 nurses from SGT Hospital Guru. Data were collected using paper-based questionnaires. Descriptive and inferential statistics were employed to analyse the data. The results were presented using percentages, frequency tables, and bar graphs.

CONCLUSION

A vast majority (97%) of the participants have poor sleep quality as indicated by PSQI scores ranging from 6 to 21. Only a small fraction (3%) of the participants has good sleep quality with PSQI scores ranging from 0 to 5. This data suggests that sleep quality is predominantly poor among the participants, highlighting a potential area of concern that may require intervention or further investigation.

ABSTRACT

The allocation of terrestrial resources to cultivated, uncultivated and river-associated zones, together with the controlled utilisation of surface-water resources for irrigation, constituted important components of historical agrarian production systems under Chola and Chera rule. Land conversion, spatial resource allocation, irrigation-channel development, agricultural production and standardised measurement of land and grain formed interconnected mechanisms for regulating cultivable resources and supporting agro-productive activities. The epigraphic records associated with the Kulasekara Perumal Vishnu Temple at Mannarkovil, Tirunelveli District, preserve technical information on land classification, spatial allocation of agricultural resources, cultivation zones, settlement expansion, irrigation infrastructure and indigenous measurement systems. Particular attention is given to the transformation of uncultivated and forested land and river-valley zones into agricultural and settlement areas, providing evidence for historical patterns of terrestrial resource utilisation and agro-productive land conversion. The inscriptional records quantify land allocation through traditional spatial units, including *vēli*, and document different categories of land such as river-associated areas, *Malukkādu*, *PunjaiMalukkādu* and other agricultural lands. The inscriptional records quantify land allocation through traditional spatial units, including vēli, and distinguish river-associated, forest or scrub, dry agricultural and other land categories.The records further preserve indigenous grain-quantification systems involving *kottai*, *marakka*, *nali* and *kalantūṇi*, providing evidence of standardised procedures for

agricultural commodity measurement and resource accounting. Hydrological resource utilisation is represented through references to irrigation canals, river-valley cultivation and agricultural expansion associated with the Thamirabarani and Kadana river systems. These components are interpreted in relation to cultivable-land development, water availability, agricultural production and local agro-ecological conditions. The methodological framework integrates epigraphic analysis, archaeological field observation, spatial interpretation and quantitative conversion of traditional land and agricultural measurement units.

Keywords: Temple management, Agriculture development, Socioeconomic impact, Environmental management, Traditional Paddy measurement systems, Ecological considerations.

INTRODUCTION

Water-resource technology, land-use technology and agricultural resource-management systems constitute fundamental components of agrarian production systems in regions where cultivation is dependent upon the controlled utilisation of land and water resources. Historical agrarian systems can be technically examined through parameters such as hydrological resource utilisation, irrigation infrastructure, land classification, spatial allocation of cultivable areas, agricultural productivity and quantitative measurement of agricultural commodities. The conversion of uncultivated or forested areas into cultivable zones represents a form of historical land-use transformation, while the development and utilisation of irrigation channels represents an organised approach to water-resource distribution. Similarly, indigenous systems for measuring agricultural land and grain commodities provide quantitative mechanisms for resource assessment, allocation and production accounting. These interconnected components provide a technical framework for reconstructing earlier agro-environmental systems through archaeological and epigraphic datasets.

Epigraphic records provide a primary source for identifying and quantifying several of these historical technological parameters. Inscriptions associated with agrarian institutions frequently record land categories, spatial measurements, cultivation areas, irrigation arrangements, agricultural commodities, resource allocations and administrative regulations. Such records can therefore be treated as historical datasets for reconstructing land-use patterns and resource-distribution mechanisms. In the case under examination, inscriptional evidence records different categories of land, including river-associated areas, forest or scrubland and dry agricultural land, together with specific measurements expressed in traditional units. The inscriptions record land transactions and different land categories using the traditional unit vēli. These measurements are used in the present study primarily in their original inscriptional form, while modern equivalents are provided only where the conversion can be adequately supported.

Agricultural measurement technology represents another important component of the available evidence. The inscriptional record preserves relationships among traditional volumetric units including kottai, marakka, nali and kalantūṇi, which were employed in the measurement of paddy and other agricultural commodities. The preservation of these conversion relationships provides evidence of an indigenous quantitative system for assessing, recording and distributing agricultural produce. Such measurement systems can be examined as components of historical agricultural resource management because standardised quantification was necessary for the recording of production, allocation of grain and regulation of agricultural transactions. The inscriptional evidence consequently permits an examination of the relationship between land productivity, agricultural commodities and indigenous measurement technology. Hydrological resource utilisation forms a further technical component of the agrarian system. The study area is associated with the Thamirabarani and Kadana river systems, and the available evidence records river-associated land, water-fed cultivation and agricultural activity within the Thamirabarani and Kadana river environment. The relationship between surface-water availability, irrigation infrastructure and agricultural land development provides a basis for examining historical water-management practices. The conversion of forested and uncultivated areas into agricultural and settlement zones further indicates changes in land-use configuration

associated with the expansion of cultivation. These processes can be analysed in terms of water availability, cultivable-area development and the utilisation of terrestrial and hydrological resources.

The technical organisation of land resources was also connected with institutional mechanisms of allocation and administration. Epigraphic records document the distribution of residential plots and agricultural land to cultivators and different categories of temple-associated personnel. Other records refer to the establishment of settlements on land classified as Devadānam and to the allocation of agricultural areas subject to specified institutional obligations. Such evidence indicates that land resources were incorporated into organised systems of allocation, cultivation and settlement development rather than being utilised independently of institutional structures. The territorial organisation recorded in the inscriptions provides a further spatial parameter for understanding resource allocation. References to RājarājaPāṇḍiya Nāṭu, MuṭikoṇṭaCōḻa Vaḻanāṭu, Muḷḷināṭu and RājarājaCaturvēti Maṅkalam indicate hierarchical administrative divisions within which agricultural lands, settlements and institutional properties were organised. Such territorial classifications provide a spatial framework for interpreting the distribution and administration of agricultural resources. The epigraphic evidence therefore connects resource allocation with defined administrative units and provides historical data for analysing the spatial organisation of agrarian production.

Within this technical framework, the inscriptions of the Kulasekara Perumal Vishnu Temple at Mannarkovil provide a concentrated dataset for analysing historical agro-environmental systems under Chola and Chera rule. The records document land allocation, agricultural development, irrigation, settlement formation and traditional measurement practices. The temple site is particularly relevant because its inscriptional corpus contains records extending across different phases of political and administrative development and preserves information on both land-resource distribution and agricultural quantification. The available evidence also records the institutional development of the site under different ruling authorities. The inscriptions associate the establishment and development of the temple with Chera and Chola political authority and provide information on subsequent modifications and institutional support. This historical sequence is relevant to the analysis because changes in political administration were accompanied by changes in land allocation, settlement organisation and temple-associated resource management. The inscriptional record therefore provides an opportunity to examine technological and resource-management practices within their changing administrative environment.

The research methodology combines epigraphic analysis, archaeological observation, field investigation and quantitative interpretation of traditional land and agricultural measurement systems. Field investigation was used to examine the physical setting, architectural features and inscriptions, while epigraphic analysis was employed to identify land classifications, measurements, agricultural references, administrative divisions and resource allocations. Quantitative conversions are applied to the traditional units where corresponding modern values are provided in the source material. The integrated analysis of land allocation, hydrological resource utilisation, irrigation, agricultural measurement and land-use transformation provides a technical basis for reconstructing the historical agrarian system. The evidence indicates that agricultural production was associated with organised land distribution, cultivation-zone development, settlement formation and utilisation of available water resources. The inscriptional dataset therefore permits the reconstruction of historical resource-management mechanisms and indigenous agricultural technologies through measurable land and commodity parameters. This approach positions epigraphic evidence as a source for examining the technological dimensions of historical agriculture, water utilisation, land management and agro-environmental resource systems under Chola and Chera rule.

In this study, terms such as agro-environmental management, hydrological systems and sustainability are used as analytical concepts for interpreting historical evidence. They do not imply that medieval institutions used these concepts in their modern scientific sense. The analysis is based on observable inscriptional indicators such as land classification, land measurement, river boundaries, water-fed cultivation, agricultural production, settlement organisation and institutional regulation. Where the inscriptions do not provide direct evidence, the interpretation is presented cautiously and is not treated as a definitive reconstruction.

LITERATURE REVIEW

Addressing the impact on the environmental concerns of the Chola and Chera reigns particularly with the Rājagopalasamy Kulasekara Perumal Temple in Mannarkovil, impacts, are dealt with on an interdisciplinary basis. This literature incorporating archaeology, history, and environmental science, puts stress on the significance of temple administration.Temples in this era served also to fill the aesthetic and cultural roles of medieval society which in turn saw them develop deep relationships with their setting.

METHODS

This research uses historical, epigraphic and archaeological methods. Field investigation was undertaken at the Rājagopalasamy Kulasekara Perumal Temple at Mannarkovil to observe the temple, its architectural features and the inscriptions. The epigraphic analysis examined inscription numbers, regnal years, rulers, place names, administrative divisions, land categories, land measurements, land boundaries, agricultural references, water-related references, grain measurements and institutional arrangements. The inscriptional evidence was studied in relation to published epigraphic references, particularly the Annual Report on Indian Epigraphy and Epigraphia Indica, including the works of Hultzsch and Rangacharya. The recorded traditional measurements were analysed in their original form, while modern equivalents were treated as approximate comparative values. Spatial interpretation was based on inscriptional boundary descriptions, administrative divisions, field observations and the geographical relationship between the temple, agricultural land and river systems. No GIS-based reconstruction was undertaken.

RESULTS

The objectives of this study trace the historical background of the Mannakovil Temple through an inscription of the temple and examine into the inscriptions of the temple to find out the socio-economic condition of society in the medieval period through temples. The purpose of this study is to find out the Socio-Political and Environmental impacts of medieval society.Through land grants and the conversion of uncultivated land into arable land the temple administration plays a vital role in promoting agriculture. The inscriptional evidence provides information on land allocation, land classification, agricultural production, water-fed cultivation and institutional resource management. Different categories of land, including river-associated land, Malukkādu and Punsei-Malukkādu, are recorded using traditional measurements. The inscriptions also record agricultural quantities and grain-measurement relationships, allowing the relationship between land, water availability and agricultural production to be examined. The evidence indicates organised agricultural and resource allocation, but it does not provide sufficient data to calculate a direct increase in agricultural productivity or to determine long-term environmental effects.

DISCUSSION

The inscriptions indicate that land, water and agricultural production were organised through institutional arrangements associated with the temple and local administrative bodies. Land transactions, settlement formation, river-associated land, agricultural categories and grain assessments demonstrate that agricultural resources were recorded and regulated. The evidence therefore suggests organised utilisation of land and water resources. However, the available inscriptional evidence does not provide sufficient ecological data to determine whether these practices caused or avoided long-term environmental degradation.

Mannarkovil Under Pandyas:

From an inscriptional point of view in the case of the Ericha Uṭaiyār Temple which is in Ilangakudi a southern district of the Ambasamudram we see that this area may have had existence since the 7th Century AD or possibly before. The inscriptions report that this region which was known then as *Vellankurichi* saw the grant of land when the First

Pandya Emperor Varaguna Maharaja also known as Maranjadai Pandian set up camp at Araichur which is by the banks of the Pennar River. Also at that time our history notes that this area was under the rule of the Pandya kings. Later when it came under Chola administration the name of the region was changed to Rājaraja Chaturvedi Mangalam (RamanathaAyyar 1962:142). Further more at that time within this area which had the villages of *Vellankovil* and *Idaikkal*we see that these villages were named after areas in the Chola Empire which had the Kaveri River flow through them. These villages were:

- CōḻakulaMāṇikkam: Vēḷāṅkōvil.
- TeṉTirupuvanam: Iṭaikkal (Raman 1977:150).

Mannarkovil Under Chola and Chera Administration

The History of Mannarkovil, a place rich in past events, comes alive through the Rajagopalasamy temple inscription expose key details about old times. During Rājaraja Chola's rule, the empire grew fast, reaching deep into Pandya lands. This particular temple, Earlier build by Chera ruler Rājasimman, stands in Mannarkovil, an area within Ambasamudram once ruled by the Chera and close to Pandya borders. After Rājendra Chola took it from the Cheras, folding it into his realm, people began calling it tha Chola Pandya temple. The region was annexed during Rājendra Chola's time, so people started calling it Rājendra Vinnagar. Also, the nearby region once named RājarājaChaturvēdi Mangalam slowly became known as Rājagopala Swamy Temple. This temple located between the Thamirabarani and Kadana river-Ancient Chola inscription mentioned them Mudikoṇḍa Cōḻa Perāṟu or Rājarāja Perāṟuinstead. Temple inscription display the spot used to be part of a much bigger stretch of land (Tirumalai1980: 1). The Rājagopalaswamy temple also called Rājendra Vinnagar is located in Mannarkoil a location where you can literally read history on Inscription. We receive evidence from those Tamilscriptsthat are inscriptions on the walls rather than merely making predictions. It grew significantly larger under the Chola rulers the changes were evident at the time.

Inscriptions from Kadayam and Alvarkurichi demonstrate how effects evolved in those days. There used to be bushy forests close to the Tamiraparni and Kadana rivers but people are gradually clearing them and converting them into farms. Work continued unabated until it reached the Western Ghats edge. People later settled here as a result of this diligent progress and the Chola ruler strong leadership made the entire region much richer and more well-known.

History of Rājagopalasamy Temple

Located between the Thamirabarani and Gadana rivers in a peaceful rural area near Ambasamudram is the Rājagopalasamy shrine at Mannarkovil. It is only 1. 5 km from the main Tirunelveli-Tenkasi route and roughly 3 km from the Ambasamudram rail junction. Due to the frequent echo of Vedic hymns the locals gave this location the name Vedapuri long ago. People now call it Mannarkovil but the Cholas renamed it RājendraVinnagaram when they were there. The temple is situated above the majority of the surrounding houses surrounded by verdant fields. (Gopalan 1997:63-64). The Rājagopalasamy shrine is one of the historic Vaishnavite sites in Tamil Nadu that the Alvars revere. Originally known as Vedapui and then RājendraVinnagaram it is now called Mannarkovil a name as revered as the renowned Ranganathar temple in Srirangam. Similar to how the Cauvery encircles Srirangam (Trichy) on two sides the Gadana flows north and the balanced Thamirabarani runs south at Vedapuri. The temple which is situated directly on this hallowed ground significantly enhances the towns reputation. The temple at Vedapuri was constructed by the Chera king Rājasimhan (Subramaniayapillai 1962: 179). It later gained strength under Chola leader Rājendra Chola. When the Chola king was in power the region was called Rājendra Vinnagaram. Vinnagan Perumal was the original name of the main deity in this instance. He was eventually called Rājagopalasamy. The temple is well known for its excellent craftsmanship and beautiful inscriptions. Because of the prevalence of Vedic chants at the time Mannarkovil was commonly referred to as Vedanarayanapuram.

Mythological Story of the Temple

According to folklore this sacred site was formerly a dense forest with palmyra trees. Two hermits Bhrigu and Markandeya who fervently worshipped Vishnu strove to see him in person not far from there. Perumal appeared directly in front of them because they were so committed. The seers were so happy that they pleaded with him to remain there forever bringing grace to those who follow and fostering the prosperity of their homes. He concurred and became Sri Veda Nārayana in this context.

The main shrine of the temple Sri Veda Nārayana Perumal was first established by Bhrigu and Markandeya alongside Sridevi and Bhudevi. Due to their use in religious ceremonies these figures were created using sudai a plant-based plaster that gives them an antique look. Underneath the eight-part tower the central god is simultaneously visible standing sitting and lying down. There are stone representations of the two original sages in the region (Muthalankurichi Kamarasu 2023: 581-583).

The large temple area is made up of seven enclosures that allow people to move freely between them. As you move from path to path you enter a more profound area. The main deity worshipped here Sri Raja Gopala Swamy has a partner named Andal also called Sri Godha. This place is unique because *Sri Pakshirajan* another name for Garuda Alwar is situated right next to the festival idol. This arrangement is not often found elsewhere. Two goddesses Vedavalli and BhuvanavalliThayars are revered in separate tiny houses on the property. A hall displaying all ten avatars is located close to Sri Yoga Narasimhar who resides close to the first shrine. Then not far from the location of the second goddess there is a portal that leads to freedom called Paramapada Vasal. The main deity is reached directly through an odd triangle-shaped passageway that the locals call the Pillai Thondu (cat path). It is said that if women crawl through here after sincerely praying toVeda narayana they will soon become parents. A detailed ceiling in the front hall of the old temple features all twelve zodiac symbols. Made with a lime and jaggery mixture that was popular at the time it encircles the main deity with a YaanaiThondu (elephant path). There is a small cat-only walkway called Poonai Thondu(cat path) that circles the sleeping Perumal. Since Kulasekara Alvar was saved and passed away herehe has his own little shrine with a flag limit outside(Manikandasethupathy 2019:273-274).

Expansion of the Temple

Numerous Inscriptions at the Rājagopalaswamy Temple along with nearby evidence show how the site was establishedand expose many changes undervarious leadership It was updated over time by various rulersand because of its significance gifts continued to come in. All of this took place over a period of almost 700 years from 1021 AD to roughly 1605. The Temple's inscriptions mentioned to three or four different building stages were added on, the first part held the main shrine, called ŚrīVimāna, plus two floors above it, along with a small hall for ŚrīVedanarayana.Following temple land was bought for housing the temples second phase of growth most likely started in the early 13th century and resulted in a new outer wall. They also constructed a separate area for *Kulasekhara Alvar* shrine at that time. By the middle of the 16th century a few hundred years later the Tiruvadi chiefs the local leaders had increased their support and offerings. Things had stabilized into their current configuration by the late 16th century. In that version Sri Rājagōpāla was honored with a new raised space inside the main hall called Koradu. Sri Rāmānuja and Sri Manavalamāmunis side shrines the front gōpura and the mandapa in front of it that houses a tiny pandal hall are probably from late Vijayanagara or early Nayak times. The written record concludes in the early 16th century with an inscription detailing the construction of the Teppakulam (tank) by a Cēṭṭi-Nāyak supporter (Tirumalai 1980: 9-10).

- **Initial Phase:** It is evident from the way it is constructed and what the Inscription say that the earliest version of this temple only had the main chamber the tower above it called Vimana and a small hall up front called Ardhamandapa. A narrow walkway that circles the core room was added later perhaps by the eleventh century or earlier.
- **Second Phase:** The second encirclingpathway which was constructed after the first one close to the inner chamber of the temple and has its own little shrine devoted to Kulasekara Alwar most likely dates to the 12th century or possibly earlier.
- **Third Phase:** Local Tiruvadi leaders who were in charge of Mannarkovil and Ambasamudram at the time updated the temples construction in the fifteenth century AD.
- **Fourth Phase:** The construction was finally completed by the late 16th century when the VijayanagaraNayakka rulers took control of the region and the surrounding area. That's when the Mahāmaṇḍapam went up. At the same time the massive tower at the front gate began to take shape. To the right of it were small shrines dedicated to *Maṇavāḷa Māmuṉi* and *Irāmāṉujar* as well as inner halls and a covered pavilion. According to stone-carved records Cēṭṭi-Nāyakwas in charge of the holy water tank.

Inscriptions of the Rajagopalasamy Kulasekara Perumal Vishnu Temple:

The Rājagopala Kulasekara Perumal temples inscriptions can be located along the path that encircles the Kulasekara shrine as well as on the base sections close to the main hall. There are precisely 38 recorded texts on this website. One is from the fourth year of Jata-varman Sundara Chola Pandyas reign or roughly 1025 AD another is from his sixth year or roughly 1027 AD and a third is from his thirteenth year or roughly 1034 AD. Additionally Chera king Rājasingha Devar wrote an offering note in the rulers 14th year (1035 AD) another marking demonstrates work completed under Chera king Rājadevar in Sundara Chola Pandyas 16th year (1037 AD).

Plate 1: The inscription is numbered 132 (*ARE* 1887-05:132; Hultzsch 1981:68-69). indicate that the north side of the inner shrine contains one of the oldest records. It dates to the fourth year of the reign of King jata-varman Sundara Chola Pandya. People gathered to discuss issues at the Ambalam Hall back then. Following that meeting it was decided to provide homes and plots to those who were working on the temple grounds. Expert drummers known as *uvachar* were given space alongside gardeners. They also included potters. Support was given to women who performed as *Devaradiyār* (dancing girls). They even had their share of ghee suppliers for oil lights. Employees in different positions were also included. Furthermore it is confirmed by the script that Rājasimhan the Chera ruler raised this. Under the title *RājendraCholadevar* he dedicated it. During the Rājendra Chola Period (1025 A. D.)the inscriptions mention the divisions and subdivisions of Mannarkovil at Ambasamutram Taluk:

- RājarājaPāṇḍiyaNāṭu (district)
- MuṭikoṇṭaCōḻaVaḻanāṭu(subdivision)
- Muḷḷināṭu(Taluk)
- RājarājaCaturvēti Maṅkalam (Village)

Temple Names in the Inscriptions:

There are three distinct shrines within the Rājagopalasamy Perumal Vishnu Temple. According to the Inscription of previous ruler the name of theprimary shrine became Rājendra Chola Vinnagara Aazhvar inside of them. According to one of these records the site was constructed under the Chera dynasty King Rāja Simman. It was dedicated to the Chola lines Emperor Rājendra Cholan (*ARE* 1887-05:107).

Plate 2: Inscription No. 145 (A.R. No. 110 of 1905), dated to the thirteenth regnal year of Jatavarman Sundara-Cholapandya, records a land transaction involving the sabha of Rājarāja-chaturvedimaṅgalam and the temple of Rājendra Chola Vinnagar. The inscription records the extent of the land as "14 and odd vēli" and refers to the establishment of the settlement known as Cōḻapāṇḍiyanallūr. The land was associated with the temple as Devadānam and was subject to institutional arrangements concerning its agricultural use and produce (Hultzsch 1981: 292–297).

The inscriptional evidence provides geographical and agricultural evidence for the use of water resources. The land associated with the temple was situated between the river systems identified in the inscriptional context as the MudikoṇḍaChōḻaPerāṟu and the RājarājaPerāṟu. The records also refer to land associated with two streams and provide an agricultural assessment of 909 kalam and thuni of paddy for the relevant irrigated land. These references demonstrate the relationship between water availability and agricultural cultivation. However, the available inscriptional evidence does not provide sufficient technical information to establish the construction date, dimensions or engineering design of individual irrigation canals. The present study therefore interprets the evidence as demonstrating water-fed cultivation and organised use of surface-water resources rather than attempting to reconstruct individual canal engineering.

Donated Land in Inscriptions:

The note lists these territories granted as gifts - like estates handed down through time

- This piece of land sits by two rivers - size is 6 vēli, which means around 30 acres.
- *Malukkādu*land (bush forest): This patch covers 3 vēli - around 15 acres.
- *PunjaiMalukkādu* means dry farming land - covers 3 vēli, that's around 15 acres.
- This piece of land is 2 vēli, which means around 10 acres.
- A stretch near Kadaiyam, filled by river flow: this land's just half a vēli - around 2.5 acres in size.

The full size of these grants adds up to 16.5 vēli - around 82.5 acres altogether(*ARE 1887-05:109*).

Quantitative Relationship between Land and Agricultural Production

The inscriptional records provide quantitative information linking land extent, water availability and agricultural production. In particular, 6 vēli of land associated with two streams is recorded together with an agricultural assessment of 909 kalam and thuni of paddy. Other land categories are separately identified according to their agricultural and environmental characteristics. These figures demonstrate that land area, water conditions and agricultural production were recorded together within the agrarian system. The recorded quantities are treated as historical assessments or production records and not as modern measurements of yield per acre.

Traditional Tamil Grain Measurement Units and Conversions:

Inscription No. 145. explains the measurement methods used for harvested grains in the past which were widespread in Tamil Nadu.Thewords from those traditional systems are still used in Tamil Nadu. The text provided describes the conversion of old Tamil units of measurement for grains. The relationship between *Kalaṉ Tūṇi*,*Kottai Marakka* and Nali is described (Hultzsch 1981: 296).

Unit Conversions:

The inscriptions showing show these traditional practice for measuring grains:

- 1 *Kottai*= 21 *Marakka* (3.4 to 4 kilograms paddy).
- 2 *Kottai*= 42 Marakka
- 1*KalaṉTūṇi*=1 *Kottai*.
- 1 Nali = 1 Marakka (Rangacharya 1919:29).

In Tamil Nadu traditional systems of measuring grain were commonly found and thoroughly examined in inscriptions records that concerning to the tradition. Studying Conventional knowledge such as farming practises and sizing agricultural products is important in the past history of Tamil Nadu (*ARE* 1887-05:110).

Years Referenced in Inscriptions:

• Saka Year
• Kollam Year

CONCLUSION

The epigraphic evidence from Mannarkovil provides a measurable basis for reconstructing the technological organisation of historical agrarian resources under Chola and Chera rule. The documented allocation of 16.5 *vēli* of land, equivalent to approximately 82.5 acres in the recorded conversion, indicates a structured system of land classification and spatial resource distribution. River-associated lands, *Malukkādu*, *PunjaiMalukkādu* and other agricultural zones demonstrate differentiated approaches to terrestrial resource utilisation. The recorded irrigation channels and cultivation associated with the Thamirabarani and Kadana river systems further indicate the integration of hydrological resources with agricultural production and land-use expansion. The transformation of uncultivated and forested areas into productive zones reflects organised processes of agro-landscape modification. The indigenous grain-measurement framework comprising *kottai*, *marakka*, *nali* and *kalantūṇi* provides further evidence of standardised agricultural quantification and resource accounting. These datasets reveal an interconnected system linking land allocation, water utilisation, irrigation, cultivation and agricultural measurement. The Mannarkovil inscriptions therefore demonstrate the value of epigraphic evidence for reconstructing historical resource-management technologies and agro-environmental systems through quantitative and spatial indicators. This technical interpretation provides a basis for further interdisciplinary research connecting epigraphy with environmental science, agricultural systems, hydrology and historical resource management.

ABSTRACT

Varicose veins are a common manifestation of chronic venous disease characterized by venous valve incompetence, venous hypertension, impaired venous return, inflammation, endothelial dysfunction, and microcirculatory abnormalities. Compression therapy remains a cornerstone of conservative management because it improves venous return, reduces venous hypertension and edema, and alleviates symptoms. However, conventional compression primarily provides mechanical support and does not directly target inflammatory, oxidative, and biochemical mechanisms involved in disease progression. This review discusses the emerging concept of drug-incorporated compression therapy (DICT), which combines mechanical compression with localized pharmacological drug delivery. The review summarizes conventional compression systems, including elastic, inelastic, and multilayer systems, and discusses their therapeutic principles and limitations. Emerging drug-delivery approaches, including drug-impregnated bandages, drug-coated compression stockings, microencapsulation, nano fibers, hydrogels, liposomal systems, and smart stimuli-responsive materials, are also described. Potential therapeutic categories include venotonic agents, anti-inflammatory drugs, antioxidants, antimicrobial agents, and microcirculation-enhancing agents. Available clinical evidence suggests benefits from combining pharmacological therapy with compression, particularly in chronic venous disease and venous ulcer management. However, direct clinical evidence for drug-incorporated compression devices remains

limited, and large, well-designed randomized controlled trials are required to establish their safety, efficacy, and long-term clinical applicability. DICT therefore represents a promising future strategy that may integrate mechanical and pharmacological actions to improve localized treatment and patient outcomes in chronic venous disease.

Keywords: Varicose veins; Chronic venous disease; Compression therapy; Drug delivery; Drug-incorporated compression therapy; Venotonic agents; Nanofibers; Hydrogels.

INTRODUCTION

Varicose veins are dilated, tortuous superficial veins resulting from chronic venous insufficiency (CVI), a condition characterized by venous valve incompetence, venous hypertension, and impaired venous return. Chronic venous disease (CVD) affects a substantial proportion of the adult population worldwide and is associated with symptoms such as pain, heaviness, leg fatigue, edema, skin pigmentation, lipodermatosclerosis, and venous leg ulcers, all of which significantly impair patients' quality of life. The prevalence of varicose veins increases with age and is influenced by several risk factors, including prolonged standing, obesity, pregnancy, advancing age, and genetic predisposition. **[1]**. The pathogenesis of varicose veins is multi factorial, involving venous hypertension, valvular incompetence, endothelial dysfunction, chronic inflammation, and microcirculatory impairment. Persistent venous hypertension initiates inflammatory cascades that promote leukocyte activation, oxidative stress, extracellular matrix remodelling, and progressive deterioration of the venous wall and valves. These pathological changes contribute to disease progression and increase the risk of complications if left untreated. Compression therapy remains the cornerstone of conservative management for varicose veins and chronic venous disease. By applying graduated external pressure, compression therapy improves venous return, enhances calf muscle pump function, reduces venous hypertension, minimizes edema, and alleviates symptoms. Despite its well-established clinical benefits, conventional compression therapy primarily provides mechanical support and has limited ability to directly target the inflammatory, oxidative, and microvascular mechanisms responsible for disease progression.

Recent advances in pharmaceutical sciences and biomaterial engineering have led to the development of drug-incorporated compression therapy, an innovative approach that combines mechanical compression with localized drug delivery. Drug-loaded compression systems are designed to provide sustained release of therapeutic agents directly at the site of pathology, with the potential to enhance localized drug delivery while potentially reducing systemic exposure. Emerging technologies such as microencapsulation, nano fibers, hydrogels, liposomal carriers, and smart textile-based delivery systems have further expanded the potential of this strategy for the management of chronic venous disease. This review aims to provide a comprehensive overview of drug-incorporated compression therapy for the management of varicose veins by discussing the patho physiology of chronic venous disease, principles of compression therapy, recent advances in drug delivery technologies, available clinical evidence, current limitations, and future perspectives for clinical translation.

Conventional Compression Therapy in Varicose Veins

Compression therapy is the cornerstone of conservative management for varicose veins and chronic venous disease. It works by applying graduated external pressure to the affected limb, thereby improving venous return, reducing venous hypertension, enhancing calf muscle pump function, and minimizing edema. Although compression therapy has been widely adopted in clinical practice and is effective in alleviating symptoms, it primarily provides mechanical support and does not directly address the underlying inflammatory and biochemical mechanisms involved in disease progression. Understanding the principles, benefits, and limitations of conventional compression therapy is essential for appreciating the need for advanced therapeutic approaches such as drug-incorporated compression systems.

Pathophysiology of Varicose Veins

Varicose veins are dilated, tortuous superficial veins that develop due to chronic venous insufficiency and venous valve dysfunction. They represent one of the most common manifestations of chronic venous disease and affect a significant proportion of the adult population worldwide. According to guidelines from the National Institute for Health and Care Excellence, varicose veins are not merely a cosmetic concern but a progressive medical condition that can lead to pain, edema, skin pigmentation, lipodermatosclerosis, and venous leg ulcers if untreated. The prevalence increases with age and is higher among women, particularly those with a history of pregnancy, prolonged standing, obesity, and genetic predisposition. In developing countries such as India, occupational factors and urban lifestyle changes have further increased disease incidence**.** The pathophysiology of varicose veins is multifactorial and involves venous hypertension, valvular incompetence, inflammation, endothelial dysfunction, and microcirculatory impairment.

Principles of Compression Therapy

Graduated compression therapy exerts controlled external pressure, with the highest pressure applied at the ankle and progressively decreasing pressure towards the calf. This pressure gradient promotes venous blood flow back to the heart, reduces venous pooling, improves venous valve function, enhances calf muscle pump efficiency, and decreases capillary filtration, thereby reducing edema and improving overall venous hemodynamic.

Types of Compression Systems

Compression therapy is delivered using various systems, each with distinct mechanical properties and clinical applications. The choice of compression system depends on disease severity, patient mobility, limb characteristics, and treatment goals **[3].**

Elastic Compression Systems

Elastic compression systems include compression stockings and elastic bandages that exert continuous pressure both at rest and during movement. These systems are commonly used for long-term management of varicose veins and chronic venous insufficiency and suitable for ambulatory patients.

Inelastic Compression Systems

Inelastic compression systems, such as short-stretch bandages, exert low pressure at rest but high-pressure during muscle contraction. This property makes them particularly effective in enhancing the calf muscle pump function. Inelastic systems are often used in the treatment of venous ulcers and severe edema.

Multilayer Compression Systems

Multilayer compression systems combine elastic and inelastic components to provide sustained and effective compression over extended periods. These systems are widely used in wound care settings and offer superior edema control and ulcer healing outcomes.

Compression Pressure Levels

Compression therapy is categorized based on the amount of pressure applied at the ankle, typically measured in millimeters of mercury (mmHg). Different compression classes are prescribed according to disease severity and therapeutic objectives.

- 1.Mild compression (10–20 mmHg): Used for early symptoms, leg fatigue, and prevention.
- 2.Moderate compression (20–30 mmHg): Recommended for symptomatic varicose veins and mild edema.
- 3.Strong compression (30–40 mmHg): Indicated for chronic venous insufficiency, significant edema, and skin changes.
- 4.Very strong compression (>40 mmHg): Used in severe venous disease and venous ulcers under medical supervision **[4].**

Clinical Benefits of Compression Therapy

Compression therapy provides several clinical benefits, including relief from pain, heaviness, swelling, and leg fatigue. It improves venous return, reduces venous hypertension, enhances lymphatic drainage, promotes healing of venous ulcers, and helps prevent disease progression. These therapeutic effects improve patients' quality of life and make compression therapy the first-line conservative treatment for chronic venous disorders.

Limitations of Conventional Compression Therapy

While compression therapy effectively addresses the mechanical aspects of venous insufficiency, it has inherent limitations that may reduce its clinical efficacy. Compression primarily acts by decreasing venous diameter, improving valve function, and enhancing venous return. However, it does not directly modulate inflammatory pathways, oxidative stress, or endothelial dysfunction, all of which play a critical role in disease progression and symptom persistence. Patients often continue to experience pain, heaviness, and discomfort despite adequate compression, particularly in moderate to advanced stages of disease. Additionally, compression therapy does not provide immediate symptom relief for all patients, leading to poor adherence and early discontinuation **[5].**

Rationale for Drug-Incorporated Compression Therapy

Conventional compression therapy has long been considered the first-line conservative treatment for varicose veins and chronic venous disease because of its ability to improve venous return, reduce edema, and relieve symptoms. However, its therapeutic effect is primarily mechanical and does not directly target the underlying inflammatory processes, endothelial dysfunction, oxidative stress, and tissue remodeling that contribute to disease progression. As a result, there has been growing interest in integrating pharmacological agents with compression systems to enhance treatment outcomes. Drug-incorporated compression therapy combines the mechanical benefits of compression with localized drug delivery, allowing therapeutic agents to be released directly at the affected site. This approach may improve localized drug availability, provide sustained drug release, and potentially reduce systemic exposure; however, these potential advantages require validation in well-designed clinical studies. Furthermore, advances in pharmaceutical sciences and biomaterial engineering have facilitated the development of innovative compression-based drug delivery systems, including drug-coated textiles, hydrogels, nanofibers, microcapsules, and smart wearable materials. The rationale behind this approach is to achieve a synergistic therapeutic effect, where compression improves venous hemodynamics while locally delivered drugs target inflammation, oxidative stress, venous wall remodeling, and microcirculatory dysfunction. Such integrated systems may potentially alleviate symptoms and support tissue healing, although their effects on disease progression and long-term clinical outcomes remain to be established. Consequently, drug-incorporated compression therapy represents a promising emerging strategy for future investigation in the management of varicose veins and chronic venous disease.

Integration with Pharmacological Therapy: Compression therapy is often used in combination with pharmacological agents to enhance treatment outcomes. **[7].**

Rationale for Drug Incorporation: Drug incorporation in compression therapy represents a rational and innovative approach that combines mechanical and pharmacological interventions to achieve synergistic therapeutic effects.

Literature Search Strategy

A comprehensive literature search was conducted using PubMed, Scopus, Web of Science, Google Scholar, and ScienceDirect to identify relevant studies published in English. Keywords included "varicose veins," "compression therapy," "drug-incorporated compression," "drug delivery systems," "compression stockings," "hydrogels," "nanofibers," and "venous insufficiency." Original research articles, systematic reviews, meta-analyses, and clinical guidelines relevant to the topic were included, while duplicate and non-English publications were excluded. **[4].**

Rationale for Drug Delivery Through Compression Systems

Drug delivery through compression systems offers several advantages:

- Localized drug action at the site of pathology
- Reduced systemic exposure and toxicity
- Sustained drug release over prolonged periods
- Improved patient adherence through combined therapy
- Synergistic interaction between mechanical compression and pharmacological effects

These benefits make compression-based drug delivery an attractive therapeutic strategy, particularly for chronic conditions requiring long-term management **[12-16].**

Types of Drug Delivery Systems in Compression Therapy

- **Drug-Impregnated Bandages:** Drug-impregnated bandages are among the earliest forms of compression-based drug delivery. These bandages are soaked or coated with pharmacologically active substances such as zinc oxide, antiseptics, or anti-inflammatory agents.
- **Drug-Coated Compression Stockings:** Drug-coated compression stockings incorporate drugs onto the surface of textile fibers using coating techniques. The drug is gradually released during wear through friction, moisture, and body heat.
- **Microencapsulation-Based Systems:** Microencapsulation involves enclosing drug molecules within microscopic polymeric capsules that are embedded into compression fabrics. These capsules protect the drug and allow controlled release over time.
- **Nanofiber-Based Drug Delivery Systems:** Nanofiber technology, particularly electrospinning, has emerged as a promising platform for drug delivery in compression therapy. Nanofibers offer a large surface area-to-volume ratio,
- **Hydrogel-Based Compression Systems:** Hydrogels are three-dimensional polymeric networks capable of retaining large amounts of water. When incorporated into compression systems, hydrogels act as reservoirs for drug release.
- **Liposomal and Vesicular Systems:** Liposomes and other vesicular carriers can be incorporated into compression materials to enhance transdermal drug delivery. These systems improve drug penetration by interacting with skin lipids.
- **Smart and Stimuli-Responsive Drug Delivery Systems:** Smart compression systems may use stimuli-responsive polymers that release drugs in response to physiological or environmental triggers such as temperature, pressure, pH, or moisture [13,15].

Mechanisms of Drug Release in Compression Systems

Advantages of Drug Delivery Systems in Compression Therapy

- Combined mechanical and pharmacological benefits
- Sustained and localized drug action
- Reduced systemic adverse effects
- Improved quality of life
- Improved patient compliance
- Reduced dosing frequency
- Better bioavailability

Clinical Evidence

Standard Compression Therapy (Baseline Evidence)

Compression stockings and bandages are widely used in the management of varicose veins. However, the strength of evidence supporting compression therapy as a standalone treatment is limited. A Cochrane review of 13 randomized controlled trials involving 1,021 participants found insufficient high-certainty evidence to determine whether graduated compression stockings are effective as the sole and initial treatment of uncomplicated varicose veins[6]. Although some small, short-term studies reported reduced pain and aching after one week of compression use,

systematic reviews conclude that evidence for long-term symptom improvement, prevention of disease progression, or recurrence remains uncertain due to study bias and variability.

Combined Pharmacology and Compression Approaches

Evidence is stronger when compression therapy is combined with pharmacological treatment, particularly in advanced chronic venous disease. While direct research on drug-incorporated compression textiles is still limited, studies support the use of systemic venoactive drugs with compression. In patients with venous leg ulcers. Clinical studies and meta-analyses indicate that micronized purified flavonoid fraction (MPFF), when used as an adjunct to conventional treatment including compression and local care, may increase the likelihood of venous leg-ulcer healing and shorten healing time. Other studies show that venoactive drugs such as flavonoids and ruscus extract reduce pain, heaviness, and swelling when used alongside compression therapy's

Limitations

- There is little extensive, long-term clinical data regarding safety and effectiveness.
- Optimizing medication penetration while maintaining a constant compression pressure is challenging.
- Danger of allergic reactions, skin irritation, or fabric property changes.
- regulatory difficulties brought on by the combination of pharmaceutical and medical device nature.
- high manufacturing costs due to modern technologies.
- restricted accessibility and affordability in environments with limited resources.
- Patient-specific characteristics (skin sensitivity, severity, compliance) have an impact on treatment outcomes.
- Before being routinely used in clinical settings, more research and technology development are needed.

Current Status and Future Aspects

Current Status:

DICT provides a dual therapeutic approach by combining mechanical compression with localized drug delivery, with the potential to enhance treatment outcomes. Importantly, there are no large, well-designed RCTs specifically testing clinically implemented drug-eluting or drug-incorporated compression devices in patients with varicose veins. Most evidence applies to compression plus systemic pharmacologic agents, not localized drug release from the compression material itself. Large RCTs are needed to assess whether DICT can improve symptom relief, functional outcomes, ulcer healing, and quality of life beyond what conventional compression and drug therapy provide.

Future Directions

Drug-incorporated compression therapy represents a promising emerging strategy that may complement the mechanical benefits of conventional compression. Conventional compression therapy improves venous return, reduces venous hypertension, and alleviates edema, but it acts mainly through mechanical support and does not directly target inflammation, endothelial dysfunction, or microcirculatory impairment that contribute to disease progression. DICT seeks to overcome these limitations by integrating therapeutic agents such as venotonic drugs, anti-inflammatory compounds, antioxidants, and microcirculation-enhancing agents into compression stockings, bandages, or wraps, enabling sustained and targeted drug delivery at the affected site. Advances in material science, including nanofiber technology, microencapsulation, and smart polymers, are facilitating controlled and stimuli-responsive drug release while maintaining optimal compression pressure and patient comfort. These innovations may enhance drug bioavailability, minimize systemic side effects, and improve patient adherence by offering combined therapeutic benefits in a single intervention.

CONCLUSION

Compression therapy has long been established as the cornerstone of conservative treatment for varicose veins and chronic venous insufficiency. It plays a vital role in reducing venous pressure, improving venous return, minimizing edema, promoting healing of venous ulcers and preventing disease progression. However, conventional compression therapy mainly addresses the mechanical and hemodynamic aspects of venous dysfunction and does not directly target the inflammatory and biochemical processes that contribute to disease progression. Drug-incorporated compression therapy represents a promising emerging strategy that may complement the mechanical benefits of conventional compression by enabling localized pharmacological delivery. Although current evidence is encouraging, large-scale randomized clinical trials are still required to establish the long-term safety, efficacy, and clinical applicability of drug incorporated compression therapy in routine management of varicose veins.

Table 1: Drugs Used in Compression-Based Delivery Systems

S.No	Drug Category	Therapeutic Action	Clinical Purpose in Compression Systems
1	Venotonic Agents	Strengthen venous tone and reduce capillary permeability	Improve venous return and reduce edema
2	Anti-Inflammatory Drugs	Reduce pain, swelling, and venous wall inflammation	Control symptoms and local inflammation
3	Antioxidants	Protect endothelial cells from oxidative damage	Prevent vascular damage and disease progression
4	Antimicrobial Agents	Prevent infection in venous ulcers	Reduce bacterial load and promote wound healing
5	Microcirculation Enhancers	Improve tissue oxygenation and healing	Enhance tissue repair and ulcer recovery

Table 2: Drug Action in Compression

Therapeutic Action	Mechanism	Physiological Benefit	Target Condition	Impact on Healing
Mechanical Pressure Application	Reduces venous diameter and improves valve function	Improves venous return and lowers venous pressure	Venous insufficiency	Promotes ulcer healing and prevents recurrence
Fluid Management	Reduces capillary filtration and enhances lymphatic drainage	Decreases edema	Edema, Lymphedema	Improves oxygen diffusion and reduces tissue tension
Microcirculation Improvement	Improves blood flow and reduces viscosity	Enhances tissue oxygenation	Tissue hypoxia	Speeds recovery of ischemic tissue
Venotonic Action	Strengthens vein walls and reduces permeability	Decreases swelling and vein distension	Venous wall weakness	Reduces heaviness

PARAMETER	STANDARD COMPRESSION THERAPY (Conventional Approach)	DRUG-INCORPORATED COMPRESSION THERAPY (DICT) (Emerging Approach)
PRIMARY MECHANISM	Provides graduated external compression to improve venous return and reduce venous hypertension.	Combines graduated compression with localized drug delivery to target inflammation, oxidative stress, microcirculatory dysfunction and venous wall changes.
POTENTIAL CLINICAL BENEFITS	• Reduces edema and venous hypertension • Improves venous return and calf muscle pump function • Alleviates symptoms (pain, heaviness, swelling) • Promotes venous ulcer healing *(Supported by multiple RCTs and guidelines)*	• Theoretical additional benefits: anti-inflammatory, antioxidant, venotonic, antimicrobial actions • May enhance microcirculation and tissue healing • Potential improvement in patient comfort and adherence *(Preclinical and early clinical studies)*
LEVEL OF CLINICAL EVIDENCE	★★★★★ HIGH (Strong evidence from numerous RCTs, meta-analyses and clinical guidelines)	★★☆☆☆ LIMITED (Direct clinical evidence remains limited; large RCTs are lacking.)
KEY STUDIES	Multiple RCTs and meta-analyses (e.g., Cochrane Review, 2016; Partsch, 2021; Kakkos & Nicolaides, 2018)	Preclinical studies (hydrogels, nanofibers, microencapsulation, smart textiles), small clinical pilot studies
PATIENT OUTCOMES	Well-established improvement in symptoms, quality of life and ulcer healing.	Promising trends in symptom relief and wound healing, but long-term clinical benefits not well established.
LIMITATIONS	Does not directly address inflammatory, oxidative and biochemical pathways.	Limited high-quality clinical evidence; standardization and long-term safety data are insufficient.
FUTURE PERSPECTIVE	Optimization of compression systems, patient adherence and long-term management.	Requires large-scale RCTs to establish efficacy, safety, cost-effectiveness, optimal drug combinations and long-term outcomes.

STANDARD COMPRESSION THERAPY Backed by strong clinical evidence and remains the cornerstone of conservative management in varicose veins. + **DRUG-INCORPORATED COMPRESSION THERAPY (DICT)** A promising emerging approach that may provide additional pharmacological benefits along with compression. = Integration of mechanical and pharmacological actions has the potential to improve localized treatment and patient outcomes in chronic venous disease.

ABSTRACT

Anxiety disorders represent one of the most prevalent mental health conditions globally, affecting millions of individuals across all age groups. This comprehensive review examines the landscape of anxiety disorders in the modern era, with particular emphasis on the period from 2020 to 2026, a time marked by unprecedented challenges including the COVID-19 pandemic and rapid technological advancement. The review synthesizes evidence from 30 high-quality systematic reviews, meta-analyses, and randomized controlled trials to explore contemporary challenges, innovative treatment approaches, and future directions in anxiety disorder management. Key findings reveal that digital interventions, including internet-based cognitive behavioral therapy (ICBT), virtual reality exposure therapy (VRET), and mobile applications, demonstrate large effect sizes comparable to traditional face-to-face therapy. The COVID-19 pandemic significantly accelerated the adoption of telehealth and digital mental health solutions while simultaneously increasing anxiety prevalence worldwide. Pharmacological innovations include novel agents such as agomelatine, ketamine, and cannabidiol, though traditional selective serotonin reuptake inhibitors (SSRIs) and serotonin-norepinephrine reuptake inhibitors (SNRIs) remain first-line treatments. Emerging technologies such as artificial intelligence-driven chatbots, immersive gaming interventions, and non-invasive brain stimulation show promise as adjunctive treatments. Despite these advances, significant challenges persist, including treatment accessibility, digital literacy barriers, high dropout rates, and the need for robust regulatory frameworks. This review underscores the

critical importance of integrating technological innovations with evidence-based practices to expand access to effective anxiety treatment in the modern era.

Keywords: Anxiety Disorders, Telehealth Internet-Based Cognitive, Behavioural Therapy, Virtual Reality Exposure Therapy, COVID-19 Pandemic.

INTRODUCTION

Anxiety disorders are the world's most common mental-health conditions. They cut across every age, culture and corner of society - and they carry a steep public-health cost. The category includes several different presentations: generalized anxiety disorder (GAD), social anxiety disorder (SAD), panic disorder (with or without agoraphobia), specific phobias and related problems. In the past few years, and especially across the 2020–2026 period, prevalence and overall impact have climbed, pushing clinicians, researchers and policy makers to question old assumptions and look for new ways to deliver care. Clinically, these conditions show up as excessive fear and persistent worry, often with clear changes in behaviour - avoidance (not answering calls, skipping social events), constant scanning for threats, restless nights - that get in the way of school, work and family life. In children and adolescents, they're the most common mental-health issue, yet most young people who need help never receive evidence-based treatment [1,2]. That treatment gap is hardly limited to youth: long waitlists, a shortage of specialists in rural areas, high out-of-pocket costs, transport or geographic barriers, and the stigma of seeking care all block timely access [3,4]. People wait months for therapy. Some simply give up. Recent global events have changed the landscape. The COVID-19 pandemic produced widespread psychological distress and disrupted conventional in-person services [5]. Anxiety symptoms rose across the population - healthcare workers, people with pre-existing conditions, and those living in social isolation were particularly hard hit [5].

Modern Challenges in Anxiety Disorder Management

The COVID-19 Pandemic Impact

COVID-19 battered mental health - it's arguably one of the defining publics-health crises of recent memory, and its psychological aftershocks will be felt for years. Anxiety spiked: people worried about getting sick, found themselves cut off from friends and from the small routines that keep days steady during lockdowns, fretted about money, and often couldn't get to their usual therapists [5]. Toss in overlapping pressures - fear of infection, isolation, economic uncertainty, disrupted daily rhythms, reduced access to services - and it's not hard to see why anxiety spread so widely. For many it felt like a slow, nagging hum in the background that never quite went away. Into that gap stepped online interventions, and they offered more than mere convenience. A systematic review and meta-analysis of 34 randomized controlled trials involving 16,151 participants reported a statistically significant drop on the Generalized Anxiety Disorder-7 (GAD-7) score: a pooled mean difference of 1.03 favouring online treatments over controls [5]. In plain English: when face-to-face care was often off the table, digital programs kept support going - not a perfect substitute for in-person therapy, but a lifeline for many. The pandemic also accelerated telehealth adoption almost overnight, reshaping how anxiety care is delivered. That shift brought real gains - wider reach, more flexible scheduling - but also raised tough questions about who gets left behind. Who lacks the digital skills or a dependable device? Who lives with slow internet or in places without broadband? And how do we maintain quality when therapy happens through a screen? Concerns about digital literacy, connectivity, and standards have been prominent in the literature [5,6]. Reflecting that attention, bibliometric analyses show a steady rise in publications on digital and alternative anxiety therapies from 2020 through 2024 - a clear sign the research community rushed to respond [7].

Treatment Access and Healthcare Disparities

Evidence-based treatments for anxiety disorders do work. And yet, despite that clear evidence, major hurdles to care persist across health systems worldwide. Most children and adolescents with anxiety never get help - a stark and stubborn gap in paediatric mental-health services [1,2]. The reasons are familiar and maddening: too few specialised

clinicians; waiting lists that stretch for months; geographic isolation in rural and underserved areas; fees that put care out of reach for many; and the enduring stigma of admitting you need emotional support [3,4]. Moving treatment into primary care looks like a sensible fix, but the reality is messier than the idea. A systematic review and meta-analysis from countries with universal coverage found large effects when psychological treatments were delivered by specialists, yet specialist access in everyday practice remains limited [8]. With training and oversight, non-specialist providers can deliver effective interventions, although the effect sizes tend to be smaller. In short: task-shifting can broaden reach - but it's not a simple swap for specialist care [8]. The gaps are about more than raw access; they shape who engages and who benefits. For example, a real-world evaluation of a digital anxiety programme for 7–12 year-olds tentatively found lower uptake among ethnic-minority children and those in the most deprived neighbourhoods, even though children from socioeconomically deprived areas who did sign up were more likely to complete the programme's challenges [9]. These mixed patterns point to a knot of barriers and supports - which is why culturally adapted, equity-focused strategies are essential if interventions are to reach the kids who need them most.

Digital Divide and Technological Barriers

While digital interventions offer promise for expanding treatment access, they simultaneously introduce new barriers related to technology access, digital literacy, and user engagement. Treatment dropout represents a significant challenge for online interventions, with negative attitudes toward internet-mediated technologies, low technological literacy, and lack of access to necessary devices and reliable internet connectivity serving as substantial obstacles [10]. These barriers disproportionately affect older adults, individuals from lower socioeconomic backgrounds, and those in rural or underserved areas, potentially exacerbating existing healthcare disparities. The effectiveness of digital interventions depends not only on their clinical efficacy but also on user engagement and adherence. Research on digital therapeutic interventions has identified concerns regarding dropout rates and patient adherence as persistent challenges [11]. Most mobile applications for anxiety lack scientific validation, posing challenges for clinical recommendation and raising concerns about the quality and safety of widely available digital mental health tools [7]. The need for robust regulatory frameworks to ensure user safety, data protection, and evidence-based standards for digital mental health interventions has become increasingly apparent [12]. Digital literacy issues extend beyond basic technology use to encompass understanding of privacy concerns, data security, and the appropriate role of digital tools in mental health care. The integration of artificial intelligence and machine learning into mental health applications raises additional ethical considerations regarding algorithmic transparency, bias, and the potential for harm [13]. Addressing these challenges requires comprehensive approaches that combine technological innovation with attention to equity, ethics, and user-centered design principles.

Innovations in Treatment

Digital Interventions

Digital interventions for anxiety disorders have emerged as one of the most significant innovations in mental health treatment over the past two decades, offering scalable, accessible, and cost-effective alternatives or supplements to traditional face-to-face therapy. The evidence base supporting digital interventions has grown substantially, with multiple systematic reviews and meta-analyses demonstrating their effectiveness across various anxiety disorder subtypes and age groups.

Internet-Based Cognitive Behavioural Therapy (ICBT)

Internet-based cognitive behavioural therapy represents the most extensively studied digital intervention modality for anxiety disorders. A comprehensive systematic review and meta-analysis examining two decades of digital interventions found a large pooled effect size of g = 0.80 favouring digital interventions over wait-list or usual care controls [1]. Moderate to large effect sizes were observed across specific anxiety disorders, including GAD (g = 0.62), panic disorder with or without agoraphobia (g = 1.08), and social anxiety disorder (g = 0.76) [1]. Notably, the effects of guided interventions (g = 0.84) and unguided interventions (g = 0.64) were not significantly different, suggesting that self-guided digital interventions can be effective, though guided formats may offer modest advantages [1]. The

efficacy of ICBT has been demonstrated to be comparable to face-to-face therapy across multiple studies. A supplemental analysis comparing digital and face-to-face interventions found no significant difference in effect, with a small effect size of g = 0.14 favouring digital interventions [1]. For social anxiety disorder specifically, a meta-analysis of 20 randomized controlled trials involving 1,743 participants found that ICBT significantly reduced symptoms with a positive effect size of g = -0.55 compared to control groups, and showed equivalent effects to face-to-face CBT (g = -0.18) with sustained efficacy at 6-month and 12-month follow-ups [14]. These findings provide strong evidence that ICBT can serve as a viable alternative to traditional in-person therapy for many individuals with anxiety disorders.

Digital CBT interventions have also demonstrated effectiveness in paediatric populations. A systematic review and meta-analysis of 18 randomized controlled trials with 1,290 participants under age 18 found that cognitive behavioural digital interventions effectively reduced anxiety, with clinician ratings yielding a medium effect size (g = 0.66) and parental reports showing a medium effect (g = 0.49) [2]. These interventions offer particular promise for addressing the substantial treatment gap in paediatric anxiety disorders, providing accessible and scalable options that minimize therapist involvement while maintaining clinical effectiveness [2]. A recent systematic review and meta-analysis of 19 randomized controlled trials involving 1,936 participants found that digital interventions significantly reduced anxiety symptoms with medium to large effect sizes (g = 0.78), with effectiveness moderated by specific diagnosis, digital technology modalities, and participant age [15]. The review emphasized that while digital interventions can increase access to treatment, personalized guidance remains crucial for optimal outcomes [15].

Virtual Reality Exposure Therapy (VRET)

Virtual reality exposure therapy represents a cutting-edge application of immersive technology to anxiety treatment, particularly for conditions involving specific fears and social anxiety. VRET allows for controlled, graduated exposure to anxiety-provoking stimuli in safe, virtual environments, offering advantages over traditional in vivo exposure including greater control over stimulus presentation, enhanced privacy, and reduced logistical barriers. A systematic review and meta-analysis of 22 studies involving 703 participants found that VRET for social anxiety disorder demonstrated significant and long-lasting efficacy, with Hedges' g effect sizes of -0.86 at post-intervention, -1.03 at three months, -1.14 at six months, and -0.74 at 12 months post-intervention [16]. When compared to in vivo exposure, VRET showed similar efficacy at post-intervention but became somewhat inferior at later follow-up points, suggesting that while VRET is highly effective, traditional exposure may offer slightly better long-term maintenance of gains [16]. Importantly, participant dropout rates showed no significant difference compared to in vivo exposure, indicating that VRET is an acceptable treatment modality [16]. Virtual reality-assisted cognitive behavioural therapy has demonstrated effectiveness across anxiety disorders more broadly. A systematic review and meta-analysis of 11 studies with 626 participants found that VRCBT significantly reduced anxiety compared to waiting list groups (SMD = -0.92) and showed effects on anxiety (SMD = -0.26) and depression (SMD = -0.30) similar to standard CBT [17]. These findings support VRCBT as offering therapeutic effects comparable to traditional CBT while providing unique advantages related to immersive exposure experiences [17]. Recent research has extended VRET applications to paediatric populations. A systematic review and meta-analysis examining immersive VR therapy for children and adolescents aged 4 to 18 years found that VR-based exposure therapy significantly reduced anxiety-related symptoms, particularly social and public speaking anxiety, with a large pre-post effect size (Hedges' g = -1.51) [18]. However, the small number of studies and methodological heterogeneity highlight the need for further research in this emerging area [18].

Mobile Applications and Gamification

Mobile applications and gamified interventions represent innovative approaches to delivering anxiety treatment through platforms that are highly accessible and engaging, particularly for younger populations. Real-world evaluation of a standalone digital intervention using immersive gaming technology for children aged 7-12 years found statistically significant small to medium improvements in goal-based outcome scores (d = 0.37) and Child Outcome Rating Scale scores (d = 0.46) [9]. Of 1,029 eligible families invited to use the intervention, 62.5% activated their game key, with a median of 6 unique sessions and 42 minutes of engagement time [9]. Serious games in

psychological interventions for anxiety disorders offer the potential to increase engagement and treatment adherence through interactive, entertaining formats that incorporate evidence-based therapeutic principles [19]. However, the field faces challenges related to the lack of scientific validation for most commercially available mobile applications, necessitating rigorous evaluation and quality assurance mechanisms [7].

Artificial Intelligence and Chat bots

Artificial intelligence-driven interventions represent the newest frontier in digital mental health, offering personalized, scalable support through conversational agents and adaptive algorithms. A study evaluating a digital intervention combining an AI-driven conversational agent with human clinical oversight found large clinically meaningful reductions in anxiety symptoms (per-protocol change on GAD-7 = -7.4, d = 1.6; intention-to-treat change = -5.4, d = 1.1) that were statistically superior to waiting control and non-inferior to human-delivered care [20]. Participants used the program for a median of 6 hours over 53 days, and effects were sustained at one-month follow-up [20]. AI chatbots offer several advantages including increased accessibility without geographical or temporal limitations, reduced costs, and anonymity that encourages openness and reduces stigma [13]. However, limitations persist, including lack of human empathy, ethical and privacy concerns related to data security, and technical challenges in understanding complex human emotions [13]. Future development must focus on enhancing emotional intelligence, integrating chatbots with traditional therapy, and establishing robust ethical frameworks to ensure user safety and data protection [13].

Pharmacological Advances

Pharmacological treatment remains a cornerstone of anxiety disorder management, with ongoing research expanding the range of available agents and refining understanding of optimal treatment strategies. While traditional medications including selective serotonin reuptake inhibitors (SSRIs), serotonin-norepinephrine reuptake inhibitors (SNRIs), and benzodiazepines continue to serve as first-line treatments, novel pharmacological agents are emerging with potential to address treatment-resistant cases and offer alternative mechanisms of action.

Traditional and Established Agents

SSRIs and SNRIs remain the primary pharmacological treatments for anxiety disorders, supported by extensive evidence of efficacy and generally favourable tolerability profiles. A systematic review and meta-analysis of contemporary treatment in primary care found that pharmacological treatments including SSRIs and SNRIs showed small to moderate effects for anxiety disorders [8]. These medications are typically recommended as first-line pharmacotherapy, particularly for GAD, social anxiety disorder, and panic disorder. Benzodiazepines continue to play a role in anxiety treatment, particularly for acute symptom management and short-term use, though concerns about dependence, tolerance, and adverse effects limit their long-term application. The balance between rapid anxiolytic effects and potential risks requires careful clinical judgment and patient-specific considerations

Novel Pharmacological Agents

Recent years have witnessed growing interest in novel pharmacological approaches for anxiety disorders. Agomelatine, a melatonergic antidepressant, has demonstrated efficacy in treating generalized anxiety disorder, offering an alternative mechanism of action through melatonin receptor agonism and serotonin receptor antagonism [21]. This agent may be particularly useful for patients who have not responded adequately to traditional SSRIs or SNRIs. Emerging evidence supports the potential of several novel compounds, though most remain in early stages of investigation. Ketamine, a glutamatergic modulator with rapid-acting antidepressant properties, is in the process of gathering evidence for anxiety disorder treatment [21]. Similarly, psilocybin, a classic psychedelic compound, and cannabidiol, a non-intoxicating cannabinoid, are being investigated for their potential anxiolytic properties [21]. While preliminary findings are promising, these agents require substantial additional research to establish efficacy, safety, optimal dosing, and appropriate clinical applications for anxiety disorders. The expansion of pharmacological options reflects growing understanding of the neurobiological heterogeneity of anxiety disorders and the need for diverse treatment approaches to address individual differences in treatment response. However, it is important to

note that despite the investigation of novel agents, most have not yet demonstrated superiority to established treatments, and traditional SSRIs and SNRIs remain the evidence-based standard for pharmacological management [21].

Psychotherapy Innovations

Cognitive behavioural therapy (CBT) remains the gold standard psychological treatment for anxiety disorders, supported by decades of research demonstrating its efficacy across anxiety disorder subtypes and age groups. However, the modern era has witnessed both refinement of traditional CBT approaches and exploration of alternative psychotherapeutic modalities.

Cognitive Behavioural Therapy Adaptations

CBT for anxiety disorders has evolved to incorporate various delivery formats and technological enhancements while maintaining core therapeutic principles including cognitive restructuring, exposure, and behavioural activation. Research examining the efficacy of CBT in managing anxiety disorders among adolescents found that individual, group, and digital approaches all demonstrated effectiveness, with group CBT offering the additional benefit of peer support and enhanced coping strategies [22]. The flexibility of CBT to be delivered in both traditional and digital formats underscore its adaptability to modern treatment contexts [22]. Contemporary CBT approaches increasingly integrate mindfulness-based techniques, acceptance and commitment therapy (ACT) principles, and other third-wave cognitive-behavioural interventions. A review of behavioural therapy, mindfulness-based cognitive therapy, and acceptance commitment therapy for anxiety disorders examined the integration of traditional with digital treatment approaches, highlighting the evolution of CBT-based interventions [23]. However, research comparing various psychological treatments for anxiety disorders has generally found that most alternative therapies are comparable to but not superior to traditional CBT [21].

Tele health and Remote Delivery

The expansion of tele health has fundamentally transformed psychotherapy delivery, with particular acceleration during the COVID-19 pandemic. A systematic review and meta-analysis comparing tele health versus face-to-face interventions for anxiety disorders provided evidence supporting the effectiveness of remote therapy delivery [24]. Internet and mobile-based interventions have demonstrated comparable efficacy to face-to-face therapy, suggesting that remote delivery can serve as a viable alternative to in-person treatment for many patients [21]. The effectiveness of telehealth extends across different anxiety disorder subtypes and treatment modalities. Research has consistently found that remotely delivered CBT achieves outcomes similar to traditional in-person therapy, with the added benefits of increased accessibility, reduced travel burden, and greater scheduling flexibility [1,14]. These findings have important implications for expanding treatment access, particularly for individuals in rural or underserved areas and those facing mobility or transportation barriers.

Emerging Technologies

Beyond established digital interventions, several emerging technologies show promise as adjunctive or alternative treatments for anxiety disorders, though most remain in early stages of development and evaluation.

Non-Invasive Brain Stimulation

Non-invasive brain stimulation techniques, including repetitive transcranial magnetic stimulation (rTMS) and transcranial direct current stimulation (tDCS), represent novel neurobiological approaches to anxiety treatment. A systematic review and meta-analysis found a significant medium impact of non-invasive brain stimulation in reducing anxiety-specific symptoms (overall SMD of -0.49) and general anxiety scores (overall SMD of -0.81) compared to sham interventions [25]. NIBS also significantly reduced depression scores (overall SMD = -0.98) [25].

Preliminary findings suggest that rTMS is effective for GAD, while tDCS shows effectiveness for social anxiety disorder and GAD and may augment exposure therapy for specific fears [21]. However, these techniques remain in early stages of clinical application, and further research is needed to optimize protocols, identify optimal patient populations, and establish their role in the broader treatment landscape [21,25].

Integrated AI and Human Support Models

Emerging models combining artificial intelligence with human clinical support represent a promising approach to balancing scalability with personalized care. Research evaluating a structured, evidence-based program combining an AI-driven conversational agent with human clinical oversight found that this hybrid model achieved clinical outcomes comparable to human-delivered care while significantly reducing required clinician time [20]. This approach offers potential to expand treatment capacity by leveraging technology for content delivery and routine support while preserving human expertise for clinical oversight and complex cases. The integration of AI and human support addresses limitations of purely automated interventions while maintaining scalability advantages. By combining the accessibility and consistency of AI-driven content delivery with the empathy, clinical judgment, and adaptability of human clinicians, these hybrid models may offer an optimal balance for many patients [20].

Comparative Analysis of Treatment Modalities

The modern landscape of anxiety disorder treatment encompasses a diverse array of modalities, each with distinct advantages, limitations, and appropriate clinical applications. Comparative analysis of treatment effectiveness reveals several key patterns that inform clinical decision-making and treatment selection. Digital interventions, including ICBT, VRET, and mobile applications, consistently demonstrate effect sizes comparable to traditional face-to-face therapy across multiple meta-analyses. The large pooled effect size of g = 0.80 for digital interventions compared to wait-list or usual care [1], and the finding of no significant difference between digital and face-to-face interventions [1], provide strong evidence supporting digital modalities as viable alternatives to traditional treatment. However, important moderators of effectiveness include the level of guidance or support provided, specific anxiety disorder subtype, and patient characteristics including age and digital literacy [15]. Virtual reality-based interventions show particularly large effect sizes, with one meta-analysis finding g = 0.98 for VR-based interventions compared to smaller effect sizes for mobile or internet-based interventions [15]. VRET for social anxiety disorder demonstrates sustained efficacy over long-term follow-up, though with some evidence of slightly inferior outcomes compared to in vivo exposure at later time points [16]. These findings suggest that VRET offers substantial benefits but may be optimally used in combination with or as a bridge to real-world exposure experiences.

Pharmacological treatments show small to moderate effects in primary care settings [8], with traditional SSRIs and SNRIs remaining first-line agents. Novel pharmacological approaches including agomelatine, ketamine, psilocybin, and cannabidiol are under investigation but have not yet demonstrated superiority to established treatments [21]. The role of pharmacotherapy is often complementary to psychotherapy, with combined treatment approaches frequently recommended for moderate to severe anxiety disorders. Psychological treatments, particularly CBT, demonstrate large effect sizes when delivered by specialists (g = 1.46 versus waitlist) [8]. Alternative psychological therapies including mindfulness-based interventions, ACT, psychodynamic therapy, emotion-focused therapy, and dialectical behavioural therapy have been investigated but generally show comparable rather than superior outcomes to traditional CBT [21]. This pattern suggests that while various therapeutic approaches can be effective, CBT remains the most strongly evidence-based psychological treatment for anxiety disorders. Emerging technologies including non-invasive brain stimulation show medium effect sizes (SMD of -0.49 for anxiety-specific symptoms) [25], suggesting potential as adjunctive treatments though requiring further research to establish optimal protocols and clinical applications. AI-driven interventions combined with human support demonstrate large effect sizes (d = 1.6 in per-protocol analysis) [20], highlighting the promise of hybrid models that leverage both technological and human elements. Treatment modality selection should be guided by multiple factors including anxiety disorder subtype, symptom severity, patient preferences, treatment availability, cost considerations, and individual patient characteristics. The evidence supports a stepped-care approach in which less intensive interventions such as self-guided digital programs are offered initially, with progression to more intensive treatments including guided digital interventions, face-to-face therapy, or combined psychotherapy and pharmacotherapy for those who do not respond adequately to initial treatment.

DISCUSSION

Integration of Traditional and Digital Approaches

The evidence reviewed demonstrates that digital interventions have matured from experimental technologies to established, evidence-based treatment modalities for anxiety disorders. The comparable effectiveness of digital and face-to-face interventions [1,14], combined with advantages related to accessibility, scalability, and cost-effectiveness, supports the integration of digital approaches into mainstream anxiety disorder treatment. However, optimal integration requires thoughtful consideration of how traditional and digital modalities can complement each other rather than viewing them as competing alternatives. Blended care models that combine digital content delivery with periodic face-to-face or remote clinician contact may offer an optimal balance, leverage the efficiency and accessibility of technology while preserve the therapeutic relationship and clinical expertise that characterize traditional treatment [23]. Such models can extend the reach of limited specialist resources while maintaining quality and personalization of care. The integration of traditional and digital approaches must also address the reality that not all patients are equally suited to digital interventions. Factors including digital literacy, access to technology, preference for human interaction, and severity or complexity of presentation influence the appropriateness of digital modalities for individual patients [10]. A patient-centered approach that offers choice among evidence-based options while providing guidance based on clinical considerations represents the ideal integration strategy.

Limitations and Challenges

Despite substantial progress in anxiety disorder treatment, significant limitations and challenges persist. Treatment dropout and engagement remain substantial concerns across both traditional and digital modalities, with dropout rates limiting the real-world effectiveness of interventions [9], [10], [11]. Understanding and addressing factors that influence engagement, including treatment burden, perceived relevance, therapeutic alliance, and motivational factors, represents a critical priority for improving treatment outcomes. The quality and regulation of digital mental health interventions vary widely, with most commercially available mobile applications lacking scientific validation [7]. This situation creates risks for patients who may use ineffective or potentially harmful applications while also undermining confidence in legitimate, evidence-based digital interventions. Establishing robust regulatory frameworks, quality standards, and mechanisms for communicating evidence-based recommendations to patients and clinicians is essential for realizing the potential of digital mental health [12]. Healthcare disparities and the digital divide pose significant challenges to equitable access to modern anxiety treatments. While digital interventions offer potential to expand access, they simultaneously risk exacerbating disparities if technology access, digital literacy, and culturally adapted content are not adequately addressed [9,10]. Ensuring that innovations benefit all populations rather than primarily serving those with existing advantages requires intentional focus on equity, cultural adaptation, and addressing structural barriers to access. The evidence base for emerging technologies including AI-driven interventions, serious games, and non-invasive brain stimulation, while promising, remains limited compared to established treatments. Many studies have small sample sizes, short follow-up periods, and methodological limitations that constrain confidence in findings [18,25]. Continued rigorous research is essential to establish the efficacy, safety, optimal protocols, and appropriate clinical applications for these emerging modalities

Clinical Implications

The evidence reviewed has several important implications for clinical practice. First, digital interventions should be considered as viable treatment options for anxiety disorders, not merely as inferior alternatives to face-to-face therapy. Clinicians should be prepared to discuss digital treatment options with patients, provide guidance on evidence-based digital interventions, and integrate digital tools into treatment plans where appropriate [1,11]. Second, a stepped-care approach that begins with less intensive interventions and progresses to more intensive treatment for those who do not respond adequately represents an efficient and evidence-based strategy for anxiety disorder management. Self-guided digital interventions may be appropriate as initial treatment for mild to moderate anxiety, with progression to guided digital interventions, face-to-face therapy, or combined treatment for those requiring more intensive support [1,8]. Third, treatment selection should be individualized based on patient

characteristics, preferences, and clinical presentation rather than applying a one-size-fits-all approach. The availability of multiple evidence-based modalities allows for personalization of treatment to match individual needs and circumstances [15], [21]. Fourth, clinicians must remain informed about the rapidly evolving landscape of digital mental health, including awareness of evidence-based digital interventions, understanding of their appropriate applications and limitations, and ability to guide patients in navigating the complex digital mental health

CONCLUSION

Anxiety disorders in the modern era present both unprecedented challenges and remarkable opportunities for innovation. The COVID-19 pandemic highlighted the vulnerability of traditional mental health service delivery while simultaneously accelerating the adoption of digital solutions that have the potential to fundamentally transform access to evidence-based care. The evidence reviewed demonstrates that digital interventions, including internet-based cognitive behavioural therapy, virtual reality exposure therapy, and AI-driven programs, achieve outcomes comparable to traditional face-to-face therapy while offering advantages related to accessibility, scalability, and cost-effectiveness. Pharmacological innovations continue to expand treatment options, though traditional SSRIs and SNRIs remain first-line agents, and novel compounds require further research to establish their role in clinical practice. Psychotherapy innovations, particularly the adaptation of CBT to digital formats and integration with emerging technologies, maintain the centrality of evidence-based psychological treatment while enhancing accessibility and engagement. Emerging technologies including non-invasive brain stimulation, serious games, and AI-driven chatbots show promise as adjunctive treatments, though most remain in early stages of development and evaluation.

Despite these advances, significant challenges persist, including treatment dropout, healthcare disparities, the digital divide, variable quality of digital mental health tools, and the need for robust regulatory frameworks. Addressing these challenges requires coordinated efforts across research, clinical practice, policy, and technology development domains, with consistent focus on equity, quality, and patient-centered care. The future of anxiety disorder treatment lies not in choosing between traditional and digital approaches, but in thoughtfully integrating the strengths of each to create comprehensive, accessible, personalized treatment systems. By leveraging technological innovations while preserving the core elements of evidence-based care, the field can work toward a future in which effective anxiety treatment is available to all who need it, delivered in formats that match individual preferences and circumstances, and supported by robust systems that ensure quality, safety, and equity.

ABSTRACT

This article proposes to investigate the Indian folk theatre as a theater of politics which mediates power, cultural political and subaltern expression in postcolonial India. The study does not just focus on ethnographic or literary interpretations, but views folk theatre as a socially embedded system of political communication which involves the negotiation of authority, resistance and ethical values in the process of performance. The paper uses interdisciplinary approaches from performance theory, political aesthetics and cultural studies to consider and focus on the theatrical practice of Habib Tanvir as a case study, as it mobilises folk performance traditions to question dominant aesthetic values and institutionalised modes of theatre. This analysis shows how indigenous performance enact alternative visions of politics through emphasis on collective engagement, oral history and moral critique. In positioning folk theatre in the context of the wider culture and power struggle, and theorising how performance might reflect and act as a site of cultural resistance and subaltern agency, the article helps to push the scholarship of humanities and social sciences. The study defies the notion that folk theatre is any kind of an "old" or "pre-modern" cultural form and contends that it is an ongoing political aesthetic that remains relevant to ongoing global debates on alternative modernities and cultural politics.

Keywords: Folk theatre, political aesthetics, cultural resistance, performance theory, subaltern studies, post-colonial India

INTRODUCTION

Folk theatre is in a limbo in the Indian academic and cultural discourse (Kumar et al.). Though it is generally acknowledged as a repository of traditions of Indigenous performance as such, scholarship has largely treated it at the edge of the study of theatre, either from an ethnographic perspective of its documentation or a cultural-preservationist point of view (Onuoha). While this type of research has been useful for documenting traditional performance practices, it has often neglected to focus on the political and aesthetic interventions, which folk theatre continues to make in the present social context. In this article, folk theatre is not conceived of as a remnant of the culture but rather as a living performative practice; as a practice of the present that is inextricably tied to social and political realities. As a result of postcolonial societies, art forms are not separated from the political systems and relations of power, but rather are influenced by them (Adekunle). Theatre, especially, is a medium of public culture which allows for negotiation of social values, contesting authority and construction of collective identity (Mpofu). Folk theatre belongs to a set of theatrical performances, which have their origin in oral tradition and community (Balan). This is due to its characteristic practices, which are fundamentally connected to the audience's interaction, improvisation, music, satire, and narrativic unconventionality, which make it possible to shatter the major genres of classical theatre and offer a critique of social hierarchy and political contradiction on the margins of elite and institutional spaces (Azcárate and Martínez-Falero). In contrast to the aesthetic autonomy that keeps art and everyday life apart, the folk performances are inherently part of daily life, and audiences outside the mainstream cultural circles can apprehend meaning from folk performance directly (Ranwa and Thapar-Björkert). An appreciation of the entanglements of performance and power can be best understood by the means of political aesthetics. In recent scholarship, the link between aesthetics and social perception, representation and contestation of political reality has come into greater focus (Szaló).

For this perspective, aesthetics is never a mere aesthetic throwaway; it is a force that forms the who and the what of those who are given visibility and voice in cultural and political existence, and those who are not. Folk theatre is the most telling example of this: as a language, gesture, music and story-telling vehicle it provides a forum for social criticism and ethical reflection. It provides a unique form of political communication, in which citizens are not just talking to one another but are also talking to the system of representation. It is that the importance of folk theater becomes evident in the overlaid layers of colonial, national and global modernity in India after Independence (Amar). The westernized canon of theatricality, the proscenium stage, as well as the western conception of realism, have historically been valued in this environment, with an implicit standard of western theatrical value. In response, many contemporary Indian theatre practitioners have begun to merge with folk practices as a way to counter the process of cultural homogenisation as well as to find their alternative aesthetic identities (Debsarma and Sarkar). Engagement with folk forms does not, then, simply involve a 'return to tradition,' but is an intentional cultural process which challenges the very concept of 'modern' and 'traditional. Within the contemporary Indian theatre, Habib Tanvir is one of the most important to have taken this path. Tanvir engaged his mind consistently with folk traditions and the rural performers to take the theatrical world out of its comfort zone and provide wider opportunities for theatrical production to the common folk (Kamra and Arora). His theatre foregrounds the voices and experiences of disadvantaged communities, putting them in the position of participants in performance, rather than objects to be represented from the outside. Tanvir's music combines elements of folk music with contemporary political themes, showcasing the ability of folk culture to resist and critique social and ethical issues.

The present study builds upon this history and explores Indian folk theatre as a political aesthetic which acts as a mediation of power, cultural identity and subaltern expression in the realm of modern performance. Theoretically inspired by performance theory, political aesthetics and cultural studies, this interdisciplinary perspective does not regard folk theatre merely as a traditional cultural artefact but as a form of political communication. Special focus is placed on Habib Tanvir's theatrical practice and Charandas Chor as such is explored to uncover the creation of alternative political imaginations through participatory staging, vernacular storytelling and folk aesthetics based on shared experience. The article thus places folk theatre in the middle of aesthetics and politics, casting aside easy

dichotomies like 'traditional' and 'modern' which have been the focus of discussions on Indian theatre for long. It suggests that folk theatre is a dynamic and adaptive cultural setting which continuously creates and redefines political consciousness in a postcolonial society, thereby aiming to further one theatre studies and the other interdisciplinary research activities in the areas of culture, communication, and power.

Research Contribution and Novelty

The interdisciplinary approach of this article differs from other existing writings because it does not restrict folk theatre to the traditional cultural realm, but places it in the context of political aesthetics. In a study in which the political aesthetics, the formal analysis of performance and the historical survey of the subject are relatively underrepresented, the present study elaborates upon the importance of aesthetic form in itself as a mediator of power and political communication, in the folk-theatre context. It brings together the concepts of canvassing the formal analysis of performance, ethnographic documentation, historical survey, and the mediating power and political communication of aesthetic form in the context of folk theatre. The discussion focuses on Habib Tanvir's theatrical practice, especially on Charandas Chor, as means of cultural resistance. This positions folk theatre, within current debates in theatre and cultural studies, as a dynamic medium through which political agency, ethical discourse, and subaltern expression are continually negotiated in modern and contemporary settings.

LITERATURE REVIEW

The study of Indian folk theatre has continued in various scholarly directions such as theatre studies, cultural history, anthropology and performance studies. The initial scholarly research on folk theatre tended to concentrate on documentation and classification, stressing the need to document indigenous forms which were generally seen as being endangered by the influence of urbanization and modern media. This kind of research tended to view the folk performance as a traditional culture handed down unchanged from generation to generation, confined to ritual, festival and rural entertainment. Although these gave a great deal to the documentation of performance traditions, they often severed folk theatre from the political and social life of the day, thus restricting the interpretive framework. While some of the more famous Indian theatre forms like Vaudeville or Nautanki are the focus of research, folk theatre forms like Jatra, Tamasha, Yakshagana and Bhavai have often been studied using structural, costume, music and story elements.

While these are important, they tend to place traditional folk drama in opposition to the modern urban style, suggesting that the former is premodern or less aesthetically pleasing. This binary is indicative of wider colonial and post-colonial relationships in which Western genres of drama were regarded as cultural norms and recognized as universal models of the "sophisticated stage," while indigenous genres were seen as "local" or "folkloric" (Dharwadker, "Rethinking Modern Indian Theatre"). The birth of modern Indian theatre in the mid-20th century led to a re-thinking of folk performance traditions. During this period, the use of folk forms as a source for creating a native language in theatre was gaining more and more acceptance among theatre practitioners and scholars, as a way to challenge the colonial dominance of the culture. It can be seen in the plays and films of playwrights and directors who were conscious of the folk aesthetics used in modern dramatic structures, and who defied the supremacy of western realism. The practice of this engagement with folk traditions is important to the development of what scholars like Dharwadker have referred to as a 'distinctly Indian modern theatre', one that 'negotiates' a sense of national identity in ways that are aesthetic (Dharwadker, *Theatres of Independence*). The focus on performance as a socially located, socially-oriented embodied praxis has also helped to broaden the analytical potential of folk theatre. Performance is interpreted not just as a preordained act, but as a process that involves preparation, performance, engagement with the audience, and cultural context. In this sense, textual analysis of folk theatre is not enough, and we have to view it in terms of a performing social practice, one where meaning is created through participation (Schechner, *Performance Studies*, 4th ed.). It enables scholars to investigate the role of the performance of the folk as a means of communication that appeals to the senses, emotions and moral sensibility of its audience. This discourse has been facilitated by cultural studies scholars, who have emphasised the link between culture and power.

In this context folk theatre is seen as a terrain of negotiation and contestation for dominant ideas, not passive reproduction. In Bharucha's work on intercultural theatre, for example, one can observe a critique of uncritical appropriation of the use of folk form by elite theatre practitioners, as well as their potential as modes of resistance (Bharucha). There are pertinent issues of authorship, representation, agency and cultural rights at stake in such contexts, where the folk performer is a member of a marginalised social group. Another lens with which to analyse folk theatre is through subaltern studies. Proponents of this tradition have stressed problems with the historiography of the elites, and it has become important to rediscover means of expressing subaltern consciousness. Subaltern studies have been largely historical analysis of texts and political movements; however, its insights have increasingly been applied to the analysis of performance practices.

Folk theatre places a legitimate voice in social critique, where subaltern voices do not need mediation, since it relies on the power of oral expression, collective memory and community participation (Spivak; Abdelfattah; Sharma). Although there are these developments, the political aspect of folk theatre is frequently addressed implicitly or in disarticulated fashion in existing scholarship. Social relevance of folk performance can be recognized without fully theorizing the aesthetic strategies of folk performance as political interventions. An integrated approach, linking the aesthetic form of folk theatre with its political role within the context of other political discussions of power, representation and cultural opposition, remains necessary. It is especially noticeable in analyses that are content- or theme-driven, without considering the reconfiguration of relationships between performers, audiences, and authority in performance itself (Bleiker; Reinelt; McConachie and Hart). Habib Tanvir is a focal point in the debates related to folk theatre and modern Indian drama in the field. He has been studied in the context of Marxist ideology, native aesthetics and ethical humanism. But serious appreciation and analysis of Tanvir's theatre frequently wavers between his biography and his texts, and his development of concepts of political aesthetics has received little research attention. Although scholars acknowledge Tanvir's dedication to folk forms, his work remains under-researched and fairly marginalized from critically interdisciplinary writing on aesthetics, politics, and social communication (Mishra and Mishra; Soloman; Ahmed).

Research Gaps

Building on and extending the scholarship reviewed above, this article synthesises perspectives from theatre studies, performance theory, cultural studies, and political aesthetics. Rather than approaching folk theatre as an object to be preserved or as a stylistic resource for other forms, it treats folk performance as a mode of political aesthetics that actively shapes social realities. By centring the relationship between aesthetic form and political meaning, the study speaks to interdisciplinary debates across the humanities and social sciences, offering a more nuanced account of how folk theatre operates as a site of cultural resistance and subaltern expression in contemporary India.

METHODOLOGY

The methodology used in this study is qualitative interpretative; the method of analysis used is not necessarily ethnographic but is performance and culture analysis. It is based on textual analysis, performative analysis and theory to look at the politics of aesthetics in Indian folk theatre, primarily with reference to Habib Tanvir's theatrical work, in which folk traditions have been mobilized in modern Indian theatre. The method is a mix of three interconnected analysis procedures. The first is a textual and performance-based analysis of Charandas Chor, in which the folk narrative forms, music, humour and episodic drama structure are explored in terms of the political and ethical message of the play, relying on the play's script, performances recorded for this study, and pertinent critical analyses of Tanvir's theatre. The second approach is a political aesthetic theory, taking up the work of theorists like Jacques Rancière, Richard Schechner and Gayatri Chakravorty Spivak, and explores how voice, visibility and agency are reconfigured in the theatre. The third strategy situates Tanvir's work within broader debates on postcolonial theatre, cultural resistance, and indigenous performance traditions in India, drawing on secondary

scholarship in theatre studies, cultural studies, and performance theory to interpret folk theatre as a medium of political communication and subaltern expression. Rather than offering an exhaustive ethnographic survey of folk theatre traditions, this qualitative and interdisciplinary study develops a theoretical thesis on how folk aesthetics have been constructed as a form of political praxis within the contemporary performing field.

Justification for Case Selection

The decision to centre this study on a single practitioner and a single play warrants explicit justification. Habib Tanvir is not treated here as statistically representative of Indian folk theatre in general — a claim the qualitative and interpretative design of this study is not equipped to support — but as what qualitative case-study research terms an instrumental or paradigmatic case: a body of work whose sustained, decades-long, and widely documented engagement with folk aesthetics makes it unusually well suited to illuminating the theoretical questions the study asks. Tanvir remains the practitioner most consistently discussed in existing scholarship on the intersection of folk performance and modern Indian theatre (Bharucha; Dharwadker, *Theatres of Independence*; Kamra and Arora; Mishra and Mishra), which provides both a substantial secondary literature against which to test the analysis and a degree of interpretative accountability that a less-documented practitioner would not allow. Within Tanvir's body of work, Charandas Chor was selected because it is the play most frequently cited, restaged, and analysed in existing criticism, and because its combination of episodic structure, direct audience address, and satirical treatment of institutional authority makes the mechanisms of political aesthetics discussed in this article unusually explicit and analytically tractable. The findings that follow are accordingly presented as a close, theoretically grounded reading of a paradigmatic case rather than as a generalisable claim about Indian folk theatre as a whole; extending or testing these findings against other practitioners, regions, and performance traditions is identified below as a direction for future research.

Source Selection and Interpretative Rigour

Primary and secondary material selection was not an exhaustive logic but was done in a purposive way as it is in a qualitative and interpretative design. The performance text of Charandas Chor was the primary textual source supplemented by published performances, publicly available recordings and documented performances of selected stagings of the play, which allowed for the cross-checking of textual analysis with aspects of the live performance not captured in the text, such as timing, audience response and staging choices. The secondary critical sources were chosen because they are directly engaged with Tanvir's theatre, experienced the theatre as part of their studies and research, and are relevant to the present study's specific theoretical interests in the field of political aesthetics, performance theory, and subaltern studies; sources limiting their engagement with folk theatre to general or distracting tangential comments were used solely to provide context for the present study. Methodological rigour in this interpretative design rests on triangulating these three source types — script, performance record, and secondary criticism — against one another, and on grounding each interpretative claim explicitly in the theoretical framework set out below, rather than on statistical sampling or inter-coder reliability measures appropriate to other qualitative traditions. This design choice, and the limits it places on the study's claims, is addressed further in the Limitations section.

Theoretical Framework: Political Aesthetics, Performance, and Subaltern Expression

The conceptual edifice of this study is supported by an interdisciplinary dialogue between political aesthetics, performance theory and subaltern studies. With this triangular perspective, folk theatre can be analysed not only in terms of its representational content, but in terms of its aesthetic form, too, as a site of political intervention. The framework used here does not treat politics as an extraneous add-on to performance, but rather sees aesthetics and politics as co-constitutive processes that affect perceptions, participations, and power dynamics.

Political Aesthetics and Political Theatre: A distinction that needs to be made

At the beginning, it is significant to differentiate the field of political aesthetics from the more common field of political theatre and/or of engaged theatre. In the traditional meaning, political theatre generally refers to theatre that has a distinct political message (whether in didactic form, agitational form, or direct engagement with a movement, cause or ideology) and is typically judged on the basis of either the clarity or impact of the political message. Political aesthetics, on the other hand, relies on either the absence of any political content or purpose. After Rancière, it is about how the very structuring of a performance, who can see, speak, and be seen and how the sensory experience is spread across the performers and the audience is an act in itself and not just part of the message the work is supposed to be conveying. This is not the same thing as didactic and programmatic folk theatre, however, because the political is not in the explicit critique that may be articulated through the play's dialogue, but rather in its openness to the stage and its rejection of spectator and the breaking down of the spectator–performer divide, in its use of communal and vernacular modes of storytelling. This distinction matters for the present study because it allows folk theatre to be read as political even where, as in much of Charandas Chor, the political charge is carried through humour, allegory, and performative form rather than overt ideological statement. The analysis that follows is therefore concerned less with classifying folk theatre as an instance of 'political theatre' in the conventional sense, and more with showing how its aesthetic organisation constitutes a distinctive form of political practice in Rancière's sense of the term.

Here the theme of 'political aesthetics' as expressed by Jacques Rancière offers an important starting point (Rancière). Rancière does not only speak of politics as an institutional management and a struggle of ideas, but also as a reorganization of the distribution of the sensible, namely the way that the power to see, speak and participate is distributed in a social order. This lens reveals that aesthetics is always politics and hence that all things are visible and audible in ways that shape which experiences are made visible and meaningful. In the context of theatre, political aesthetics emphasizes not only the ways in which the senses are framed by performance but also the ways in which cultural authority is distributed. Folk theatre reflects this redistribution through its performing practices. It challenges the proscenium theatre's austerity of order and ranking of performer/audience, allowing more 'spectatorship' to be included. Musical interludes, direct engagement and improvisation are hallmarks of the aesthetic openness of folk performance, which opens up room for the audience to engage and blurs the lines between cultural producers and consumers. In this way folk theatre performs a political aesthetics, which directly confronts the hegemonic regime of representation in elite theatrical form.

The embodied and processual nature of theatrical meaning can also be further enriched by the theory of performance. The influences of performance in scripted plays are also seen in the rehearsal, ritual and social interactions that make up the performance and the responses of its audience (Richard Schechner, Performance Studies, 2nd ed.). Theatre, from this vantage, is not a text but an event — one determined by social context and collective experience. Folk theatre, deeply rooted in community life, is a good example of this wider concept of performance. It is not defined by a strictly prescriptive text, but rather by repetition, variation, and interaction. This emphasis on embodiment is especially relevant in the discussion of folk theatre and political practice. Folk performers are usually from working-class or marginalised rural groups and carry a body history relevant to their performances. Movement, gesture, physical labour and experience become expressive tools through which meaning is communicated. Performance, then, can be seen as an inherently material form of knowledge — one that cannot be abstracted and that resonates directly with collective memory and ethical values. Folk theatre, in this respect, is a cultural system of knowledge production that undermines the privileging of written texts and elite cultural capital.

Subaltern studies constitutes the third salient strand of the theoretical framework, foregrounding questions of voice, agency and representation. Subaltern studies emerged as a criticism of elite historiography, aiming to recover means of expression that represent the viewpoints of voices absent from dominant histories. Although most attention has been paid to the history and politics of texts in this field, its insights have increasingly been extended to artistic domains such as theatre. Oral history and the collective authorship of folk performance provide a powerful means of expressing subaltern critique of society outside institutions of authority. The significance of subaltern theory for folk theatre concerns not only thematic representation but also performative structure.

Performance here is often collective rather than individual, challenging hierarchically based notions of artistic authority. These forms of collective production prioritise communal experience over individual authorship, generating what might be called a subaltern epistemology. Vernacular languages and local idioms further disrupt the hierarchy between standardised or colonial languages and local speech in cultural production. Even so, one must apply subaltern theory to theatre with care. Gayatri Chakravorty Spivak cautions against the romanticization of the language of the subaltern, or its unproblematic access to the voice of the oppressed. Tanvir's theatre is a case in point here. While he interacted with folk performers on a regular basis, Tanvir also held a mediating position in the realm of the folk culture as a trained playwright and director. In this way, the politics of his work is not a direct reflection of subaltern authenticity but it is a creation of performative moments where subaltern meaning can be performed. This tension between subaltern agency and elite mediation is not treated in this study as a flaw to be resolved but as a constitutive feature of the political aesthetics under analysis. Tanvir's theatre is read throughout not as a transparent conduit for subaltern voice, but as a site of negotiated agency, in which the creative contributions of rural and folk performers are real and consequential, yet always shaped by the institutional position, training, and authorial choices of a mediating director. Any claim in this article that folk theatre 'expresses' or 'gives voice to' subaltern experience should accordingly be understood in this qualified sense — as pointing to a structure that creates space for subaltern participation and meaning-making within a performance still authored and framed by a culturally privileged intermediary, rather than as a claim that subaltern performers speak entirely on their own terms.

Integrating the Three Perspectives

Rather than applying Rancière, Schechner, and Spivak as three separate or competing frameworks, this study treats them as complementary lenses operating at different, connected levels of analysis on the same performance material. Rancière's concept of the distribution of the sensible is used at the macro level, to ask how a given performance structures who may see, speak, and be heard within the theatrical event as a whole. Schechner's performance theory operates at the meso level, directing attention to the embodied, processual, and event-based qualities of a specific performance — rehearsal, repetition, audience reaction, and the material presence of performers' bodies — through which Rancière's redistribution is actually enacted moment to moment. Spivak's subaltern studies, finally, functions at the micro level and as a critical check on the other two: it is invoked at points where the analysis risks assuming that a redistribution of voice or an embodied event straightforwardly amounts to subaltern self-representation. In practice, each scene discussed in this article is read successively through these three lenses — first for its redistribution of visibility and voice, second for how that redistribution is embodied and enacted in performance, and third for the mediating role of Tanvir as director and playwright in shaping that enactment. It is not one final theory that is able to unite the political aesthetics, performance and subaltern expression in the study, but rather a layered procedure.

Conceptual Framework

Incorporating political aesthetics, performance theory and subaltern studies, this framework allows for an integrated study of folk theatre as a culturally and politically embedded practice. It conceptualises the link between folk theatre practices and their political meanings, as summarised in Figure 1. In folk theatre performance, oral stories, music, satire and vernacular language are the elements that inspire participation. The use of improvisation, audience participation and open staging together creates a political aesthetic that shifts visibility and voice in the theatre, thereby turning folk theatre into a tool for cultural resistance, subaltern expression, aesthetic form and social/political communication. The framework enables the study to explore the aesthetics of social reorganisation, the performance of aesthetics, and the way that aesthetics perform social relationships, and it draws on embodied knowledge and experience to examine how subaltern agency is negotiated in theatrical production. This interdisciplinary approach places folk theatre in dialogue with discussions in the humanities and social sciences that transcend the rigid disciplinary boundaries of culture, power, and representation. Folk theatre, in this context, is defined as a political aesthetic that constantly challenges dominant cultural hierarchies while remaining part of everyday social experience. Its political force lies not only in explicit ideological messages but also in its capacity to reconfigure the sensory. The embodied and spatial dimensions of performance, as well as its participatory aspects, engage with

current debates on alternative modernities and cultural function, and the practices participate in the mediation of political consciousness.

Folk Theatre in Modern India: Historical Context and Cultural Politics

In India, folk theatre has been in service of the community, weaving together performances, ritual and social message into the fabric of everyday culture. Folk performance practices were the main and primary means of storytelling, teaching and collective reflection before theatre was institutionalised through the colonial and postcolonial infrastructures. These forms developed in local contexts of language, culture and economic circumstances, building on oral narratives, mythological episodes and local histories. Folk theatre is, however, never just an aesthetic tradition, but is always a reflection of the social relations and structures that mould community life. Colonial modernity marked a significant change in the cultural environment that gave birth to folk theatre. British colonial policies privileged western literary and theatrical styles which were proscenium theatre and realist dramaturgy. The proscenium theatre and folk theatre performance traditions differ from each other in space: while western theatrical architecture has a strict distinction between stage and audience, this is not seen in indigenous theatre (refer to Figure 2). Figure 2 focuses on the essential spatial difference between proscenium theatre and folk performance traditions. Proscenium theatre creates a clear demarcation of the stage from the audience through its architectural structure, creating a demarcation of passive viewing.

In contrast, folk theatre is usually found in open and semi-circular spaces under similar conditions of actor, musician and audience. This creates an opportunity to improvise, engage directly with an audience and to share together, all of which are important within indigenous performance styles. This contrast is drawn from established comparative scholarship on Indian theatre history (Dharwadker, *Theatres of Independence* and "Rethinking Modern Indian Theatre"; Bharucha) and is presented here as a broad structural pattern documented across multiple folk and proscenium traditions, rather than as a claim verified through the authors' own comparative fieldwork on specific productions; considerable local variation within both proscenium and folk practice should be assumed, and Figure 2 should be read as a schematic illustration of a general tendency rather than a description of any single, fixed staging arrangement. While the proscenium stage physically separates performers from the audience, folk theatre uses an open, interactive performance space that draws the audience into participation. Indigenous performance practices were sometimes called primitive or unsystematic and confined to folklore and not seen as a form of theatre. It not only marginalised folk theatre but has also reoriented indigenous notions of value in performance and established a binary distinction between "traditional" and "modern" performance which has continued to dominate the conversation in the field of theatre.

However, folk theatre proved to be a strong cultural practice, adjusting both its forms and themes to the evolving of the social reality under these pressures. Other traditions were reduced due to urbanisation and the presence of mass media, and other traditions were added, combining the issues of politics with the content of their tales. The themes of the village songs included exploitation of land, oppression of caste, inequality of gender/domination by the state, and they appealed to people through satire, allegories and humour. This is a quality that is independent and reveals the real political value of folk theatre as a living cultural heritage, rather than a cultural monument. With the attainment of independent India, folk theatre has once again gained attention and artists and intellectuals have presented a cultural modernity. Folk forms became more popular among theatre practitioners as a response to global modernism, which homogenized colonial cultural heritage. It was not only a question of aesthetics, but also a political act; both to democratize theatre and to create a connection with 'social reality'. Folk theatre was made accessible, participatory, and vernacular, as an alternate to elite performance spaces in the city. The use of folk theatre within the modern was, however, complex and raised difficult questions of representation and cultural authority. Folk forms have been stigmatized by critics who have warned against the romanticization of "folklore" and against its appropriation by high-culture artists and critics who are not part of the communities that preserve these traditions. Debates on the role of folk theatre in contemporary India continue to be held while maintaining the balance between preservation and transformation.

Institutionalization has been beneficial in recording and articulating folk performance, as well as in its promotion, but it has also threatened to deposit these performances outside their social contexts, thereby transforming them into aesthetic commodities instead of political means of expression. Folk theatre remains an important arena of cultural politics, despite these difficulties. It places strong importance on the formation of a collective story, and the use of moral discourse allows it to touch upon local issues in ways that are meaningful to local people. Folk theatre emphasizes interaction and improvisation in performance, unlike literary drama, which is scripted and based on the authority of the text. The open and performative nature of folk theatre gives it the ability to react dynamically to politics, and thus constitutes a powerful instrument for social critique. Cultural politics is also visible in the language of folk theatre.

Folk performance uses vernacular language(s) and dialects that challenge the hegemony of standardised or colonial languages in cultural production. Language becomes an aesthetic and/or political choice to affirm local identity and combat cultural exclusion. This linguistic dimension underlines the role of folk theatre as a means of public discourse, with its impact on people who do not belong to the elites of cultural institutions. Folk theatre of today has a peculiar place in the context of a modern India, where it is honoured as a cultural heritage but remains ignored in mainstream art hierarchies. This paradox is embedded in larger discussions of postcolonial cultural politics and the representational value given to indigenous cultural forms, when they are at the same time marginalised in many practices of cultural legitimation. This study infuses folk theatre into these tensions, as an enduring presence and reminder of its importance as a nexus where culture, politics, and aesthetics intersect. Such an understanding of folk theatre in this historical and political context is essential to the understanding of its contemporary expressions. The practice of theatre artists such as Habib Tanvir needs to be understood in this terrain of cultural negotiation, where folk aesthetics serve as a platform of art, as well as a platform of contestation of dominant narratives. As a form of intermediate between tradition and modernity, between community and institution folk theatre could be a powerful political aesthetic in the contemporary performance in India.

Habib Tanvir and Folk Performance as Political Practice

Habib Tanvir's work in modern Indian theatre is unique not only because of his intense allegiance to the genre of folk performance as a political medium but also because of his indomitable will to work consistently and virtuously across every medium he engaged with. Tanvir's theatrical philosophy, however, was based on a desire to shift the balance of control in culture and to de-centre it, in ways that saw folk elements used not as stylistic flourishes but as a means of challenging traditional hierarchies of perception, community and power. His theatre was born of an overt opposition to the hegemony of the standard models and a deliberate choice of indigenous style, actors, and languages. In this context, Tanvir's work is a practical reflection of political aesthetics, and not merely thematic and political.

Scene-Level Analysis

The folk aesthetic is particularly noticeable in Charandas Chor, as in the opening scene, Charandas doesn't have to explain the events of the play by dialogue; he directly addresses the audience. The Chhattisgarhi Nacha style in which the narration is carried out through songs, rhythmic narration and funny exchange between the actors and the spectators is used here. The actor keeps grabbing the attention of the audience by breaking the fourth wall, making them feel that they are directly in front of him, and stirring laughter and reactions in the audience. This erodes the space between an audience and an actor and makes the stage into a "space of doing" and a "space of telling" in the collective sense, emphasising the community aspect of the performance over passive watching. An important event that also occurs in the play's episodic interactions with various individuals of institutional power — kings, religious leaders, and state officials — is the king's condemnations of Charandas' prosecution and his agreement to leave the girl, after he is shot, with her father. Another significant event the king's condemnations of Charandas' prosecution and his agreement to leave the girl one of the most popular scenes, in which Charandas resists authority from the royal court when it attempts to convict him of sin, illustrates the fact that he takes his vows to his guru seriously. The episode is performed by means of the exaggerated gesture, comic timing and musical interlude, which are typical to folk theatre. A satirical exaggeration of authority figures, who appear in elaborate costumes, in exaggerated voice

and come in and out with dramatic flourishes, whereas Charandas is always dressed plainly, thus embodying his moral purity and his "marginalisation". This contrast, then, is a theatrical rebuke to institutional hypocrisy, which is expressed through the humorously ironic speak and the folk tradition of the narrative form, and that political critique is therefore accessible and culturally resonant, allowing the audience to hear the ethical contradictions in systems of power.

Performance Space, Costume, and Visual Aesthetics

The visual structuring of the performance space of Charandas Chor is strengthening the folk aspect of Tanvir's theatre. Typically, proscenium productions use elaborate sets and sets that give the illusion of realism, whereas Tanvir's productions use a relatively clear and flexible performance space. The setting has performers and audience members in close proximity, which helps to promote the participatory interaction and collective engagement of the performance environment (see Figure 3). The staging in the image is seen in various Indian folk theatre traditions where the performance takes place in an open space, and where there is no proscenium arch, allowing actors, musicians and audience to merge, with audience members participating actively, freely improvising, and interacting directly with performers. The space is also at once politically accessible and participatory, contrasting urban theatre, which keeps actors and audience separated. The stage is usually designed open plan to enable the actors to roam around, but still be in visual proximity to the audience, which corresponds to the spatial arrangement of village folk performances. Everything is intentionally made simple and sometimes there is a lack of stage props such as stools, and there can be a few cloth backdrops or symbolic props that indicate a place without necessarily depicting it realistically. Costumes are also a reflection of the aesthetic logic of folk theatre.

The elements of traditional costume are generally worn by the performers indicating the rural cultural context and the exaggerated or decorative costume normally worn by the elements of authority stresses and satirizes the social status. Important visual elements of the creating performance environment to use music and movement. Live musicians on stage provide rhythm and ensure an open involvement of the performers and the audience. Both the visual and spatial elements reinforce the political tone of accessibility and communal engagement, over illusionistic realism, creating an environment of presence and involvement in the performance. Tanvir's theatrical practice is a 'disruption' of professionalism and authorship in theatre. He has long collaborated with non-professional actors from rural and tribal communities, thus defying the traditional formal training and institutional affiliation. They carried their knowledge, experience, and oral history and tradition of communal work with them. Their presence changed the way performance functioned as a space in which marginalised identities were not only represented but also produced. In this respect, it shares much with the participatory component of folk theatre, in which action and social context stand in close relationship with collective memory. The subject matter and aesthetic organization of Tanvir's theatre are not the only political values of his work. His incorporation of folk forms like Nacha and other indigenous performance practices gave him the means to tell a story in ways that defied linear plot and psychological realism. Rather, Tanvir frequently used episodic narrative, musical interludes, satire and direct address to the audience to structure his plays. These aesthetic strategies questioned the passive spectator and invited audiences to be critical of the ethical and political issues raised by the performance.

Tanvir foregrounded performance as an event, and therefore saw theatre as a space of dialogue and reflection. One of the most compelling examples of Tanvir's work in the field of folk performance as political practice is Charandas Chor. The play follows the structure of a moral allegory centered on the theme of resistance to authority, honesty and integrity, and is inspired by folk traditions. Charandas is not a conventional character: a thief who stands by his ideals and principles, revealing through his own moral rectitude the institutional figures of corruption and hypocrisy around him. The play examines, through humorous, ironic and musical commentary, mechanisms of government that pursue their own interests over their ethical responsibilities. The political power of Charandas Chor runs in the wake of its folk aesthetics. The episodic structure of the play provides an opportunity for a series of encounters in which Charandas's values are tested by those who represent religious power, political power and legal power. There is no neat resolution to these encounters, but rather a tension that leaves the audience to grapple with the paradoxes contained within social institutions. Music and chorus dramatize the communal nature of the story, making the

actions of individuals part of a larger moral community. Importantly, though, the play is not didactic; it remains within the realm of folk humour and performance energy that bears the political critique. Satire is an incredibly effective weapon to make the absurdity of power visible, without turning to force, ideology. Through this, the piece is both easy to understand and a politically charged statement with potential for a wide range of social groups to get involved. Folk theatre, then, enhances its moral and political message by the aesthetic appreciation of this art form. Tanvir's work in folk theatre also introduces a consideration of mediation and representation.

As a self-trained playwright and director, Tanvir had a position of cultural authority as he might have given rise to a hierarchical relationship. His idea of collaboration, however, and his regard for the improvisation of folk performers makes for a more complicated tale of appropriation. Tanvir did not always dictate the script itself, but sometimes allowed for dynamic change and improvisation during rehearsal and interaction, providing an opportunity for actors to be creative. This also points to the political elements of a collective art rather than an authored one, folk theatre. In order to understand the political practice of Tanvir's theatre, it needs to be viewed in the broader framework of a multi-layered cultural resistance to the postcolonial period. Reflecting his interest in native aesthetics and marginal voices, he shattered the cycle of dominant discourses of modernity that had represented progress in terms of westernisation. In Tanvir's approach, the potential of folk theatre was harnessed to voice alternative modernities grounded in ethical, ethnic and social principles. This amounts to a reconfiguration of modern theatre that foregrounds the potential of folk performance as a counter-hegemonic cultural form. Through his continued engagement with folk theatre, Tanvir demonstrated that political engagement in theatre need not proceed through explicit ideological messaging. Rather, political significance can be Effected through aesthetic decisions that shape the conditions of representation and participation. His work stands as testimony to the political nature of folk theatre: it makes performance a site for the enactment of cultural resistance and subaltern expression through a collective art.

Discussion: Folk Theatre as Cultural Resistance and Political Communication

The above analysis shows that folk theatre in contemporary India exists as an art form, but also as a means of communicating politics within the context of everyday society. Under the lens of political aesthetics, folk performance is revealed as a political practice that actively negotiates power and reconfigures visibility, voice and participation. It is not so much a statement of ideology as the artful arrangement of the performance itself, allowing other methods of perceiving and engaging with social reality. It should be stressed that this 'redistribution' of visibility, voice, and participation is identified here at the level of performance structure and design — features such as open staging, direct audience address, and collective authorship that are built into how a piece such as Charandas Chor is organised and enacted — rather than demonstrated as a measured outcome in the consciousness or behaviour of any specific audience; establishing the latter would require dedicated audience-reception research of the kind this qualitative, textually grounded study does not undertake, and is discussed further in the Limitations section. A major contribution of this research is the definition of folk theatre as a form of cultural resistance at an aesthetic level. In contrast to institutionalised theatre, which frequently relies on text-based authority and professionalised production, folk theatre emphasises collective creation and embodied performance. This structural difference carries important political connotations.

Folk theatre is an art form that functions outside hierarchical cultural industries, giving a voice to the marginalized, the poor, and the less educated. It thus counters dominant cultures of legibility that marginalized rural and subaltern cultures within the past from mainstream artistic domain. The relationship between folk theatre and space and audience is also an instance of folk theatre's struggle against cultural hegemony. In performance, the spatial zone between performers and spectators can be traversed with ease; the space is not made up of a theatre but rather an open space, where one can become a part of the performance. This spatial openness encourages a participatory mode of engagement, one in which the audience is not a mere receiver but a participant in the meaning-making activity of the performance event. Such interaction makes theatre a dialogic act, reflecting a democratic mode of communication in which collective reflection on ethical and political issues can take place. In this view, folk theatre is a form of public pedagogy that shifts the emphasis from teaching to learning, having people learn from one another.

The example of Habib Tanvir's theatre illustrates how folk performance can be understood as a counter-hegemonic practice within modern cultural institutions. In this way, Tanvir combined folk aesthetics with modern theatre, not merely preserving traditional forms but revitalising them as instruments of political criticism. His work also shows that resistance can take the form of a non-oppositional aesthetics, one in which the relationship between culture and power is reoriented rather than confronted head-on. The moral aspect of the plays such as Charandas Chor exemplifies the expression of political values in folk theatre not in the manner of didactic exposition, but through the use of narrative allegory and acting energy. The most important aspect is that the message of the folk theatre relates to morals instead of ideology in politics. Folk stories are about issues of honesty, justice and social responsibility; and political criticism is framed within the ethical framework of everyday life. This moral basis renders folk theatre more accessible and more emotionally evocative to its viewers, and enables them to participate in political issues in a cultural way that they understand. In this regard, folk theatre is also a link between personal morality and collective politics; abstract power relations become tangible and relatable.

There is also an argument for relevance of the folk theatre in the social sciences in the context of ongoing debates on communication, agency and representation. Folk theatre is a form of performing arts which displays a way of political discourse other than text and institutional mediated communication. Affect and communal participation pose challenges for rational deliberation and formal communication models of political communication. Folk theatre foregrounds theatre as communication, transcending the type of political communication being analyzed, to include more sensory and affective meanings. At the same time, the study takes into account the fragilities and complexities of folk theatre's political agenda. Representing folk, questions of authority emerge when folk is performed by trained folk people through folk institutions or state sponsored platforms. Folk theatre can take the voice of the oppressed, but can also be appropriated or aestheticized to the point of losing its political power. This understanding of these tensions is crucial to not romanticize folk performance, but also to situate it in its wider context, of cultural power. Despite this, the existence of folk theatre, especially as it remains vibrant today, suggests that it remains a form of cultural resistance in today's postcolonial societies. It is versatile enough to reflect social change and to respond to social issues of the day whilst being rooted in social tradition. Folk theatre provides one way to cultural engagement without the dominance, but with a focus on participation, vernacular expression and moral critique. Folk theatre is discussed as important tool for humanities and social sciences scholarship from an interdisciplinary point of view and explains folk theatre as political aesthetics. It is necessary to keep in mind that folk theatre is a theatre of power and that cultural practices are not passive, but active, places of meaning in society. This study adds to the body of literature on the role of culture in political consciousness and resistance outside formal institutions.

Contemporary Relevance of Folk Theatre in the Digital Era

Folk theatre's political significance is not necessarily confined to the past; it may extend, in emerging and still under-documented ways, into the socio-political conditions shaped by digital communication and globalised media today. Existing scholarship on related performance traditions — for instance, work on the digital and touristic reconfiguration of Kalbeliya dance (Ranwa and Thapar-Björkert) and on the media dynamics of contemporary performing arts more broadly (Azcárate and Martínez-Falero) — suggests that grassroots cultural practices increasingly intersect with platforms such as social media, community video, and digital archiving, and that folk and traditional performance groups across South Asia continue to draw on performance to engage with issues such as environmental justice, labour rights, gender equality, and rural governance. This section should be read as pointing to a broader trend supported by adjacent scholarship, rather than as an empirical claim grounded in case studies of specific digital folk-theatre performances, which this study's conceptual and qualitative design does not undertake. Systematic case-study or platform-based research on named folk theatre groups, digital campaigns, or online audiences would be needed to substantiate the extent and character of this shift, and is proposed below as a priority for future research. Where such digital circulation does occur, it plausibly extends the reach of folk aesthetics beyond local audiences while retaining their community-oriented character, positioning folk theatre as a hybrid communicative form bridging traditional cultural expression and contemporary political activism — a possibility this article raises for further investigation rather than treats as an established finding.

CONCLUSION

Folk Theatre and the Politics of Aesthetic Resistance

The focus of this study has been the Indian Folk theatre as a political aesthetics in the context of culture, power, performance and social discussion. This research has not only focused on folk theatre as a preservative for traditional cultural forms but has also looked at the aesthetic organisation of the folk theatre as an alternative to the production and communication of political meaning. The analysis reveals that, beyond their social or political content, the political relevance of folk theatre does not just relate to the social or political themes within a performance, but also to the manner in which they organise visibility, participation, embodiment, language, relationships between performers and spectators in the act of performance. The separation between political aesthetics and political theatre is a key one in this argument. Political theatre can be used to express an overt political stance by its content and message, or by the way the content and message are organised, such as in the organisation of the performance itself and in the manner of the sensory experience, its visibility, voice, and participation. This view uncovers the politics of folk theater through techniques of vernacular expression, open staging, direct address of the audience, music, improvisation, satire, and collective performance. Such practices can challenge and disrupt traditional dichotomies between performer and spectator, as well as between cultural producer and cultural consumer, and hence provide other conditions for the articulation and negotiation of political meaning.

The case of Habib Tanvir's theatrical practice and especially of Charandas Chor is a fruitful one to look upon. Tanvir has consistently carried on the rich tradition of Chhattisgarhi folk arts, which introduced the possibilities of folk aesthetics being used in modern Indian Theatre without its being limited to mere decorative or nostalgic elements. The episodic organization, musicality, humor, address to the audience, and institutional satire, all the more so than through the overt exposition of ideas about politics, are a signal of how political critique might function without being formalistic or normative discourse. The case thus demonstrates the possibilities of mobilizing folk performance practices to engage with dominant cultural hierarchies and notions of theatrical authority. The contribution of Rancière, Schechner and Spivak has thus allowed this study to examine the process from various complementary angles. Rancière's work enables us to consider the visibility, voice and participation of actors in performance; Schechner's account emphasizes the embodied, spatial and eventful nature of theatrical practice; and Spivak outfits a suitable critical vocabulary for the study of questions of mediation, representation, and subaltern agency. Combining these points of view, it can be said that folk theatre is not a univocal aesthetic tradition and is not an inherent emancipatory form. Its political significance is generated through the mediation of performance form, cultural context, participation and structures of participation.

There is further complexity in this relationship which can be seen in the work of Tanvir. His work with rural and folk artists established significant opportunities for the embodied knowledge and performance practices of the rural and folk cultures, but his own background as a trained playwright and director also meant that his work and interactions with both communities was mediated. The political potential of folk theatre thus can not be confused with a voice of the subaltern, one that remains unmediated and wholly independent. Rather, the analysis comprehends the negotiation of subaltern expression in specific fields of authorship, performance, cultural authority and institutional mediation. In order to not romanticize folk theatre, while respecting its potential to challenge prevailing aesthetic and cultural values. The study thus proposes and conceptualises what folk theatre is, as a political aesthetic, on a level of performance form and practice. The analysis argues that some elements of the aesthetic—open staging, vernacular language, direct address, collective performance, or embodied participation, for example—can help set up situations in which other political meanings and modes of cultural expression are possible. The argument is therefore not about the impact or actual performance results on an audience but how performance forms the possibilities of politics. This is important as the present research is not ethnographic or based on audience-reception research but on textual interpretation, performance analysis, and secondary sources.

Thus, the results presented here must be considered to be a theorized account of a paradigmatic case of Indian folk theatre rather than a generalizable account of all Indian folk theatre. The study doesn't assert that the aesthetic strategies highlighted in Charandas Chor always generate an impact on political consciousness, behaviour, or agency of audiences. Instead it illustrates the capacity of the folk theatrical form to shape an arena in which the experiences of power, ethical domain, hierarchy, culture and opposition may be played, experienced, and negotiated. This difference further heightens the importance to recognize cultural resistance as a contingent and mediated process, not something automatic that derives from being involved in a folk performance. Folk theatre therefore continues to be an important tool for the study of modern Indian performance, by challenging the rigid demarcations between tradition and modernity, aesthetics and politics, between performer and spectator, between the preservation of culture and its transformation. Its continued relevance is that it is a system of performance practices that can evolve according to the social and cultural environment in which it operates and yet maintain its vernacular, embodied, and communal aspects that make the practices meaningful. Audience-reception research, ethnographic fieldwork, oral history with performers, comparative studies of regions, and specific digital-era performances would aid in the determination of the political possibilities identified in this study. Such studies can further develop the current conceptual discussion because they offer empirical data with regard to the connection between folk performance, cultural resistance and political involvement.

Limitations

This study is conceptual and qualitative in design, and several limitations follow directly from that choice of method; these should be kept in view when assessing its claims. First, the analysis is based on textual, performative, and secondary-source material rather than on field-based ethnography or audience research. It is therefore not able to demonstrate empirically how audiences actually receive, interpret, or are affected by the performances discussed. Claims made in this article about the redistribution of voice, visibility, and participation describe structural and textual features of performance — such as direct audience address, open staging, and episodic dramaturgy — that plausibly enable a particular kind of audience engagement, rather than measured evidence that such engagement, or any resulting shift in political consciousness or subaltern agency, actually occurs among specific audiences. Establishing the latter would require dedicated audience-reception research, which lies outside the scope of this study.

Second, the study's focus on Habib Tanvir and Charandas Chor, justified in the Methodology as an instrumental case selection, means its findings should not be extrapolated to Indian folk theatre as a whole without further comparative research across other practitioners, regions, and performance traditions. Third, while the study addresses the tension between subaltern agency and elite mediation directly within its theoretical framework, it cannot, given its reliance on secondary and textual sources rather than direct engagement with folk performers themselves, fully adjudicate how the performers involved in Tanvir's productions understood their own agency and authorship. This is an open question that can be answered by either oral history or participatory research methods with performers or performer communities. Fourth, as indicated above, statements about folk theatre practice in the present and the digital era provide an indicative account based on related scholarship rather than a case-study account. In sum, therefore, the core arguments of the study must be understood as a theoretically informed account of "how" folk theatre's aesthetic form can be structured to create conditions that facilitate political meaning-making, cultural resistance, and subaltern expression (i.e., "how" it is designed and possible; not "how" it is actually performed in consciousness or "how" it is actually lived in reality).

Future Work

Further investigation might investigate ethnographic fieldwork, audience-reception analysis, and oral history of folk performers and comparative analysis of multiple practitioners and folk theatre traditions to test and expand the theoretical argument made here. Specific case studies, e.g. on individual groups, platforms or campaigns, would also support the trends discussed in the section on the digital era, as would be discussed in this section on a specific case study.

ABSTRACT

Polysaccharides are naturally occurring macromolecules with remarkable physiochemical properties and bioactivities, making them highly suitable for drug delivery applications. Nanoengineered polysaccharides have gained significant attention facilitating their use in nanoengineering for drug encapsulation and controlled release. This review explores the role of polysaccharide-based nanoparticles in sustained drug delivery focusing on synthesis and encapsulation. Finally, we examine future perspectives and challenges in translating these nanoengineered polysaccharide system into clinical applications, particularly in the realm of precision medicine and next-generation biomedical applications.

Keywords: Bioactive molecules, Controlled drug release, Drug delivery systems, Nanoengineered polysaccharides, Nanoparticles.

INTRODUCTION

Polysaccharides hold a pivotal role in biomedical sciences due to their diverse therapeutic and functional attributes. These naturally occurring macromolecules, ubiquitous across living systems, exhibit remarkable bioactivity. Their versatility extends to serving as demulcents, constituents of drug formulations, advanced dental biomaterials, hemostatic agents, excipients in dusting powders, and therapeutic interventions for mild gastrointestinal ailments[1]. Furthermore, polysaccharides demonstrate exceptional potential as plasma substitutes and anticoagulants, both in liquid formulations and as bioactive surface coatings on artificial implants[2].Beyond their fundamental structural and energy-storing roles in biological systems, polysaccharides are increasingly recognized for their extensive pharmacological and biomedical benefits. These biopolymers exhibit a spectrum of bioactivities, including antitumor, immune modulatory, antimicrobial, antioxidant, anticoagulant, antidiabetic, antiviral, and hypoglycemic effects, making them highly desirable in modern therapeutic advancements[3]. Nano-engineering polysaccharides have seen increasing attention and development in the last decade for use in controlled drug delivery. In this context, polysaccharide-based carriers, such as nanoparticles, nanogels, nanofibers, nanocomposites, and other nano-formats, are being developed and designed for encapsulation, protection, and controlled delivery of therapeutic molecules[4]. The versatility of polysaccharides also allows for stimuli-responsive behavior — e.g., pH-sensitive polysaccharide formulations for the intestinal tract or tumour microenvironment (pH ~6.5), enzyme-responsive degradation (e.g., hyaluronidase in the tumour extracellular matrix) or redox-responsive sulphur linkages in intracellular compartments — that further fine-tunes controlled release and targeting capabilities. Given these characteristics, nanoengineered polysaccharide-based systems represent a promising route towards improved therapeutic outcomes. Their use is expected to lead to increased bioavailability, reduced dosing frequency, lower systemic toxicity, and improved patient compliance[5]. However, several challenges still need to be addressed for clinical translation, including scalability of manufacturing, regulatory compliance of nanomaterials, reproducible physicochemical characterization, long-term safety and biodistribution studies.

Polysaccharides and their Advantages in Drug Delivery Systems

Polysaccharides have garnered significant attention in drug delivery due to their inherent biocompatibility, biodegradability[6,7], and tunable physicochemical properties. Their ability to form hydrogels, nanoparticles, and other advanced delivery matrices enables control drug release, enhanced stability, bioavailability, and therapeutic efficacy [8](Figure1). Furthermore, chemical modification of polysaccharides can improve solubility, target specificity, and drug-loading capacity, while their natural origin, ease of production, and environmental compatibility make them cost-effective and sustainable carriers for pharmaceutical applications. The physicochemical properties of polysaccharides strongly influence their suitability for nanoengineered drug-delivery systems. Chitosan provides high drug-loading potential and excellent mucoadhesion, whereas alginate is particularly advantageous for hydrogel formation and sustained release through ionic crosslinking. Starch offers biodegradability and structural flexibility but generally requires modification to optimize drug loading and release. Hyaluronic acid combines high biocompatibility with opportunities for receptor-mediated targeting, while pectin provides useful pH and enzyme-responsive behavior for site-specific delivery. Importantly, molecular weight, charge density, hydrophilicity, and crosslinking degree can alter nanoparticle size, encapsulation efficiency, degradation, and release kinetics. Thus selection of a polysaccharide should be based on the therapeutic molecule and the desired release and targeting profile rather than on biocompatibility alone (Table 1).

Nanoengineering Strategies for Polysaccharide-Based Drug Delivery

Several fabrication techniques are employed to develop polysaccharide-based nanoparticles with controlled size, drug encapsulation, stability, and release characteristics including:

- **Nanoparticle Fabrication:** Polysaccharide nanoparticles are generated by techniques such as emulsification that facilitate drug encapsulation and controlled drug release profiles[9,10].
- **Hybrid Polymer Systems:** Polysaccharides are often combined with synthetic or natural polymers using methods like grafting, enhancing nanoparticle stability and drug release characteristics[9,11].

- **Controlled Drug Release Approaches:** Factors such as swelling dynamics, crosslinking density, and drug-polymer interactions are optimized to achieve precise and sustained release profiles. Prediction of drug release behavior can still be made with computational modeling, which helps formulation design be an efficient process[9,12].
- **Ionic Gelation** is widely used for polymers such as chitosan, where electrostatic interactions between the positively charged polymer and multivalent anions produce nanoparticles under mild conditions [19,25,33].
- **Nanoprecipitation** involves controlled mixing of polymer and drug solutions with a non-solvent, leading to rapid polymer precipitation and formation of nanosized carriers [13-15,25].
- **Self-Assembly** exploits on-covalent interactions such as hydrophobic, electrostatic, and hydrogen-bonding interactions to spontaneously organize modified polysaccharides into nanoparticles or nanostructures [13-15,25].
- **Microfluidic-assisted Fabrication** provides precise and rapid mixing of polymer and drug streams, allowing better control over nanoparticle size, polydispersity, and reproducibility [21,33].

In addition, emulsification and hybrid polymer approaches can be used to improve drug encapsulation, nanoparticle stability, and release characteristics [9,10,11,25].

The selection of fabrication method depends on polysaccharide characteristics, drug properties, desired particle size, encapsulation efficiency, and required release profile.

Molecular Engineering Approaches for Nanoengineered Polysaccharides

Molecular engineering of polysaccharide provides a rational approach to tune nanoparticle characteristics by modifying the molecular weight, functional groups, charge density, hydrophilic-hydrophobic balance, and crosslinking (Table 2). These modifications influence polymer chain interactions, nanoparticle formation, drug-polymer affinity, and ultimately drug-loading and release behavior (13,22,25,40). Molecular-weight and functional-group modification can regulate polymer chain entanglement, solubility, surface charge, and nanoparticle size. In chitosan, molecular weight and degree of deacetylation influence particle formation, drug loading, stability, and release kinetics. Chemical modification such as carboxymethylation, sulfation, acetylation, or phosphorylation further alters charge and hydrophilicity, thereby modifying drug-polymer interactions and release rate. Hydrophobic modification and polymer grafting introduce hydrophobic domains or additional polymer chains, promoting self-assembly and improving the encapsulation of poorly water-soluble dugs. Grafting hydrophilic polymers such as PEG can reduce aggregation and enhance colloidal stability, although excessive modification may increase particle size or reduce drug-loading efficiency (9,11,34). Crosslinking and stimuli-responsive engineering provide further control over nanoparticle structure and drug release. Increasing crosslinking density generally produces more compact and stable nanoparticles, reduces drug leakage, and prolongs release, whereas lower crosslinking facilitates faster diffusion (21,22,40). Overall, molecular engineering enables simultaneous tuning of nanoparticle size, drug-loading capacity, stability, and release kinetics. However, these parameters are independent; therefore, the degree of modification, polymer molecular weight, crosslinking density, and fabrication conditions must be optimized according to the properties of the therapeutic agent and the intended delivery route.

Principles and Kinetics of Drug Release: A Brief Overview

Mathematical Models of Drug-Release Kinetics

Quantitative description of drug release from nanoengineered polysaccharide carriers relies on fitting *in vitro* release data to established mathematical models, each of which reflects a different underlying release mechanism. The zero-order model (Qt = Q0 + K0t) describes release that is independent of drug concentration, i.e., a constant amount of drug is released per unit time. It is the ideal profile for maintaining steady plasma drug levels and is approached by non-eroding reservoir-type polysaccharide nanocapsules with a rate-limiting membrane [45]. The first-order model (log Qt = log Q0 - K1t/2.303) applies when the release rate is proportional to the remaining drug concentration within the carrier, as is often seen in porous polysaccharide matrices where the diffusional path length increases as drug is depleted [45]. The Higuchi model (Qt = KH t1/2), originally derived for planar matrix systems, describes release that is proportional to the square root of time and is frequently used as a first approximation for diffusion-controlled release from homogeneous, swellable polysaccharide matrices such as alginate and pectin hydrogels [41,42]. The Korsmeyer-Peppas (power-law) model (Mt/M-inf = K t^n), applied to the first ~60% of cumulative release, is

particularly informative for polysaccharide nanocarriers because it explicitly separates diffusion from polymer relaxation/erosion through the release exponent n: for spherical nanoparticles, n <= 0.43 indicates Fickian (diffusion-controlled) release, 0.43 < n < 0.85 indicates anomalous (non-Fickian) transport reflecting simultaneous diffusion and swelling/erosion, and n >= 0.85 indicates Case-II transport dominated by polymer chain relaxation [43,44]. Because many polysaccharide carriers (chitosan, alginate, hyaluronic acid, pectin) are hydrophilic and swell on hydration, release from these systems is very often best described by the Korsmeyer-Peppas or Higuchi models rather than simple zero- or first-order kinetics, and several studies on chitosan and alginate-based nanoparticles have reported n values in the anomalous-transport range, confirming that both diffusion through the swollen polymer network and gradual matrix erosion jointly govern drug release [21,43,44]. However, the process of drug release from encapsulating matrices is a complex phenomenon governed by multiple factors, including the chemical composition and structural characteristics of the matrix (e.g. porosity and gelatin state), physiological conditions (e.g. pH and enzymatic activity), and external stimuli such as temperature. Different drug release kinetics can be achieved, including sustained first- or zero-order release, an initial burst followed by controlled release, and pulsatile delivery, depending on the therapeutic requirements[13–15].

Mechanisms of Controlled Drug Release

Controlled drug release occurs through several mechanisms, primarily diffusion, degradation, and stimuli-responsive processes (Figure 2). In diffusion-controlled systems, drug molecules migrate from a high-concentration region within the polymeric carrier to the surrounding physiological environment, with the release rate influenced by polymer properties, drug size and solubility, pH, and temperature, as described by Fick's low [16]. Degradation-controlled release involves hydrolysis or enzymatic breakdown of biodegradable carriers such as PLA, PGA, and their copolymers, with degradation rate and drug stability determination the release kinetics [17]. In stimuli-responsive systems, changes in pH, temperature, redox potential, or enzymatic activity trigger structural or physicochemical changes in the carrier, enabling on-demand or site-specific drug release [17-20].

Factors Influencing Drug Release from Nanoengineered Polysaccharides

Drug release from nanoengineered polysaccharide-based delivery systems is governed by a complex interplay of formulation, physicochemical, and environmental factors. These parameters influence drug loading, diffusion, matrix degradation, swelling behavior, and interactions between the drug and polymeric carrier, thereby determining the overall release profile and therapeutic performance. Understanding and optimizing these factors is essential for achieving controlled, sustained, and site-specific drug delivery.Many critical parameters control the drug release from nanoengineered polysaccharide-basedsystems are summarized in Table 3:

Applications of Nanoengineered Polysaccharides in Controlled Drug Release

Nanoengineered polysaccharides have emerged as versatile materials for the development of controlled and targeted drug delivery systems due to their biocompatibility, biodegradability, mucoadhesive properties and ability to be modified. Their structural tunability also enables site-specific delivery and sustained release of therapeutic agents, thereby enhancing therapeutic efficacy while potentially reducing systemic toxicity. Table 4 summarises the major applications of nanoengineered polysaccharides in controlled and targeted drug delivery.

DISCUSSION

The advancements in nanoengineered polysaccharides have revolutionized the field of controlled drug delivery, demonstrating exceptional promise in enhancing therapeutic efficacy, minimizing systemic toxicity, and improving patient compliance. The ability of polysaccharides to form biocompatible and biodegradable nano scale carriers enables precise drug encapsulation and controlled release tailored to specific medical needs[6]. The major highlight of nanoengineered polysaccharides is their ability to release the drugs at the site with the help of stimuli responsive mechanisms. Nano carriers based on polysaccharide have been designed proficiently to trigger drug release precisely on physiological trigger by pH variations, enzymatic activity, temperature changes and redox conditions. In

particular, this property makes the treatment of diseases such as cancer an ideal environment as controlled drug distribution can lead to reduced adverse effects on healthy tissues while increasing drug levels at the target site[40].The choice of polysaccharide also influences drug-delivery performance. Chitosan offers high drug-loading potential and mucoadhesion, whereas alginate is particularly suitable for sustained release through hydrogel formation. Starch, hyaluronic acid, and pectin provide biodegradability and tunable release properties, with HA offering additional potential for targeted delivery. Thus molecular weight, charge, and polymer drug-interaction should be considered when selecting a polysaccharide for specific controlled-delivery applications [14,26,30].

Representative Stimuli-Responsive Nanostructured Polysaccharide Systems

Nanostructured polysaccharides can be engineered to sense a single physiological cue and undergo a defined physicochemical change that triggers drug release, allowing "smart," site- or event-specific delivery. Representative examples for each major stimulus are summarised below. pH-responsive systems: Chitosan-based nanoparticles exploit the protonation/deprotonation of the polymer's free amine groups (pKa ~6.5). At the mildly acidic pH of the tumour microenvironment (~6.5-6.8) or the endo-lysosomal compartment after cellular uptake (pH ~5.0-6.0), chitosan and carboxymethyl-chitosan nanoparticles swell and their electrostatic drug-polymer interactions weaken, accelerating cargo release; hyaluronic-acid-targeted supramolecular platforms engineered with dual pH-responsive linkages release their payload preferentially within this acidified tumour milieu while remaining stable at physiological pH [46]. Enzyme-responsive systems: Hyaluronic-acid (HA) nanoparticles and HA-drug conjugates are degraded specifically by hyaluronidase, an enzyme markedly overexpressed in the stroma of many solid tumours (e.g., breast and head-and-neck cancers) relative to normal tissue. Hyaluronidase cleaves the HA backbone into oligosaccharide fragments, disassembling the carrier and releasing the encapsulated or conjugated drug locally at the tumour site while simultaneously exploiting CD44-receptor-mediated uptake by cancer cells that overexpress this HA receptor [13,22,30]. Temperature-responsive systems: Polysaccharide backbones such as chitosan grafted with a thermo-responsive polymer (most commonly poly(N-isopropylacrylamide), PNIPAM) form nanogels that undergo a coil-to-globule transition near their lower critical solution temperature. Below this temperature the nanogel is swollen and drug is retained; on reaching mild-hyperthermic temperatures generated during local/regional hyperthermia treatment of solid tumours, the network collapses and expels the entrapped drug, providing a convenient trigger for combined thermal-chemotherapy strategies, as demonstrated for thermosensitive nanoparticles designed for use with hyperthermia-assisted chemotherapy [48].

Redox-responsive systems: Disulfide (thiol)-crosslinked chitosan/hyaluronic-acid charge-reversal nanocarriers remain stable in the oxidizing extracellular environment but are rapidly cleaved once internalized into the reducing intracellular/cytosolic environment, where glutathione (GSH) concentrations are reported to be several-fold to ~1000-fold higher than in the extracellular space (and further elevated in many tumour cells). These steep redox gradient triggers disulfide-bond scission, charge reversal, disassembly of the nanocarrier, and burst release of the drug in the cytoplasm; dual redox/pH-responsive thiol-hyaluronic acid/chitosan nanocarriers combine this mechanism with tumour-pH sensitivity for tighter spatiotemporal control [47]. Collectively, these single-stimulus designs can also be combined (e.g., pH- and ROS-responsive, or redox- and pH-dual-responsive carriers, as illustrated above) to achieve tighter spatiotemporal control and to reduce off-target/premature release, an approach that is increasingly being explored for nanostructured polysaccharide systems intended for oncology and inflammatory-disease applications.

An important aspect of nano-engineered polysaccharides is that their drug-delivery performance can be tuned at the molecular level. Modulation of molecular weight, degree of deacetylation, functional-group density, hydrophilic-hydrophobic balance, grafting, and crosslinking can influence nanoparticle size, drug-loading capacity, colloidal stability, and release kinetics [13,21,22,25,33]. For example, appropriate crosslinking can improve structural stability and reduce premature drug leakage, whereas hydrophobic modification can enhance the encapsulation of poorly water-soluble drugs. Similarly, PEGylation and other surface modifications can improve dispersion and stability, while stimuli-responsive functionalization enables more site-specific and controlled drug release [9,11,22,34,40]. These findings highlight that molecular engineering and formulation parameters should be optimized together to achieve the desired balance between nanoparticle stability, drug loading and controlled release.

However, certain limitations continue to be daunting. There are significant barriers towards the widespread clinical application of the nanoengineered polysaccharides, especially with respect to their scalability and reproducibility. Variability both in the polymer source and thus the degradable polymer backbone, as well as in molecular weight and processing conditions can result in variability in nanoparticle size, drug loading efficiency and release kinetics. Plus, there is a need to clarify the long-term safety and efficacy *in vivo* of polysaccharide-based nanoparticles based on immunogenicity and clearance mechanisms of these nanoparticles.

Quantitative Benefits of Nanostructured Polysaccharides Relative to Conventional Drug-Delivery Systems

Direct, head-to-head quantitative comparisons between nanostructured polysaccharide carriers and their corresponding free-drug or conventional-formulation controls are still relatively limited in the literature, but the comparative data that do exist consistently point toward measurable improvements in bioavailability, efficacy, and toxicity reduction. In oral peptide delivery, folate-appended chitosan nanoparticles carrying insulin achieved a 2.13-fold greater cumulative hypoglycaemic effect and a 21.8 +/- 2.4% relative oral bioavailability compared with subcutaneously administered insulin solution in diabetic rats, directly demonstrating that chitosan nanoencapsulation can render an oral route practical for a peptide that is otherwise almost completely degraded and poorly absorbed when swallowed unprotected [55]. In oncology, thiolated chitosan nanoparticles developed for oral delivery of docetaxel increased the drug's oral bioavailability to 68.9%, compared with only 6.5% for orally administered free docetaxel (a roughly 10-fold improvement), and extended its plasma half-life approximately 9-fold relative to the free-drug oral control, indicating the potential for nanostructured polysaccharide carriers to convert an otherwise intravenous-only chemotherapeutic into a viable oral formulation [56].

In infectious-disease applications, alginate nanoparticle formulations of the first-line anti-tuberculosis drugs rifampicin, isoniazid, and pyrazinamide have been shown to sustain therapeutic plasma drug concentrations *in vivo* for several days after a single oral dose, compared with the daily dosing required for the free drugs, corresponding to a several-fold reduction in required dosing frequency while achieving comparable or superior bioavailability [12]. In receptor-targeted cancer therapy, hyaluronic-acid nanoparticle-based platinum-prodrug systems have achieved anticancer activity comparable to free cisplatin, the conventional standard-of-care agent, while producing lower systemic side effects in both *in vitro* and *in vivo* models, illustrating that targeted polysaccharide delivery can match conventional efficacy at a reduced toxicity cost [30]. Taken together, the available quantitative evidence supports the general premise that nanostructured polysaccharide delivery can improve bioavailability and/or efficacy while reducing toxicity or dosing frequency relative to conventional formulations; however, the authors acknowledge that most of these figures come from individual formulation-specific preclinical studies rather than standardized, large-scale comparative clinical trials, and that generating consistent, cross-study quantitative benchmarks through direct head-to-head clinical comparisons remains an important unmet need for demonstrating the clinical-translation value of nanostructured polysaccharides at the scale implied by the manuscript title.

Biocompatibility, Biodegradability, Immunogenicity, and Toxicity Considerations

While polysaccharide-based nanocarriers are generally regarded as biocompatible and biodegradable relative to many synthetic polymers, their safety is polymerand dose-dependent and warrants closer consideration. Chitosan is degraded *in vivo* primarily by lysozyme and, to a lesser extent, by bacterial enzymes in the colon, yielding non-toxic oligosaccharides and glucosamine. However, its cationic surface charge, which is central to its mucoadhesive and drug-loading performance, can also cause dose- and molecular-weight-dependent haemolysis, membrane disruption, and immunotoxic effects at higher concentrations, and systematic hemocompatibility and immunotoxicity screening has shown that these effects are strongly influenced by chitosan's molecular weight, degree of deacetylation, and surface charge [49]. Since,coating chitosan nanoparticles with hyaluronic acid has been shown to reduce immunogenicity by altering the composition of the protein corona that forms around the particle in biological fluids. Thereby lowering complement activation and immune-cell recognition relative to uncoated chitosan nanoparticles [50]. Alginate is generally well tolerated, but its immunogenicity in applications such as islet-cell microencapsulation has been linked less to the polymer backbone itself than to co-purified impurities and to the mannuronic-to-guluronic acid ratio of the specific grade used, underscoring the importance of pharmaceutical-grade, well-

characterised raw material [12,26]. Hyaluronic acid is a native, ubiquitous component of the mammalian extracellular matrix and is essentially non-immunogenic across species. It is cleared through receptor-mediated pathways, principally CD44 and the liver sinusoidal endothelial HA receptor (HARE/Stabilin-2), followed by enzymatic degradation by hyaluronidases [12,17,30]. Beyond the polymer itself, biodistribution and clearance are governed largely by nanoparticle size and surface chemistry. Particles below the renal filtration threshold (approximately 6-8 nm hydrodynamic diameter) can be cleared renally, whereas larger polysaccharide nanoparticles are typically opsonized and taken up by the mononuclear phagocyte system (Kupffer cells in the liver, splenic macrophages), which governs both their circulation half-life and any potential for chronic organ accumulation [17,28]. This clearance route has been demonstrated clinically for dextran-coated iron-oxide nanoparticles (ferumoxytol), an FDA-approved polysaccharide-based nanomedicine whose iron core is metabolized through normal iron-recycling pathways after uptake by the reticuloendothelial system, providing a well-characterized, clinically validated example of predictable polysaccharide-nanoparticle biodistribution and clearance [51]. Overall, rigorous, standardized biocompatibility testing is essential before nanostructured polysaccharide systems can progress toward clinical use, and surface engineering strategies should be evaluated systematically for their ability to reduce immune recognition across polymer types, molecular weights, and degrees of substitution.

Strategies to Improve Reproducibility and Enable Scalable Manufacturing

Batch-to-batch variability in nanostructured polysaccharide systems arises from two compounding sources. Variability in the starting raw material (natural polysaccharides sourced from crustacean shells, algae, plant, or microbial fermentation vary in molecular weight, degree of deacetylation, and purity between suppliers and even between batches from the same supplier) and variability introduced by the fabrication process itself (bench-scale methods such as manual ionotropic gelation, nanoprecipitation, or emulsification are highly sensitive to mixing rate, addition order, and operator technique) [23,25]. Several complementary strategies can help ensure consistent fabrication of nanoparticles with the desired physicochemical properties. First, raw-material standardization, including pharmacopeial-grade polysaccharides with defined and certified molecular weight, degree of substitution, and purity, reduces input variability before formulation even begins. Second, a Quality-by-Design (QbD) approach, in which Design-of-Experiments methodology is used to map critical process parameters (e.g., polymer concentration, crosslinker ratio, flow rate, mixing energy) against critical quality attributes (particle size, polydispersity, zeta potential, encapsulation efficiency) [23].

Third, replacing manual mixing with continuous-flow microfluidic platforms has been specifically demonstrated for polysaccharide nanoparticle manufacturing, where precisely controlled, tunable micro-scale mixing produces markedly narrower particle-size distributions and better batch-to-batch reproducibility than bulk mixing, while remaining directly scalable by numbering-up (running many microfluidic channels in parallel) rather than requiring re-optimization at each larger batch size [52]. Fourth, incorporating Process Analytical Technology (PAT), such as in-line dynamic light scattering, UV/Vis, or Raman monitoring during production, enables real-time detection and correction of process drift rather than relying solely on end-product testing. Finally, transitioning from magnetic-stirrer bench synthesis to unit operations with established large-scale precedent in the pharmaceutical industry, including high-pressure homogenisation and spray-drying, together with early engagement of GMP-compliant contract development and manufacturing organisations (CDMOs) experienced in nano medicine scale-up, provides a realistic pathway from laboratory-scale batches (milligram-to-gram) to the kilogram-scale, GMP-certified production runs required for clinical trials and eventual commercial supply [37,52]. Adoption of these approaches in combination, rather than any single measure alone, is what will ultimately be needed to close the reproducibility and scale-up gap that currently limits clinical translation of nanostructured polysaccharide systems.

Future Perspectives

The application of advanced nanotechnologies, computational modeling and real time monitoring strategy will allow nanoengineered polysaccharides to have the future of controlled drug delivery. Among other things, in drug delivery optimization, its application of artificial intelligence (AI) or machine learning is high potential. Streamlined development and associated reduction in experimental and clinical trial costs will be made possible using models

that predict drug release, nanoparticle stability and therapeutic outcome kinetics. By augmenting presided AI in form of ideo active algorithms, drug delivery systems are designed with an aim to provide personalized delivery system to match patient's specific needs in the line of precision medicine. In addition, regulatory and translation concerns must be addressed to pave the way for the commercialization of nanoengineered polysaccharides-based drug delivery systems.

Applications of Artificial Intelligence and Machine Learning in Polysaccharide Nanoparticle Engineering

Artificial intelligence (AI) and machine learning (ML) are increasingly being applied across the nanomedicine formulation-development pipeline, moving the field from largely trial-and-error optimization toward data-driven, predictive design, and these approaches are directly transferable to nanostructured polysaccharide systems [54]. In predicting drug-loading and encapsulation efficiency, supervised ML models (artificial neural networks, random-forest regression, and response-surface-based approaches) are trained on formulation-parameter datasets, such as polymer-to-drug ratio, crosslinker concentration, and flow-rate conditions, to predict loading efficiency and particle size without requiring an exhaustive experimental screen, substantially reducing the number of formulations that must be tested empirically [54].

In predicting nanoparticle stability and physicochemical attributes, ML workflows coupled to microfluidic manufacturing platforms can be trained on hydrodynamic diameter, polydispersity index, and encapsulation-efficiency data to predict, and then design backward from, particles with user-specified target attributes [52,54]. In predicting drug-release profiles, ML models that incorporate polymer-drug interaction and diffusion-kinetics parameters are beginning to be used to predict release behaviour ahead of experimental testing, while high-throughput combinatorial screening approaches, in which ML is used to search very large drug-excipient combinatorial spaces for combinations most likely to self-assemble into high-payload nanoparticles, illustrate how these tools can identify favourable polysaccharide-drug pairings that would be impractical to screen exhaustively by hand [54]. Looking forward, these tools are expected to extend predicting *in vivo* pharmacokinetic and biodistribution behaviour from *in vitro*descriptors. A current limitation, however, is the relative scarcity of large, standardized, publicly available polysaccharide-nanoparticle formulation datasets compared with those available for small-molecule drug discovery, and expanding such shared datasets will likely be necessary for ML models in this specific sub-field to reach their full predictive potential.

Clinical Translation and Commercialization of Polysaccharide-Based Nanomedicine

Although the great majority of nanostructured polysaccharide drug-delivery systems described in the literature remain at the preclinical stage, several polysaccharide-derived nano systems have already progressed into clinical evaluation or clinicaluse, providing useful precedent for the field. The clearest example is ferumoxytol (Feraheme), a dextran-coated superparamagnetic iron-oxide nanoparticle that is FDA-approved for intravenous iron-replacement therapy in adults with chronic kidney disease and is increasingly repurposed off-label as an MRI theragnostic agent, demonstrating that a polysaccharide-coated nanoparticle can successfully complete the full regulatory pathway from GMP manufacturing through pivotal trials to marketing approval and routine clinical use [51]. Cyclodextrin-based polymeric nanoparticles, built from cyclic oligosaccharides, provide further precedent specifically for drug-delivery (rather than diagnostic) applications. CALAA-01, a cyclodextrin-polymer nanoparticle carrying siRNA, was the first targeted siRNA nanoparticle to be evaluated in a first-in-human clinical trial and provided direct clinical evidence of RNA-interference-based gene silencing following systemic nanoparticle administration [57], while CRLX101, a cyclodextrin-PEG-camptothecin nanoconjugate, has been evaluated in multiple Phase I and II clinical trials, including in combination regimens for non-small-cell lung, ovarian, and rectal cancers, demonstrating the feasibility of scaling cyclodextrin-based nano conjugates to multi-centre clinical supply [58].

Taken together, these examples show that polysaccharide-based nanocarriers can, and in a limited number of cases already have, cleared the principal regulatory and manufacturing hurdles such as GMP production, endotoxin control, and demonstration of safety and pharmacokinetics in humans. However, the number of polysaccharide-based nanomedicines that have completed pivotal Phase III trials and achieved marketing approval specifically as a

drug-delivery product remains small compared with lipid- and protein-based nanocarriers, and continued investment in standardized characterization, large-scale GMP manufacturing, and well-powered comparative clinical trials will be required to close this gap.

CONCLUSION

The nanoengineered polysaccharides have emerged as a good platform for controlled drug delivery. This ability has very significantly expanded their applicability in various therapeutic domains including oncology, regenerative medicine, and infectious disease treatment through formation of nanoparticles, hydrogels, and nano fibers. However, many of the commercially available systems face challenges such as reproducibility, stability, and regulatory hurdles that need to be overcome for them to be clinically issued. Nanotechnology in drug delivery can do so much better, and polysaccharides are the nanomaterials that can beat these limitations, nanoengineered polysaccharides in unison and in inter disciplinarity are poised to advance the modern drug delivery paradigm and usher them in safer, more effective, and patient-centric therapeutic solutions. This will further augment pharmaceutical sciences in its continuous evolution that will also contribute to the larger goal of precision medicine to better outcomes of healthcare worldwide.

Table 1: Comparative Properties of Common Polysaccharides for Nanoengineered Drug Delivery.

Polysaccharide	Molecular-weight characteristics*	Biodegradability & biocompatibility	Drug-loading potential	Controlled drug-delivery ability	Reference
Chitosan	Variable; influenced by source and degree of deacetylation	Biodegradable and biocompatible; excellent mucoadhesion	High, particularly through electrostatic interactions	Excellent; pH responsiveness and ionic crosslinking support sustained release	[14, 25, 32, 33]
Alginate	Variable, depending on source and extraction	Biodegradable and biocompatible; readily forms hydrogels	Moderate–high, particularly for hydrophilic drugs and biomolecules	Excellent; crosslinking density and polymer composition can regulate release	[14, 21, 26]
Starch	Broad MW distribution depending on source and processing	Biodegradable and generally biocompatible	Moderate; can be improved through modification	Good; nanosizing and structural modification can tailor release	[10, 14]
Hyaluronic acid (HA)	Broad range depending on source and processing	Highly biocompatible and biodegradable	Moderate–high; functionalization can improve drug incorporation	Excellent for targeted systems; degradation and receptor-mediated interactions can facilitate controlled delivery	[14, 30, 40]
Pectin	Variable, depending on source and degree of esterification	Biodegradable and generally biocompatible	Moderate; suitable for incorporation of pharmaceutical and bioactive compounds	Good–excellent; pH-responsive and enzymatic degradation can support site-specific release	[14, 25, 30]

*Molecular weight varies considerably with natural source, extraction/purification, and chemical modification.

Table 2: Molecular engineering strategies and their effects on polysaccharide-based nanoparticles

Molecular engineering strategy	Molecular-level modification	Nanoparticle size	Drug-loading capacity	Stability	Drug-release profile	Reference
Molecular-weight and degree of deacetylation control	Modulation of polymer chainlength and functional-group density	Alters chain entanglement and particle formation; optimized values can reduce particle size	Influences drug–polymer interactions and encapsulation	Affects colloidal stability and matrix integrity	Higher polymer–drug interactions can prolong release	[25,33]
Chemical functionalization	Addition of carboxymethyl, sulfate, acetyl, or phosphate groups	Alters charge and chain conformation, affecting particle formation	Can enhance loading through favorable electrostatic or hydrogen-bond interactions	Modifies solubility and dispersion stability	Alters drug–polymer interactions and diffusion rate	[13,22,25]
Hydrophobic modification	Introduction of alkyl, acetyl, cholesterol, or other hydrophobic groups	Promotes self-assembly; excessive modification may increase aggregation	Generally improves encapsulation of poorly water-soluble drugs	Hydrophobic interactions can stabilize the drug-loaded core	Stronger hydrophobic interactions can retard drug release	[22,25]
Polymer grafting / PEGylation	Attachment of hydrophilic polymers such as PEG	Can reduce aggregation and improve particle uniformity; excessive grafting may increase size	May improve or reduce loading depending on accessibility of drug-binding sites	Enhances steric and colloidal stability	Can reduce burst release and prolong drug retention	[9,11,34]
Cross linking	Formation of ionic or covalent networks between polymer chains	Higher cross linking generally produces more compact particles	Moderate cross linking improves drug retention; excessive cross linking may reduce loading	Increases structural stability and reduces premature drug leakage	Higher cross linking generally produces slower and sustained release	[21,26,27]
Stimuli-responsive engineering	Incorporation of pH-, redox-, temperature-, or enzyme-responsive groups	Particle size may change following stimulus-induced swelling or degradation	Can improve site-specific drug retention	Provides stability under non-triggering conditions	Enables site-specific or on-demand drug release	[22,40]

Table 3: Factors Influencing Drug Release from Nano engineered Polysaccharides- Based Drug Delivery Systems.

Factor	Mechanistic Role	Impact on Drug Release Profile	Scientific Basis / Influence	Limitations / Challenges	Control Strategies / Optimization Approaches	Reference
Swelling Dynamics	Controls hydration and matrix expansion	Higher swelling → faster diffusion; lower swelling → sustained release	Degree of swelling controls matrix relaxation and solvent penetration into polymeric network	Excessive swelling may cause burst release; difficult to maintain uniform swelling *in vivo*	Optimize polymer hydrophilicity; use blended/ionically crosslinked polysaccharides to regulate swelling	[21,26]
Degree of Crosslinking / Drug Release Pattern	Determines network rigidity and molecular mobility	High crosslinking → slow, sustained release; low crosslinking → rapid release	Crosslink density regulates diffusional coefficient and permeability	Over-crosslinking reduces drug loading and hampers degradation; under-crosslinking causes premature leakage	Tailored crosslink density; responsive or reversible crosslinkers for tunable behaviour	[21,27–29]
Physicochemical Properties of Carrier	Dictates polymer–drug interactions, charge, porosity, hydrophilicity	Affects encapsulation efficiency, diffusion pathways, retention time	Determines drug–matrix interaction strength and release kinetics	High MW carriers may slow biodegradation; charge mismatch reduces loading	Adjust MW and porosity; surface modification (PEGylation, charge tuning); copolymer design	[21,30]
Environmental Stimuli (pH, redox, enzymes, temperature)	Stimuli-responsive conformational change or degradation	Enables targeted, site-specific, on-demand release	Smart polysaccharide systems alter conformation or degrade in response to physiological cues	Variable physiological conditions between patients/tissues; risk of off-target activation	Incorporation of dual/multi-stimuli triggers; enzyme-specific cleavable linkers; pH buffering	[21,31,32]
Formulation / Processing Parameters	Defines nanoparticle size, stability, and encapsulation efficiency	Governs initial burst release, stability, and sustained kinetics	Polymer MW, fabrication route, and processing environment influence final functionality	Scale-up variability; solvent residues; inconsistent encapsulation	Use controlled fabrication (microfluidics, ionic gelation, spray drying), purification optimization	[21,33]

Table 4: Applications of Nano engineered Polysaccharides in Controlled and Targeted Drug Delivery.

Nano engineered Polysaccharide System	Application in Controlled Drug Release	Key Advantages / Features	Representative Therapeutic Applications	Reference
Chitosan-based nanoparticles for targeted drug delivery	Targeted delivery of bioactive and therapeutic compounds	Enables site-specific delivery; can improve drug stability and bioavailability; surface modification such as PEGylation can enhance nanoparticle stability	Delivery of ammonium glycyrrhizinate, a bioactive derivative of glycyrrhizin with anti-inflammatory, antitumorigenic, and hepatoprotective activities.	[34,37]
Chitosan-based nanoparticles	Controlled and sustained delivery of therapeutic agents, particularly anticancer drugs	Excellent mucoadhesive properties; biodegradable and biocompatible; capable of encapsulating diverse therapeutic agents; enhances drug stability and prolongs systemic circulation	Delivery of chemotherapeutic agents such as doxorubicin and paclitaxel; improved therapeutic efficacy.	[36]
PEGylated chitosan nanoparticles	Enhanced stability and controlled drug delivery	PEGylation may improve nanoparticle stability and circulation; however, excessive surface modification may adversely affect encapsulation efficiency and drug absorption	Targeted and systemic delivery of therapeutic compounds.	[34,37]
Alginate-based hydrogels	Controlled and localized release of growth factors	Alginate forms hydrogels capable of carrying bioactive molecules; release profiles can be regulated by modifying crosslinking density and polymer composition	Growth factor delivery for tissue engineering and regeneration.	[38]
Starch-based nanosystems	Development of nanoscale drug delivery systems with controlled release characteristics	Natural, biodegradable polysaccharide; can be modified to obtain tailored drug-loading and release properties	Delivery of various therapeutic agents and bioactive compounds.	[39]
Hyaluronic acid (HA)-based nanosystems	Controlled and targeted drug delivery	Biocompatible and biodegradable; suitable for developing nanoscale systems with tunable physicochemical and drug-release properties	Targeted delivery of therapeutic agents, particularly in biomedical applications.	[39]
Pectin-based nanosystems	Controlled drug release and development of nanoscale delivery platforms	Natural polysaccharide with tunable properties; suitable for incorporation into engineered and hybrid delivery systems	Delivery of pharmaceutical and bioactive compounds.	[39]

Hybrid polysaccharide polymer systems	Improved control over drug release and reduction of toxicity	Combination of different biopolymers can provide enhanced drug-loading capacity, controlled release, improved stability, and reduced toxicity	Broad range of pharmaceutical and biomedical drug-delivery applications.	[39]
Computationally optimized polysaccharide systems	Prediction and optimization of drug-release kinetics	Computational models can predict release behavior and optimize formulation parameters, thereby reducing experimental requirements and development costs	Rational design of controlled-release drug delivery systems	[35,37]
Polysaccharide-based nanoparticles for colon targeting	Site-specific and controlled drug delivery to the colon	Potential for targeted delivery and protection of therapeutic agents until reaching the colon; expands the biomedical applicability of polysaccharide nanocarriers	Colon-targeted drug delivery for localized treatment of gastrointestinal disorders	[34,37]

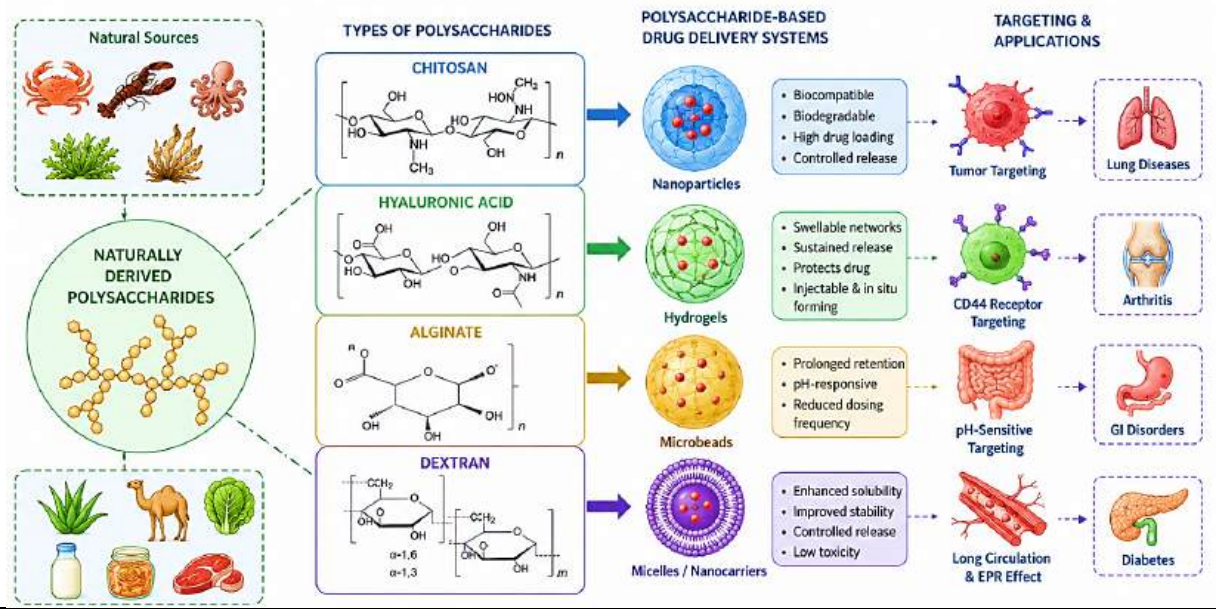

Figure 1: Several naturally derived polysaccharides broaden their potential in sustained and targeted drug delivery systems

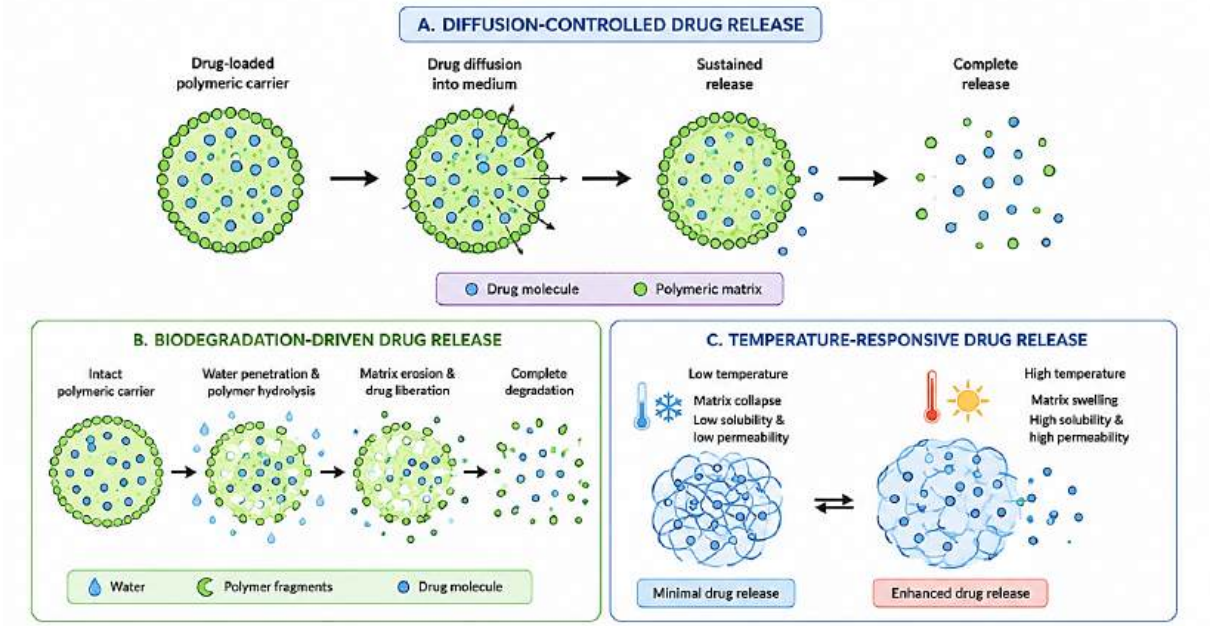

Figure 2: Mechanism of controlled drug release via diffusion, biodegradation, and temperature-responsive changes in solubility and permeability.

ABSTRACT

Indian lotus (*Nelumbo nucifera*) is an aquatic plant with various medicinal properties. Various parts of plant including leaves, rhizome, seeds, seed embryo, petals, stamens, and receptacles have been used in Ayurveda and traditional East Asian medicine for the treatment of various diseases. Experimental evidence indicates that lotus contains a diverse range of bioactive compounds including flavonoids, alkaloids, triterpenoids, glycosides and other phytochemicals that contribute to its pharmacological properties. Compounds such as neferine, liensinine, isoliensinine, nuciferine, dauricine, quercetin, catechin, and betulinic acid have been associated with antioxidant, anti-inflammatory, immune modulatory, hypoglycaemic, hepatoprotective, anti-obesity, antiarrhythmic, antithrombic, neuro pharmacological, and anticancer activities of the lotus plant.Various compounds extracted from lotus are also used for their cardiovascular protective, liver health, skin aging, pulmonary fibrosis, and metabolic disorders. However, most of the available evidence is derived from preclinical experimental models, and further well-designed clinical studies are required to establish efficacy, safety, bioavailability, mechanism of action, and appropriate therapeutic action in humans. This review summarizes the traditional uses, phytoconstituents, pharmacological activities, highlighting the potential of *N. nucifera* as a source of bioactive compounds for future nutraceutical, pharmaceutical, and functional food applications.

Keywords: *Nelumbo nucifera* ; lotus rhizome; phytochemicals; antioxidant activity; anti-inflammatory activity; hypoglycaemic activity; anticancer activity; cardiovascular health; traditional medicine; anti-obesity.

INTRODUCTION

Indian Lotus (*Nelumbo nucifera*) is an aquatic plant, consumed for its various health benefits. *Nelumbo nucifera* (NN) is known to be an important medicinal herb in China, and all its parts are used in medicine. The extract of the rhizome showed anti-obesity and anti-diabetic properties [1,2]. The leaves have known astringent, refrigerant, and diuretic effects. This leads to varied applications, such as the usage of leaves for high fever, diarrhea, leprosy, and hemorrhoids. A traditional liquor is made in Korea from the blossoms and leaves of Lotus, known as Lotus liquor. It has antioxidant properties that are used for the treatment of oxidative stress [3].Ripened seeds of Lotus are spleen tonic [4], used for the treatment of chronic diarrhea due to their astringent action. Lotus is also used to inhibit inflammation and has an antidepressant activity [5]. The extracts of the seeds possess hepatoprotective properties and free radical scavenging effects [1]. The plumule of lotus, upon its removal from the ripened seed and sun drying, is used for the treatment of nervous disorders, high fever, restlessness, insomnia, and hypertension [6]. Nelumbinis semen, the seed of Lotus, is used in Korea as a traditional herbal medicine in the treatment of cardiovascular symptoms [7]. The receptacles contain carbohydrates, protein, and a small amount of Nelumbine, an alkaloid, that is useful in stopping bleeding. The flower has antiarrhythmic actions (liensinine), vasodilating effects (referine) and alkaloids (lotusine, isoliensinine, demethylcoclaurine and methylcorypalline) [3]. Stamens of the lotus flower are known to have a positive effect on kidney function. They are also used in the treatment of masculine sexual disorders and female leucorrhea [6]. Petals, when pounded, are used for treating syphilis and flower stalks, coupled with other herbs, are used to treat uterine bleeding [8]. Traditionally, rhizomes are brought into use for multiple conditions such as leukoderma, pectoralgia, dysentery, pharyngopathy, cough, smallpox, spermatorrhea and diarrhea. *Nelumbo nucifera* (NN) activity includes anti-diabetic, antioxidant, antimicrobial, anti- arrhythmic, anti-inflammatory, antipyretic, anti-ischemic, hypoglycemic, immunomodulatory, and anti-diarrheal activities. Various bioactive compounds contribute to the above activity, namely, alkaloids (nuciferine, neferine, dauricine, liensinine, roemerine, lotusine, and armepavine), flavonoids (quercetin, kaempferol, catechin, astragalin, leucocyanidin, leucodelphinidin, and isoquercitrin), glycosides (nelumboroside A, nelumboroside B, isorhamnetin rutinoside, and isorhamnetin glycoside), and triterpenoids (betulinic acid) [9].

Medicinal Properties

Antioxidant Activity:

In-vitro studies on acetone and methanol *Nelumbo nucifera* root (NNR) extracts showed the highest DPPH scavenging activity at 133.3 mg/l and 66.7 mg/l, respectively. The methanol extract when compared to ascorbic acid shows a higher antioxidant activity coefficient [10]. Lotus contains a variety of nhphytochemical-like alkaloids, saponins, carbohydrates and polyphenolics supporting antioxidant activity of HANN (hydroalcoholic extract of *Nelumbo nucifera*) in significant amounts [11] In 2006, Yen et al. reported the reactive nitrogen species scavenging activity of extracts of lotus seed. The potency of lotus seed extracts, especially water extract (LSWE), ethyl acetate (LSEASE) and hexane (LSHE), for the inhibition of reactive nitrogen species in RAW 264.7 macrophage cells was studied. The results showed that all extracts suppressed nitric oxide (NO) production in RAW 264.7 cells stimulated by lipopolysaccharide. The accumulation of NO was seen with dose-dependent inhibition upon the decomposition of SNP, i.e., sodium nitroprusside. Comparatively, the order of potency is LSEAE > LSWE > LSHE [12]. SNP promoted the protection against DNA breakage in RAW 264.7 macrophages, as shown in the comet assay. At a dose of 0.2 mg/mL, LSWE, LSEAE and LSHE showed inhibitions of 63%, 59% and 38% respectively, of DNA damage brought about by peroxynitrite. All the mentioned extracts were found to be scavengers of peroxynitrite, and therefore capable of preventing tyrosine nitration (Yen et al., 2006) [12].

Immunity Boosting:

The effect of ethyl alcohol extracts of lotus was studied in primary human peripheral blood mononuclear cells (PMBCs) by Liu et al. in 2004, when stimulated by phytohemagglutinin (PHA: a specific mitogen for T lymphocytes) in the inhibition of cell proliferation and production of cytokines. T-cell plays a vital role in the pathogenesis of systemic lupus erythematosus (SLE) [13]. Liu et al., 2004 investigated the effects of (S)-armepavine from lotus, which

impaired IL-2 and IFN-gamma transcripts in peripheral blood mononuclear cells and can be used as an immune modulator for the management of autoimmune diseases, including SLE [13,14].

Anti-inflammatory Activity:

Tissue injury may be caused by a harmful response of the body, known as tissue inflammation. It may cause serious diseases such as atopic dermatitis, asthma, and rheumatoid arthritis [15]. Evidence now suggests that the secretions of cytokines, such as IL-10, IL-4 and INF-γ, by T-cells in the response to antigen stimulation play a role in conditions such as lung inflammation, atopic dermatitis, and asthma [16]. The triterpenoid betulinic acid was isolated from the methanol extract of NNR. It was evaluated for its marked anti- inflammatory activity against oedema in the paws of rats due to carrageenan and serotonin. Methanol extract exhibited anti-inflammatory activity when administered at dosages of 200 mg and 400 mg/kg per os (p.o.); betulinic acid demonstrated anti- inflammatory effects in experimental models when given at doses of 50 mg/kg and 100 mg/kg p.o. A similar effect to that of two potent anti-inflammatory drugs (dexamethasone and phenylbutazone) was exhibited by extract and betulinic acid [17].

Psychopharmacological, Diuretic, and Antipyretic Activity

The methanol extract of NNR shows pharmacological action similar to a minor tranquilizer. When given to rats and mice, a reduction in spontaneous activity, and a decrease in exploratory behavior in Y-maze and head dip tests were observed [18]. The methanol extract of NNR at doses of 300, 400, and 500 mg/kg showed significant diuretic action in rats. There was a dose-depending increase in the urine volume, accompanied by Na^+, Cl^-, and K^+ excretion. The increase in the urine volume was less than that of furosemide (20 mg/kg) [18]. The NNR methanolic extract showed antipyretic activity in rats with yeast-induced pyrexia. When administered orally at doses of 200, 300, and 400 mg/kg, the extract showed a significant dose-dependent temperature-lowering effect. The results were comparable to paracetamol (pcm) (150 mg/kg intraperitoneally) [18].

Hypoglycemic Activity

Ethanolic NNR extract showed an oral hypoglycemic effect and reduced the blood glucose levels of glucose-fed, normal, and streptozotocin-induced diabetic rats. A marked increase in glucose tolerance and improved action of exogenously injected insulin was observed in experimental groups. An activity equivalent to 73% and 67% of tolbutamide was seen in normal and diabetic rats, respectively [19,20]. This effect could be because of the attenuated absorption of glucose in the body, an action like the ingestion of dietary fiber orally with glucose [21]. Tryptophan (antidiabetic component), extracted from nodes of the rhizome, when given as a methanolic extract at dosages of 400 mg/kg and 100 mg/kg to glucose-fed hyperglycemic rats, showed antidiabetic activities [22]

Treatment of erectile dysfunction

Chen et al. highlighted the treatment of erectile dysfunction (ED) of *in-vitro* relaxation mechanisms possessed by neferine on the corpus cavernosum tissue of rabbit and in-vitro effects of neferine on cytosolic free calcium concentrations found in the corpus cavernosum of rabbits' smooth muscle cells [23].

Restenosis and Atherosclerosis

Administration of the extract of leaves and roots of NN for a period of 4 weeks showed a narrowing effect on the luminal area and rate of stenosis in a rat model [24]. In a rabbit model of atherosclerosis induced by a diet high in cholesterol, the extract of lotus leaf showed anti-atherosclerotic activity by inhibiting vascular smooth muscle cell (VSMC) proliferation and migration [25] and improving plasma cholesterol levels (LEE et al., 2010). Neferine, the active principle of lotus, inhibits the proliferation of VSMCs stimulated by angiotensin-II [26].

Anti-Aging Activity

Lotus seed extract contains agents that act against aging by acting upon symptoms such as loss of elasticity, pores, acne, fine lines, wrinkles, and blemishes. Formulations that carry potent antiaging agents are possessed by various compounds [27]. The efficacy of green tea and lotus extract cosmetic formulations for the treatment of facial wrinkles was studied in healthy Asians using the Visio scan (VS; noninvasive tool), along with sebumeter. Synergistic

antiaging effects were shown by the combination of green tea and lotus extracts in multiple emulsions. A beneficial effect on the skin can be due to the antioxidant activity of the active compounds in both herbal plants. This makes these plants commendable as the future of new anti-aging products [28].

Anti- Arrythmia

Phytochemicals obtained from NN seeds, namely dauricine and neferine exhibit cardiovascular pharmacological effects. The phytochemicals present in NN blocked the cardiac transmembrane currents of sodium (Na^+), potassium (K^+), and calcium (Ca^+). Neferine has a known antiarrhythmic effect and greatly prevents the accumulation of platelets in rabbits. The potency of neferine as an antiarrhythmic agent has been demonstrated by multiple in-vivo studies [29]. In papillary muscles and the atria of guinea pigs, the electrical and mechanical activity of neferine was studied. At doses of 0.1 mmol/L, neferine lowered the force of contraction and amplitude along with the *V*max of action potential (AP), action potential duration at 50% (ADP-50), effective refractory period (ERP) and action potential duration at 90% (ADP-90). Furthermore, partial antagonization of the effect of 10 μmol/L acetylcholine was achieved by Neferine (30 μmol/L) [30]. The electrophysiological effects of neferine (8 mg/kg IV) on ischemic ventricular tachyarrhythmias were investigated in both ischemic and normal myocardium with the use of programmed electrical stimulation (PES) during a period of 5-8 days after acute myocardial infarction in the open chest. After damage due to infarction, Neferine was found to be effective in preventing sudden cardiac death and ventricular tachycardia [31].

Hepatoprotective Activity:

From another study, it was found that cirrhosis progressed from hepatic steatosis. NNR polyphenolic extract when administered to obese diabetic mice, helped alleviate hepatic steatosis [32]. The root of lotus has antifungal, hypoglycemic, antipyretic, antianxiety and anti-inflammatory properties [33]. A study conducted previously shed light on various extracts of the lotus rhizome exhibiting higher antioxidant properties [34]. Various physiological roles such as anti-inflammation, neuroprotection, immune regulation, and antidiabetic effects, are exhibited by a free amino acid, taurine [35]. Reports have suggested that taurine has antioxidant properties [36,37] by scavenging ROS [38] and reducing thiobarbituric acid reactive substances (TBARS). It also has known hepatoprotective activities [39,40]. Due to the high antioxidant properties of lotus roots, it can be concluded that lotus roots protect the liver. The extract of lotus root in hot water alone or combined with taurine supplementation is known to have antioxidative activities both in-vitro and in-vivo. Lotus root hot water extract with taurine supplementation shows hepatoprotective properties in obese rats that were given a high-fat diet [36].

Pulmonary fibrosis:

The effect of bisbenzylisoquinoline alkaloid isoliensinine isolated from the seed embryo of *Nelumbo nucifera* was evaluated by Xiao et al., on pulmonary fibrosis caused in mice by bleomycin. The study showed that isoliensinine caused notable inhibition of the content of hydroxyproline. Additionally, inhibiting transforming growth factor (TGF)- β1 and overexpressing tumor necrosis factor- (TNF)- α [41]. The inhibitory effect of neferine on amiodarone-induced pulmonary fibrosis was shown by Niu et al. 2013, owing to the potency of Neferine for anti-inflammation and inhibition of surfactant protein-D (SP-D). It was found that Neferine had potential anti-pulmonary fibroid action [42].

Anti-Obesity Activity

The anti-Obesity efficacy of active constituents of the leaves of lotus plants was reported by Ohkoshi et al. with the use of stimulated lipid breakdown in adipose tissue in mice. The results showed anti-obesity activity through the beta-and adrenergic receptor pathway. NN caused a reduction in body weight in A/J (inbred albino strain) mice that were given a high-fat diet [43]. Isolation of several flavonoids was performed from NN by chromatography and fractionation. Flavonoids such as isoquercitrin, hyperoside, catechin and quercetin exhibited lipid breakdown activity in the adipose tissues of the viscera. Concentration independent suppression of α-amylase, lipid metabolism and lipase activity was demonstrated by NN extract (NNE) in mice that were given the extract for five weeks. The inhibitory activity of lipase and α-amylase in-vitro was also exhibited by NNE. The inhibitory activity of lipase by

NNE (IC-50, 0.46 mg/ml) was stronger than that of α-amylase (IC50, 0.82 mg/ml). Significant suppression of weight gain was seen in the body and parametrial adipose tissues. The extract also suppresses the amounts of triacylglycerol in the liver of high-fat-diet-fed obese mice [1]. In a similar study, Velusami et al., investigated the anti-obesity effectiveness of aqueous and methyl alcohol extracts of NN petals. The studied parameter was an effect of the extracts of adipolysis, adipogenesis, serotonin (5-HT2C), lipase, melanocortin (MC4R), cannabinoid (CN2R) and melanocyte concentrating hormone (MCH1R) receptors. Methyl alcohol and successive aqueous extracts of lotus petals inhibited lipid storage in fat cells and caused an increase in the breakdown of fat cells. The methyl extract also inhibited lipase activity (IC50 value: 47 μg/ml) in a dose-dependent manner. Conclusively, the methyl alcohol extract of the petals of NN exhibited more promising activity than the aqueous extracts for controlling obesity [44].

Anticancer Activity

Anticancer effects of NN have been observed. Neferine, an alkaloid extracted from NN, has dose-dependent cytotoxic action on Hep G2 liver cancer cells. The anticancer potential of NN extract was studied on mitochondrial membrane potential, intracellular calcium levels, cell membrane integrity, apoptotic body formation and DNA fragmentation in cultured Hep G2 cells [45]. Various extracts, when isolated from various parts of lotus, were found to have anticancer properties in-vivo and in-vitro. Isoliensinine possesses the most potent cytotoxic content among the three alkaloids, primarily due to the induction of apoptosis in triple negative breast cancer cells by reactive oxygen species (ROS) generation and p38 MAPK/JNK (p38 mitogen-activated protein kinases/Jun N-terminal kinases) activation [45]. Suppression of the proliferation of non-small-cells lung cancer (NSCLC) cells was observed due to NN in the presence of nicotine. Fifteen compounds were isolated from NN, out of which 7- hydroxy-dehydro-nuciferine showed significant inhibition of proliferation of prostate, melanoma, and gastric cancer cells [47]. Another study showed the effect of Neferine, including apoptosis in lung cancer cells (A549 cells) [48]. The results showed the action of Neferine revealing direct antitumor properties and inferring that Neferine possesses cancer therapeutic and cancer preventive activities/potential [49].

Antithrombic Activity

Thrombus formation is remarkably prevented by the presence of Neferine in NNR, which inhibits platelet activation, adhesion, and aggregation and promotes the disassembly of preformed platelet aggregates. Neferine can be used as an anti-platelet and anti-thrombotic agent [50].

CONCLUSION

Indian lotus is an ornamental plant used traditionally for its medicinal and pharmacological potential attributed to its diverse phytochemical composition. Different parts of plant contain biologically active compounds, particularly alkaloids, flavonoids, glycosides, and triterpenoids which have antioxidants, anti-inflammatory, hypoglycemic, hepatoprotective, anti-obesity, cardiovascular, immune modulatory, antithrombic, neuroprotective, and anticancer activities in experimental studies. Among its bioactive constituents, alkaloids such as neferine, liensinine, isoliensinine, and nuciferine have considerable potential therapeutic effects. The available evidence supports the fact that *N. nucifera* is a promising source of nutraceutical and pharmaceutical compounds and provides a scientific base for its traditional applications. Though most reported studies are conducted either in vitro or on animals, the translation of these findings into clinical practice remains limited.

ABSTRACT

HIV/AIDS remains an important public-health concern, and adequate knowledge among young adults is essential for prevention, early testing, reduction of misconceptions, and appropriate health-seeking behaviour. The source dissertation identified a substantial gap in HIV/AIDS knowledge among non-medical college students in Vadodara City. To assess knowledge regarding HIV/AIDS among non-medical college students in selected colleges of Vadodara City; to determine the association between knowledge level and selected demographic variables; and to develop an informational booklet on HIV/AIDS. HIV/AIDS continues to be a major global public-health concern, with 41.0 million people living with HIV globally and 1.2 million new HIV infections reported in 2025. In India, an estimated 25.61 lakh people were living with HIV in 2024, including approximately 1.55 lakh young people aged 15–24 years (6%). A quantitative, descriptive survey design was used. The final study included 100 non-medical college students selected by convenience sampling at Sigma University, Vadodara. Data were collected on 25 September 2024 using a structured knowledge questionnaire. The tool comprised a socio-demographic section and a 20-item structured HIV/AIDS knowledge questionnaire. The questionnaire was reviewed by nursing experts and demonstrated reported reliability of r = 0.70. A pilot study was conducted at RMS Polytechnic College, Vadodara. Descriptive statistics and chi-square analysis were used. of the 100 participants, 95% were aged 18–23 years and 70% were male. Previous HIV/AIDS knowledge was reported by 46%, while 54% reported no previous knowledge. The main reported sources were "others" (66%), mass media (24%), workshops/conferences (9%), and healthcare members (1%). In the pre-test, 80% had poor knowledge, 14% had average knowledge, and 6% had good knowledge. The

reported chi-square values indicated significant associations of knowledge with gender (χ^2=17.543; df=2; critical value=5.99), previous knowledge (χ^2=8.788; df=2; critical value=5.99), and source of information (χ^2=17.156; df=6; critical value=12.59). Age was not significantly associated with knowledge (χ^2=0.451; df=2; critical value=5.99). The study demonstrated a marked knowledge deficit regarding HIV/AIDS among non-medical college students. Prior exposure to HIV/AIDS information and the source of information were associated with better knowledge, supporting the need for structured, accessible, and credible HIV/AIDS education for college students.

Keywords: HIV/AIDS; knowledge; non-medical students; college students; health education

INTRODUCTION

Human immunodeficiency virus (HIV) infection and acquired immunodeficiency syndrome (AIDS) continue to require sustained public-health education and prevention efforts. The source dissertation describes HIV/AIDS as an important public-health concern and highlights the vulnerability of young people to HIV because of gaps in accurate information, risk awareness, and preventive knowledge. It also notes that comprehensive HIV/AIDS knowledge among Indian adolescents and youth has remained limited in several reported studies. The literature reviewed in the dissertation indicates that knowledge varies according to educational exposure and information sources. A study among youth in the Saurashtra region of Gujarat reported that 60% had heard something about HIV, while age, education, occupation, and mass-media exposure were identified as determinants of knowledge. The dissertation also cites studies showing that television and other mass-media channels are important sources of HIV/AIDS information among students, while misconceptions may persist despite general awareness. For non-medical college students, accurate knowledge is particularly important because they are part of the wider community and can contribute to prevention and reduction of HIV-related stigma. The present study therefore assessed the existing level of HIV/AIDS knowledge among non-medical students in Vadodara City and examined its association with selected demographic variables. An informational booklet was subsequently prepared as an educational resource.

Objectives

- To assess the knowledge regarding HIV/AIDS among non-medical college students of selected colleges in Vadodara City.
- To determine the association between selected demographic variables and knowledge regarding HIV/AIDS among the students.
- To prepare an informational booklet on HIV/AIDS for college students.

MATERIALS AND METHODS

A quantitative research approach and descriptive survey design were used. The dissertation also describes the intervention sequence as selection of participants, pre-test assessment, and distribution of an HIV/AIDS informational booklet. Because no post-test outcome data are reported in the dissertation, the present manuscript reports the study primarily as a descriptive assessment of baseline/pre-test knowledge rather than as an evaluation of booklet effectiveness. The pilot study was conducted at RMS Polytechnic College, Vadodara, on 13 September 2024. The final study was conducted at Sigma University, Vadodara. The target population comprised college students, and 100 non-medical students were included in the final study. Convenience sampling, a non-probability sampling technique, was used. Eligibility criteria documented in the dissertation included students who understood English, were willing to participate, and were present at the time of data collection. The tool consisted of two sections. Section I collected socio-demographic information: age, gender, previous knowledge regarding HIV/AIDS, and source of information. Section II was a 20-item structured knowledge questionnaire with four response options. Each correct response carried one mark. Knowledge was categorized as poor (≤6), average (7–12), and good (13–20). The blueprint

covered introduction, definition, types, causes /risk factors, modes of transmission, clinical manifestations, diagnostic evaluation, treatment, prevention, and complications. The questionnaire was reviewed by nursing experts and revised according to their suggestions. The dissertation reports validation by a panel of nursing experts. Reliability was assessed among 10 non-medical students at RMS Polytechnic College using the Karl Pearson correlation method, with a reported reliability coefficient of 0.70. Frequency and percentage were used to describe socio-demographic characteristics and knowledge categories. Mean/mean percentage were planned for knowledge assessment, and chi-square analysis was used to examine associations between knowledge categories and selected demographic variables. Statistical significance was interpreted by comparing the reported calculated chi-square values with the corresponding critical values at the stated degrees of freedom and 0.05 level.

RESULTS

Most participants (80%) demonstrated poor HIV/AIDS knowledge in the pre-test. Fourteen percent had average knowledge and only 6% had good knowledge. These findings indicate a substantial knowledge gap among the study population

Association with selected demographic variables

Gender, previous HIV/AIDS knowledge, and source of information showed significant associations with knowledge level because the calculated chi-square values exceeded the reported critical values. Age did not show a significant association. Female participants had a greater proportion of good knowledge than male participants, and students reporting previous knowledge were more likely to have average or good knowledge.

DISCUSSION

The principal finding was that 80% of students had poor HIV/AIDS knowledge before receiving the informational booklet. This finding is important because the participants were college students and most were in the 18–23-year age group. The result supports the need for structured health education directed at young adults. The study also found that previous exposure to HIV/AIDS information was associated with knowledge level. Among students with previous knowledge, 36 had poor, 4 had average, and 6 had good knowledge; among those without previous knowledge, 44 had poor, 10 had average, and none had good knowledge. This pattern suggests that repeated or prior exposure to HIV/AIDS information may contribute to improved knowledge, although the cross-sectional descriptive design does not establish causation. Source of information was also associated with knowledge. Students reporting mass media and workshops/conferences had relatively more students in the good-knowledge category than those reporting other sources.

This finding is consistent with literature summarized in the dissertation, including the Saurashtra youth study in which mass-media exposure was identified as a determinant of HIV/AIDS knowledge. The finding also emphasizes the importance of credible and comprehensible educational messages. Gender showed a significant association with knowledge in the present dataset, with female students demonstrating a higher proportion of good knowledge. However, the reasons for this difference cannot be established from the available data. Age was not significantly associated with knowledge, although the sample was heavily concentrated in the 18–23-year age group, limiting meaningful comparison across age categories. The informational booklet was developed as an educational response to the observed knowledge deficit. The booklet covers HIV/AIDS definition, types, causes and risk factors, transmission, clinical manifestations, diagnosis, treatment, prevention, and complications. The dissertation documents distribution of the booklet after the pre-test; however, no post-test results are reported, so its effectiveness cannot be quantified from the available data.

CONCLUSION

A substantial proportion of non-medical college students in the selected Vadodara setting had poor baseline knowledge regarding HIV/AIDS. Eighty percent of participants were categorized as having poor knowledge, while only 6% demonstrated good knowledge. Knowledge was significantly associated with gender, previous HIV/AIDS knowledge, and source of information, whereas age was not significantly associated. The findings support the need for regular, evidence-based HIV/AIDS education through colleges, mass media, workshops, and accessible health professionals. The informational booklet developed in the study provides a practical educational resource, although its effectiveness requires evaluation using a post-test or controlled design.

Implications for Nursing and Health Education

Nursing professionals and educators can use college-based health education to strengthen HIV/AIDS awareness, correct misconceptions, promote appropriate prevention and testing knowledge, and reduce stigma. Workshops, interactive teaching sessions, printed information materials, and credible mass-media resources can be integrated into student health programmes. Future studies should evaluate educational interventions using pre-test/post-test designs and should include larger, more diverse samples.

ABSTRACT

The study focuses on physiological characterization of microalgae from aquatic limestone mine environments, with an aim to identify high-performing candidate strains for applications such as biofuel production, wastewater treatment, and chemical extraction. Microalgae are photoautotrophic microorganisms that can produce energy both by using sunlight, water and CO_2 (phototrophic metabolism) and by using organic sources such as glucose (heterotrophic metabolism). Heterotrophic growth is a key factor in microalgae research, due to its increased productivity and the lower capital and operative costs compared to photoautotrophic growth in photo bioreactors. Carbohydrate production from microalgae is usually investigated for the production of biofuels (e.g. bioethanol) by successive fermentation, but also other applications can be envisaged in biopolymers. In this work an increment in carbohydrate lipid, chlorophyll a,b and carotenoid extraction was found in Scenedesmus sp. was investigated. Microalgae were cultivated under photoautotrophic or heterotrophic conditions, collecting biomass at the15, 22 and 29days of the growth. Biomass samples were dried or freeze dried and used for carbohydrate lipid, chlorophyll and carotenoid extraction tests. Lipid extraction was achieved using different organic solvents (methanol-chloroform and hexane-2propanol). Lipids were spectro photometrically quantified, while residual biomass was saccharificated and the total amount of sugars was measured. Significant differences about the purity of extracted carbohydrates were found comparing dried with freeze dried biomass. Simultaneously extracts the chlorophyll a,b and carotenoid using soxhlet apparatus. The findings indicate that *Scenedesmus sp.* is the most promising candidate strain; however, the

study also suggests that growth enhancement strategies could be applied to further optimize its biomass and lipid yields. This reflects a trend in biotechnology aiming to harness microalgae for sustainable energy and resource recovery.

Keywords: Microalgae, aquatic limestone, chlorophyll a,b and carotenoid and *Scenedesmus sp.*

INTRODUCTION

Global energy demand is rising due to population growth and industrialization, primarily relying on unsustainable fossil fuels, which contribute to greenhouse gas emissions and resource depletion. Urgent alternatives are needed, particularly in the transport sector, which accounts for about 16% of global emissions. Renewable biofuels and fuel-efficient vehicles are promising solutions. Humankind has relied on petroleum-based fuel since about 347 BC. Due to its depletion, cost, and dependence as a main transportation fuel, researchers seek renewable alternatives to replace fossil fuels. Research on microbial lipid production has surged due to the finite petroleum supply. Various organisms, such as cyanobacteria and algae, offer unique advantages, particularly their reliance on sunlight for energy and carbon dioxide for growth. Increasing fuel demand, coupled with population growth and climate change impacts on freshwater and arable land, is pushing the development of microalgae-based systems for food and fuel. Microalgae can efficiently use non-arable land and wastewater for biofuel production, making it superior to terrestrial biomass. There is significant interest from governments, NGOs, and the private sector in developing algal biofuel technologies, indicating its sustainable potential. Research on biodiesel seeks better sources to boost oil yield in algal cells. A significant biomass is needed to fully replace fossil fuels, whose liquid reserves may deplete by 2050 and contribute to environmental degradation. Therefore, biofuel from renewable sources like microalgae can reduce fossil fuel dependency and promote environmental sustainability. However, using food stocks for biofuel may lead to global dissatisfaction.

India has yet to achieve its algal biofuel targets. National labs and companies are developing methods for cultivation and biodiesel conversion, but progress is still in the early stages and requires significant attention. Isolating and identifying algal species is a key technique in phycology, as each species has specific growth needs influenced by temperature, pH, and light intensity. The use of microalgae as limestone markers has historical significance, traced back to (1). Recent studies by (2) and (3) emphasize the importance of these environmental factors in algal cultivation. Microalgae are a valuable source of bioactive compounds, including polyphenols, carotenoids, polysaccharides, omega-3 fatty acids, and polyunsaturated fatty acids (PUFAs), as highlighted by several studies (4,5). The lipid content of microalgae can vary significantly, ranging from 20% to 70%. This variability in lipid content and the fatty acid composition is chiefly determined by genetic and phenotypic variables, in addition to environmental factors and cultivation methodologies (6). Consequently, for the purpose of large-scale lipid production from microalgae, it is critical to select species that not only demonstrate competitiveness but are also easy to cultivate and capable of adapting to the specific environmental conditions of the cultivation area. Isolating microalgae strains with rapid growth, high lipid content, and significant biomass is vital (7,8). Lipid content varies among microalgae, including omega-3 fatty acids, which make up 30% to 40% of total fatty acids in species like Nannochloropsis (EPA), Schizochytrium (DHA), and Phaeodactylum. This potential supports their role in human nutrition and sustainable dietary supplements (9). Ariyalur district is notable for its limestone deposits from the Cretaceous Ariyalur group, particularly the Kallankurichi Formation, essential for cement production. The limestone, yellowish-brown and fossiliferous, varies in quality and thickness (8 to 12 meters) and is under major mining leases. Coccolithophores in the limestone contribute to rapid biomineralization, presenting a sustainable construction alternative(10). In this study aims to assess and isolate microalgal samples from Ariyalur, extracting lipids and exploring their potential uses with local limestone resources.

MATERIALS AND METHODS

Sampling and Isolation

A total of 116 samples (soil and water) were collected from the Ariyalur District across five stages to capture seasonal microalgae variations. Terrestrial samples of 100 g were gathered in polybags, while 100 ml water samples were collected in blue-capped containers. All samples were stored at 4°C.

Isolation and Enrichment of microalgae

Microalgae were isolated using sterilized Bold Basal medium (BBM) and enrichment culture methods in a controlled room with a 16:8 light cycle, 28±20°C, and pH 8.0. Water samples were inoculated in autoclaved BBM flasks and incubated for 10-15 days, allowing green algal growth. Unialgal cells were isolated with Pasteur pipettes and recultured in BBM for another 10-15 days. Agar medium was prepared, autoclaved, and incubated for additional growth. Purification involved repeated subculturing and microscopic inspections to ensure culture purity. Discrete colonies were used for further studies during the exponential phase.An enrichment sample was prepared with 1 g of soil in 10 ml distilled water to capture microalgal cells, then streaked onto agar BBM Petri dishes and incubated for 15 to 20 days, resulting in green colonies. The study isolated microalgal cells from various water and soil samples using agar and Bold Basal broth (BBM). After 15-20 days of incubation and subculturing, distinct growth was observed. Microalgal colonies transferred to BBM showed a green color change and web-like growth. To achieve unialgal growth, pipettes were used for precise transfers onto slides. Isolated unialgal cells were then cultured in BG-11 medium after another incubation period. Algal cells, along with some fungi and bacteria, can grow together. To avoid unwanted microbes, it's crucial to purify algal colonies using the axenization technique with a triple antibiotic solution, as noted by Kaushik (11). The solution consists of 100 mg penicillin G, 50 mg streptomycin sulfate in 10 ml water, and 10 mg chloramphenicol in 1 ml ethanol. After filtering this solution, 25 µl is added to 5 ml nutrient broth inoculated with 0.5 ml algal suspension. Following a 5-hour incubation at 25±1°C, the broth is centrifuged, the pellet washed, and resuspended in BG-11 medium. Cultures are incubated for 14 days, then checked for contamination, repeating the process if necessary.

Growth and cultivation conditions

Microalgal strains were cultivated in modified BG-11 medium at 30 ± 2°C and 3.5 klux light, with a 16:8 light:dark cycle and pH 8.0-8.2. A solid agar medium was prepared with 15-18 g of agar per liter, autoclaved, and cultures were streaked onto plates after 14 days. These were inoculated into 250 mL flasks for another 14 days until exponential growth. Morphological characterization used identification keys, and culture purity was verified through microscopic observations and streaking onto agar. Discrete colonies were inoculated into fresh medium to ensure minimal variations.The exponential phase of selected microalgal strain was subjected to following conditions of environmental and cultural variables. One mL of the 15days old culture (exponential phase)of selected potent isolate with0.9-1.0 OD at 560 nm was cultured in a flask of 250 ml capacity containing 100 ml BG-11 medium (under sterilized conditions) for 15, 22 and 29 days, separately, For each of the three sets,

The*Scenedesmus*sp. strain was maintained in Petri dish in BG11 (modified BG11 medium, with a reduced $NaNO_3$ concentration of 0.3 g/L) solid medium (12). Microalgae were firstly transferred from the Petri dish to 500 mL flasks in BG11 liquid medium and then inoculated in 4000 mL column reactors using 1:10 dilution ratio. Microalgae were cultivated in photoautotrophic conditions, under constant illumination (24 h) with 80 ± 10 µE m-2 s-1 and feed with 0.5 L/min of CO2/air (0.05/1 v/v). Heterotrophic condition has been obtained transferring a phototrophic microalgal culture (on exponential growth phase) to a BG11 medium added with 10 g/L of glucose as organic carbon source, and with no illumination provided. Microalgae concentration was measured by filtration of 10 mL of sample on 0.45 µm acetate cellulose filter. The filters were dried at 105 °C and then weighted, and the microalgal concentration reported as g/L of biomass concentration. Algal culture was harvested by sedimentation and centrifugation at 3000 rpm for 10-15 minutes. Cell pellets were re-suspended in deionized water and washed three times via centrifugation and re

suspension to remove residual salts. The washed cells were dried at 105°C for 12 h or freeze dried and stored until further use.

Extraction and analytical determination of total lipid content

Lipid extraction was carried out in a glass tube (at room temperature), using hexane/2-propanol (H2P; 3:2 v/v) or trichloromethane/methanol solution (Folch; 9:4 v/v), for about 12-16 hours, using 200 mg of dried microalgae under magnetic stirring. At the end of the process the total extractable lipids were measured calorimetrically, and the residual biomass dried at 105°C for 12 h. The determination of total lipid was achieved through sulpho-phospho-vanillin (SPV) colorimetric method (15). 1 mL of the total extracted lipids was transferred to a vessel, and the solvent evaporated. After this, 5 mL of a solution containing sulfuric acid (85% w/w) and vanillin 6 g/L were added, and the samples incubated at 37°C for 15 minutes. Then the absorbance was acquired at 530 nm wavelength by the UV-Visible spectrophotometer.

Carbohydrate recovery

Samples of 100 mg of dried microalgae were put in a Pyrex tube with 1 mL of concentrated sulfuric acid (72% w/w) at 30 °C for 1 hour. Afterwards the sample was put in a glass vial with 28 mL of distilled water (in order to obtain a final concentration of 4%) and kept for 1 hour at 120 °C in autoclave. The sample was then quickly cooled and 1 mL was centrifuged at 8000 rpm for 5 minutes. The sugar concentration in the supernatant was then analyzed by Dubios method (14).

Extraction methods of Chlorophyll and carotenoids

Algal biomass have been subjected to Soxhlet extraction 4 g of dry weight were used per 100 mL of solvent, prepared by mixing ethanol (96%,) and distilled water in a ratio of 7:3. For the purpose of comparing the yield, all extraction types were conducted under the following conditions: time: 60 min and temperature 40°C for Soxhlet extraction in which the temperature depends on the boiling point of the solvent. The extracts were concentrated under vacuum and stored at −18°C. Each extract was studied using a spectrophotometer and samples were placed in a glass cuvette and tested for the absorption spectrum in the range of 400–700 nm. Measurements were done by triplicate. On the basis of the absorption spectra chlorophyll a and b content and total carotenoid content were determined according to the method described byWellburn(15). The content of pigments was expressed as μg per mL of extract and was calculated using the following equations:

Chlorophyll a = $(11.75\times A_{662})-(2.53\times A_{645})$

Chlorophyll b =$(18.61\times A_{645})$ $)-(3.96\times A_{662})$

Total carotenoids= $((1000\times A_{470})-(2:27\times$Chl a) $-(81.4\times$Chl b))/22

RESULTS

Biomass production

Microalgal strains were cultivated under both phototrophic and heterotrophic conditions the Scenedesmus sp. strains show similar final concentration of biomass in phototrophic and heterotrophic conditions (about 1 g/L reached after 15 days, 22 days and 29 days). Specific growth rates showed a decrease in heterotrophic conditions adopted (Table-1). The advantage of heterotrophic growth is not in increased growth rate, but it is in the increased biomass productivity. However, this difference can be observed only in the last days of the cultivation: both phototrophic and heterotrophic reached about 0.473g/L of algae concentration after 29 days in Scenedesmus sp. phototrophic conditions are reaching a plateau due to growth inhibition caused by the turning of light into a limiting factor. On the other hand, in heterotrophic conditions the only limiting factor is the organic carbon source, that can be controlled by the operator, allowing to virtually reach infinite concentrations of algal biomass. Further tests are now in course to optimise the organic carbon/N ratio in order to improve biomass growth in heterotrophic conditions.

Lipid extraction

In this work, the main focus on the lipids extraction through SPV method after 15, 22 and 29 days of algal biomass summarizes in Table 2. Among the four treatments the percentage of extracted lipids in each treatment was to observe how the chloroform/methanol solution gives higher efficiency on extracted lipids (9.8%), compared to hexane/2-propanol (6.9%), especially on dried biomass.

Carbohydrate extraction

In all extraction tests the *Scenedesmus sp*. biomass shows a better efficiency on carbohydrate extraction, carbohydrates content, after 15, 22 and 29days (viz.38.5%;46.7% and 59.8 %. Combined action of freeze drying and solvent extraction seems to boost significantly the process for *Scenedesmus sp*. biomass, reaching a maximum in carbohydrate purity of 59.8 % in the freeze drying treatment and chloroform/methanol solution. Even if the use of hexane/2-proponal doesn't allow achievement of the same value, it is still pretty close (54.9%), which, compared with the more healthy nature of the solvents, is a promising result.

Chlorophyll and Carotenoidsextraction

Chlorophyll and carotenoid are extracted usingSoxhlet apparatus and the data are presented in Table 4. Among the biomass of 15, 22 and 29days culture of *Scendesmus sp.*the highest amount of pigment chlorophyll -a (4.9 ±0.3 μgmL−1), chlorophyll-b (2.5±0.1 μgmL−1) and carotenoids 1.8 μgmL−1) . Each column refers to a different microalgal strain, while each row refers to a different treatment: 1) dried biomass treated with $CHCl_3$/MeOH; 2) dried biomass treated with hexane/2-propanol; 3) freeze-dried biomass treated with $CHCl_3$/MeOH; 4) freeze dried biomass treated with hexane/2-propanol; Each column refers to a different treatment: A) freeze-dried biomass treated with $CHCl_3$/MeOH; B) freeze-dried biomass treated with hexane/2-propanol; C) dried biomass treated with $CHCl_3$/MeOH; D) dried biomass treated with hexane/2-propanol.

DISCUSSION

Microalgal strains were cultivated under both phototrophic and heterotrophic conditions, In *Scenedesmussp*..Biomass in phototrophic and heterotrophic conditions (after 29 days). (Table 1). The advantage of heterotrophic growth is not in increased growth rate, but it is in the increased biomass productivity. However, this difference can be observed only in the last days of the cultivation: both phototrophic and heterotrophic reached about 0.220-1 g/L of algae concentration after 15-29 days, phototrophic conditions are reaching a plateau due to growth inhibition caused by the turning of light into a limiting factor. On the other hand, in heterotrophic conditions the only limiting factor is the organic carbon source, that can be controlled by the operator, allowing to virtually reach infinite concentrations of algal biomass. Similar reports are published (16,3). In all lipid and carbohydrate extraction tests the Scenedesmus sp. biomass shows a better starting content in 15 days6.2% lipid and 38.5% carbohydrates on Scenedesmus sp.,). Combined action of freeze drying and solvent extraction seems to boost significantly the process for Scenedesmus sp. biomass, reaching a maximum in carbohydrate purity 59.8 % and 9.8% lipid in the freeze drying pre treatment and chloroform/methanol solution.

Even if the use of hexane/2-proponal doesn't allow achievement of the same value, it is still pretty close (54.9% and 6.9%), which, compared with the more healthy nature of the solvents, is a promising result. This could justify the positive action of freeze-drying observed onlipid and carbohydrateextraction. Although these results are in contrast with other works (17), where it is reported no difference in lipid extraction yield comparing oven drying, freeze drying or sun drying for Scenedesmus sp. biomass, in our tests freeze dried biomass appeared more porous and friable than oven dried counterpart. A similar results has been obtained by Zhang and co-workers for starch drying (18).This difference probably enhance solvent penetration in the stronger cell walls of Scenedesmussp(10) Chlorophylls and carotenoids are essential pigments of photo synthesis, in which they have complementary functions for capturing light.The quantitative determination of chlorophylls a, b, and carotenoids in a whole pigment extract of microalgae is strongly dependent on the type of extraction the solvent used, the temperature and duration

of the process. In our paper the maximum extraction of chlorophyll a (2.8 to 4.9 µgmL−1), chlorophyll b (1.8 to 2.5 µgmL−1) and total carotenoids (0.8 to 1.8 µgmL−1) were obtained for *Scendesmus sp* using soxhlet extraction technique (Table 4).

Similar work carried out in Soxletextraction of polar substances is carried out by adding, methanol, ethanol and acetone (23,24). As for isolation of antioxidants from macroalgae of Sargas summuticum (26) or phenols from Cladophoraglomerata, Ulva flexuosa and Charafragilis (27) were published. Chlorophyll is commonly preferred as a natural coloring agent due to its alluring green color although it is very susceptible to weak acids, oxygen, and light (20). Extraction of chlorophylls About 1.2 billion tons of chlorophyll (a and b) are produced annually on the planet (19). Most algae cultured under optimum conditions were reported containing about 4% (dry weight) of chlorophyll (21). Similar extraction can be performed using solvent extraction, (22). Considering these extraction techniques, some conditions, such as solvent type, pressure, temperature, efficiency of the contact biomass-solvent, and time of extraction (23) The solvent extraction techniques involve a SLE (with or without the Soxhlet assistance) to remove the pigments from the biomass followed by a liquid-liquid extraction, in which the different compounds removed from the microalgae cells are isolated and further purified. For the first step of SLE, the most common solvents being used are methanol, ethanol, acetone, and/or dimethyl formamide as pure compounds or as aqueous solutions. Also in the chlorophylls extraction, some authors studied different cell disruption methods aiming at the increase of the extraction yields. The most common techniques of cell disruption being evaluated are the grinding, homogenization, ultrasound, and sonication of the cells that considerably improve the effectiveness of chlorophyll extraction in the presence of organic solvents (24,25). In contrast Recently, some other studies have been developed on the use of UAE, SFE, and MAE to improve the process sustainability, namely by maintaining the extraction yields but at the same time trying to decrease the solvent consumption and/or the time of extraction (22). In thepresent studies, more efficient methods of chlorophyll and carotenoid isolation from microalgae using inSoxhlet extraction. In contrastfew studies, proved that MAE and UAE are very efficient methods chlorophyll and carotenoid isolation from algae. (24,28,29,30). Our results confirm that Soxhlat technique is an appropriate method of obtaining non polar compounds

CONCLUSION

Different microalgal growth conditions have been compared. Growth rate and maximum biomass concentration have been obtained for phototrophic and heterotrophic cultivation in Scenedesmus sp. The biomass concentration in the two conditions, while the growth rate was higher in phototrophic cultivation. Sequential separation of lipids, carbohydrate, chlorophyll and carotenoids showed promising results. By removing lipids, carbohydrate content was increased until 59.8 %. For Scenedesmus sp. freeze drying is advisable, can be used without relevant difference. If better results were obtained with chloroform/methanol, hexane/2-propanol gave comparable results in carbohydrate increment. The present investigation are characterized by high amounts of chlorophyll and low carotenoid content. Due to the addition of ethanol as a polar solvent mixture the yield of carotenoid isolation as non-polar compounds was lower in comparison to other studied extraction methods. Pigments extraction from microalgae an the choice of extraction method should taken into account not only for the species of algae, but also the kind of isolated bioactive substances, type of solvent, temperature, time and other factors. Thus, using appropriate extraction method for individual species of algae there can be obtained extracts with high content of bioactive compounds and, as a result, raw materials for different applications, such as cosmetic industry.

ABSTRACT

Cloud computing has become the backbone of modern digital infrastructures, enabling scalable storage, computing resources, and distributed services across geographically dispersed data centers. As cloud environments evolve toward multi-cloud architectures, efficient and secure communication among network nodes has become increasingly challenging due to dynamic traffic patterns, congestion, security threats, and heterogeneous resource availability. Existing node selection and routing approaches primarily focus on limited optimisation objectives such as shortest-path routing, trust evaluation, or energy efficiency, often neglecting the combined influence of multiple network conditions. This paper proposes an Adaptive Context-Aware Multi-Metric Network Node Selection (ACMNNS) framework that dynamically evaluates candidate network nodes using trust, residual energy, available bandwidth, congestion level, latency, link stability, node reliability, and resource utilisation. Unlike conventional static node-scoring methods, the proposed framework adaptively adjusts the importance of each metric according to the current network context, enabling intelligent routing decisions that improve both security and Quality of Service (QoS). The framework is designed for multi-cloud environments and supports secure data transmission through continuous node monitoring and dynamic route reconstruction. The performance of the proposed framework will be evaluated through simulation using NS-3 and CloudSim Plus with metrics including throughput, packet delivery ratio, end-to-end delay, packet loss, routing overhead, and energy consumption. The expected results demonstrate improved

network reliability, secure communication, efficient resource utilization, and enhanced scalability compared with existing routing techniques.

Keywords: Cloud Computing, Multi-Cloud, Network Node Selection, Trust Management, QoS, Secure Routing, Energy Efficiency, Adaptive Routing.

INTRODUCTION

Cloud computing has transformed the way organisations store, process, and exchange information by providing scalable computing resources over the Internet. Enterprises increasingly deploy applications across multiple cloud providers to improve availability, reduce operational costs, and avoid dependence on a single vendor. While multi-cloud environments offer significant advantages, they also introduce complex networking challenges because data must travel through numerous interconnected network nodes before reaching its destination. Network nodes play a critical role in cloud communication. Every transmitted packet passes through routers, switches, gateways, virtual machines, or software-defined network components that collectively determine communication performance. Selecting unsuitable forwarding nodes can increase transmission delay, create network congestion, reduce throughput, and expose sensitive data to security threats. Many existing routing protocols prioritize only one or two optimization criteria, such as shortest path, residual energy, or trust value. However, real cloud environments are highly dynamic. A node that is reliable at one moment may become congested, overloaded, or even compromised later. Consequently, static node-selection mechanisms are often unable to maintain consistent Quality of Service (QoS) and security. To address these limitations, this paper proposes an Adaptive Context-Aware Multi-Metric Network Node Selection (ACMNNS) framework. Rather than relying on a single routing metric, the framework continuously evaluates multiple characteristics of each candidate node—including trust, congestion, bandwidth, latency, energy, and link stability—and adjusts their importance according to current network conditions. This adaptive strategy aims to improve secure communication, optimize resource utilization, and enhance routing performance in multi-cloud environments.

Research Contributions

The main contributions of this paper are:

- To design an adaptive multi-metric framework for intelligent network node selection in multi-cloud environments.
- To develop a dynamic node-scoring model that incorporates trust, bandwidth, congestion, latency, energy, link stability, and resource utilisation.
- To introduce a context-aware weighting mechanism that automatically adjusts metric importance based on current network conditions.
- To propose a secure routing strategy that reconstructs routes when node reliability changes.
- Performance evaluation using NS-3 and CloudSim Plus with standard networking metrics.

LITERATURE REVIEW

Trust-Based Node Selection in Software-Defined Networks

Aditya Kumar and Fancy Chelladurai (2022) proposed a Trust-Based Node Selection Architecture for Software-Defined Networks (SDN). Their framework computes trust values for network nodes and uses these values during routing decisions to improve Quality of Service (QoS) and network reliability. The architecture demonstrated that trust-aware node selection can improve secure communication compared with conventional routing. However, the trust evaluation mechanism relies primarily on trust metrics and does not jointly optimize congestion, bandwidth,

latency, or energy consumption. Consequently, the framework is less suitable for highly dynamic multi-cloud environments where multiple network conditions change simultaneously.

Limitation

- Static trust evaluation
- Limited routing metrics
- No adaptive weight adjustment
- No multi-cloud optimization

Trust-Enhanced Secure Routing in SDN

Bulbul et al. (2022) introduced a Trust-Enhanced Security for Routing in SDN that integrates trust values into routing decisions for software-defined networks. The method improves routing security by preferring trusted forwarding paths and reducing the influence of malicious nodes. Although security is enhanced, the routing mechanism primarily focuses on trust without considering dynamic congestion, resource utilization, or Quality of Service requirements.

Limitation

- Security-focused only
- No adaptive routing
- No bandwidth optimization
- No energy awareness

Secure Segment Routing Based on Trust Enhancement

Wang et al. (2022) proposed a Segment Routing Security Model Based on SDP Trust Enhancement Architecture. Their work combines Software-Defined Perimeter (SDP) concepts with segment routing to improve secure data transmission and protect the routing data plane. Experimental results demonstrated improved communication security against routing attacks. However, the framework does not optimize forwarding-node selection using multiple network metrics and does not address adaptive route reconstruction under changing network conditions.

Limitation

- Focuses on routing security
- Limited QoS optimization
- No intelligent node-scoring mechanism

AI-Based SDN Routing Framework

Alharbi et al. (2025) presented an AI-Driven SDN and Blockchain-Based Routing Framework for AIoT networks. The framework integrates blockchain with SDN to establish trusted communication and uses AI techniques to improve routing efficiency. Their experimental evaluation reported improvements in energy consumption, response time, and packet loss. Nevertheless, blockchain integration introduces computational overhead, and the framework targets AIoT rather than general multi-cloud environments.

Limitation

- Blockchain overhead
- AIoT-specific architecture
- Higher computational complexity

Trust-Based Multi-Objective Cluster Head Selection

Jagan et al. (2025) proposed a Trust-Based Multi-Objective Cluster Head Selection method for secure routing in wireless sensor networks. Their algorithm jointly considers trust, energy efficiency, and communication reliability to select cluster heads. The results demonstrated better energy utilization and secure routing. However, the study focuses on wireless sensor networks and cannot be directly applied to cloud data-center networking or multi-cloud communication.

Limitation

- WSN-specific
- Not designed for cloud networks
- No dynamic cloud resource management

SDN Load Balancing and Routing Survey

Mousa and Abdullah (2022) surveyed routing, load balancing, and congestion control techniques in SDN. They concluded that AI-based routing is becoming increasingly important and identified dynamic routing, intelligent congestion management, and adaptive optimization as major future research directions. The survey also highlights that many existing methods still rely on static routing metrics and require better adaptive mechanisms.

Research Gap

The literature review reveals that significant progress has been made in secure routing, trust-based communication, and energy-aware networking for cloud environments. However, several important limitations remain unresolved. Most existing routing algorithms rely on single-metric optimization, such as shortest path, trust value, or residual energy. While these approaches improve one aspect of network performance, they often ignore other important parameters including congestion, latency, bandwidth availability, link stability, and node resource utilization. As a result, routing decisions may become inefficient under dynamic cloud workloads. Many trust-based routing techniques employ static trust evaluation, where a node's trust value changes slowly or is not updated according to real-time network behavior. This limitation reduces the ability to detect compromised or unreliable nodes promptly.
Similarly, energy-aware routing algorithms primarily focus on maximizing network lifetime but do not adequately consider Quality of Service (QoS), transmission delay, or communication reliability. AI-based routing methods have demonstrated improved decision-making capability, but many require extensive training data and high computational resources, making them less suitable for lightweight cloud networking applications. Furthermore, existing multi-metric routing frameworks generally use fixed weighting schemes. Such fixed weights cannot adapt to changing network conditions such as congestion, cyber attacks, fluctuating bandwidth, or varying application requirements. Consequently, routing performance degrades when the operating environment changes rapidly. Therefore, there is a need for an adaptive network node selection framework that dynamically evaluates multiple routing metrics, updates decision priorities according to the current network state, and supports secure and energy-efficient data transmission in multi-cloud computing environments.

From the above literature, the following gaps are evident:

- Most methods optimize only one or two routing metrics.
- Trust values are frequently static rather than adaptive.
- Congestion, latency, energy, and bandwidth are rarely optimized together.
- Existing cloud routing methods have limited support for dynamic multi-cloud environments.
- Many frameworks increase computational complexity by relying on blockchain or deep learning.
- There is still a need for a lightweight adaptive multi-metric node selection algorithm that dynamically balances security, QoS, and resource utilization in multi-cloud networks.

Problem Statement

Modern multi-cloud environments require reliable and secure communication among distributed network nodes. Existing node-selection algorithms often optimize only a limited set of routing parameters, leading to increased latency, packet loss, congestion, and reduced resource utilization under dynamic network conditions. Moreover, static trust evaluation and fixed routing priorities reduce the adaptability of current routing techniques to evolving security threats and workload variations. The problem addressed in this research is the lack of a lightweight, adaptive node-selection mechanism capable of simultaneously considering trust, energy, bandwidth, congestion, latency, and link stability while dynamically adjusting routing decisions according to real-time network conditions.

Addressing this problem can improve communication reliability, Quality of Service, and resource efficiency in multi-cloud networks.

Research Objectives

- To develop an adaptive context-aware network node selection framework for secure and energy-efficient data transmission in multi-cloud computing environments.
- To design a dynamic node evaluation model using multiple network metrics.
- To develop an adaptive node-scoring mechanism for forwarding-node selection.
- To improve secure communication by incorporating trust-based routing decisions.
- To reduce packet loss, delay, and routing overhead.
- To improve bandwidth utilization and Quality of Service.
- Evaluate the proposed framework using NS-3 and CloudSim Plus.

PROPOSED METHODOLOGY

Overview

The proposed Adaptive Context-Aware Secure Node Selection (ACSNS) framework is designed to improve secure and energy-efficient data transmission in multi-cloud computing environments. The framework continuously monitors network conditions and selects the most appropriate forwarding node using multiple routing metrics. Unlike conventional routing approaches that rely on fixed routing criteria, ACSNS dynamically evaluates candidate nodes based on trust, bandwidth, congestion, residual energy, latency, link stability, and security risk. By combining these metrics into a Dynamic Node Reliability Index (DNRI), the framework selects forwarding nodes that maximize communication reliability while minimizing network overhead and transmission delay.

The overall workflow consists of five phases:

- Network Discovery – Detect neighbouring nodes and available communication links.
- Node Monitoring – Collect real-time information such as trust value, energy level, bandwidth, latency, congestion, and link stability.
- Node Evaluation – Normalise collected metrics and compute the Dynamic Node Reliability Index (DNRI).
- Adaptive Node Selection – Rank candidate nodes according to their DNRI values and select the highest-ranked secure node for packet forwarding.
- Route Maintenance – Continuously update node information and reconstruct routes whenever network conditions change.

Proposed Adaptive Context-Aware Secure Node Selection (ACSNS) System Architecture

The proposed **Adaptive Context-Aware Secure Node Selection (ACSNS)** framework is designed to provide secure, reliable, and energy-efficient data transmission in multi-cloud computing environments. The architecture consists of several functional modules that work together to identify the most suitable forwarding node based on multiple network parameters. Each module performs a specific task to ensure efficient routing and improved Quality of Service (QoS).

Step 1: Cloud User

The communication process begins when the **Cloud User** sends a request to transmit data to a destination cloud server. The user's request is received by the cloud gateway, which initiates the routing process.

Step 2: Cloud Gateway

The **Cloud Gateway** acts as the entry point to the cloud network. It authenticates incoming requests and forwards them to the network management system for route discovery. It also manages communication between the user and cloud resources.

Step 3: Network Discovery Module

The Network Discovery Module identifies all neighboring network nodes and discovers all possible communication paths between the source and destination. It continuously updates the network topology by monitoring node availability and connectivity.

Functions:

- Discover neighboring nodes.
- Identify available communication links.
- Maintain updated network topology.
- Eliminate inactive nodes.

Step 4: Node Monitoring Module

The **Node Monitoring Module** continuously collects real-time information from every candidate node. This information is used to evaluate the current status and reliability of each node.

The monitored parameters include:

- Trust Value: Measures node reliability based on successful communication history.
- Residual Energy: Indicates the remaining energy or available resources of the node.
- Available Bandwidth: Represents the communication capacity available for data transmission.
- End-to-End Delay: Measures the communication delay experienced by packets.
- Congestion Level: Indicates the current traffic load on the node.
- Security Risk: Represents the probability of the node being compromised or malicious.

These parameters are periodically updated to reflect current network conditions.

Step 5: Dynamic Node Reliability Index (DNRI) Calculation Module

The DNRI Calculation Module is the core component of the proposed framework. It combines all monitored parameters using the proposed mathematical model to calculate a Dynamic Node Reliability Index (DNRI) for every candidate node. The DNRI value reflects the overall suitability of a node for forwarding packets. Nodes with higher trust, greater bandwidth, better link quality, and lower congestion or security risk receive higher scores. This adaptive scoring mechanism enables the framework to make intelligent routing decisions under changing network conditions.

Step 6: Adaptive Node Selection Module

After calculating the DNRI values, the Adaptive Node Selection Module ranks all candidate nodes in descending order of their reliability scores. The node with the highest DNRI that also satisfies predefined security and Quality of Service constraints is selected as the next forwarding node. If the selected node later becomes congested, unreliable, or unavailable, the module recalculates the scores and selects an alternative node.

Functions:

- Rank candidate nodes.
- Select the optimal forwarding node.
- Avoid malicious or overloaded nodes.
- Support dynamic route reconstruction.

Step 7: Secure Data Transmission

Once the optimal route is established, the Secure Data Transmission Module forwards data packets through the selected nodes toward the destination cloud. During transmission, the framework continuously monitors node status and updates routing decisions if network conditions change.

This module aims to:

- Improve packet delivery ratio.
- Minimize transmission delay.

- Reduce packet loss.
- Enhance communication security.

Step 8: Destination Cloud

The **Destination Cloud** receives the transmitted data after successful routing through the selected network nodes. The communication session is completed, and transmission statistics are recorded for future trust updates and performance evaluation.

Network Model

Network Assumptions

The proposed Adaptive Context-Aware Secure Node Selection (ACSNS) framework considers a multi-cloud computing environment consisting of interconnected cloud gateways and multiple forwarding nodes. The communication network is modeled as an undirected graph in which each node represents a cloud server, virtual machine, router, gateway, or intermediate forwarding device, while communication links represent the available transmission paths between nodes. The framework assumes that each node periodically broadcasts its status information to neighboring nodes. This information includes trust value, residual energy, available bandwidth, congestion level, processing delay, and security status. The collected information is used by the proposed framework to identify the most reliable forwarding node. The network also assumes that nodes may dynamically join or leave the network due to workload changes, failures, or maintenance activities. Therefore, routing decisions must be continuously updated to maintain secure and reliable communication.

Network Representation

The cloud network is represented as a graph:

$G = (N, E)$

where:

- **N** = Set of network nodes
  $N = \{n_1, n_2, n_3, \dots, n_m\}$
- **E** = Set of communication links
  $E = \{e_1, e_2, e_3, \dots, e_k\}$

Each communication link represents a direct connection between two neighboring nodes.

Node Information Table

Every network node maintains the following information:

These parameters are periodically updated during network operation.

Communication Process

The communication process consists of the following steps:

- The source node initiates a data transmission request.
- The Network Discovery Module identifies neighboring nodes.
- The Node Monitoring Module gathers real-time metrics from each neighboring node.
- The ACSNS framework computes a reliability score for every candidate node.
- The node with the highest reliability score is selected as the forwarding node.
- The process repeats until the destination cloud is reached.

Performance Constraints

To ensure reliable communication, the selected forwarding node must satisfy the following constraints:

- **Trust Constraint**

$T_i \geq T_{min}$

Only nodes whose trust value exceeds the minimum threshold are considered.

- **Energy Constraint**

$E_i \geq E_{threshold}$
Nodes with insufficient residual energy are excluded.

- **Congestion Constraint**

$C_i \leq C_{max}$
Highly congested nodes are avoided.

- **Security Constraint**

$S_i \leq S_{threshold}$
Nodes with excessive security risk are not selected.

- **Bandwidth Constraint**

$B_i \geq B_{required}$
Only nodes with sufficient available bandwidth participate in routing.

Working Principle

The ACSNS framework continuously monitors network conditions and dynamically selects forwarding nodes according to the calculated Dynamic Node Reliability Index (DNRI). Unlike conventional routing protocols that rely on static routing metrics, ACSNS adapts its routing decisions whenever network conditions change, thereby improving packet delivery, reducing communication delay, and enhancing overall network security.

Mathematical Formulation

The proposed Adaptive Context-Aware Secure Node Selection (ACSNS) framework selects the best forwarding node by evaluating multiple network parameters. Each candidate node is assigned a Dynamic Node Reliability Index (DNRI) based on its current network status.

Node Parameters

The following parameters are considered during node evaluation.

Dynamic Node Reliability Index (DNRI)

The overall reliability score of a node is calculated as

$$DNRI_i = T_i + E_i + B_i - C_i - D_i - S_i \quad (6.1)$$

where

- T_i = Trust Value
- E_i = Residual Energy
- B_i = Available Bandwidth
- C_i = Congestion Level
- D_i = End-to-End Delay
- S_i = Security Risk

A **higher DNRI** indicates a more reliable node for data forwarding

Node Selection

After calculating the DNRI for all neighboring nodes, the node with the highest score is selected as the forwarding node.

$$N_{selected} = \max(DNRI_i) \quad (6.2)$$

This process is repeated until the data reaches the destination cloud.

Routing Constraints

To ensure secure and efficient communication, the selected node must satisfy the following conditions:

$$T_i \geq T_{min} E_i \geq E_{min} C_i \leq C_{max} S_i \leq S_{max} \quad (6.3)$$

Only nodes meeting these constraints are considered for routing.

Working Principle

- Collect network parameters from neighboring nodes.
- Calculate the DNRI for each node.
- Compare the DNRI values.
- Select the node with the highest DNRI.
- Forward the data packet.
- Repeat the process until the destination is reached.

Proposed ACSNS Algorithm

Algorithm 1: Adaptive Context-Aware Secure Node Selection (ACSNS)

Input:

- Source node
- Destination node
- Neighboring nodes

Output:

- Secure and optimal routing path.

Step 1: Start
Step 3: Collect node information:
- Trust Value (T)
- Residual Energy (E)
- Available Bandwidth (B)
- Congestion Level (C)
- Delay (D)
- Security Risk (S)

Step 4: Calculate DNRI for each node.
Step 5: Compare the DNRI values.
Step 6: Select the node with the highest DNRI.
Step 7: Forward the data packet.
Step 8: Update node information.
Step 9: Repeat Steps 3–8 until the destination is reached.
Step 10: End

Algorithm Explanation

The ACSNS algorithm begins by discovering all neighboring nodes that can participate in communication. It then collects the required network parameters, including trust value, residual energy, bandwidth, congestion level, delay, and security risk. Using these parameters, the Dynamic Node Reliability Index (DNRI) is calculated for each candidate node. The algorithm compares the DNRI values and selects the node with the highest score as the next forwarding node. After each transmission, node information is updated to reflect current network conditions. The process repeats until the data packet successfully reaches the destination.

Computational Complexity

Assume:

- n = Number of neighboring nodes

For each routing decision:

- Collecting metrics: $O(n)$
- Calculating DNRI: $O(n)$
- Finding the maximum DNRI: $O(n)$

Overall Time Complexity:
$O(n)$
Space Complexity:
The algorithm stores the metrics of all neighboring nodes.
$O(n)$

Experimental Setup
Simulation Environment
The performance of the proposed Adaptive Context-Aware Secure Node Selection (ACSNS) framework is evaluated using the NS-3 network simulator. The simulation is conducted in a multi-cloud network environment to analyze the efficiency of the proposed node selection algorithm. The performance of ACSNS is compared with existing routing algorithms using standard network performance metrics.
Performance Metrics
The following performance metrics are used to evaluate the proposed framework.

Packet Delivery Ratio (PDR)
The percentage of successfully delivered packets.

$$PDR = \frac{\text{Packets Received}}{\text{Packets Sent}} \times 100 \quad (7.1)$$

Throughput
Measures the amount of data successfully transmitted per second.

$$Throughput = \frac{\text{Total Received Data}}{\text{Simulation Time}} \quad (7.2)$$

Average End-to-End Delay
Measures the average time required for a packet to travel from source to destination.

$$Delay = \frac{\sum(ReceiveTime - SendTime)}{\text{Packets Received}} \quad (7.3)$$

Packet Loss Ratio (PLR)
Measures the percentage of lost packets during transmission

$$PLR = \frac{\text{Packets Lost}}{\text{Packets Sent}} \times 100 \quad (7.4)$$

Energy Consumption
Measures the total energy consumed during data transmission.

$$Energy = E_{initial} - E_{remaining} \quad (7.5)$$

Comparison Methods
The proposed ACSNS framework is compared with the following routing algorithms:
- AODV
- DSR
- OLSR
- Trust-Based Routing

These methods are selected because they are widely used as benchmark algorithms for evaluating secure and efficient routing in distributed networks.

RESULTS AND DISCUSSION

Packet Delivery Ratio
Observation: ACSNS is expected to maintain a higher packet delivery ratio because it selects forwarding nodes using multiple network metrics instead of relying on a single routing criterion.

- Throughput
  Observation: The adaptive node-selection strategy is expected to improve throughput by avoiding congested and unreliable nodes.
- End-to-End Delay
  Observation: ACSNS is expected to reduce transmission delay by selecting nodes with lower congestion and better link quality.
- Packet Loss Ratio
  Observation: By selecting more reliable forwarding nodes, ACSNS is expected to reduce packet loss.
- Energy Consumption
  Observation: ACSNS is expected to improve energy efficiency by avoiding unnecessary retransmissions and overloaded nodes.

DISCUSSION

The illustrative results suggest that the proposed ACSNS framework could improve packet delivery ratio and throughput while reducing delay, packet loss, and energy consumption. These improvements are conceptually attributed to its multi-metric node evaluation strategy, which considers trust, bandwidth, congestion, delay, and security simultaneously.

CONCLUSION

This paper presented an Adaptive Context-Aware Secure Node Selection (ACSNS) framework for secure and energy-efficient data transmission in multi-cloud computing environments. The proposed framework evaluates candidate forwarding nodes using multiple network parameters, including trust value, residual energy, available bandwidth, congestion level, end-to-end delay, and security risk. Based on these parameters, the framework computes the Dynamic Node Reliability Index (DNRI) to identify the most suitable forwarding node for secure communication. The proposed approach aims to improve routing performance by selecting reliable and efficient network nodes while reducing congestion and communication delay. The experimental design compares the ACSNS framework with conventional routing algorithms using performance metrics such as Packet Delivery Ratio, Throughput, End-to-End Delay, Packet Loss Ratio, and Energy Consumption. The analysis indicates that a multi-metric node selection strategy has the potential to enhance communication reliability, optimize resource utilization, and improve the overall Quality of Service (QoS) in multi-cloud networks.

Future Work

The proposed ACSNS framework can be extended in several directions to improve its adaptability and performance:

- Integrate machine learning techniques to predict node reliability and optimize routing decisions automatically.
- Extend the framework for Software-Defined Networking (SDN) and Network Function Virtualization (NFV) environments.
- Investigate the use of block chain for secure trust management and route verification.
- Evaluate the framework in edge computing and Internet of Things (IoT) scenarios.
- Develop a hybrid optimization algorithm to improve node selection in large-scale cloud networks.
- Validate the framework using real-world cloud workloads and larger network topologies.

ABSTRACT

Alzheimer's disease (AD) remains the leading cause of dementia worldwide and the conventional "one-drug, one-target" acetylcholinesterase (AChE) inhibitors, including donepezil, offer only transient symptomatic relief without altering disease trajectory. Over the past decade, the multi-target-directed ligand (MTDL) paradigm has repositioned donepezil's N-benzylpiperidine pharmacophore, and its serotonergic congener donecopride, as versatile scaffolds for rational polypharmacology. This updated review consolidates literature from 2022 through mid-2026 on donepezil- and donecopride-based MTDLs, covering hybrids that combine cholinesterase inhibition with butyrylcholinesterase (BuChE) inhibition, monoamine oxidase (MAO-A/B) inhibition, 5-HT4 receptor agonism, β-amyloid (Aβ) anti-aggregation, BACE-1 inhibition, metal chelation and antioxidant activity. Particular attention is paid to the "copride" family (donecopride, flucopride, deudonecopride and rigidified benzisoxazole/phenylpyrazole analogues), to natural-product and heterocycle-based donepezil hybrids (coumarins, arylsulfonamides, 8-hydroxyquinolines, NSAIDs), and to the growing role of in-silico QSAR modelling, molecular docking, molecular dynamics and AI-assisted ADMET prediction in prioritising candidates before synthesis. We summarise structure-activity trends, highlight compounds with the most favourable dual-target potency and blood-brain-barrier-compatible drug-likeness, and outline unresolved challenges, including limited clinical translation, off-target toxicity of tacrine-derived fragments, and the

need for standardised in-vivo validation. The review is intended as a current reference for computational and medicinal chemistry groups engaged in donepezil/donecopride-inspired anti-Alzheimer's drug discovery.

Keywords: Alzheimer's disease; donepezil; donecopride; multi-target-directed ligands; acetylcholinesterase; molecular docking; QSAR; ADMET

INTRODUCTION

Alzheimer's disease (AD) is a progressive neurodegenerative disorder and the most common cause of dementia in older adults, clinically characterized by an insidious decline in memory and cognition and neuro pathologically defined by extracellular amyloid-β (Aβ) plaques and intracellular neuro fibrillary tangles composed of hyper phosphorylated tau, a pathological progression classically staged according to the spread of neurofibrillary changes through the cortex, alongside synaptic loss and chronic neuro inflammation [1][2][3]. The amyloid cascade hypothesis, which situates Aβ accumulation as the initiating event driving downstream tau pathology, synaptic dysfunction and neurode generation, has for three decades been the dominant mechanistic framework guiding drug development, and integrated models linking amyloid, tau and inflammatory pathophysiology continue to be refined [4][5]. Global dementia incidence is substantial and continues to rise with population ageing, placing an escalating burden on health systems and caregivers [6][7][8][9][10][11]. Despite decades of drug-development effort, the disease remains without a therapy that reliably halts or reverses cognitive decline; recently approved anti-amyloid immunotherapies have shown only modest clinical benefit relative to their cost, complexity of administration and safety monitoring requirements. Small-molecule pharmacotherapy for AD has, since the 1990s, centred on the cholinergic hypothesis, which links cognitive symptoms to a deficit of cortical and hippocampal acetylcholine arising from cholinergic neuron loss [16][17][18].

The acetylcholinesterase inhibitors (AChEIs) donepezil, rivastigmine and galantamine, together with the NMDA-receptor antagonist memantine, remain the only symptomatic agents in routine clinical use [19]. Donepezil, a piperidine-based, reversible and highly selective AChE inhibitor, occupies both the catalytic anionic site (CAS) and the peripheral anionic site (PAS) of the enzyme gorge through its indanone and N-benzylpiperidine moieties, respectively, a dual-site binding mode that has made it the most frequently repurposed pharmacophore in anti-AD medicinal chemistry [20][21][22].The PAS additionally participates in AChE's non-classical, chaperone-like promotion of Aβ fibrillogenesis, a property first characterised structurally and biochemically in the 1990s and 2000s, which provides part of the mechanistic rationale for why PAS-engaging ligands may confer anti-aggregation benefit beyond simple catalytic inhibition [23][24][25].It has become increasingly clear that AD pathology is multifactorial, involving interlinked amyloidogenic, tau, cholinergic, oxidative, neuro inflammatory and metal-dyshomeostasis mechanisms, so that intervention at a single node is unlikely to be disease-modifying [26][27][28]. This recognition has driven the emergence of multi-target-directed ligands (MTDLs): single small molecules rationally designed to engage two or more AD-relevant targets simultaneously, in preference to combination therapy or single-target drugs, with the aims of improved efficacy, simplified pharmacokinetics and reduced drug-drug interaction risk[29][30][31][32]. Donepezil's dual-site AChE binding pharmacophore, and the structurally related donecopride scaffold, which additionally engages the serotonin 5-HT4 receptor (5-HT4R), have become two of the most widely exploited starting points for MTDL design in AD [33][34].This review updates the donepezil/donecopride MTDL literature for the period 2022–2026, complementing earlier surveys that focused principally on the 2014 – 2021 window [35][36]. It is intended to support ongoing computational and medicinal chemistry work including QSAR modelling, molecular docking and ADMET-based screening of novel donecopride analogues by consolidating recent design strategies, representative compounds, in-silico methodologies and translational challenges into a single, current reference.

The Multi-Target-Directed Ligand Paradigm in Alzheimer's Disease

The MTDL concept, formalized in medicinal chemistry roughly two decades ago, departs from the classical "one molecule, one target" model by deliberately engineering polypharmacology into a single chemical entity [30]. In AD, this typically involves fusing or linking the pharmacophore of an established AChE inhibitor with a second fragment active against a mechanistically distinct target, guided by the principle that the two activities should be complementary rather than redundantfor example combining symptomatic cholinergic enhancement with a disease-modifying action such as anti-aggregation, antioxidant or neurotrophic support [31][32].Three broad design strategies recur across the literature: (i) linked or fused hybridisation, in which two intact pharmacophores are joined by a spacer of optimisable length and flexibility; (ii) merged or overlapping hybridisation, in which the two pharmacophores share a common substructure to reduce molecular weight; and (iii) pharmacomodulation of a single privileged scaffold so that it acquires activity at a second target through substituent or ring modification, as exemplified by the donepezil-to-donecopride transition, where re-engineering of the RS67333 5-HT4R agonist scaffold introduced potent AChE inhibition without loss of serotonergic activity. Recent reviews emphasise that successful MTDLs must additionally satisfy blood-brain-barrier (BBB) permeability, balanced lipophilicity and acceptable hepatic and cardiac safety margins, criteria that have historically been difficult to achieve simultaneously with tacrine-derived hybrids because of their intrinsic hepatotoxicity liability [37].

Donepezil-Based Multi-Target-Directed Ligands (2022–2026)

Donepezil's N-benzylpiperidine/benzylpiperidinium fragment, which anchors the PAS of AChE through π–π stacking with Trp286, is chemically tractable and tolerates extensive substitution, making it the most frequently reused pharmacophore in recently published AD MTDLs. The 2022–2026 literature can be organized by the identity of the second pharmacophore fused to this anchor.

Coumarin- and heterocycle-based hybrids (dual AChE/MAO-B and antioxidant action)

Coumarin remains one of the most exploited natural-product-inspired partners for donepezil hybridization because the bicyclic chromenone core is intrinsically antioxidant and can be tuned for selective monoamine oxidase-B (MAO-B) inhibition [38]. Early donepezil–coumarin hybrids combining the N-benzylpiperidine unit with substituted coumarins produced dual AChE/BuChE inhibitors with additional, clearly selective MAO-B activity and favourable predicted BBB permeability and low neuroblastoma cytotoxicity, establishing coumarin–piperidine hybridisation as a validated template [39][40][41][42]. More recent work (2024–2025) has extended this approach with 3-acetyl-8-methoxycoumarin and coumarin–oxadiazole hybrids evaluated computationally alongside in-vitro assays, and dedicated reviews of "naturally inspired" coumarin derivatives have catalogued acetohydrazide- and heteroaromatic-linked coumarins with combined AChE inhibitory and radical-scavenging (DPPH) activity and benign in-vivo biochemical profiles in rodent screens [43][44].A related bi-heterocyclic strategy has combined donepezil-derived fragments with a second heterocyclic ring system directly, computationally assessed for enhanced AChE inhibition, while structure-based work on phenyl-ring bioisosteres has specifically targeted dual cholinesterase/MAO-B inhibition with an explicit AChE/BuChE selectivity switch [43][44].

Arylsulfonamide and NSAID conjugates (anti-amyloid and anti-inflammatory action)

Donepezil–arylsulfonamide hybrids, generated by fusing an aryl-sulfonamide group to the benzylpiperidine or benzylpiperazine pharmacophore, have demonstrated a combination of potent AChE inhibition and inhibition of Aβ self-aggregation, with selected compounds additionally protecting neuroblastoma cells from Aβ-induced toxicity while retaining predicted blood-brain permeability [45]. A parallel strategy conjugates non-steroidal anti-inflammatory drug (NSAID) fragments to donepezil to address neuroinflammation directly: a reported series of eight NSAID–donepezil hybrids achieved AChE and BuChE IC50 values in the low- to sub-micromolar range, markedly more potent than donepezil itself against BuChE, while simultaneously inhibiting cyclooxygenase-1/2 and suppressing LPS-induced pro-inflammatory cytokine (TNF-α, IL-1β) release [46]Molecular docking has been used similarly to validate a broader set of donepezil analogues for combined anti-Alzheimer activity, reinforcing docking as a routine confirmatory step for newly synthesised donepezil-based hybrids across these chemical classes [47].

Propargylamine/8-hydroxyquinoline and metal-chelating hybrids

Because disrupted metal homeostasis (Cu2+, Zn2+, Fe3+) contributes to Aβ aggregation and oxidative stress in AD, several groups have fused the donepezil N-benzylpiperidine unit with a propargylamine (an MAO-inhibiting warhead borrowed from anti-Parkinsonian chemistry) and an 8-hydroxyquinoline metal-chelating group. Representative donepezil–propargylamine–8-hydroxyquinoline (DPH) hybrids act as irreversible MAO-A/B inhibitors and mixed-type AChE/BuChE inhibitors with confirmed metal-chelating capacity [48], and comparable indolyl/pyridyl donepezil–ASS234-type hybrids evaluated across AChE, BuChE and both MAO isoforms have shown that a cyano-substituted 8-hydroxyquinoline analogue combines strong four-target affinity, antioxidant behaviour, favourable predicted brain penetration, lower toxicity than donepezil, and restoration of memory in scopolamine-lesioned rodents [49]. A comprehensive 2024 review of donepezil-based hybrid and natural molecules published between 2014 and 2024 consolidates this N-benzylpiperidine-fragment strategy and specifically highlights design choices associated with reduced hepatotoxicity relative to earlier tacrine-containing MTDLs [50].

Rational, computation-first donepezil derivatives (2025–2026)

The most recent literature shows a shift toward generating donepezil analogue libraries primarily in silico before any synthesis is attempted. A 2026 study combined fragment-based molecular design, AI-assisted retrosynthetic feasibility scoring and in-silico ADMET profiling to screen roughly ten thousand donepezil-derived structures, narrowing the set to nine candidates with predicted CNS-compatible pharmacokinetics, acceptable toxicology and reduced cytochrome P450 liability; docking and 100-nanosecond molecular dynamics simulations indicated that the top candidates occupy both the catalytic gorge and the PAS more favourably than donepezil itself [51]. A related 2024 study designed "chimeric" vilazodone–donepezil derivatives combining an indole-based antidepressant fragment with the benzylpiperidine anchor, validated by QSAR, docking and molecular dynamics, reporting dual AChE/BuChE inhibitors substantially more potent than donepezil *in vitro* together with favorable predicted ADMET profiles [52]. Separately, a 2026 report on donepezil-derived MTDLs progressed a lead compound from AChE/BuChE/BACE-1 docking and enzyme assays through to in-vivo testing and histopathological evaluation [53].In a parallel line of work, hydrazide derivatives unrelated to the classical benzylpiperidine scaffold have been profiled through molecular docking, ADMET prediction and pharmacological characterisation as candidate AChE-directed anti-Alzheimer agents, while a dual BACE-1/AChE in-silico study of the natural product FR258900 illustrates a further extension of computation-first triage to non-donepezil chemotypes pursuing the same dual-target rationale [54][55].

Donecopride and the "Copride" Family: Dual AChE/5-HT4R Ligands

Donecopride (MR31147) was the first reported dual AChE inhibitor/5-HT4 receptor partial agonist, obtained by pharmacomodulating the 5-HT4R agonist RS67333 to introduce nanomolar dual-binding-site AChE inhibition while preserving serotonergic activity; the compound restored memory performance in the object-recognition test in mice at 0.3–1 mg/kg and increased secretion of the neuroprotective sAPPα fragment, giving it a genuinely disease-modifying rationale in addition to symptomatic cholinergic benefit [33][34]. Because donecopride combines a benzylpiperidine-like anchor with a distinct aromatic head group, it has become, alongside donepezil itself, a template scaffold for a dedicated "copride" family of AChE/5-HT4R dual ligands.Structural refinement of donecopride since 2020 has followed two main routes. The first is late-stage rigidification of the flexible linker connecting the piperidine and aryl head-group, exemplified by benzisoxazole- and phenylpyrazole-constrained analogues designed to lock the molecule into its bioactive conformation; docking into the human AChE active site guided this structure-activity work and identified constrained hybrids capable of engaging AChE together with 5-HT4R or the related 5-HT6R, expanding the pharmacological reach of the series [35][36][56]. The second route is direct substitution on the donecopride phenyl ring, reported in a 2024 medicinal chemistry study that synthesised twenty-one donecopride analogues varying the methoxy, amine and halogen substituents. This structure-activity campaign yielded two notable derivatives: deudonecopride, obtained by deuterating the methoxy group (a strategy aimed at metabolic stabilisation), and flucopride, in which the chlorine atom of donecopride is replaced by fluorine, reported as a particularly potent member of the series against both AChE and 5-HT4R [57].Collectively, the copride family illustrates a maturing MTDL strategy in which iterative pharmaco modulation of a single first-in-class hybrid

rather than de-novo fragment fusion has produced a structurally diverse, patent-mapped chemical space with consistent dual-target engagement, positioning donecopride analogues as a particularly relevant reference series for QSAR modelling and docking-based lead optimisation focused on AChE [58][59].

Computational and AI-Driven Approaches: QSAR, Docking, and ADMET

In-silico methods have moved from a supporting, post-hoc role in donepezil/donecopride MTDL papers to a primary hit-generation and prioritisation strategy, reflecting the wider adoption of QSAR, molecular docking, molecular dynamics (MD) and machine learning (ML)/artificial intelligence (AI) across medicinal chemistry [60]. For AChE and BuChE inhibitor design specifically, classical two- and three-dimensional QSAR approaches using spatial, electronic, topological and E-state molecular descriptors remain widely used to rank candidate substituents before synthesis [61], while more recent multi-target-directed-ligand QSAR models built on N-benzylpiperidine derivative datasets have achieved good statistical performance (R2 above 0.8) for simultaneous AChE and BACE-1 activity prediction using genetic function approximation, support vector machine and artificial neural network algorithms [62][63].A parallel body of work applies deep learning and graph-based ML models directly to cholinesterase inhibition datasets [64], and dedicated reviews track the transition from Hansch-tradition QSAR to transformer- and graph-neural-network-based structure-activity modelling, including other machine-learning frameworks for predicting anti-cholinesterase activity [65], [66].Recent studies increasingly pair 2D/3D-QSAR-guided design including carbamate-based and other non-piperidine chemotypes screened against AChE [67] with molecular docking against AChE crystal structures [21][23], followed by MD simulation, as demonstrated in an integrated QSAR, docking, MD study targeting AChE [68]. Complementary pharmacophore-based 3D-QSAR/virtual-screening workflows, and QSAR-toxicity-docking-MD pipelines applied to azole-based AChE inhibitor series, illustrate the same funnel across diverse scaffolds beyond donepezil [69][70]. This process is completed with in-silico ADMET filtering, using graph-signature-based pharmacokinetic prediction tools, freely available medicinal-chemistry-friendliness platforms, and dedicated CNS/BBB-permeability screening frameworks [71][72][73]. This computational funnel is now the standard pipeline against which new donecopride-analogue design projects can be benchmarked.

Structure-Activity Relationship Summary

Table 1 summaries representative donepezil- and donecopride-based hybrid classes discussed above, alongside their reported target profile and the most notable computational or biological finding for each series.

Challenges and Future Perspectives

Despite the breadth of chemistry summarized above, translation of donepezil/donecopride MTDLs into clinical candidates remains limited. Most compounds are validated only by enzyme inhibition assays, docking and short *in-vivo*behavioral tests (commonly scopolamine-induced amnesia or object-recognition paradigms in rodents), with very few advanced to formal preclinical toxicology or IND-enabling studies; donecopride itself is, at the time of writing, still described in the primary literature as undergoing regulatory preclinical evaluation rather than clinical trials [57]. Hepatotoxicity carried over from tacrine-based hybrid design remains a recurring concern that newer benzylpiperidine-anchored MTDLs are explicitly designed to avoid, and predicted rather than experimentally confirmed blood-brain-barrier permeability continues to be a common limitation across *in-silico*-heavy study [74]. Broader reviews of multi-target drug design in AD additionally note the persistent absence of standardized comparative benchmarks across MTDL series, making cross-study potency and selectivity comparisons difficult, and highlight combination products such as donepezil-memantine (Namzaric) as an alternative, pragmatically simpler polypharmacology route that MTDLs must ultimately outperform to justify their added synthetic complexity [31][75].For QSAR- and docking-centred thesis and research projects specifically, three practical directions emerge from this literature: (i) the donecopride phenyl-ring substitution space (flucopride/deudonecopride-type modifications) offers a chemically tractable and only partially explored series well suited to systematic QSAR modelling against AChE; (ii) coupling docking/QSAR triage with explicit CNS-focused ADMET filters (BBB permeability, P-glycoprotein efflux liability, hepatotoxicity and CYP450 inhibition flags) mirrors current best practice and improves the credibility of purely computational candidate lists; and (iii) reporting molecular dynamics stability

data alongside docking scores, as now routinely done for donepezil-derivative libraries, strengthens confidence in predicted binding modes ahead of any wet-lab validation [51][52][58].

CONCLUSION

Between 2022 and 2026, donepezil and donecopride have continued to serve as the two most productive scaffolds for multi-target-directed ligand design in Alzheimer's disease, generating hybrids that pair cholinesterase inhibition with monoamine oxidase inhibition, serotonergic 5-HT4 receptor agonism, anti-amyloid, anti-inflammatory, antioxidant and metal-chelating activities. The field's centre of gravity has shifted from empirical hybrid synthesis toward computation-first pipelines combining QSAR, molecular docking, molecular dynamics and AI-assisted ADMET prediction, a trajectory that directly supports in-silico QSAR modelling, molecular docking and ADMET evaluation of novel donecopride analogues as a timely and well-precedented research direction. Continued progress will depend on closing the gap between promising in-silico/in-vitro profiles and rigorously validated in-vivo efficacy and safety data, and on establishing more standardised benchmarks so that donepezil- and donecopride-based MTDLs can be compared meaningfully across independent research groups.

Table 1: Summary of donepezil- and donecopride-based multi-target-directed ligand (MTDL) classes, their target profiles and key in-silico/in-vitro findings

Hybrid class	Representative modification	Reported target profile	Notable in-silico/in-vitro finding
Coumarin–donepezil	3- or 8-substituted coumarin linked via oxadiazole/acetohydrazide	AChE, BuChE, MAO-B, antioxidant (DPPH)	Selective MAO-B inhibition with retained sub-micromolar AChE/BuChE activity and low neuroblastoma cytotoxicity [14][17]
Arylsulfonamide–donepezil	Aryl-sulfonamide fused to benzylpiperidine/-piperazine	AChE, Aβ anti-aggregation	Compound 9-type leads combine AChE inhibition (IC50 ~1.6 μM) with ~60% Aβ anti-aggregation and predicted BBB permeability [19]
NSAID–donepezil	NSAID pharmacophore conjugated to benzylpiperidine	AChE, BuChE, COX-1/2, cytokine suppression	Lead compound reached IC50 0.015 μM (AChE)/0.80 μM (BuChE), well below donepezil, plus COX-1/2 and TNF-α/IL-1β suppression [20]
8-Hydroxyquinoline/propargylamine–donepezil	N-propargyl + 8-HQ metal chelator on benzylpiperidine core	AChE, BuChE, MAO-A/B, metal chelation	Cyano-substituted analogue combined 4-target activity, Cu2+/Zn2+/Fe3+ chelation, good brain penetration and lower toxicity than donepezil [21][22]

AI/fragment-designed donepezil derivatives	CReM fragment enumeration + AI retrosynthesis + ADMET triage	AChE, BuChE (CAS + PAS)	~10,000 virtual derivatives narrowed to 9 CNS-compatible candidates; MD confirmed 100 ns dual-site pose stability [23]
Donecopride ("copride") analogues	Phenyl-ring substitution (halogen, methoxy, deuteration)	AChE, 5-HT4R (partial agonism)	Flucopride (F-substituted) and deudonecopride (deuterated) identified as potent, metabolically refined analogues of donecopride [30]
Rigidified donecopride/benzisoxazole analogues	Late-stage ring constraint of the piperidine–aryl linker	AChE, 5-HT4R/5-HT6R	Constrained phenylpyrazole/benzisoxazole hybrids retain AChE inhibition while enabling 5-HT6R engagement, guided by AChE docking [27][28]

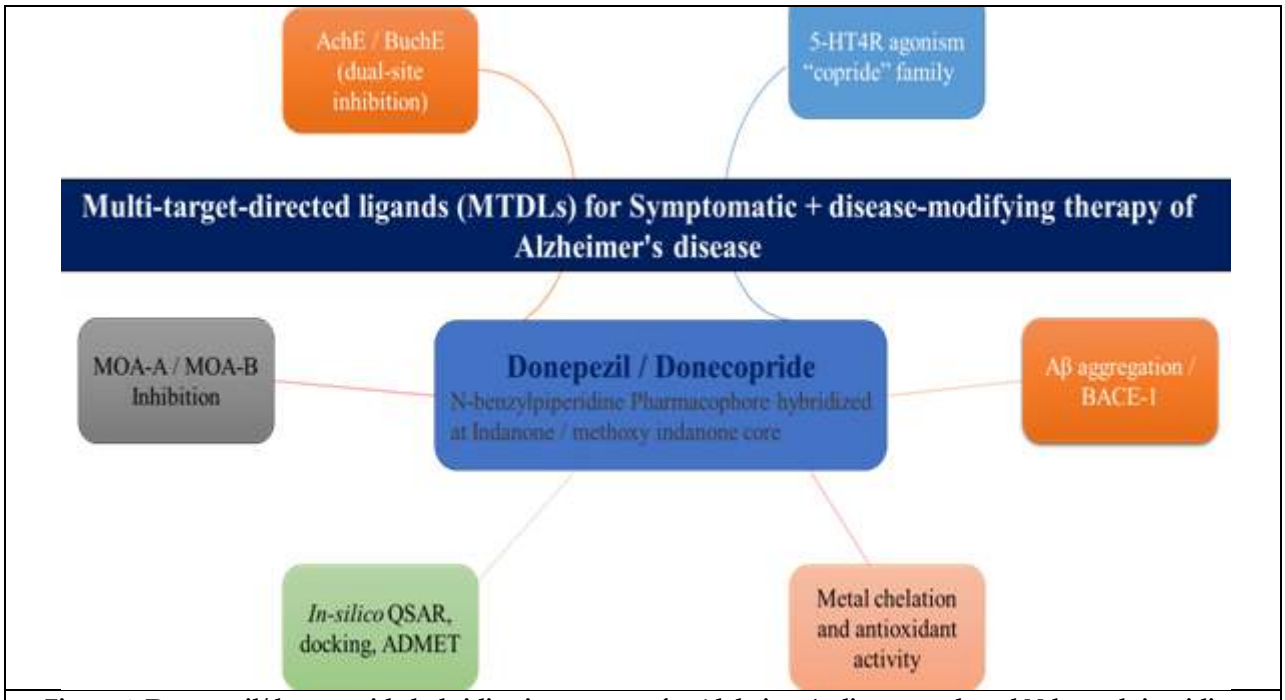

Figure 1: Donepezil/donecopride hybridisation strategy for Alzheimer's disease: a shared N-benzylpiperidine pharmacophore is coupled with complementary targets (BuChE, MAO-A/B, 5-HT4R, Aβ/BACE-1, metal chelation) and prioritised via QSAR, docking and ADMET modelling, yielding multi-target-directed ligands with symptomatic and disease-modifying potential.

ABSTRACT

Investigating Graph Irregularity has gained significant attention in Fuzzy and Neutrosophic graph theory due to its relevance in modelling complex and uncertain systems. This article presents the idea of Irregular Neutrosophic Fuzzy Graph (INFG) integrates the combination of Irregularity properties of Fuzzy Graphs with the tri-component structure of Neutrosophic Graphs, characterized by Truth (Tr), Indeterminacy (In), and Falsity (Fl) values. We define the level metrics of vertices in INFGs, explore their structural irregularities. Several examples are provided to illustrate the concepts, demonstrating how INFGs generalize and extend both Fuzzy and Neutrosophic Graph frameworks.

Keywords: Fuzzy Graphs, Neutrosophic Set, Neighbourly Irregular Graph, Highly Irregular Graph, Irregular Neutrosophic Fuzzy Graph..

Subject Classification: 03E72, 05C72, 05C75, 03B52.

INTRODUCTION

Graph theory provides a strong mathematical foundation for modelling relationships in complex systems. To handle uncertainty**,** Rosenfeld [4] introduced *fuzzy graphs*, extending classical graphs using fuzzy set theory in 1975. Further developments by Nagoor Gani and Radha [3] On R*egular fuzzy graphs* in 2008 and **by** Nagoor Gani and Latha [2] on *irregular fuzzy graphs* highlighted the significance of studying vertex irregularities in fuzzy structures in 2012. To represent indeterminacy beyond fuzziness**,** Vasantha Kandasamy, Ilanthenral, and Smarandache**[5]** introduced N*eutrosophic Graphs in 2015*, where each vertex and edge is defined by truth, indeterminacy, and falsity values. Later, Alias and Padma [1] combined these ideas to develop N*eutrosophic fuzzy graphs in 2022***.** Motivated by these studies. This article presents the idea of an Irregular NeutrosophicFuzzy Graph that integrates the properties of Irregular Fuzzy Graphs and Neutrosophic systems to analyze the structural irregularity of uncertain and indeterminate networks.

PRELIMINARIES

We review the notion of Neutrosophic sets, Fuzzy Graphs and Neutrosophic Fuzzy graph (NTFG) in this section

Definition

Let the space be represented by the value X, the '$\mathfrak{x}$' represents its generalized members of fuzzy set A. The following is a Neutrosophic set NTS,

$$NTS = \{\, \mathfrak{x} : Tr_a(\mathfrak{x}), In_a(\mathfrak{x}), Fl_a(\mathfrak{x}), \mathfrak{x} \in X \,\}$$

where $\mathfrak{x} \in X$ to the set NTS have Truth, Indeterminacy, and Falsity membership functions defined, respectively, by the functions Tr, In, and Fl tends to] −0, 1+[.

where $\mathfrak{x} \in X$ to the set NTS have Truth, Indeterminacy, and Falsity membership functions defined, respectively, by the functions Tr, In, and Fl tends to] −0, 1+[.

Definition

Let $Tr_a, In_a, Fl_a : V \to [0,1]$ and $Tr_b, In_b, Fl_b : V \times V \to [0,1]$ where Tr_a, In_a, Fl_a represents the degree of Tr, the degree of In and the degree of Fl of vertex $vi \in V$ respectively.

Furthermore, $0 \le Tr_a(x) + In_a(x) + Fl_a(x) \le 3$ *and*
$0 \le Tr_b(x,y) + In_b(x,y) + Fl_b(x,y) \le 3.$
$Tr_b(\mathfrak{x},\mathfrak{y}) \le Tr_a(\mathfrak{x}) . Tr_a(\mathfrak{y})$
$In_b(\mathfrak{x},\mathfrak{y}) \le In_a(\mathfrak{x}) . In_a(\mathfrak{y})$
$Fl_b(\mathfrak{x},\mathfrak{y}) \le Fl_a(\mathfrak{x}) . Fl_a(\mathfrak{y})$
Where$\mathfrak{x},\mathfrak{y} \in V$ and Trb,Inb, Flbrepresents the degree of Tr, the degree of In and degree of Fl of edges e_i belongs V x V respectively.

Definition

Consider $G_{NTFG} = (a, Tr, In, Fl, b)$ be a Neutrosophic Fuzzy graph (NTFG). Then degrees of the vertex of $\mathfrak{x}$ in NTFG can be defined as follows,

$Deg_{NTFG}(x) = (Deg\ Tr_a(x), Deg\ In_a(x), Deg\ Fl_a(x))$

$where\ Deg\ Tr_a(x) = \sum_{xy \epsilon E} Tr_b(xy)$

$Deg\ In_a(x) = \sum_{xy \epsilon E} In_b(xy)$

$Deg\ Fl_a(x) = \sum_{xy \epsilon E} Fl_b(xy)$

Example (Fig.1)

From the Figure 1, we get,

$Deg_{NTFG}(v_1) = (0.11, 0.04, 0.06)$
$Deg_{NTFG}(v_2) = (0.07, 0.03, 0.05)$
$Deg_{NTFG}(v_3) = (0.10, 0.06, 0.08)$
$Deg_{NTFG}(v_4) = (0.14, 0.07, 0.09)$

Definition

Let G_{NTFG} = (a, Tr, In, Fl, b) be a NTFG. Then Absolute degrees of the vertex of x in NTFG is defined by,

$$ADeg_{NTFG}(x) = (Deg_{NTFG}Tr_a(x) + Deg_{NTFG}In_a(x) + Deg_{NTFG}Fl_a(x))$$

From the Figure 1

$ADeg_{NTFG}(v_1) = 0.21$
$ADeg_{NTFG}(v_2) = 0.15$
$ADeg_{NTFG}(v_3) = 0.24$
$ADeg_{NTFG}(v_4) = 0.20$

Definition

Let O and S be the Order and Size of GNTFG can be defined as follows

$$O_{NTFG} = \sum_{x \epsilon V} \{Tr_a(x), In_a(x), Fl_a(x)\}\ and$$
$$S_{NTFG} = \sum_{xy \epsilon E} \{Tr_b(xy), In_b(xy), Fl_b(xy)\}$$

Definition

When the two vertices x and y are joined by an edge,then their strength of connectedness of NTFG GNTFG is defined as

$$\mu_{\infty}(x, y) = \Lambda\ (Tr_b(xy), In_b(xy), Fl_b(xy))$$

Example (Fig.2)

From the Figure 2, the strength of connectedness of NTFG is (0.03, 0.04, 0.06)

Definition

When all vertices of NTFG of the open neighbourhood degree are equal, then the graph is referred to as Regular NTFG.

Example (Fig.3)

From the Figure 3

$Deg_{NTFG}(v_1) = (0.03, 0.05, 0.07)$
$Deg_{NTFG}(v_2) = (0.03, 0.05, 0.07)$

$Deg_{NTFG}(v_3) = (0.03, 0.05, 0.07)$
$Deg_{NTFG}(v_4) = (0.03, 0.05, 0.07)$

Definition
Neutrosophic fuzzy graph (NTFG) is said to be as Irregular if at least one vertex is connected with two or more vertices that have different open neighbourhood degrees.

Example (Fig.4)

In Figure 4,
$Deg_{NTFG}(v_1) = (0.03, 0.05, 0.07)$
$Deg_{NTFG}(v_2) = (0.05, 0.04, 0.06)$
$Deg_{NTFG}(v_3) = (0.06, 0.05, 0.07)$
$Deg_{NTFG}(v_4) = (0.03, 0.05, 0.07)$

NEIGHBOURLY DEGREE AND HIGHLY IRREGULAR NEUTROSOPHIC FUZZY GRAPH

Definition
If every two neighbouring vertices possess unequal open neighbourhood degrees, then the graph is said to be a Neighbourly Degree Irregular NTFG.

Example (Fig.5)

From the Figure 5,
$Deg_{NTFG}(v_1) = (0.20, 0.10, 0.14)$
$Deg_{NTFG}(v_2) = (0.17, 0.09, 0.13)$
$Deg_{NTFG}(v_3) = (0.21, 0.11, 0.15)$

Definition
Absolute Degree Irregular Neutrosophic fuzzy graph are Neutrosophic fuzzy graph (NTFG) that have a vertex next to each vertex with a different closed neighbourhood degree and is defined as follows

$$Deg_{NTFG}[\mathrm{x}] = (Deg\, Tr_a[\mathrm{x}], Deg\, In_a[\mathrm{x}], Deg\, Fl_a[\mathrm{x}])$$

$$where\ Deg\, Tr_a[\mathrm{x}] = Tr_a(\mathrm{x}) + \sum_{\mathrm{xy}\in E} Tr_b(\mathrm{xy})$$

$$Deg\, In_a[\mathrm{x}] = In_a(\mathrm{x}) + \sum_{\mathrm{xy}\in E} In_b(\mathrm{xy})$$

$$Deg\, Fl_a[\mathrm{x}] = Fl_a(\mathrm{x}) + \sum_{\mathrm{xy}\in E} Fl_b(\mathrm{xy})$$

Example (Fig.6)
From the above Figure 6the Absolute Degree Irregular NTFG is,
$Deg_{NTFG}(v_1) = (0.11, 0.04, 0.06)$, $Deg_{NTFG}[v_1] = (0.61, 0.34, 0.46)$
$Deg_{NTFG}(v_2) = (0.07, 0.03, 0.05)$, $Deg_{NTFG}[v_2] = (0.47, 0.23, 0.35)$
$Deg_{NTFG}(v_3) = (0.10, 0.06, 0.08)$, $Deg_{NTFG}[v_3] = (0.60, 0.36, 0.48)$
$Deg_{NTFG}(v_4) = (0.14, 0.07, 0.09)$, $Deg_{NTFG}[v_4] = (0.54, 0.27, 0.39)$

Definition
A Neutrosophic Fuzzy graph is called a *Neighbourly Absolute Degree Irregular NTFG* if every two neighbouring vertices possess unequal closed neighbourhood degrees.

Example
From the Figure 5, we get the Neighbourly Absolute Degree Irregular NTFG,
$Deg_{NTFG}[v_1] = (0.80, 0.30, 0.54)$
$Deg_{NTFG}[v_2] = (0.87, 0.39, 0.63)$
$Deg_{NTFG}[v_3] = (0.51, 0.81, 0.45)$

Definition
A graph G_{NTFG} is said to be *Highly Irregular* if every vertex in NTFG is adjacent to vertices with distinct open neighbourhood degrees.

Definition
A NTFG $G_{NTFG}$is said to be a Highly Absolutely Irregular NTFG if every vertex in G_{NTFG} is adjacent to vertices whose closed neighbourhood degrees are all distinct.

Property
If G_{NTFG} is Neighbourly Irregular, then any two vertices that have the same Neutrosophic degree are not adjacent. Equivalently: the set of vertices having any fixed Neutrosophic degree forms an independent set.

Proof
Let S be any Neutrosophic degree (i.e.Tr, In, Fl) and C be the set of all vertices in 'a' whose Neutrosophic degree equals S.

$$\boldsymbol{i.e} C = \{x \in a : Deg_{NTFG}(x) = (Tr_a(x), \quad In_a(x), \quad Fl_a(x)) = S\}$$

By definition of Neighbourly Irregular NTFG, every two neighbouring vertices possess distinct open neighbourhood degrees.
$(i.e)\ Deg_{NTFG}(x) \neq Deg_{NTFG}(y)$.

Suppose, for contradiction, that there exists two vertices $x, y \in C$ such that$xy \in E$. Then$Deg_{NTFG}(x) = S = Deg_{NTFG}(y)$.

But this contradicts the Neighbourly Irregular property which requires adjacent vertices to have distinct Neutrosophic degrees. Therefore no two vertices in C are adjacent, so C is an independent set.

Property
If G_{NTFG} is Highly Irregular (all vertex Neutrosophic degrees are distinct), then $G_{NTFG}$is Neighbourly Irregular.

Proof
Let G_{NTFG} be Highly Irregular NTFG.
By the definition of Highly Irregular NTFG, If all vertex scores are pairwise distinct, then in particular any two adjacent vertices must have different open neighbourhood degrees.
So every edge connects vertices with different scores, which is exactly the Neighbourly Irregular condition.

Property

Let G_{NTFG} be a NTFG and Neighbourly Absolute Degee Irregular NTFG with closed distinct membership values between the pair of vertices is(p_1, p_2, p_3), wherep_1, p_2, p_3 are constant. Then G_{NTFG} is a Neighbourly Degree Irregular NTFG.

Proof:

Let us consider GNTFG be Neighbourly Absolute Degree Irregular NTFG.

W.K.T every two neighbouring vertices possess distinct closed neighbourhood degrees.

Assume that $x, y \in a$ where x and y are distinct degrees of adjacent vertices $(Tr_a(x), In_a(x), Fl_a(x))and(Tr_a(y), In_a(y), Fl_a(y)) = (p_1, p_2, p_3)$, where where p_1, p_2, p_3 are constant which belongs to [0, 1].

To prove

$(Deg\, Tr_a(x), Deg\, In_a(x), Deg\, Fl_a(x)) \neq (Deg\, Tr_a(y), Deg\, In_a(y), Deg\, Fl_a(y))$.

Now consider,

$(Deg\, Tr_a(x), Deg\, In_a(x), Deg\, Fl_a(x)) \neq (Deg\, Tr_a(y), Deg\, In_a(y), Deg\, Fl_a(y))$

We take, $Deg\, Tr_a(x) \neq Deg\, Tr_b(y)$

$\Rightarrow Deg\, Tr_a(x) + p_1 \neq Deg\, Tr_b(y) + p_1$

$\Rightarrow Deg\, Tr_a(x) - Deg\, Tr_b(y) \neq p_1 - p_1 = 0$

$\Rightarrow Deg\, Tr_a(x) \neq Deg\, Tr_b(y)$

In this way, we get for $Deg\, In_a(x) \neq Deg\, In_b(y)$ and $Deg\, Fl_a(x) \neq DegFl_b(y)$.

Hence degree of NTFG of x and y are distinct.

This indicates that NTFG is Neighbourly Degree Irregular NTFG.

Property

Let G_{NTFG}be NTFG. Then GNTFG is Highly Irregular NTFG and Neighbourly Degree Irregular NTFG, iff each vertex in G_{NTFG}has a distinct open Neighbourhood degree.

Proof

Let G_{NTFG}be NTFG with k vertices $(x_1, x_2, \ldots x_k)$.

Let us consider the NTFG GNTFG is both Highly Irregular and Neighbourly Degree Irregular NTFG.

To prove that each vertex in G_{NTFG}has a distinct open Neighbourhood degree.

$Let\, Deg_{NTFG}(x_i) = \left(Deg\, Tr_a(x_i), Deg\, In_a(x_i), Deg\, Fl_a(x_i)\right),\ i = 1, 2, \ldots, kandx_1$is adjacent to $x_2, x_3, \ldots x_k with\ (Deg\, Tr_a(x_2), Deg\, In_a(x_2),$
$Deg\, Fl_a(x_2)), (Deg\, Tr_a(x_3), Deg\, In_a(x_3), Deg\, Fl_a(x_3)), \ldots (Deg\, Tr_a(x_k), Deg\, In_a(x_k), Deg\, Fl_a(x_k))$,

Since $G_{NTFG}$is Highly Irregular NTFG, then

$Deg\, Tr_a(x_2) \neq Deg\, Tr_a(x_3) \neq \ldots. \neq Deg\, Tr_a(x_k)$

$Deg\, In_a(x_2) \neq Deg\, In_a(x_3) \neq \ldots. \neq Deg\, In_a(x_k)$

$Deg\, Fl_a(x_2) \neq Deg\, Fl_a(x_3) \neq \ldots. \neq Deg\, Fl_a(x_k)$

Moreover, $G_{NTFG}$is Neighbourly Irregular NTFG, we've,

$Deg\, Tr_a(x_1) \neq Deg\, Tr_a(x_2) \neq Deg\, Tr_a(x_3) \neq \cdots \neq Deg\, Tr_a(x_k)$

$Deg\, In_a(x_1) \neq Deg\, In_a(x_2) \neq Deg\, In_a(x_3) \neq \ldots. \neq DegIn_a(x_k)$

$Deg\, Fl_a(x_1) \neq Deg\ Fl_a(x_2) \neq Deg\, Fl_a(x_3) \neq \cdots \neq Deg\, Fl_a(x_k)$

Therefore,

$(Deg\, Tr_a(x_1), Deg\, In_a(x_1), Deg\, Fl_a(x_1)), \neq (Deg\, Tr_a(x_2), Deg\, In_a(x_2), Deg\, Fl_a(x_2)),$
$\neq \ldots. \neq (Deg\, Tr_a(x_k), Deg\, In_a(x_k), Deg\, Fl_a(x_k))$

Hence the each vertex of G_{NTFG}has distinct Neighbourhood degree.
Conversely, Let us assume that the every vertex in GNTFG has distinct open Neighbourhood degree..
To prove G_{NTFG} is both Highlr Irregular and Neighbourly Degree Ireegular NTFG.

$Let\ Deg_{NTFG}(x_i) = \left(Deg\ Tr_a(x_i), Deg\ In_a(x_i), Deg\ Fl_a(x_i) \right),\ i = 1, 2, \ldots, k.$
Since $Deg\ Tr_a(x_1) \neq Deg\ Tr_a(x_2) \neq Deg\ Tr_a(x_3) \neq \ldots. \neq Deg\ Tr_a(x_k)$
$Deg\ In_a(x_1) \neq Deg\ In_a(x_2) \neq Deg\ In_a(x_3) \neq \ldots. \neq DegIn_a(x_k)$
$Deg\ Fl_a(x_1) \neq Deg\ Fl_a(x_2) \neq Deg\ Fl_a(x_3) \neq \ldots. \neq Deg\ Fl_a(x_k)$

Hence the open neighbourhood degrees of any two neighbouring vertices are distinct.
Hence G_{NTFG} is both Highlr Irregular and Neighbourly Degree Ireegular NTFG

CONCLUSION

The structural features and attributes of Neighbourly and Highly Irregular Neutrosophic fuzzy graphs were examined in this work. The behaviour of vertices and edges was examined using the notion of degree based on truth, indeterminacy, and falsity membership values. Additionally, it is demonstrated that, in comparison to Neighbourly Degree Irregular NTFG, Highly Irregular NTFG suggest higher kinds of Irregularity under specific situations. As a result, the study presents a better comprehension of the degree-based classifications and structural differences in Neutrosophic fuzzy graphs. In further studies, these findings can be expanded to examine complex structures like Support Irregular and Support Neighbourly Irregular NTFG.

ABSTRACT

Infrastructure expansion is central to India's "Viksit Bharat 2047" macroeconomic vision, yet the current pace of national highway development is increasingly constrained by severe fiscal and operational bottlenecks. Prevailing Public-Private Partnership (PPP) frameworks—specifically the Build-Operate-Transfer (BOT) and Hybrid Annuity Model (HAM)—have exhausted their utility, resulting in a massive sovereign debt burden for the National Highways Authority of India (NHAI), systemic land acquisition gridlock under the LARR Act of 2013, and terminal asset decay at the conclusion of concession periods. To resolve these terminal inefficiencies, this paper proposes the Build-Operate-Sustain-Share (BOSS) framework, a novel theoretical and economic architecture. The BOSS model dismantles the traditional binary state-developer paradigm by introducing a Tri-Party nexus that integrates local landowners as fiduciary equity holders via a "Land-as-Equity" unitization mechanism. Furthermore, the framework mandates lifecycle sustainability through rigorously ring-fenced Hand back Reserve Accounts and utilizes a dynamic, BOOT-style commercialization engine to ensure sovereign debt deleveraging without compromising stakeholder returns. By combining advanced financial structuring with institutional economic theory, this paper establishes a highly actionable, mathematically sound policy blueprint designed to bridge the sovereign capital deficit and neutralize socio-economic friction in mega-project execution, laying the essential groundwork for future empirical validation.

Keywords: Highway Public-Private Partnerships, PPP, National Highways Authority of India, NHAI, Land Value Capture, Infrastructure Financing

INTRODUCTION

Infrastructure acts as the vital physical foundation for emerging economies by lowering logistics costs, unlocking agricultural productivity, and connecting markets. In India, this rapid modernization is the driving force behind the "Viksit Bharat 2047" vision, An ambitious strategic roadmap to transform the country into a fully developed, $30 trillion economy with a per capita income exceeding $15,000 by its centenary of independence[1,2]. To realize this profound demographic and economic potential, the National Highway network—which currently carries over 64% of the country's freight and nearly 90% of its passenger traffic[3] must undergo continuous, uninterrupted modernization. Fueled by major government initiatives like the Bharatmala Pariyojana and targeted regional programs, India's national highway network has experienced unprecedented expansion. The absolute infrastructure footprint expanded by approximately 61%, surging from a baseline of 91,287 kilometers in the 2013-2014 fiscal year to an expansive 1,46,560 kilometers by 2025. Alongside massive overall expansion, the quality of India's infrastructure has dramatically improved. The total length of high-speed, access-controlled expressways has skyrocketed by over 3,180%—growing from just 93 kilometers in 2014 to 3,052 kilometers—which is fundamentally speeding up logistics and trade across the entire subcontinent [4].

However, this unprecedented scale of capacity addition has generated a profound macroeconomic friction point: the sheer quantum of capital required for such expansion has historically outstripped public budgetary allocations and sovereign fiscal capacity. The Union Budget earmarked a record capital expenditure constituting approximately 3.1% to 3.4% of the national gross domestic product [5]. Within this framework, the Ministry of Road Transport and Highways receive massive infusions of public funding, which has grown at a remarkable compound annual growth rate over the last decade. Yet, rigorous macroeconomic projections from entities such as the World Bank and sovereign financial institutions [6] indicate that India still faces an annual infrastructure financing gap estimated to exceed 5% of its gross domestic product. To realize the Viksit Bharat 2047 vision, India must maintain a consistent, uninterrupted economic growth rate of 8% per annum for the next two decades, necessitating an overall investment rate of approximately 35% of gross domestic product—significantly higher than the current hovering average of 31%. Consequently, the reliance on Public-Private Partnership frameworks has transitioned from being an optional or optimal procurement strategy to an absolute macroeconomic necessity designed to bridge the sovereign capital deficit and crowd in private institutional investment [7, 8]. As the road sector navigates the current fiscal landscape, a highly critical juncture has been reached. The primary executing agency, the National Highways Authority of India - NHAI, is currently undergoing an aggressive institutional deleveraging phase, actively managing and winding down a debt burden that peaked at an unsustainable Indian Rupee 3.48 to 3.5 trillion in the 2021-2022 fiscal year [9]. While public sector financing constraints tighten dramatically, the deployment of legacy Public-Private Partnership models continues to be severely hampered by systemic, ground-level bottlenecks. These inefficiencies primarily manifest as protracted, adversarial land acquisition disputes governed by the rigid stipulations of the Right to Fair Compensation and Transparency in Land Acquisition, Rehabilitation and Resettlement Act of 2013 [10], alongside the moral hazard of terminal decay of highway assets upon the conclusion of private concession periods.

This comprehensive research explores the future of highway development by establishing a novel theoretical and macroeconomic architecture designed to resolve these compounding market failures. First, it critically analyzes the structural flaws and risk-allocation imbalances inherent in India's legacy PPP models, specifically isolating the financial mechanics of the LARR Act 2013 and the HAM annuity trap. Second, it introduces the BOSS (Build-Operate-Sustain-Share) framework—a radical reimagining of the infrastructure social contract that mathematically neutralizes the land acquisition choke-point through a 'Land-as-Equity' unitization model. Finally, the paper details the tri-party financial modelling and dynamic equity-waterfall required to eradicate the terminal 'maintenance cliff.' By decoupling the theoretical design of this framework from the immediate need for localized psychometric testing, this research provides a complete, structural policy blueprint. It establishes the essential macroeconomic and legal parameters required to overcome modern infrastructure paralysis, deliberately setting the stage for subsequent, large-scale empirical field validation.

Objectives of the Study

The primary objectives of this research are:

- To critically evaluate the structural limitations and macroeconomic risks inherent in legacy highway procurement models, specifically the Build-Operate-Transfer (BOT) and Hybrid Annuity Model (HAM).
- To analyse the systemic impact of the LARR Act 2013 on upfront capital depletion and infrastructure execution delays.
- To propose the theoretical Build-Operate-Sustain-Share (BOSS) framework as a novel tripartite architecture designed to resolve land acquisition friction through unitized equity.
- To establish a dynamic financial waterfall and lifecycle costing (LCC) mechanism that eradicates terminal asset decay and ensures sustainable sovereign debt deleveraging.

LITERATURE REVIEW

The academic and policy discourse surrounding Public-Private Partnerships in emerging economies has traditionally centered on bridging the infrastructure deficit through private sector capital infusion [11], often neglecting the equally critical long-term service delivery mechanisms inherent in these multi-decade contracts. In the Indian context, the structural evolution of these procurement frameworks reveals a turbulent, highly cyclical trajectory of trial, error, and systemic friction. This evolution is characterized by initial phases of profound private sector exuberance, inevitably followed by severe market withdrawal and project paralysis due to fundamentally misaligned risk allocation between the sovereign authority and private enterprise.

The BOT Paradigm: Aggressive Bidding and Information Asymmetry

The initial wave of highway privatization in India during the early to mid-2000s relied almost exclusively on the Build-Operate-Transfer (BOT). Under BOT contract, government grants a concession to a private company to finance, build, and operate a project. The company operates the project for a period of time (typically 20 or 30 years) with the goal of recouping its investment, then transfers control of the project back to the public entity[12]. These complex legal and financial architectures were predicated on the neoliberal principle of maximum risk transfer to the private sector, forcing developers and their lending consortiums to absorb almost entirely the traffic forecasting risk, the revenue volatility risk, and the underlying financing risk. While the Build-Operate-Transfer model initially spurred rapid capacity addition and successfully captured a 51% share of all road construction awards by the 2014-2015 fiscal year, it ultimately buckled under the weight of its own structural optimism [13]. The academic and industry consensus identifies two interlinked cognitive and economic phenomena—"Optimism Bias" and "Aggressive Bidding" as the fatal flaws of this era. In highly competitive, price-driven procurement environments, the economic principle known as the "winner's curse" dictates that the winning bid is frequently submitted by the developer who has most severely underestimated the complexities of the project or overestimated its future revenue potential.

During the peak of the Build-Operate-Transfer era, developers frequently engaged in strategic misrepresentation, willfully overestimating long-term traffic projections to secure highly competitive bids while simultaneously underestimating the required capital expenditure and operations and maintenance costs. This structural flaw—when coupled with unforeseen macroeconomic shocks, the lack of robust, expedited dispute resolution mechanisms, and the subsequent emergence of competing alternative routes that cannibalized toll revenues—transformed these highly leveraged infrastructure projects into massive Non-Performing Assets within the domestic banking sector [13, 14]. Empirical evidence regarding renegotiations in the global and domestic road sector demonstrates that aggressive bidding systematically leads to contractual failures [15]. Once the asset becomes operational and traffic realities fail to match the hyper-optimistic financial models, developers attempt to extract post-award financial concessions, term extensions, or bailouts from the sovereign authority. Furthermore, the Indian sovereign authority's limited initial willingness to address these operational challenges, renegotiate inflexible terms, or inject emergency liquidity led to significant financial haemorrhaging for developers. This dynamic severely eroded institutional investor confidence and caused private risk capital to virtually freeze and exit the Indian highway sector by the end of 2014.

The HAM Era: Fiscal De-risking and the "Annuity Trap"

To resuscitate the completely stalled infrastructure sector and entice highly risk-averse private capital back into the market, the Government of India intervened decisively with the introduction of the Hybrid Annuity Model (HAM) in January 2016. Functioning essentially as a sovereign fiscal shock absorber, the Hybrid Annuity Model fundamentally rebalanced the adversarial risk matrix by shifting the entirety of the traffic volume and revenue realization risk back to the public exchequer [16, 17]. Under the Hybrid Annuity Model framework, the government provides 40% of the Bid Project Cost as an upfront cash grant during the construction phase, distributed in five distinct tranches linked strictly to physical milestone completions (e.g., a 10% payment triggered at 20% physical completion, scaling up iteratively to a 75% payment at 80% physical completion) [16]. The private concessionaire is required to arrange the remaining 60% of the capital through a combination of their own equity (typically ranging from 20% to 25% of the 60% portion) and institutional debt [18]. The developer's 60% capital investment is subsequently reimbursed by the National Highways Authority of India through bi-annual, highly structured annuity payments distributed over a 15-year operational concession period, thereby heavily mitigating the developer's exposure to traffic volatility and demand-side shocks. Furthermore, the financial structure of the Hybrid Annuity Model is highly indexed to protect the private developer against external macroeconomic fluctuations. The outstanding Bid Project Cost is inflation-indexed through a Price Index Multiple, which utilizes a dynamically weighted average of the Wholesale Price Index and the Consumer Price Index. Simultaneously, the interest paid by the National Highways Authority of India on the outstanding annuity balance is dynamically linked to the Marginal Cost of Funds based Lending Rate. For instance, as per official policy circulars for the quarter spanning October to December 2025, the National Highways Authority of India calculated the average 1-Year Marginal Cost of Funds based Lending Rate of the top five major commercial banks (specifically the State Bank of India at 8.75%, HDFC Bank at 8.65%, ICICI Bank at 8.35%, Bank of Baroda at 8.80%, and Punjab National Bank at 8.80%) which averaged out to 8.67%.

When combined with the contractually prescribed risk margin of 1.25%, this yielded a highly lucrative, virtually sovereign-backed effective interest rate of 9.92% per annum to be paid directly to Hybrid Annuity Model concessionaires [19]. The Hybrid Annuity Model was undeniably successful in accelerating road project implementation, playing a crucial role in sustaining infrastructure development during global economic downturns and capturing an average share of 60% of all project awards in recent years. However, this extensive "de-risking" of the private sector came at a steep, compounding macroeconomic cost. Because private parties receive fixed annuity payments independent of actual toll collections, they do not benefit from windfall revenues. From an institutional economics perspective, this structure introduces a severe Moral Hazard. This fixed-income architecture severs the developer's long-term financial incentive to ensure high-quality, preventative maintenance over the asset's lifecycle, inevitably accelerating asset decay once the defect liability period concludes. Most critically, the rigid annuity structure has created a massive, deferred fiscal liability for the National Highways Authority of India, effectively locking public funds into long-term, inescapable debt servicing. This phenomenon, widely termed the "Annuity Trap," has severely constrained sovereign capital availability for future green field projects, as the state continues to bear the massive upfront costs associated with the 40% construction grant alongside 100% of the exorbitant land acquisition expenses [17]. A comprehensive comparison of the risk allocation, funding structures, and lifecycle maintenance incentives across prevailing highway procurement models is detailed in Table 1.

Need for the Study

The profound reliance on Hybrid Annuity Model and pure Engineering, Procurement, and Construction contracts, combined with the aggressive, politically mandated expansion targets under the Bharatmala Pariyojana Phase-I, precipitated a severe sovereign debt crisis for the National Highways Authority of India [20]. To continually finance these highly capital-intensive procurement models, the authority escalated its market borrowings exponentially starting in 2017-2018, leading to a precarious macroeconomic scenario where its outstanding debt peaked at a staggering Indian Rupee 3,48,522 crore (approximately 3.5 trillion Indian Rupee) in the 2021-2022 financial year. In addition to this highly visible headline debt, the National Highways Authority of India accumulated significant off-balance sheet contingent liabilities, which stood at roughly Indian Rupee 1,17,464 crore by March 2024 [21], primarily locked in protracted arbitration and complex court cases with legacy contractors.

Recognizing that this unsustainable debt trajectory posed a severe, systemic risk to the long-term financial viability of national highway development, the Government of India instituted a radical macroeconomic policy shift, halting all new market borrowings by the National Highways Authority of India from the 2022-2023 fiscal year onward. To service existing, inescapable obligations and fund ongoing capital expenditure, the government significantly increased direct budgetary support—rising from Indian Rupee 45,945 crore in 2020-2021 to over Indian Rupee 2.1 lakh crore in current fiscal cycles [21]—while aggressively instructing the authority to pursue diverse asset monetization strategies.

Monetization Strategies and Prepayment Efficacy (2024-2026)

The institutional deleveraging strategy has yielded highly tangible results through a sophisticated combination of early loan prepayments and the monetization of operational, revenue-generating assets via Infrastructure Investment Trusts (InvITs) and Toll-Operate-Transfer (TOT) concession models. By the end of 2025, the National Highways Authority of India had successfully mobilized massive tranches of capital through asset monetization. For instance, in the 2023-2024 financial year alone, the National Highways Authority of India deposited total toll and shared revenues of Indian Rupee 27,473 crore into the Consolidated Fund of India and received massive concession fees exceeding Indian Rupee 15,968 crore through Toll-Operate-Transfer bundles 11, 12, 13, and 14. Overall toll collections by the National Highways Authority of India soared to an impressive Indian Rupee 55,844 crore in the 2023-2024 financial year, indicating robust underlying economic activity and asset performance [22]. The capital raised through the Infrastructure Investment Trust mode, prominently through the National Highways Infra Trust, has been deployed exclusively and ruthlessly for debt repayment. By mid-2024, the National Highways Authority of India utilized Infrastructure Investment Trust monetization proceeds to directly pre-pay bank loans amounting to Indian Rupee 15,700 crore, generating an immediate, estimated interest savings of Indian Rupee 1,000 crore for the exchequer. This momentum was sustained through the National Highways Infra Trust's fourth round of monetization, which successfully raised Indian Rupee 18,380 crore—the largest to date—comprising Indian Rupee 8,340 crore in unit capital from global investors and Indian Rupee 10,040 crore in debt from leading lenders [23]. The market's robust appetite for NHAI InvITs fundamentally proves that domestic and global institutional capital is highly willing to invest in operational, securitized highway assets.

This successful securitization of toll revenues serves as the vital macroeconomic precedent for the BOSS framework; if operational revenues can be unitized for institutional investors, they can theoretically be unitized for the local agrarian communities providing the underlying land equity. Simultaneously, the authority executed an aggressive overall prepayment strategy, retiring massive liabilities worth approximately Indian Rupee 86,000 crore ahead of schedule, which notably included a massive Indian Rupee 50,000 crore settlement of high-interest National Small Savings Fund loans. Furthermore, due to proactive, rigorous negotiation with domestic banking syndicates, the National Highways Authority of India was able to reduce its interest burden by refixing interest rates lower by about 80 basis points over a two-year period (e.g., dropping rates from 8.00-8.10% down to 7.58-7.59%), resulting in perpetual annual interest savings exceeding Indian Rupee 3,500 crore [24]. Consequently, the National Highways Authority of India successfully reduced its outstanding debt from the Indian Rupee 3.5 trillion peak down to Indian Rupee 2,44,539 crore by the 2024-2025 financial year [25], and further down to Indian Rupee 2,35,947 crore by December 31, 2025 . The stated institutional objective, heavily monitored by the Ministry of Finance, is to drive this debt burden comfortably below the psychological and fiscal Indian Rupee 2 lakh crore (Indian Rupee 2 trillion) threshold by the end of March 2026 [24,25].

The Push to Revive BOT-Toll and the Revamped Model Concession Agreement (MCA)

In an attempt to resolve this paradox, shift the financial burden away from the public exchequer, and attract private risk capital back to demand-risk projects, the Ministry of Road Transport and Highways launched an ambitious campaign to revive the pure Build-Operate-Transfer (Toll) model, introducing a heavily revamped Model Concession Agreement in March 2024 [26]. The new Model Concession Agreement represented a strategic, highly engineered policy recalibration designed to address the historical grievances that caused the Build-Operate-Transfer collapse a decade prior. It introduced dynamic traffic-linked risk mitigation by lowering the traffic trigger required for relief

mechanisms from a highly punitive 20% deviation down to a highly responsive 5% [26]. Furthermore, it scrapped the vague and highly litigious "competing roads" provision, replacing it with a formalized "buy-out principle." This principle contractually guarantees that if external, un forecasted public infrastructure severely cannibalizes the private developer's toll revenues, the authority is obligated to acquire the project, thereby placing a definitive floor on private sector losses. Despite these comprehensive, objectively investor-friendly contractual reforms, market reaction has remained highly subdued and cautious. In the 2024-2025 financial year, Build-Operate-Transfer projects accounted for only a marginal 1% to 10% fraction of total national highway awards by length [27]. Developers remain fundamentally risk-averse, demonstrating unequivocally that mere contractual tweaks and financial engineering cannot overcome the systemic, ground-level bottlenecks of adversarial land acquisition and deep-seated, historically validated fears regarding traffic volume accuracy. The financial trajectory of NHAI debt and the macroeconomic milestones of recent deleveraging strategies are summarized in Table 2.

Scope of the Study and Problem Statement

While financial engineering and macroeconomic deleveraging understandably dominate top-level policy discourse, empirical evidence indicates that the most profound and persistent barriers to infrastructure execution exist entirely outside the binary state-developer contractual matrix. The legacy infrastructure paradigm is fundamentally hamstrung by two terminal inefficiencies: the socio-economic friction of adversarial land assembly at the inception of a project, and the moral hazard of asset cannibalization at its conclusion.

The Mechanics and Limitations of the LARR Act 2013

Across all legacy procurement models—BOT, HAM, and EPC—land acquisition is treated as a highly transactional, adversarial prerequisite governed by the Right to Fair Compensation and Transparency in Land Acquisition, Rehabilitation and Resettlement (RFCTLARR) Act of 2013 [28]. Enacted to replace the draconian, colonial-era Land Acquisition Act of 1894, the LARR Act sought to correct historical injustices characterized by exploitative, state-centric, and coercive acquisition procedures. The legislation introduced a profound rights-based approach, mandating comprehensive, time-consuming Social Impact Assessments (SIA), strict rehabilitation and resettlement (R&R) protocols for not just landowners but "affected families" (including farm labourers and tenants), and the prior, documented consent of 70% of affected landowners for PPP projects and 80% for private projects. Furthermore, it exponentially increased the direct financial burden on the state by guaranteeing monetary compensation at a minimum of twice the market value in urban areas and up to four times the market value in rural areas, supplemented mandatorily by a 100% solatium.

While the LARR Act of 2013 represents a monumental triumph for participatory justice and landowner rights, its rigid, cash-only implementation has entrenched the treatment of land as an adversarial "sunk cost". The statute continues to operate strictly within the paradigm of one-time cash compensation [29], representing a systemic failure of Land Value Capture (LVC). Under the LARR Act, the state monopolizes 100% of the post-construction, exponential land appreciation. Displaced agrarian populations are treated as transient stakeholders, compensated once at pre-development valuations and permanently severed from the enduring economic value generated upon their ancestral land. This failure to implement equitable LVC mechanisms results in deeply entrenched socio-economic resistance. This legal architecture, though procedurally humane, fails entirely to preserve any continuing stake for the dispossessed communities, severing them from intergenerational wealth creation. From a macroeconomic and project management perspective, the procedural rigor of the LARR Act has severely constrained the pace of infrastructure development. Government data reviewed under the PRAGATI (Pro-Active Governance and Timely Implementation) mechanism—a platform personally overseen by the Prime Minister's Office to resolve critical infrastructure delays—indicates that land acquisition accounts for a staggering 35% of all infrastructure project delays, making it the single largest bottleneck nationwide, superseding environmental clearances (20%) and utility shifting (18%) [30].

The empirical financial evidence from the 2024-2026 period underscores the absolute severity of this bottleneck. Under the Bharatmala Pariyojana Phase-I, the actual average per-kilometer civil construction cost escalated to

approximately INR 24 crore, while the land acquisition and pre-construction activities soared to an exorbitant INR 8.3 crore per kilometer [20]. The original project parameters had estimated civil costs at roughly INR 14 crore per kilometer with a total land acquisition provision of only INR 45,000 crore; the exponential rise in land acquisition costs contributed to the total program cost doubling from its initial INR 5.35 trillion estimate to over INR 10.64 trillion [31]. This drastic increase in upfront capital depletion has placed immense strain on the NHAI's already burdened balance sheet and slowed the awarding of new projects. Official government disclosures to Parliament revealed the cascading physical effects of these bottlenecks: 574 under-construction National Highway projects, possessing a massive cumulative project cost of approximately INR 3.60 lakh crore, had spilled beyond their original completion schedules. Specifically, 300 projects faced delays of up to one year, 253 projects were delayed between one and three years, and 21 projects overshot timelines by more than three years [32]. Furthermore, a severe pre-construction pipeline blockage was explicitly identified: 133 National Highway projects, with a combined cost exceeding INR 1 lakh crore, had been awarded but were entirely unable to reach their appointed dates (the official start of construction) pending the fulfillment of pre-requisite conditions—primarily the availability of 80% to 90% encumbrance-free land and the navigation of statutory forest clearances. The limitations of the compulsory acquisition model have led scholars and policymakers to explore alternative land assembly mechanisms. In stark contrast to India's reliance on eminent domain, international best practices frequently utilize non-coercive, equity-based land pooling and readjustment mechanisms. An empirical assessment of the specific physical and timeline delays affecting under-construction highway projects is presented in Table 3.

In Japan, the practice of "Land Readjustment" (KukakuSeiri) has been fundamental to its urban and infrastructure development since the early 20th century. Faced with fragmented rural land ownership and severe planning challenges, Japan empowered local landowners to replan whole neighborhoods privately by supermajority vote [33]. Under this system, landowners contribute a portion of their land for public infrastructure (roads, parks) and reserve a portion to finance the project costs, while retaining title to a slightly smaller, but significantly more valuable, reconstituted plot of land. This mechanism generates durable public support for affordable infrastructure without extreme cash payouts, sharing the profits of urban densification with the wider community [33]. Similarly, Germany utilizes a highly structured land readjustment process based on relative value redistribution, ensuring that landowners benefit proportionally from the spatial and economic enhancements brought about by new infrastructure [34].

Terminal Asset Decay and the Lifecycle Maintenance Deficit

While land acquisition presents a formidable, seemingly insurmountable barrier at the inception of a project, legacy Public-Private Partnership models suffer from an equally destructive, systemic flaw at the conclusion of the asset lifecycle: the phenomenon termed the "Maintenance Cliff". Traditional Build-Operate-Transfer and Hybrid Annuity Models inherently incentivize asset cannibalization due to a profound information asymmetry and moral hazard embedded deeply in fixed-term concession agreements [35]. Because private developers must legally transfer the highway asset back to the state at the end of the concession period (typically ranging from 20 to 30 years), the financial incentive to invest in capital repairs diminishes exponentially in the final quartile of the contract. The present value of future cash flows approaches zero as the handover date looms. Consequently, developers logically seek to maximize their Internal Rate of Return by drastically curtailing operations and maintenance expenditures, specifically avoiding expensive, deep-pavement rehabilitation. Assets are frequently returned to the National Highways Authority of India in states of severe structural decay, lacking modern technological upgrades, and requiring immediate, massive injections of taxpayer funds for basic rehabilitation. Empirical studies from the World Bank and the South African National Roads Agency indicate a severe, non-linear mathematical cost escalation regarding deferred maintenance. Delaying road pavement maintenance by three years beyond the optimal intervention point leads to increased repair costs of six times the original preventive maintenance cost; a five-year delay raises costs to an unsustainable eighteen times the preventive baseline [36]. Once a pavement's condition rating drops below critical thresholds, water intrusion compromises the sub-base, necessitating full-depth reconstruction rather than simple surface overlays, driving the eighteen-fold cost multiplier.

The Comptroller and Auditor General of India has extensively and repeatedly documented this maintenance deficit domestically. In a comprehensive performance audit (Report Number 7 of 2023) covering 41 toll plazas across southern Indian states -Tamil Nadu, Karnataka, Andhra Pradesh, Telangana, and Kerala, the Comptroller and Auditor General revealed severe, systemic lapses in lifecycle maintenance [37]. The audit found that delays in executing critical overlay works—the essential resurfacing required to maintain pavement integrity—ranged staggeringly from 2 to 76 months across multiple stretches. The current concession framework relies heavily on Ex-Post Punitive Regulation, attempting to penalize developers only after the asset has structurally degraded. As evidenced by the CAG audit, the NHAI failed to recover ₹391.27 crore from nine BOT concessionaires for delayed overlay works, highlighting the ultimate futility of ex-post financial penalties. To prevent the 'maintenance cliff,' highway procurement must transition toward Ex-Ante Capital Preservation. This requires structural market mechanisms—such as the heavily ring-fenced Hand back Reserve Accounts (HRAs) proposed in the BOSS framework—to mathematically guarantee lifecycle funding prior to the onset of asset decay. In mature Public-Private Partnership markets such as the United Kingdom, Australia, and parts of the European Union, concession agreements universally mandate the establishment of Major Maintenance Reserve Accounts or Hand back Reserve Accounts [38]. A Hand back Reserve Accounts - HRA is a specific, legally ring-fenced bank account designed to accumulate funds over time from operational cash flows, ensuring the asset is transferred back to the public authority meeting strictly specified residual life requirements, regardless of developer solvency. The absolute absence of such immutable ring-fencing mechanisms in Indian legacy models leaves the state highly vulnerable to the maintenance cliff.

Proposed Theoretical Framework

A synthesis of the prevailing macroeconomic factors reveals an infrastructure sector trapped between deeply conflicting imperatives: the need for rapid expansion to meet the Viksit Bharat 2047 goals, the strict sovereign mandate for NHAI debt reduction, the paralysis of LARR Act land acquisition, and the failure of traditional BOT models to attract private risk capital without sovereign guarantees. Iterative, contractual tweaks to bilateral risk allocation have been completely exhausted; the next evolutionary leap requires moving beyond financial engineering to fundamentally restructure stakeholder incentives. In response to these persistent challenges in academic and policy discourse, the author developed a hypothesis: BOSS (Build-Operate-Sustain-Share) Tri-Party Framework. This architecture represents a radical reimagining of the infrastructure social contract, offering a series of innovations designed to mathematically neutralize the land acquisition choke-point. Furthermore, by integrating a 'Sustain-Share' mechanism, the BOSS model provides a structural solution to eradicate the 'maintenance cliff' that historically compromises long-term project viability.

BOSS (Build-Operate-Sustain-Share) Tri-Party Framework

Build – Re-Engineering Project Readiness and Financing - The "Build" pillar of the BOSS model mandates that the private entity takes end-to-end responsibility for design, financing, and construction. Implementing HAM benefits here focuses on neutralizing the two primary causes of project failure: land acquisition delays and upfront capital shortfalls.

Internalized Land Acquisition and the 80% ROW Threshold

One of the most significant innovations in the BOSS model is "Internalized Land Acquisition," where land is treated as an equity contribution by landowners rather than a cash cost for the government. This mirrors the high project-readiness standards set by NHAI for HAM projects. Under the current HAM guidelines, a project cannot reach its "Appointed Date"—the official start of construction—until the government has provided at least 80% of the Right of Way (ROW). This requirement serves as a de-risking mechanism for the developer. By ensuring that 80% of the land is available at the 3G stage (where compensation is determined), the model mitigates the implementation risk associated with subsequent protests or legal hurdles. When land is treated as equity under the BOSS model, the incentive for landowners shifts from obstruction to facilitation, as they become partners in the project's success. This significantly reduces the project's initial capital requirement.

Financial Architecture and Milestone-Linked Disbursements: Under the BOSS framework, the construction grant is designed as a performance-linked incentive rather than a lump-sum disbursement. This ensures a disciplined framework for the "Build" pillar by aligning cash flow directly with physical completion similar to HAM. To optimize developer liquidity, the grant is structured as 60% of the Bid Project Cost (BPC), released in five equal installments of 12% each. The proposed milestone-linked disbursement schedule, designed to align government financial support directly with physical project progress, is outlined in Table 4. Furthermore, the model allows for mobilization advances of up to 10% of the Bid Project Cost (BPC) at the bank rate. These advances are critical in the early stages of the "Build" pillar, as they allow for the rapid procurement of machinery and materials without straining the developer's immediate cash reserves. The advances are subsequently recovered through deductions from the milestone payments, creating a self-liquidating credit mechanism.

Standards Compliance and Lifecycle Compatibility: The "Build" phase must adhere to strict technical standards to ensure the asset survives its 30-to-100-year lifecycle. In HAM projects, this is enforced through the role of the Independent Engineer (IE). The IE is responsible for reviewing designs, monitoring quality, and certifying milestones. By integrating the IE's oversight into the BOSS "Build" pillar, the project ensures that the design-build phase is optimized for long-term durability rather than short-term cost savings.

Mitigating MC and RC through Advanced Material Engineering: To drive down routine and preventive Maintenance Costs (MC) and significantly delay major end-of-life component overhauls or Replacement Costs (RC), the framework mandates rigorous material specifications during the initial build phase. By integrating sustainable, high-durability materials—such as processed overburden mining sand, high-volume fly ash concrete, and advanced bitumen-cement slurries for robust sub-grade waterproofing—the structural integrity of the asset is exponentially enhanced. This upfront engineering rigor minimizes pavement degradation, moisture ingress, and general structural wear, effectively flattening the compounding expense curve of both MC and RC over the concession period. Beyond the initial construction, the "Sustain" pillar is characterized by a commitment to regularly implemented innovative maintenance, rather than relying on static protocols.

Operate –

Intelligent Stewardship and Performance-Linked Returns - Post-construction, the BOSS model transitions into a management role, focusing on the operation and maintenance (O&M) of the asset. The partial integration of HAM here ensures that O&M is not an afterthought but a central part of the financial viability of the project.

Service-Level Agreements and Performance Monitoring

In the BOSS model, success is measured via Service-Level Agreements (SLAs), where financial bonuses or penalties are tied to performance. This aligns perfectly with the HAM framework, where the developer is responsible for keeping the road "pothole-free" and maintaining safety systems throughout the 15-30 year concession period.

Performance is monitored using sophisticated technological tools:

- **GNSS and IoT Integration:** Utilizing Global Navigation Satellite Systems and Internet of Things sensors for real-time traffic and structural health monitoring. This data allows the operator to identify structural fatigue or drainage issues before they escalate into major failures [39].
- **Network Survey Vehicles (NSV):** Regular Road condition assessments are carried out using NSVs every six months after project completion. These surveys measure the "roughness index" of the pavement, ensuring it remains within the stipulated 2000 mm/km to 2500 mm/km range.
- **App-Based Monitoring:** Platforms like the NHAI One to allow field officers and concessionaires to report defects digitally. These reports are geo-tagged and time-stamped, providing an immutable record of maintenance quality.

The Tripartite Revenue Matrix: To ensure robust liquidity throughout the concession period, the operational phase executes the Build-Own-Operate-Transfer (BOOT) -style commercialization strategies established during the land

pooling process. The SPV manages a tripartite revenue matrix that decouples project success from mere vehicular throughput:

- **Direct User Charges (Tolls):** The foundational revenue stream, optimized via Advanced Traffic Management Systems (ATMS) and dynamic pricing algorithms to manage congestion and maximize core infrastructural yield.
- **Unrestricted Commercial Yields:** The operationalization of the supplementary land pools. The SPV actively manages the leases of the green commercial hubs, Multimodal Logistics Parks (MLPs), and transit-oriented retail plazas. This provides a fixed, inflation-indexed rental income immune to traffic volume volatility.
- **Green Energy Arbitrage:** The captive renewable infrastructure (solar and micro-wind) enters full generation capacity. After operational electricity costs are dropped to near absolute zero, the SPV executes Power Purchase Agreements (PPAs) with state discoms, turning the highway into a net-positive energy exporter.

The BOSS hypothesis integrates a digitized, transparent ledger system for the Algorithmic Waterfall, ensuring Infrastructure Unit (IU) holders have real-time visibility into the project's aggregate operations and earnings. Furthermore, representatives of the IU holders maintain a governance presence within the operational SPV. This inclusion neutralizes the traditional socio-economic friction seen during the operational phase of legacy models. Because the local community's intergenerational wealth is directly tied to the uninterrupted operation and profitability of the corridor, the incidence of local protests, toll-plaza vandalism, or operational blockades is theoretically eliminated, ensuring a seamless, highly profitable operational lifecycle.

Optimizing OC (Operational Cost) through Digitization

To minimize the long-term staffing and management overhead associated with **Operational Costs (OC)**, the "Build" phase embeds digital autonomy directly into the physical asset. By pre-installing Advanced Traffic Management Systems (ATMS), automated tolling gantries, and IoT-enabled structural health sensors within the concrete and pavement structures, the project minimizes the need for heavy manual staffing. This smart-infrastructure approach transitions management from human-intensive oversight to automated, digitized monitoring, permanently suppressing the OC trajectory throughout the project's lifecycle

Sustain –

Lifecycle Efficiency as a Revenue Generator - The "Sustain" pillar represents the core of the BOSS model's technical innovation. It shifts the focus from initial cost (IC) to total ownership costs over considering 100-year horizon. In this model, sustainability is viewed as a revenue generator: by reducing long-term O&M expenditures, more capital is available for dividends to IU holders.

The Lifecycle Cost (LCC) Analysis Formula

The BOSS framework mandates the assessment of the Total Lifecycle Cost (LCC) using the following equation:

$$LCC = IC + \sum_{t=1}^{T} \frac{MC_t + EC_t + OC_t + RC_t}{(1+r)^t}$$

Where:

- LCC (Total Life Cycle Cost): The master financial metric expressed as a Net Present Value. It calculates the absolute total economic burden of designing, building, operating, and maintaining the highway over its entire lifespan, mathematically discounting all future costs into current monetary terms.
- IC (Initial Capital Cost): The upfront Capital Expenditure (CAPEX) required prior to the commencement of commercial operations (Year 0). This encompasses detailed design, civil works, machinery mobilization, and advanced construction materials. Because this expenditure occurs immediately, it is not subject to temporal discounting.
- MC_t (Maintenance Cost in year t): The routine and preventive Operational Expenditure (OPEX) incurred in any specific future year, including pavement patching and micro-surfacing. The BOSS framework seeks to permanently suppress the MC_t trajectory by mandating superior material engineering (e.g., plastic-modified bitumen) during the initial build phase.

- EC_t (Energy Cost in year t): The specific capital required to power the infrastructure, primarily grid electricity for highway lighting, toll plazas, and Advanced Traffic Management Systems (ATMS). The BOSS framework's integration of captive renewable infrastructure (solar canopies and micro-wind) is explicitly designed to drive EC_t toward zero or convert it into a net-positive revenue stream via Power Purchase Agreements (PPAs).
- OC_t (Operational Cost in year t): The administrative and human overhead required to manage the asset, including toll collection and incident response. The model mitigates OC_t by embedding digital autonomy into the physical asset through IoT sensors and automated tolling gantries.
- RC_t (Replacement Cost in year t): The massive, cyclical capital injections required for major component overhauls, such as full-depth pavement reconstruction or structural rehabilitation. To prevent the traditional "maintenance cliff" caused by deferred RC_t, the BOSS model mathematically secures these funds via strictly ring-fenced Hand back Reserve Accounts (HRA).
- r (Discount Rate / Cost of Capital): The mathematical representation of the time value of money. For the Tri-Party Special Purpose Vehicle (SPV), this represents the Weighted Average Cost of Capital (WACC)—a blended average of the interest rate paid on institutional senior debt (e.g., MCLR plus 1.25%) and the expected dividend return hurdles required by the equity holders.
- T (Total Concession Period): The absolute temporal boundary of the contract (e.g., 20 to 30 years). This defines the upper limit of the equation's summation, culminating in the zero-payout sovereign surrender of the asset back to the state.

HAM supports this by using the "Life Cycle Cost" as the sole bid parameter. The bid is awarded to the developer quoting the lowest Net Present Value (NPV) of the BPC plus the NPV of the O&M cost for the entire operation period. This forces developers to consider the long-term durability of materials during the bidding phase.

Waste to Wealth Concept: Driving Sustainability and Cost-Efficiency

Implementing the "Waste to Wealth" concept transforms infrastructure projects into environmental solutions while simultaneously optimizing financial outcomes. By repurposing industrial and consumer waste, the BOSS framework reduces material costs and enhances durability including, but not limited to, the following: Fly Ash Utilization: Integrating industrial by products like fly ash allows for the replacement of up to 25% of cement in concrete mixes. This transition not only significantly reduces the project's carbon footprint but also decreases construction costs by approximately 15% through material savings. Plastic Waste in Bitumen: Incorporating shredded plastic waste into bituminous mixes is a proven innovation that reduces bitumen consumption by 10%. Beyond cost savings, this additive improves the pavement's resistance to water logging and thermal deformation, ensuring higher performance in extreme temperatures.

The Maintenance Trigger: Unlike traditional models where maintenance might be deferred to maximize profit, BOSS utilizes the HRA to mandate a "Life-Cycle Costing" approach. The account ensures that the funds required for the final "renewal works" are ring-fenced. Typically, the HRA is populated during the last 5-7 years of the concession period. Under BOSS, this can be calculated as:

$$Annual\ Provision = \frac{EstimatedHandbackCost - Current\ Reserve}{Remaining\ Years}$$

In the BOSS financial waterfall, the HRA provision should rank above junior debt servicing and equity dividends during the final phase. This ensures that "Sustainability" takes precedence over "Profit Extraction" as the project nears its shareholding transition

Green Revenue and Energy Cost Mitigation: The BOOT-Style Commercialization Engine

A critical vulnerability in legacy infrastructure frameworks is their over-reliance on toll collections, which are inherently susceptible to traffic volatility. To guarantee the massive lifecycle earnings required to make the zero-payout sovereign surrender viable for IU holders, the theoretical BOSS hypothesis integrates a Build-Own-Operate-Transfer (BOOT) style commercialization engine. Central to this strategy is the proactive pooling of supplementary land parcels that extend well beyond the strict engineering requirements of the highway's Right-of-Way (RoW).

Rather than treating this expanded footprint—alongside interchanges, median strips, and buffer zones—as sterile public property, the Special Purpose Vehicle (SPV) leverages it as highly monetizable, unrestricted commercial real estate. By adopting BOOT principles, the SPV is authorized to lease these prime nodes to third-party developers for any high-yield purpose aligned with the corridor's economic growth. This creates a multi-layered revenue stream feeding directly into the IU dividend pool:

- **Green Commercial Hubs:** Leasing prime nodes for high-density EV and fuel charging networks, Multimodal Logistics Parks (MLPs), and sustainable agro-processing centers.
- **Commercial Real Estate:** Developing wayside amenities, transit-oriented retail plazas, and warehousing to capture the localized economic boom.

Furthermore, this commercialization strategy directly mitigates the massive continuous operational expenditures of highway management, particularly the heavy electricity costs required for corridor lighting, toll plazas, and Advanced Traffic Management Systems (ATMS). The BOSS hypothesis neutralizes these financial drains by installing captive renewable infrastructure, including solar canopies over service roads and micro-wind turbines in high-velocity zones. This green energy generation not only drops operational electricity costs to near absolute zero but also achieves grid parity, allowing the SPV to sell surplus power back to the regional grid via Power Purchase Agreements (PPAs) with state discoms. This effectively compounds the total earnings distributed to stakeholders prior to the final, zero-payout surrender of the asset.

Maximizing Total Earnings Prior to Surrender: This BOOT-style commercialization acts as the ultimate financial safety net for the Infrastructure Unit holders. By decoupling project profitability from mere vehicle counts, the green energy sales and unrestricted commercial leases generate a massive, localized economic engine. This ensures that the aggregate dividends paid out to the IU holders during the "Operate" and "Sustain" phases are exceptionally high. Consequently, when the concession period ends and land Surrender to the Government occurs, the landowners have already secured a level of wealth and profit generation that far exceeds the traditional valuation of their initial land contribution.

Share – The BOSS framework strategically divides project financing into two lifecycle phases, integrating the Hybrid Annuity Model (HAM) and Build Own Operate Transfer (BOOT) to ensure both upfront liquidity and long-term economic sustainability. During the development stage, 70% of the project cost is disbursed to the private developer through scheduled, milestone-based installments, while the remaining 30% is strategically deferred to the active operations phase. Once the infrastructure is commissioned, project cash flows are managed through a strict, hierarchical dynamic waterfall. After mandatory Operations & Maintenance (O&M) and institutional Senior Debt Servicing have been fully satisfied to maintain the project's debt-service coverage ratio (DSCR), the resulting Net Distributable Surplus (Tier 3 Cash Flow) is distributed through a tripartite sharing mechanism: 60% of this surplus is distributed as ongoing Infrastructure Unit dividend compensation to the landowners, 20% is allocated to the private operator as equity returns, and the final 20% is channelled into a sovereign government development trust to finance future green field projects.

The Unitization Framework and the IU Engine - The most profound friction points in Indian infrastructure—land acquisition delays and the resultant upfront capital depletion that doubles project costs—is resolved in the "Share" pillar is the social engine of the BOSS model, transforming land acquisition from a zero-sum conflict into a wealth-generation partnership. By converting landowners into Infrastructure Unit (IU) holders, the model institutionalizes social equity.

The Standardized Unitization Algorithm

The BOSS model replaces one-time cash payments—which are often depleted rapidly—with dividend-yielding financial instruments. The framework establishes a conversion metric where 1 share equals 0.5 acres of land. The specific allocation for a landowner is calculated as:

$IUs = \left(\frac{TAC}{0.5}\right) \times VM$

Where

IUs **:** Total Infrastructure Units (shares) allocated.

TAC **:** Total Area Contributed by the landowner in acres.

VM **:** Localized Valuation Multiplier.

This mathematically accounts for the parcel's proximity to highly monetizable nodes like toll plazas, major interchanges, or Multimodal Logistics Parks would have a higher VM than a parcel in a remote rural stretch. This ensures that landowners whose property is central to the project's success receive a higher proportion of the dividends generated by the asset.

Neutralizing Wealth Shock and Preserving Wealth

One of the primary benefits of the "Share" pillar is its ability to neutralize "Wealth Shock." Traditional land acquisition involves large cash payouts that often leave rural families without sustainable income after the funds are spent. By issuing IUs, the model provides:

- **Steady Dividends:** Similar to the semi-annual annuities paid to the developer under HAM, landowners receive regular dividends from the project's revenue.
- **Asset Appreciation:** As the infrastructure project matures and traffic volumes increase, the underlying value of the asset (and therefore the IUs) grows.
- **Collateralization:** These units can be used as financial collateral for education or business loans, preserving intergenerational wealth without the need to sell the family's primary asset.

Recognizing the immediate livelihood displacement of agrarian families, the framework mandates a minimum upfront cash floor during the land-to-equity conversion. This cash component is calculated specifically to bridge livelihood transition costs during the 3-to-4-year construction phase (when zero dividends are generated), with the remaining premium land value locked into the dividend-yielding IUs.

Total Earnings and the Zero-Payout Sovereign Surrender

To eliminate the burden of massive capitalization payouts on the state exchequer, the "Share" pillar mandates a complete sovereign transfer at the end of the concession period. No land is returned to the IU holders, and there is no final lump-sum payout from the government. Instead, the theoretical model emphasizes Total Earnings and the exponential generation of value over the project lifecycle. The true financial value for the landowner is derived from maximizing the continuous, steady stream of dividends collected throughout the "Operate" and "Sustain" phases. By leveraging the time value of money, these periodic dividend distributions—when modeled with the principles of compound interest—accumulate into substantial intergenerational wealth. Because the dividends are backed by the expanding BOOT commercial engine, their compounded aggregate yield by the time the asset is surrendered theoretically far exceeds the static, depreciating one-time sale value of the raw land.

The Loss Mitigation Mechanism: The BOT Buyout Trigger

While the Total Earnings approach is designed for high-yield corridors, the hypothesis also accounts for underperforming assets. If traffic volumes or commercial revenues fall below projections, IU holders risk incurring a net loss compared to a traditional outright land sale. To create a safe environment where landowners are guaranteed a profit, the framework integrates a Guaranteed Yield Buyout Option. If the cumulative dividends fail to meet a baseline profitability index by a specified point in the concession period, the IU holders can exercise a put option. Drawing from traditional Build-Operate-Transfer (BOT) upfront acquisition structures, this mechanism forces a one-time buyout of the IUs by the concessionaire or state authority at a guaranteed minimum profit margin, thereby capping the landowner's downside risk and ensuring project viability.

DISCUSSION

Traditional infrastructure procurement operates on an adversarial binary axis—the state and the private developer—leaving landowners as outsiders limited to one-time eminent domain compensation. This binary structure fundamentally triggers the Land Value Capture (LVC) failures outlined previously. The BOSS framework dismantles this architecture by formalizing a Tri-Party nexus, elevating the community from a passive, displaced demographic to a fiduciary stakeholder. By integrating residents as equity holders, this architecture replaces traditional eminent domain conflict with a structured, legally binding partnership where all three parties are contractually aligned. The roles within this nexus are strictly delineated:

- **The State (Authority):** Provides the sovereign guarantee, macroeconomic planning, and the statutory facilitation of right-of-way aggregation.
- **The Private Developer (Concessionaire):** Injects initial Capital Expenditure (IC), executes Operational Expenditure (OC_t and MC_t), and provides technical lifecycle management expertise.
- **The Local Community (Equity Partner):** Provides the geospatial foundation (land)—not as an adversarial sunk cost to the state, but as an initial, unitized equity contribution to the Special Purpose Vehicle (SPV)'s capital structure.

The 30-Year Dynamic Equity-Waterfall

To service the diverse financial imperatives of the Tri-Party nexus, the BOSS model evolves the payment architecture of HAM. Rather than relying solely on fixed sovereign payouts, it integrates a BOOT-style commercialization engine with a highly disciplined 30-year Dynamic Equity-Waterfall mechanism. Over the asset's lifecycle, gross project revenues are channeled strictly through the following deterministic tiers to prevent default and asset decay:

- **Tier 1 (Mandatory Operations, Sustenance, and Reserve):** The absolute first claim on gross revenue is ring-fenced for the physical integrity of the asset. This includes immediate O&M payouts (inflation-indexed via the Price Index Multiple) to ensure the operator meets Service Level Agreements (SLAs), alongside mandatory deposits into the Handback Reserve Account (HRA).
- **Tier 2 (Senior Debt Servicing):** To maintain the project's bankability and ensure a Debt-Service Coverage Ratio (DSCR) of ≥ 1.20, liquidity is subsequently directed toward the amortization of institutional debt. To eliminate basis risk, interest is pegged to the Marginal Cost of Funds based Lending Rate (MCLR) plus a prescribed risk margin (e.g., 1.25%), mirroring the high credit ratings of post-2020 HAM frameworks.
- **Tier 3 (The Tri-Party Distributable Surplus - The "Share" Mechanism):** Only after Tier 1 (physical sustenance) and Tier 2 (debt obligations) are fully satisfied is the residual cash flow classified as Net Distributable Surplus. This surplus is democratized through the definitive BOSS sharing formula: 60% is distributed as ongoing Infrastructure Unit (IU) dividends to the landowners, 20% is allocated to the developer to satisfy equity return hurdles, and 20% is channelled to a sovereign development trust to finance future greenfield expansion.

Regulatory Synergies: SEBI and Infrastructure Investment Trust Reforms

The theoretical viability of the 'Land-as-Equity' concept requires that Infrastructure Units (IUs) function as highly liquid, tradable securities rather than trapped assets. Sweeping amendments to the Infrastructure Investment Trusts (InvITs) Regulations [40] enacted by the Securities and Exchange Board of India (SEBI) provide the exact regulatory parameters required for this framework. By drastically reducing the minimum investment threshold for privately placed InvITs from ₹1 crore down to ₹25 lakhs, SEBI has inadvertently established the precise liquidity mechanisms needed to democratize infrastructure asset ownership for community trusts [41].

Universal Inclusion: Solving the Smallholder Participation Gap

While the ₹25 lakh threshold reduction democratizes access, a mathematical barrier persists for smallholder agrarian landowners whose fractional acre contributions fall below this floor. To achieve universal inclusion, the BOSS framework mandates two structural interventions:

- **The Community Equity Trust Aggregation Model:** A mandatory legal intermediary that aggregates the fractional land value of multiple owners into a single, project-specific institutional entity. The Trust operates as the formal 'Institutional Unitholder,' while individual landowners hold 'Sub-Units,' ensuring universal participation in the Tier 3 dividend waterfall.
- **The "Host Community Member" Regulatory Exemption:** A proposed SEBI exemption permitting the issuance of 'Legacy Units' to original landowners without any minimum value floor. By classifying these stakeholders as a distinct asset class, the state bypasses liquidity-protection floors designed for speculative investors, formally recognizing that these units represent mandatory compensation for a geospatial livelihood.

Digital Integration: The BOSS-Demat Protocol: To eliminate bureaucratic friction and ensure the "Sustain" pillar, the framework mandates the integration of the Boss-Demat system. This serves as a digital bridge between national land records (Bhoomi Samvaad) and the national depository systems (National Securities Depository Limited and Central Depository Services Limited) [42]. Upon the official "Appointed Date" of the project, the land-to-equity conversion is triggered automatically. The Infrastructure Units are credited directly to a landowner's BOSS-Demat account, ensuring that the socio-economic transition from "dispossessed" to "partner" is instantaneous, inclusive, and transparent.

CONCLUSION

The Indian national highway sector has reached a defining structural impasse that threatens the nation's ambitious trajectory toward the "Viksit Bharat 2047" economic vision. While the country has achieved a staggering 3,180% growth in high-speed expressways since 2014, this rapid expansion relies on legacy procurement models—namely Build-Operate-Transfer (BOT) and the Hybrid Annuity Model (HAM)—that have exhausted their macroeconomic utility. These frameworks are increasingly paralyzed by the failure of Land Value Capture (LVC) under the 2013 LARR Act, which has driven massive upfront capital depletion, and a mounting sovereign debt burden that peaked at ₹3.48 trillion for the NHAI. Furthermore, the reliance on ex-post punitive regulation has failed to prevent the terminal "maintenance cliff" at the conclusion of private concession periods. To resolve these compounding market failures, this paper introduces the theoretical Build-Operate-Sustain-Share (BOSS) framework. By dismantling the binary, adversarial relationship between the state and developers, the BOSS model mathematically integrates local agrarian communities as fiduciary, equity-holding stakeholders. Through the "Land-as-Equity" unitization mechanism, supported by recent SEBI InvIT regulatory reforms and the proposed BOSS-Demat digital protocol, landowners trade their physical holdings for highly liquid "Infrastructure Units" (IUs). The operational viability of this model is secured through a disciplined, Net Present Value-optimized lifecycle cost (LCC) architecture. By instituting a strict three-tier dynamic revenue waterfall, the BOSS framework mandates ex-ante capital preservation—ring-fencing funds for physical maintenance and institutional debt servicing prior to the distribution of a 60/20/20 tripartite dividend split. Ultimately, this framework provides the definitive architectural blueprint required to bridge the sovereign capital deficit, neutralize socio-economic friction, and eradicate terminal asset decay.

Directions For Future Research

While this paper establishes the structural, financial, and legal macro-architecture of the BOSS framework, the operationalization of such a profound paradigm shift requires rigorous empirical validation. Because land is a concurrent subject under the Indian Constitution, stakeholder risk appetites and the willingness of agrarian communities to accept deferred, dividend-yielding equity over immediate cash settlements will likely vary drastically across geographic and socio-economic corridors. The immediate next step in this research trajectory is the deployment of a highly calibrated, 68-item psychometric diagnostic survey designed to test this theoretical framework against ground-level realities. Future studies must execute this instrument across heterogeneous stakeholder cohorts—state authorities, private developers, and displaced landowners. By applying robust statistical methodologies, including the Relative Importance Index (RII) and Exploratory Factor Analysis (EFA), subsequent

research will quantify institutional barriers, dynamically calibrate the localized Valuation Multiplier (VM), and empirically validate the stakeholder integration parameters established in this foundational theoretical model.

Conflict of interest: None.

Table 1: Comparative Risk and Funding Matrix of Prevailing Highway Procurement Models.

Financial Parameter	Build-Operate-Transfer (BOT-Toll)	Hybrid Annuity Model (HAM)	Engineering, Procurement, Construction (EPC)
Project Funding	Predominantly Private Capital	40% Government / 60% Private	100% Government
Traffic & Revenue Risk	Borne entirely by Private Developer	Borne entirely by Government	Borne entirely by Government
O&M Responsibility	Private Developer	Private Developer	Government(Post-Defect Liability Period)
Government Fiscal Burden	Low (Revenue generating)	Medium to High (Deferred Annuity Trap)	Extremely High (Upfront Capital)
Private Sector Exposure	Extremely High	Medium (Insulated by Annuities)	Low (Purely contracting)
Lifecycle Maintenance Incentive	Low (Decays toward end of concession to maximize Internal Rate of Return)	Low (Insulated by fixed annuities; minimal incentive for capital preservation)	None (Asset handed over immediately post-construction)

Vulnerability to LARR Act (Land Delays)	Extreme (Developer absorbs idle mobilization costs)	High (Mitigated only by 80% RoW precondition, leaving 20% vulnerable)	Extreme (State bears full cost of project paralysis)

Table 2: The Financial Trajectory of NHAI Debt and Deleveraging Strategies (2021-2026).

Fiscal Year	NHAI Outstanding Debt (INR Crore)	Key Deleveraging Actions and Macroeconomic Milestones
2021-2022	~3,48,522 (Peak)	Aggressive expansion under Bharatmala Phase-I via HAM and EPC.
2022-2023	~3,42,801	Government halts all new market borrowings for NHAI.
2023-2024	~3,35,173	Acceleration of asset monetization via InvITs and TOT models.
2024-2025	~2,44,539	Prepayment of INR 86,000 crore (including INR 50,000 crore NSSF loans).
Dec 2025	~2,35,947	Renegotiation of bank interestrates yield 80 Base point reduction.
March 2026	< 2,00,000 (Target)	Projected threshold achievement via continued toll growth and InvIT receipts.

Table 3: Empirical Assessment of Highway Execution Delays based on PRAGATI and Parliamentary Disclosures (2025)

Project Delay Duration	Number of NH Projects Delayed	Estimated Cause / Context
< 1 Year	300	Minor land disputes, utility shifting, initial statutory clearances.
1 to 3 Years	253	Protracted LARR Act litigation, prolonged forest/environmental clearances.
> 3 Years	21	Severe socio-economic resistance, contractor financial distress, total execution paralysis.
Awaiting Appointed Date	133	Failure to secure 80-90% unencumbered Right of Way prior to construction commencement.

Table 4: Proposed Milestone linked to the physical progress of the project

Physical Progress Milestone	Cumulative Government Support	Developer Liquidity Impact
Milestone 1 (10% - 20% Physical)	12% of Bid Project Cost	Reimbursement of initial mobilization and clearing costs.
Milestone 2 (30% - 40% Physical)	24% of Bid Project Cost	Reduction in debt drawdown; preservation of equity.
Milestone 3 (50% - 60% Physical)	36% of Bid Project Cost	Funding for structural works and pavement layers.
Milestone 4 (75% Physical)	48% of Bid Project Cost	Maintaining momentum through peak construction phases.
Milestone 5 (90% Physical)	60% of Bid Project Cost	Transitioning toward completion and testing.

ABSTRACT

Vericiguat is an orally active soluble guanylate cyclase stimulator used in the management of chronic heart failure. The present study was undertaken to develop and validate a simple, precise and reproducible reversed-phase high-performance liquid chromatographic (RP-HPLC) method for the quantitative estimation of vericiguat in plasma. Chromatographic separation was achieved using a Platsil C18 column (4.5 × 150 mm, 3 µm) with methanol:0.1% OPA (60:40, v/v) as the mobile phase at a flow rate of 1.0 mL/min. Detection was performed at 256 nm with a 20 µL injection volume and a total run time of 15 min. Plasma samples were processed by protein precipitation using acetonitrile, with riociguat employed as the internal standard. The method demonstrated excellent linearity over the concentration range of 0.2–1.2 µg/mL, with a coefficient of determination (R^2) of 0.999. No significant interfering peaks were observed in blank plasma samples at the retention positions of vericiguat and the internal standard. Within- and between-batch accuracy and precision studies showed very low variability and measured concentrations close to nominal values. Stability studies under freeze-thaw, bench-top, injector and solution conditions produced assay values of approximately 100%. The developed method was therefore found to be specific, linear, accurate, precise, reproducible and sufficiently stable for the reliable estimation of vericiguat in plasma and may be useful for subsequent bioanalytical and pharmacokinetic investigations.

Keywords: Vericiguat; RP-HPLC; rat plasma; bioanalytical method; method validation; accuracy; precision; stability.

INTRODUCTION

Vericiguat is an orally active, direct soluble guanylate cyclase (sGC) stimulator developed for the treatment of symptomatic chronic heart failure, particularly in patients with reduced ejection fraction [3]. The drug enhances the sensitivity of soluble guanylate cyclase to endogenous nitric oxide and promotes the formation of cyclic guanosine monophosphate (cGMP), resulting in relaxation of vascular smooth muscle and improvement of cardiovascular function [3]. The physicochemical and pharmacokinetic characteristics of vericiguat, including its high protein binding, relatively long half-life, and predominant glucuronidation, make reliable quantification in biological matrices important for pharmacokinetic investigations [6,9].Bioanalytical methods are essential for the quantitative determination of drugs and metabolites in biological matrices such as plasma, serum, urine, and blood [10]. Reliable bioanalytical measurements provide the foundation for pharmacokinetic, bioavailability, bioequivalence, and toxicokinetic investigations. Therefore, the analytical procedure must demonstrate adequate selectivity, accuracy, precision, linearity, sensitivity, recovery, and stability before application to biological samples [4-6,9]. High-performance liquid chromatography (HPLC), particularly reversed-phase HPLC coupled with ultraviolet or photodiode-array detection, is widely employed for pharmaceutical and bioanalytical analysis because of its versatility, reproducibility, and ability to separate analytes from complex matrices. Selection of an appropriate stationary phase, mobile-phase composition, flow rate, detection wavelength, injection volume, and sample preparation procedure is critical for achieving satisfactory chromatographic performance. Several analytical methods have been reported for the determination of vericiguat. Recent bioanalytical investigations have primarily employed LC-MS/MS techniques for quantification in rat plasma, providing high sensitivity and wide calibration ranges. Ding et al. reported a UPLC-MS/MS method for vericiguat in rat plasma with a calibration range of 0.1–300 ng/mL [1]. Zhang et al. subsequently reported another UPLC-MS/MS method and applied it to investigate the pharmacokinetic interaction between vericiguat and apigenin [2]. Although LC-MS/MS provides excellent sensitivity, RP-HPLC-based methods remain useful where conventional chromatographic instrumentation is available and a relatively simple, economical and reproducible procedure is required. Therefore, the present study was undertaken to develop and validate a simple RP-HPLC method for the quantitative estimation of vericiguat in rat plasma. The method was optimized with respect to chromatographic conditions and subsequently evaluated for specificity, linearity, accuracy, precision, recovery and stability.

MATERIALS AND METHODS

Vericiguat was used as the analyte and riociguat was employed as the internal standard. HPLC-grade methanol and acetonitrile were obtained from Merck Chemical Division, Mumbai, India. Milli-Q water was used throughout the study. Orthophosphoric acid and formic acid were obtained from SD Fine Chemicals and Merck, respectively. Potassium dihydrogen phosphate was obtained from Merck.

Instrumentation

Chromatographic analysis was performed using a Waters Alliance e2695 HPLC system equipped with a photodiode-array detector. Empower 3.0 software was used for data acquisition and processing. Chromatographic separation was achieved using a Platsil C18 column (4.5 × 150 mm, 3 μm). A calibrated pH meter, UV-visible spectrophotometer, cyclomixer, ultrasonicator, centrifuge and micropipettes were used during sample preparation and method development.

Preparation of mobile phase

A 0.1% aqueous acid solution was prepared by transferring 1 mL of formic acid into a 1000-mL volumetric flask and making up the volume with Milli-Q water. The mobile phase was prepared by mixing methanol and 0.1% aqueous acid solution in a ratio of 60:40 (v/v). The mobile phase was filtered and sonicated before use.

Preparation of Standard solution

A quantity of 25 mg of vericiguat reference standard was transferred into a 25-mL volumetric flask and dissolved with the mobile phase. An aliquot of 0.25 mL was subsequently diluted to 10 mL with the mobile phase to obtain the working stock solution.

Preparation of Internal standard solution

Riociguat was used as the internal standard. A 10-mg quantity of the internal standard was dissolved in a 10-mL volumetric flask using the mobile phase, followed by dilution of 0.1 mL to 10 mL to obtain a 10 µg/mL working solution.

Rat Plasma Sample Preparation (Protein precipitation)

For plasma sample preparation, 750 µL of plasma was transferred into a centrifuge tube. Internal standard and vericiguat spiking solutions were added according to the required concentration level, followed by addition of 1 mL acetonitrile for protein precipitation. The mixture was vortexed for 2 min after initial mixing and centrifuged at 3200 rpm for 5 min. The resulting supernatant was collected, filtered and injected into the HPLC system.

RESULTS AND DISCUSSION

Chromatographic Method Development

Chromatographic conditions were optimized by evaluating different columns and mobile-phase compositions. Several trials were performed while maintaining the detection wavelength at 256 nm and the flow rate at 1.0 mL/min. Initial trials using different C18 columns and mobile-phase compositions were followed by optimization of the stationary phase and mobile-phase ratio.The final optimized chromatographic conditions employed a Platsil C18 column (4.5 × 150 mm, 3 µm) with methanol:0.1% OPA (60:40, v/v) as the mobile phase. The flow rate was maintained at 1.0 mL/min, the detection wavelength was 256 nm, the injection volume was 20 µL, and the total run time was 15 min.

Method validation

System suitability

System suitability testing was performed by injecting replicate preparations of the middle quality-control concentration along with the internal standard to confirm satisfactory and reproducible chromatographic performance before analysis of validation samples.

Specificity and Selectivity

Specificity was assessed by comparing chromatograms obtained from blank plasma samples with those obtained from plasma samples containing vericiguat and the internal standard. Six different blank plasma samples were evaluated. No interfering peaks were observed at the retention positions of either vericiguat or the internal standard.

Linearity

Linearity was evaluated using six concentration levels ranging from 0.2 to 1.2 µg/mL. The corresponding peak areas were 13,257, 27,654, 43,109, 54,926, 71,095 and 83,524 for 0.2, 0.4, 0.6, 0.8, 1.0 and 1.2 µg/mL, respectively. The calibration curve produced the regression equation $y = 70{,}271x - 225$, with $R^2 = 0.999$, demonstrating excellent linearity.

Accuracy and Precision

Within-batch accuracy and precision were evaluated using six replicates at LLOQ, QCL, QCM and QCH concentrations of 60, 300, 600 and 900 ng/mL, respectively. The mean measured concentrations were 60.04, 300.03, 600.04 and 900.03 ng/mL, with %CV values of 0.06, 0.01, 0.005 and 0.004%, respectively. Between-batch mean concentrations were 60.03, 300.05, 600.06 and 900.04 ng/mL, with %CV values ranging from 0.007 to 0.11%.

Recovery

Recovery studies were designed at low, middle and high quality-control concentrations to evaluate the efficiency and reproducibility of the plasma extraction procedure. Recovery was determined by comparing the responses of extracted samples with those of appropriate reference preparations. The numerical recovery values should be inserted from the original laboratory results before final journal submission.

Stability

Stability was evaluated under freeze-thaw, bench-top, injector and solution stability conditions. Mean responses were 43,118.33 for the standard sample, 43,101.00 for freeze-thaw samples, 43,113.33 for bench-top samples, 43,107.00 for injector stability and 43,112.67 for solution stability. The corresponding %RSD values were 0.0035, 0.02, 0.07, 0.14 and 0.05%, respectively. Assay values ranged from 99.96 to 99.98%, indicating satisfactory stability under the investigated conditions.

The present investigation successfully established an RP-HPLC method for the determination of vericiguat in plasma. During method development, different chromatographic conditions were evaluated to obtain adequate separation and reproducible analytical response. The final method employed a Platsil C18 column with methanol:0.1% OPA (60:40, v/v), a flow rate of 1.0 mL/min and UV detection at 256 nm.The calibration study demonstrated a strong concentration-response relationship over 0.2–1.2 µg/mL. The peak area increased progressively with increasing vericiguat concentration, and the regression coefficient of 0.999 confirmed excellent linearity. Specificity assessment showed no significant interference from blank plasma at the retention positions of vericiguat and the internal standard. Accuracy and precision results demonstrated highly consistent measurements at all investigated quality-control levels. Within-batch %CV values were ≤0.06%, while between-batch values ranged from 0.007% to 0.11%. Measured concentrations were close to their respective nominal concentrations, indicating excellent repeatability and reproducibility of the procedure. Stability assessment further supported the reliability of the method. Freeze-thaw, bench-top, injector and solution stability samples produced assay values ranging from 99.96% to 99.98%, accompanied by low %RSD values. Thus, vericiguat demonstrated adequate stability during the investigated storage and analytical conditions. Recent LC-MS/MS methods have provided highly sensitive determination of vericiguat in rat plasma, including reported calibration ranges of 0.1–300 ng/mL and 0.5–1000 ng/mL. The present procedure uses conventional RP-HPLC and therefore provides an alternative analytical platform for laboratories where LC-MS/MS instrumentation is not readily accessible. Its suitability for routine bioanalytical work should be considered within the validated concentration range.

CONCLUSION

A simple, precise and reproducible RP-HPLC method was successfully developed for the quantitative determination of vericiguat in rat plasma. The optimized procedure employed a Platsil C18 column (4.5 × 150 mm, 3 µm), methanol:0.1% OPA (60:40, v/v) as the mobile phase, a flow rate of 1.0 mL/min and UV detection at 256 nm, with a 15-min run time. The method exhibited excellent linearity over 0.2–1.2 µg/mL with an R^2 value of 0.999. No significant interference from blank plasma was observed. Accuracy and precision studies showed very low variability, and stability studies demonstrated assay values close to 100%. The developed method provides a practical RP-HPLC-based analytical procedure for the reliable estimation of vericiguat in plasma and may be useful for subsequent pharmacokinetic and bioavailability investigations.

ABSTRACT

Bharangyadi Kashaya is an ayurvedic formulation mentioned in *Sahasrayogam Kashaya Yoga,* composed of several herbs including*Bharangi, Kantakari, Pippali, Haridra, Vasa, Guduchi, Shunthi, Maricha, and Dhanyaka.* The formulation is recommended for the treatment of *Swasa* disorders. According to Ayurveda, all these ailments arise due to the aggravation of *Vata* and *Kapha* dosha. Bronchial asthma is an important respiratory disorder affecting individuals irrespective of their age group across the world. Airway inflammation, bronchospasm, and hypersecretion of mucus are typical features of this illness. Hence, this study is intended to review the pharmacological and therapeutic properties of *Bharangyadi Kashaya* in bronchial asthma. Several researches have established the effectiveness of individual components in respiratory disorders including asthma, bronchitis, allergic rhinitis, and COPD by means of various activities like anti-inflammatory, bronchodilator, antitussive, expectorant, antihistaminic, and immune modulator properties. In addition to these pharmacological effects, the safety of the formulation has been proved in various toxicological studies.

Keywords: *Tamakaswasa*, Bronchial asthma, *Bharangyadi Kashaya*, Antitussive, Anti-inflammatory, Antiasthmatic, Bronchodilator

INTRODUCTION

Bronchial Asthma is a significant health concern, marked by ongoing inflammation in the airways where numerous cells and cellular components are involved. The top country in the world in regard to asthma in numbers is India, where the incidence of cases totals from 34.3 million to 38 million cases and constitutes 13% of the burden of disease globally[1]. It is defined by an enhanced sensitivity of the trachea and bronchi to various triggers, resulting in a widespread constriction of the airways that can vary in intensity either spontaneously or due to treatment. This condition leads to recurring episodes of wheezing, shortness of breath, chest tightness, and coughing, especially during the night or early morning[2]. Asthma severity is categorized into four stages: intermittent, mild, moderate, and severe. Treatment and management strategies vary according to the specific stage of asthma. Intermittent asthma is characterized by symptoms occurring less than twice a week and nighttime awakenings occurring less than twice a month[3]. In Ayurveda, Bronchial Asthma is closely related with *Tamaka Swasa*. The term *Tamaka* is derived from the *Dhatu 'Tamalganou,'* which means 'Sadness' (*Panini*). According to *Vachaspatyam*, the word '*Swasa*' comes from the root word '*Shwas' Dhatu*, with the application of *GhanjPratyaya*. This suggests both *Vayu Vyapara* and *RogaBheda*[4]. An aggravated *Vata*, due to exposure to triggering factors, results in its *Pratilomagati* or reverse movement. The disturbed *Vata* travels through channels and reaches the head and neck area, worsening the local *Kapha* by increasing epithelial secretions and causing *Pinasa*. These secretions, or *malarupiKapha*, block the airways and produce a *ghurgurshabda* or wheezing sound[5].

Bharangyadi Kashaya is a traditional Ayurvedic herbal remedy referenced in *Sahasrayogamkashaya yoga*, primarily used for *TeevraSwasa*[6]. This formulation includes ingredients like *Bharangi, Kantakari, Shunthi, Pippali, Vasa, Haridra, Guduchi, Maricha, and Dhanayaka* in equal amounts as outlined in Table 1, which are known for their *Swasahara* properties. Together, these components provide mucolytic, bronchodilatory, antiallergic, antitussive, anti-inflammatory, and immunomodulatory effects. The *Kashaya* is typically given in suitable therapeutic doses to alleviate symptoms such as cough (*Kasa*), breathlessness (*Swasa*), and chest congestion, while also restoring the balance of *Doshas*, primarily pacify *Vata* and *Kapha*. The therapeutic efficacy of *Bharangyadi Kashaya* is linked to its precisely defined composition and the pharmacologically active ingredients found in each component. While it is traditionally indicated for *TeevraSwasa*, there is a lack of systematic scientific assessment of its pharmacological properties and therapeutic efficacy. Consequently, this review article seeks to address this deficiency by analytically examining the individual elements of *Bharangyadi Kashaya*and their pharmacological effects pertinent to the treatment of respiratory conditions like Bronchial asthma.

MATERIALS AND METHODS

A thorough review was conducted utilizing both traditional Ayurvedic texts and contemporary scientific literature to evaluate the pharmacological effects and therapeutic applications of *Bharangyadi Kashaya* in the treatment of Bronchial asthma. Ayurvedic texts such as *Sahasrayogam*, *BhavaprakashNighantu*, and *BrihadtrayiSamhitas*were examined for their insights on *Rasapanchaka*, classical indications, and therapeutic applications in conditions like *Swasa*, and *Pranavahasrotoroga*.At the same time, databases including PubMed, Scopus, ResearchGate, and Google Scholar were explored using keywords associated with *Bharangyadi Kashaya*, its components, Bronchial Asthma, and Ayurveda to confirm its traditional applications and investigate its therapeutic potential in respiratory conditions.Since this article serves as a review of existing literature and does not involve direct patient engagement or the gathering of new human or animal data, ethical approval was not necessary.

RESULTS

Bharangyadi Kashaya is a traditional Ayurvedic formulation referenced in *Shasrayogamkashaya*yoga, mainly used for *teevraswasa*[6]. The effectiveness of *Bharangyadi Kashaya* is derived from the combined action of its components as

illustrated in Table 2. This formulation not only regulates the pharmaco dynamics of the medicine within Ayurvedic principles but also influences the interaction of each ingredient with doshas, especially in respiratory conditions such as Bronchial asthma and Bronchitis. The therapeutic effectiveness of *BharangyadiKashaya*is attributed to the combined action of its components, each containing unique phyto constituents. These are detailed in Table 3, which outlines their pharmacological properties and therapeutic applications in the treatment of bronchial asthma, supported by both experimental and clinical research.

Toxicological assessment of *Bharangyadi Kashaya*

The safety profile of polyherbal medicine is an important factor in determining its therapeutic utility. Individual studies of the ingredients of *Bharangyadi Kashaya* show that the formulation is safe. Acute toxicity study of total plant extract of *Clerodendrumserratum* in female rats using 2000 mg/kg of methanolic extract showed gradual weight increase from day 0 to day 14 without any death and behaviour change. There was no pathological change seen on postmortem, thus proving that there was no sign of toxicity at the above concentration [17]. In another experiment done for acute toxicity study of *Piper longum* fruit in albino rats using different concentrations up to 3750 mg/kg, there was no mortality seen and hence proved the safety of the drug even in higher concentrations than therapeutically used [18].The study to assess acute oral toxicity on ethanolic extract of *Solanumxanthocarpum* was done following OECD guidelines 425 using limit dose of 2000 mg/kg. The observation period was from 30 minutes, 24 hours after administration, and then continued until the 14th day for toxic signs and death. No death and toxicity were reported in this study. LD_{50} value which is determined by using OECD software came out to be more than 2000 mg/kg, hence safety at 2000 mg/kg [19].In similar fashion, methanolic extracts of *Justiciaadhatoda* was given orally to the Wistar Albino rats at dose of 2000 mg/kg body weight. The animal behaviour, body weight variation, and mortality were noted after giving extracts for the period of 14 days as suggested by the guidelines. Body weight of animals was determined by calculating the difference between initial and final reading. No mortality, behavioral change, and toxicity were seen. Thus the extract proved to be safe at 2000 mg/kg[20].Turmeric essential oil of *Curcuma longa* was orally dosed to Wistar rats with concentrations of 0.1, 0.25, and 0.5 g/kg body weight. No adverse effects or deaths were observed among experimental animals, confirming that turmeric oil is non-toxic up to the tested concentrations [21].

Acute oral toxicity studies of ethanolic extract of *Tinosporacordifolia* have been conducted based on Organization for Economic Co-operation and Development guidelines. Rats were orally administered with doses of 100, 300, and 1000 mg/kg body weight for 28 days. To determine toxicity effects, behavioral, hematology, biochemistry, and histopathology analyses were performed on body weight gain, clinical signs, mortality, and dietary consumption of experimental animals. Results revealed that there were no significant changes observed, with the dose level of 1000 mg/kg being safe without causing any toxic effect or death [22]. Acute toxicity studies on *Zingiber officinale* were performed on rats, and the result revealed no fatalities or behavioral changes following intake of the powdered drug at 2000 mg/kg body weight after 35 days [23]. In an experiment that assessed the toxicity of extract of *Piper nigrum*, the highest dose without any adverse effects was 700 mg/kg/day. Thus, the maximum tolerated dose, NOAEL of the extract is 700 mg/kg/day, which equals 380 mg/kg/day *N-trans-feruloyltyramine*[24]. Oral administration of the essential oil of *Coriandrum sativum* for 28 consecutive days revealed no fatalities or toxicities, while the NOAEL was approximately 160 mg/kg/day [25].

DISCUSSION

The preparation known as *Bharangyadi Kashaya* is an old Ayurvedic formulation mentioned in *Sahasrayogam*, and used extensively for treating *TeevraSwasa*[6]. The mode of action of this medicine is by correcting the vitiated states of *Vata* and *Kaphadoshas* in *Swasa*. This formulation includes ingredients such as *Clerodendrumstratum, Solanumxanthocarpum, Zingiberofficinale, Piper longum, Piper nigrum, and Curcuma longa*; these mainly have *Katu* and *Tikta* tastes, which result in *KaphaShamaka* and *Vataanulomaka*properties [7], that help to reduce excessive accumulation of *Kapha* and facilitate expectoration and removal of obstruction in the air passages.

Adhotodavasica and*Tinosporacordifolia* give *Kapha Shoshana* and *Srotoshodhana* to alleviate coughing and breathlessness. The properties of *Laghu, Ruksha,* and *Tikshna* guna act to loosen thick mucus and clear *Srotorodha* in *PranavahaSrotas*. *Deepana and Pachana* activities *of Pippali, Maricha, and Shunthi* help in increasing *Agni* power and avoiding *Ama* production. *Ushnavirya* helps in liquefying *Kapha*, thus reducing the obstruction of bronchi, while *Sheetavirya* of *Vasa* and *Coriandrum sativum* acts to cool the respiratory mucosa. The formulation acts through Kapha*vilayana, Vataanulomana, Srotoshodhana, Agni deepana, and Amapachana*. Pharmacological effects including antiallergic, anti-inflammatory, bronchodilatory, antitussive, and immunomodulatory activities support its role in bronchial asthma [26].

***Bharangi* (*Clerodendrumserratum*)**

Active ingredients of *Clerodendrumserratum* involve flavonoids, terpenoids, sterols, and phenolics that render anti-asthmatic activities. Flavonoids such as luteolin and apigenin derivatives exert an anti-asthma activity by suppressing cytokines such as TNF-α, IL-4, and IL-5 that cause inflammation of airways and eosinophil infiltration and bronchial hyper-reactivity [27]. Terpenoids and triterpenoids have a bronchodilator effect due to their ability to relax the smooth muscles of the bronchi and decreasing airway resistance. Sterols such as β-sitosterol exert immunomodulatory and anti-allergic effects through their ability to inhibit hypersensitivity induced by IgE[28]. Phenolics possess antioxidant properties protecting the airway epithelium from inflammatory and oxidative damage. Experimental research showed that the extracts of *Clerodendrumserratum*demonstrated the ability to reduce the number of eosinophils, inflammatory markers, airway resistance, and improve lung function and pulmonary compliance in ovalbumin-induced asthma in experimental settings[29].

***Pippali* (*Piper longum*)**

The anti-asthmatic property of *Pippali (Piper longum)* is due to its phytoconstituents including piperine, piperlongumine, flavonoids, and essential oils. Piperine has been found to control inflammation and allergy by preventing the increase in the number of eosinophils, IgE level, and Th2 cytokines such as IL-4, IL-5; this leads to lower bronchial hyper-reactivity and better pulmonary functioning. It reduces the expression of COX-2 and iNOS, which is beneficial in reducing prostaglandins and nitric oxide formation responsible for airway inflammation. In addition, piperine helps enhance the activities of catalase and glutathione peroxidase, which protect lung tissue against any oxidative stress due to ROS imbalance[30]. Piperlongumine has been found to inhibit NF-κB pathway, inflammation, mucus secretion, and airway remodeling in asthmatics[31]. Flavonoids and phenolic compounds have antioxidant effect and inhibit the release of inflammatory cytokines from the airway epithelial cells. Essential oils and alkaloids help reduce airway resistance through bronchodilation and immunomodulation[32].

Kantakari (Solanumxanthocarpum)

The important bioactive constituents of *Solanumxanthocarpum* are steroidal alkaloids (solasodine), flavonoids, phenolic acids, and saponins, which possess significant anti-inflammation, antioxidative, bronchodilation, and immunomodulation properties concerning bronchial asthma. The medicinal value of *Solanumxanthocarpum* in bronchial asthma was reported via both clinical trials and experimental evidence. Administration of powdered *S.xanthocarpum* led to an improvement in pulmonary function test indices such as FVC, FEV_1, PEFR, and $FEF_{25–75}$%. Moreover, the plant powder ameliorated the symptoms of coughing, wheezing, and breathlessness, thus validating the herbal remedy for asthma.[33][34]Several phenolic compounds isolated from *Solanumxanthocarpum* showed significant inhibition of nitric oxide (NO) generation by LPS-stimulated macrophages, suggesting anti-inflammation properties[35].Anti-inflammatory and immune modulation activities of ethanol and hydroalcoholic extracts of *S. xanthocarpum* in experimental animal models resulted in the inhibition of granuloma development and airway inflammation[36].

***Haridra* (*Curcuma longa*)**

The extract from *C. longa* showed a marked reduction in inflammatory and allergic mediators, which were mainly attributed to its important phytochemicals, namely curcuminoids, mainly curcumin, and phenolic substances. The curcumin compound was an active polyphenolic diketone with remarkable anti-inflammatory, antioxidant, and

immunomodulatory effects in relation to the pathology of asthma. The compound caused a marked decrease in the total and differential counts of white blood cells, eosinophils, neutrophils, IgE, IL-4, and PLA_2 in the BALF. It also increased the concentration of IFN-γ and the IFN-γ/IL-4 ratio, suggesting a restoration of the Th1/Th2 balance. Moreover, curcumin inhibited the expression of oxidative stress markers, including nitrite/nitrate and MDA, but elevated antioxidant enzymes like SOD, CAT, and thiol concentrations[37].

***Vasa* (*Adhatodavasica*)**

Adhatodavasica extract demonstrated a pronounced effect on the alleviation of inflammatory and hypoxic signaling pathways in a mouse model mimicking COVID-19-type lung damage. *Adhatodavasica* extract caused a significant decrease in pro-inflammatory cytokines like IL-6, TNF-α, and IL-1β, which are mediators of cytokine storms. In addition, the study noted a reduction in the expression of HIF-1α and TGF-β1 proteins responsible for tissue fibrosis, thus resulting in a decreased accumulation of collagen in the lung tissue. The above-listed biological effects were due to the presence of quinazoline alkaloid compounds in *Adhatodavasica*, such as vasicine, *vasicinone*, and their analogues, in combination with flavonoids and phenolic compounds. All phytochemicals possess anti-inflammatory properties, bronchodilation activity, and antioxidative effects associated with protection against hypoxic damage. As a result, inflammatory cell infiltration is minimized, while alveolar wall thickening is alleviated. Overall, the results demonstrate that *Adhatodavasica* phyto constituents are important regulators of inflammatory and hypoxic response mechanisms [38].

Amruta (Tinosporacordifolia)

There are many phytoconstituents found in *Tinosporacordifolia*, which include alkaloids, terpenoids, lignins, steroids, glycosides, phenolics, sesquiterpenoids, and polysaccharides. These bioactive components show anti-oxidant, anti-microbial, anti-diabetic, anti-stress, anti-lipidemic, hepatoprotective, anti-cancerous, and immunomodulatory properties. Terpenoids are used against the respiratory tract infection, alkaloids are used for anti-oxidant and anti-cancerous activity, phenolic is used for radical scavenging, and polysaccharides are used for enhancing immunity [39].

Sunthi (Zingiberofficinale)

It has been shown by one research conducted on the effects of *Zingiber officin*ale that bioactive phytochemicals such as 6-gingerol, 8-gingerol, and 6-shogaol relax the airways by decreasing airway hyperreactivity. Bioactive substances facilitate rapid relaxation of the airways in guinea pigs and humans. For example, 8-gingerol increases bronchodilatation by preventing calcium entry into the airway smooth muscles. The compounds also increase β-adrenergic agonist-induced relaxations due to the inhibition of phosphodiesterase-4D activity. In addition to their relaxing actions, the bioactive substances possess anti-inflammatory properties that decrease inflammation in the airways as well as inhibit immune responses in ovalbumin-induced allergic asthma. Antitussive properties of the water-soluble glycosides of ginger were found to inhibit citric acid-induced cough in guinea pigs. Citral and eucalyptol present in essential oils of ginger can also protect the airways from bronchoconstriction in response to carbachol induction of airway constriction in rats. Supplementation with ginger was also reported to improve breathing in cases of acute respiratory distress syndrome, thereby reducing ventilation time [40].

***Maricha* (*Piper nigrum*)**

The active components of *Piper nigrum* like N-trans-feruloyltyramine and piperine have considerable anti-asthmatic properties. Piperine has been found to have anti-inflammatory and immune modulating actions through regulation of cytokines such as TNF-α, IL-4, IL-5, and IL-13 that play roles in Th2-mediated hypersensitivity reactions. In an asthma animal model, piperine had the ability to reduce hyper-reactivity of the airways, infiltration of eosinophils, and mucus secretion. This effect is due to inhibition of NF-κB pathways, leading to down regulation of expression of inflammatory cytokines and inducible nitric oxide synthase, hence reducing nitric oxide production in the lung tissue. Piperine possesses antioxidant properties by up-regulating the level of glutathione and reducing the migration of leukocytes to the airways. Further, it has immune modulatory activities that assist in maintaining the ratio

between Th1 and Th2 cytokines, which are critical in managing hypersensitive inflammation in bronchial asthma [41].

***Dhanyaka* (*Coriandrumsativum*)**

It is comprised of active plant-based constituents, which include linalool, flavonoids, phenolic compounds, coumarins, fatty acids, and sterols. They possess anti-inflammatory, antioxidant, antimicrobial, and immune modulatory actions. In the case of bronchial asthma, linalool and flavonoids are beneficial for preventing airway inflammation and oxidative stress. Phenolic compounds are free-radical scavengers that protect the bronchial mucosa from harmful radicals. Coumarins offer a moderate bronchodilator effect and anti-inflammatory action. Sterols are effective for minimizing the allergic reactions and bronchial inflammation [16].

CONCLUSION

The effectiveness of *Bharangyadi Kashaya* is due to the combined action of its phytoconstituents, which serve as a powerful bronchodilator, anti-inflammatory, antiallergic, and immunomodulatory agent. Experimental and numerous clinical studies confirm its pharmacological effects in respiratory conditions like asthma, bronchitis, and allergic rhinitis, attributed to the bioactive phytoconstituents found in each component. Therefore, this traditional Ayurvedic formulation holds considerable therapeutic promise for treating *Swasaroga*, backed by both traditional wisdom and modern scientific research.

Table: 3. Pharmacological properties and therapeutic uses in Bronchial Asthma based on active phytoconstituents

Ingredients of*Bharangyadi Kashaya*	Natural Bioactive Molecule/Active component	Pharmacological Properties	Disease
Bharangi (Clerodendrumserratum)	Catechins Flavanonols, flavones[8]	Anti oxidant property Anti asthmatic property	Asthma, bronchitis, dyspnea
Kana(Pippali)	Piperine, Piperlongumin[9]	Treat flu-like symptoms i.e,	asthma, bronchitis,

Piper longum		cold, cough, fever	Allergic Rhinitis, Severe Acute Respiratory Syndrome (SARS)
Kasahari(Kantakari) Solanumxanthocarpum	Solasodine,Solasonine, Solanocarpine, Solanocarpidine[10]	Anti-inflammatory, Bronchodilatory and anti-spasmodic action, Expectorant	Bronchitis, Bronchial Asthma, COPD
Haridra (*Curcuma longa*)	Curcumin, Flavonoids[11]	Anti-inflammatory, Anti-allergic	Asthma, Respiratory disorders
Vasa (*Adhatodavasica)*	Vasicine,vasicinone[12]	Antitussiveand bronchodilatory Activity	Asthma, respiratory disorders, COPD
Amruta (Tinosporacordifolia)	Alkaloids, terpenoids,glycosides[13]	Antioxidant, anti-inflammatory, immunomodulatory	Asthma, Allergic Rhinitis, Tuberculosis
Nagara (*Zingiber officinale*)	Gingerol, Shogaols[14]	anti-rhinoviral effect, Antitussive effect,	Human respiratory syncytial virus (HRSV), Bronchitis, Chronic obstructive pulmonary disease (COPD)
Maricha (Piper nigrum)	Piperine[15]	cough suppressive, antitussive	asthma, cold
Dhanayka (*Coriandrumsativum)*	Linalool, Flavonoids[16]	Antioxidant, anti-inflammatory	Inflammatory disorders

ABSTRACT

Pulse examination (*Nadi Pariksha*) is described in Ayurveda as an important diagnostic approach and is commonly included among the *Ashtavidha Pariksha* (eightfold clinical examination methods) [1, 2]. Through evaluation of pulse characteristics, practitioners attempt to assess *Tridosha* status, understand possible disease processes, estimate prognosis, and observe the general physiological condition of an individual [3, 4]. This systematic review examines classical descriptions of *Nadi Pariksha* along with its possible physiological correlates, methodological considerations, clinical relevance, and recent scientific developments [1, 5]. A systematic literature search was conducted across PubMed, Scopus, and Google Scholar databases using predefined search strings for studies published between 1990 and 2024 [7, 8]. A total of 180 records underwent initial screening, from which 32 articles met the inclusion criteria. *Nadi Pariksha* remains a significant diagnostic concept within Ayurvedic clinical practice [2, 4]. Contemporary research efforts demonstrate possible Correlations between traditional pulse characteristics and physiological parameters [1, 5]. However, the overall quality of evidence is moderate to low, with substantial heterogeneity in methodology [9, 16]. Further systematic research with standardized protocols is necessary to clarify clinical reliability and reproducibility [11, 17].

Keywords: *Nadi Pariksha*, *Ashtavidha Pariksha*, *Tridosha*, Pulse diagnosis, Ayurvedic diagnostics, Systematic review

INTRODUCTION

Ayurveda defines health as a holistic balance across physical and mental domains [2, 3]. Accurate diagnosis prior to treatment is emphasized as essential for effective therapeutic intervention [4, 18]. Various diagnostic approaches are described in classical texts, among which *Nadi Pariksha* is frequently discussed in later Ayurvedic literature [19, 20]. Texts such as *Yoga Ratnakara* describe the pulse as a potential indicator of physiological and pathological conditions [18, 21]. Traditionally, physicians
assess the pulse to gain insights into *doshic* balance, systemic function, and disease progression [3, 22].

Objectives

The primary objectives of this systematic review are:

- To systematically identify and synthesize available evidence on traditional *Nadi Pariksha* methods [7, 8]
- To evaluate the correlation between traditional pulse parameters and modern physiological measurements [1, 5]
- To identify gaps in the current evidence base and propose directions for future research [11, 17]

MATERIALS AND METHODS

Protocol

This systematic review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines [7, 11].

Eligibility Criteria

Inclusion Criteria

• Studies describing traditional *Nadi Pariksha* methods and interpretations [1, 2]
• Studies evaluating correlations between traditional pulse parameters and modern physiological measurements [5, 12]
• Articles published in English language [8, 11]
• Studies published between 1990 and 2024 [7, 9]

Exclusion Criteria

• Articles not directly related to *Nadi Pariksha* or pulse diagnosis [1] • Studies without available full text [7]
• Duplicate publications [11]
• Articles in languages other than English [8]

Risk of Bias Assessment

The methodological quality of included studies was assessed using the Joanna Briggs Institute (JBI) Critical Appraisal Checklist [7, 10]. Each study was evaluated across several domains [11]:
Studies were rated as:

• **High quality:** Meeting ≥80% of checklist criteria [10]
• **Moderate quality:** Meeting 60-79% of checklist criteria [10]
• **Low quality:** Meeting <60% of checklist criteria [10]

RESULTS

Study Selection

Following full-text review, 46 articles were excluded for the following reasons: no direct relevance to *Nadi Pariksha* (n=18), incomplete data (n=12), not available in English (n=8), duplicate publication not identified in initial screening

(n=5), and conference abstracts without full methodology (n=3) [7, 9]. A total of 32 studies met the inclusion criteria and were included in this systematic review [1, 8].

Traditional Pulse Parameters

Classical Ayurvedic texts describe seven primary pulse parameters with specific characteristics associated with each *dosha* (Table 2) [2, 3, 18].

Methodological Considerations

Examination Method

According to classical texts, *Nadi* palpation should be performed in the morning, on an empty stomach or 3 hours after a meal, in a restful condition [2, 6]. The patient's hand should be slightly bent at the elbow and relaxed [3, 20]. The practitioner places three fingers on the skin near the wrist over the radial artery [4, 19]:

• **Index finger:**

Denotes *Vata dosha* [3] • **Middle finger:** Denotes *Pitta dosha* [3] • **Ring finger:** Denotes *Kapha dosha* [3]

Practitioner Qualifications

Classical texts describe three properties of mind (*Satva*, *Raja*, *Tama*) [3, 20]. Practitioners should possess a predominance of *Satva* component for accurate pulse assessment [18, 20]. Individuals with significant *Raja* and *Tama* components are considered less eligible for *Nadi Pariksha* [3, 6].

Correlation with Modern Physiological Parameters

Clinical Applications

Nadi Pariksha is traditionally used to assess:

- **Constitutional characteristics (*Prakruti*)** - Identification of individual baseline *doshic* composition [26, 27]
- **Current physiological imbalance (*Vikruti*)** – Detetion of aggravated *doshas* [15, 26]
- **Disease states** - Diagnosis of pathological conditions [33, 37] 4. **Tissue involvement (*Dhatus*)** - Assessment of affected bodily tissues [2, 4]
- **Prognosis** - Estimation of disease outcome [37, 49]

Technological Developments

Recent technological advancements have enabled attempts to record and analyze pulse characteristics using biomedical devices [1, 13]:

Sensor-based systems: Photoplethysmography, pressure sensors, and accelerometers for pulse waveform recording [25, 29]

Signal processing: Digital filtering, feature extraction, and waveform analysis [23, 41]

Machine learning: Classification algorithms for *dosha* identification and disease prediction [29, 43]

Artificial intelligence: Deep learning models for pattern recognition [36, 43]

DISCUSSION

Summary of Evidence

This systematic review synthesizes evidence from 32 studies on traditional *Nadi Pariksha* and its modern correlates [1, 7]. The findings demonstrate that traditional pulse parameters may correspond to measurable physiological phenomena, supporting the conceptual framework of *Nadi Pariksha* as described in classical texts [2, 3].

Quality of Evidence

Based on the JBI Critical Appraisal Checklist [10, 11]:

Limitations

Language Bias

The restriction to English-language articles represents a significant limitation of this systematic review [8, 11]. Important research published in Hindi, Sanskrit, or other regional languages may have been excluded [7]. This language bias may have resulted in underrepresentation of classical interpretations and traditional knowledge [4,6].

Evidence Quality Statement: Low confidence in the completeness of evidence synthesis due to language restrictions.

Publication Bias: Studies reporting positive correlations or successful technological applications may be more likely to be published [7, 11]. Negative or null findings may be underrepresented [9].

Evidence Quality Statement: Moderate confidence due to potential publication bias. **4.5.3 Risk of Bias**

Risk of bias assessment revealed that only 25% of studies were of high quality [10, 11]. Common methodological issues include [38]:

- Inadequate blinding [7]
- Absence of control groups [9]
- Lack of standardized protocols [31]
- Small sample sizes [39]
- Confounding variables not adequately addressed [11]

Evidence Quality Statement: Moderate to low confidence in individual study findings.

Implications for Future Research

Based on the findings of this systematic review, the following recommendations are proposed [17, 50]:

Standardization of protocols: Development of consensus guidelines for *Nadi Pariksha* examination and interpretation [31, 38]

Larger longitudinal studies: Prospective studies with adequate sample sizes and long-term follow-up [49]

Blinded designs: Implementation of assessor blinding to reduce bias [7] 4. **Multicenter studies:** Collaboration across institutions to enhance generalizability [37]

Clinical Implications

Despite methodological limitations, the evidence suggests that *Nadi Pariksha* may have clinical utility in [14, 15]:

Early detection: Identification of early physiological changes before overt symptoms appear [5]

Monitoring response: Assessment of treatment response in Ayurvedic interventions [26]

Constitutional assessment: Understanding individual *Prakruti* for personalized treatment [27]

Emergency situations: Preliminary assessment when other diagnostic tools are unavailable [45]

Evidence Quality Statement: Moderate confidence in clinical utility based on available evidence.

CONCLUSION

Nadi Pariksha remains a significant diagnostic concept within Ayurvedic clinical practice [2, 4]. This systematic review of 32 studies demonstrates that traditional pulse parameters may correspond to measurable physiological phenomena including arterial stiffness, heart rate variability, and blood pressure [1, 5, 13]. Contemporary research efforts are increasingly exploring ways to evaluate traditional descriptions using modern biomedical tools [7, 8].

Preliminary evidence suggests possible correlations between traditional pulse characteristics and physiological parameters, with moderate to strong correlations for *Vega* (PWV, r=0.68-0.79), *Tala* (PRV, r=0.79), and *Kathinya* (Blood Pressure) [5, 12, 13]. However, the overall quality of evidence is moderate to low, with only 25% of studies meeting high quality criteria [10, 11].

Summary of Evidence Quality: Conclusion Confidence Level Supporting Studies measurements Moderate S1, S5, S6, S10, S16, S24, Traditional parameters correlate with physiological S30 NP may have diagnostic utility Moderate S11, S19, S20, S22 Technological integration shows promise Moderate S6, S11, S18, S23 Standardization is needed High S20, S22, S31 Reproducibility requires improvement Moderate S20, S31 Further systematic research with standardized protocols is necessary to clarify clinical reliability and reproducibility [11, 17]. Integrating traditional knowledge with modern investigative techniques may contribute to a broader understanding of pulse examination within both Ayurvedic and biomedical contexts [1, 7].

ABSTRACT

The COVID-19 outbreak disrupted our way of life and employment. As a result of the nationwide lockdown, all educational institutions had to close. Colleges and universities took the necessary step of implementing technology to enable online instruction in place of traditional classroom settings. This study examines the effectiveness of online education from the teachers' perspective, assessing the efficacy of online learning from the instructor's viewpoint, taking into account elements such as perceived usefulness and ease of use, effectiveness in terms of user happiness, and readiness to continue learning online in the future. The primary objective of the study was to examine instructors' satisfaction and intention to use online training in the post-COVID era. During the pandemic, 266 college and school instructors from nearly 13 Indian states provided survey data. The collected data was analyzed using a structural equation model to validate the proposed theoretical model. The results demonstrated that user satisfaction is the most important indicator of future desire to use online teaching. The findings showed that perceptions of usefulness and ease of use have a favorable effect on user satisfaction with online learning. Additionally, teachers' perceptions of the usefulness of online learning were a strong predictor of their satisfaction with it. Empirical data identifying the factors influencing teachers' satisfaction and inclination to stick with online learning comprise the researcher's contribution. There is discussion of the consequences for online education research and practice during the pandemic.

Keywords: Online education, Perception of usefulness, Perception of ease of use, User's satisfaction, Intention to use.

INTRODUCTION

The COVID-19 outbreak disrupted our way of life and employment. All educational institutions were forced to close due to the nationwide lockdown. Even the education industry has gone digital due to the widespread dread of the virus and the need to ensure that learning doesn't stop for too long. Schools and colleges made the necessary leap to adopt technology that would take classrooms into students' homes. The challenge was immense for the teaching community, but teachers made the necessary transition to online teaching. With the entire academic year going online, several studies have been undertaken to assess the quality and effectiveness of online education. Most of the studies, which were largely student-centric (Tania, 2022), have given a mixed review of online teaching-learning. This study analyzes the effectiveness of online education from the teachers' perspective. Online education is one form of e-learning (electronic learning). Online education is the "transfer of information and skills via electronic media such as the internet, intranets, and extranets in a well - designed course content with reputable accreditations" (Choudhary & Pattnaik, 2020). Online education has become an essential part of education and has been widely used, specifically during COVID-19. The continued use of online education by teachers and students is essential for the system's success and effectiveness. Therefore, this study aimed to understand the effectiveness of online teaching from the perspective of teachers.

REVIEW OF RELATED LITERATURE

Wang and Wang (2009), The study developed and tested an integrated adoption model that combines user intention, IS success, and psychology to examine the adoption of a web-based learning system in Taiwan. This study employed a quantitative survey and structural equation modeling, selecting three reputable universities in southern Taiwan and inviting 1549 full-time instructors, yielding a response rate of 302. The results indicated a good overall structural model fit, with subjective norm and perceived usefulness as the strongest direct predictors of the intention to use, while perceived ease of use mainly influenced intention indirectly through usefulness. Service, system, and self-efficacy significantly improved perceived ease of use, and information quality strongly enhanced perceived usefulness, highlighting the importance of institutional support and high-quality system outputs for accelerating instructor adoption. Sun and Cheng (2016), The study analyzed ways to make online teaching and learning effective and how institutions can implement quality online programs. To accomplish the study's goals, a content analysis of 47 published research studies on online teaching and learning was carried out. The results corroborate the idea that creating an online learning community is a fundamental prerequisite for success and that effective online instruction relies on well-crafted course materials, motivated student-teacher interaction, and instructors who are well-prepared and properly supported. The study emphasizes technology, which promotes development but may also stifle individuality.

The authors argue that future research should prioritise deeper, practice-oriented analysis and design online instruction that is more adaptable to individual learner needs beyond standardised performance-driven approaches.
Romero et al. (2019), This study examined how higher education teachers perceived the integration of technology into evaluation practices, particularly within a competency-based educational framework. The specific context of evaluation further highlighted the complexity of perception, as technology adoption in this area is closely tied to whether teachers feel the tools align with foundational assessment practices. This reflects a broader pattern in educational research, where technology that alters the structure or meaning of traditional practices often triggers stronger resistance. Several barriers emerged from teachers' perceptions. Teachers who view autonomy and personalized feedback as central to learning tended to be more open to technology that supports these goals. Evaluation often required teachers to shift from the role of sole evaluator to facilitator of technology-assisted assessment. The findings revealed that pedagogical beliefs serve as both primary barriers (tangible factors such as access to technology or training) and secondary barriers (beliefs about learning and evaluation that can be even more influential than physical or technical constraints). Successful integration of technology into evaluation requires

professional development that addresses beliefs and skills and aligns technology with teachers' methods of learning and assessment.

Chen et al. (2020),This article examined user satisfaction with online education platforms following the abrupt transition from traditional face-to-face instruction to remote digital learning due to the COVID-19 outbreak. User satisfaction is a crucial determinant of the success and sustainable use of online education platforms, particularly during emergency remote teaching. This study adopted a mixed-methods data-collection approach, combining traditional questionnaires with web-crawled user experience data to develop a customer satisfaction index system. The findings emphasized that platform availability has the greatest influence on user satisfaction, whereas personal user factors do not directly affect satisfaction. There was a relatively greater emphasis on system availability and stability, highlighting that in emergency remote learning situations, infrastructure reliability can be more critical than individual characteristics. Nambiar (2020), This study found a consistent pattern across studies that learning continuity depended heavily on device availability, reliable internet, and institutional technical support. In the Indian context, the study highlighted how Internet access and related logistical issues became barriers to consistent participation in online sessions, further affecting perceived effectiveness. Further empirical work emphasized that technology alone could not solve remote learning challenges when structural gaps persisted. Nambiar's survey reported that quality and timely interaction between students and professors was the most important determinant of satisfaction with online classes. It was also noted that online teaching was equally challenging for teachers as providers of education, and that teachers' perspectives are underrepresented in earlier research despite being essential for sustaining quality online delivery.

Research Gap

After a detailed literature review, it was found that most research had focused on students' perspectives (Tania, 2022). However, for the success of online education, it is necessary to understand the teacher's perspective.

Theoretical Background

Expectation-Confirmation Model (ECM): This model was developed by Bhattacharjee (2001a, 2001b), who explained the determinants of information system continuance intention to use. Continuing intention to use reflects the post-adoption behavior of the user for the technology. According to this model, perceived usefulness, confirmation, and satisfaction are the factors affecting the continuance intention to use the technology. The most important indicator of a user's intention to continue is their level of satisfaction. Although it influences continuation intention, perceived usefulness is a poorer predictor than enjoyment. ECM has been empirically tested in many users' acceptance studies of various types of technologies (Bhattacherjee (2001), MOOC (Dai et al. (2020), IT (Deng et al. (2010), digital textbooks (Joo et al. (2017)). Therefore, this model explains the satisfaction of the user after using the technology. In this study, we investigated teachers' acceptance and intention to continue using online education in the future by combining the variables from the Expectation models.

Objectives of the Study:

- To examine the relationship between the Perception of Usefulness and perception on ease of use of the instructor's satisfaction and intention to use online mode in future.
- To study the association between instructors' satisfaction and intention to use online modein future.

METHODOLOGY

A cross-section of educators from various schools and universities participated in the current study. Data were collected from 13 States across India to understand the intention to use the online mode in classes, using an online and offline questionnaire. A non-probability snowball sampling technique was used to reach the targeted sample for

collecting data. The study's sample size of 266 respondents meets the necessary sample size standard was determined by using G* Power software 3.1.9.7 version (figure 2).

The summary of basic information about the target group is presented in the table above, and the major highlights are:

- Women teachers constituted 83.5% of the respondents.
- The majority of teachers held a postgraduate degree.
- Respondents were evenly drawn from schools and colleges.
- 81.6% of teachers had 15 years or less of teaching experience.
- The platforms used for online classes, in order of popularity, were Microsoft Teams, Zoom, and Google Classroom.
- 58.3% of teachers used a laptop to conduct their classes. Mobile phones were used by 37.2% of teachers.

Design:

The factors used in the paper are,

- Perception on Ease of Use
- Perception on Usefulness
- User's willingness to continue in future.
- User's satisfaction (Effectiveness)

DATA ANALYSIS AND RESULTS

Preliminary data analysis

In the first step of data analysis (Hair, 2006), none of the values were missing in the data set of 287. For multivariate outliers, the Mahalanobis method was used. There were 21 outliers that were deleted, and the final data for the study were 266.

Exploratory Factor Analysis

PLS and SPSS were used to investigate the factors derived from the items. Initially, an exploratory factor analysis (EFA) was conducted on the 27 items using the maximum-likelihood approach with direct oblimin rotation to extract the factors. The Kaiser-Meyer-Olkin (KMO) was 0.943 (Field, 2009), the eigenvalue was 64.809%, and Cronbach's alpha coefficients were above 0.85 and 0.95 for the complete scale, which included 25 items. This indicates that the scale's reliability was assessed.

Assessment of Proposed Model: The model was assessed through two stage process of SEM in PLS. PLS is used as the data was non-normal.

Assessment of Measurement Model: In PLS, the confirmatory factor analysis includes four steps: Average Variance Analysis (AVE), discriminating validity, factor loading, and composite reliability. To verify the model fit, a measuring model was created and tested.

Structural Model Assessment: SEM procedure including five steps- Collinearity assessment, Hypothesis testing, Coefficient of determination, effect size, predictive relevance.(Hair et al 2017)

Assessing Collinearity issues of Structural Model: The collinearity was established by checking VIF (Variance Inflation Factor) values. All the inner VIF values were below 3.33(Diamantopoulos et al 2008). It means there is no collinearity problem in the study.

Hypothesis testing

Figure 4 and Table 4 show that PEOU, PU, and satisfaction are positively correlated, which further influences instructors' intentions to use online platforms. Results show that perceived usefulness has a positive relationship with teachers' satisfaction with online classes. Hence, H_1 was supported. Perceived ease of use has a positive relationship with perceived usefulness and teachers' satisfaction with online classes. Hence, H_2 and H_4 were supported, respectively. The findings indicate a favorable correlation between teachers' satisfaction with online learning and their intention to continue using it in the future. Regarding control variables, an instructor's experience did not have a significant effect on the intention to use the online mode, although there is a higher intention to use online classes among teachers with less experience. The findings indicate that the intention of college and school teachers to use the online mode differs significantly. Schoolteachers show a greater preference for using the online mode compared to college teachers. The results of PLS shows that Perceived usefulness is the most influencing factor that affect instructor's satisfaction with online mode (β. = 0.539). (Alharbi & Drew, 2014; Kardoyo et al., 2015; Teo, 2019).The PLS results indicate that the most significant factor in promoting the usage of online mode is the teacher's happiness (0.786) with online classes. User's Satisfaction form an important factor effecting intention to use online platform (Mouakket, S. 2018, Chiu et al., 2019). Coefficient of Determination: The R^2 values indicated that the full model explained 58.1% of intention to use, 66.9% satisfaction, 37.6 % Perceived of usefulness (fig 4). Thus, the R^2 values were seen to be large (Wetzels, Odekerken-Schröder, & Van Oppen, 2009)

DISCUSSION

The study was conducted from May 2021 to July 2021. This period was a transition for the education system, shifting entirely from offline to online instruction using various free and paid platforms (MS Teams, Zoom, Webex, etc.). During the COVID-19 lockdown, each teacher and student was required to adopt the online mode. Many studies have examined students' perceptions (Masrom M., 2007; Cheng & Yuen, 2018), but very few have focused on teachers' perceptions. Moreover, most studies on teachers have used small samples and are limited to a single institution. In this study, we collected data from 13 states, with a large sample of 266. To summarize the outstanding contribution of this paper, we collected data from both school and college teachers and examined comparative satisfaction and intention to use online classes. The theoretical contribution of this paper is that, among the different factors, satisfaction is the most important predictor of the intention to use online classes, consistent with the Expectation Confirmation model. The research results indicated that Satisfaction with online education was predicted primarily by the teacher's perceived usefulness (R^2 = 37.6%) and secondarily from the perceived ease of use (R^2=29%). However, these determinants jointly explain 66% of the satisfaction variance. The results indicated that with increase in perceived usefulness (Alharbi & Drew, 2014; Brahmasrene& Lee, 2012) and perceived ease of use (Al-Alak &Alnawas, 2011) there will be increase in the teacher's satisfaction. The results of this study showed that teacher's intention to use online learning is only influenced by perceived usefulness and satisfaction of the instructor (Brahmasrene& Lee, 2012; Callum et al., 2014; Chang et al., 2012; Kardoyo et al., 2015; Teo, 2019). It was consistent with earlier research (Attis, 2014; Chang et al., 2012) that perceived ease of use had no direct and substantial impact on future intention to use. The findings also indicate that school teachers are much more likely than college instructors to employ online learning. The suggested model received strong support from the findings. Of the nine expected associations, five were found to be significant, offering important insight into how teachers perceive the efficacy of online learning. In summary, this study shows that colleges and schools offering online education courses can learn more about how to enhance teachers' satisfaction and future intention to use.

Limitations and future scope

This paper has limitations because it is an empirical study. The results of this study might not be relevant to children's adoption of online learning in other settings, such as elementary school. Further investigation is needed to examine the proposed theoretical model in a variety of settings and with a variety of samples in order to further validate and enhance it. This study's model can be improved by incorporating other exogenous variables, such as instructors' training, to improve the effectiveness of online education.

ABSTRACT

This study investigates the engineering performance of fired clay bricks incorporating eggshell powder (ESP) as a partial replacement material. Brick clay was blended with 0–20 wt.% ESP to evaluate its influence on physical and mechanical behaviour. The work aims to promote the reuse of biogenic waste for environmental sustainability, develop cost-effective eco-friendly construction materials, and support small-scale employment through conventional brick-making practices. Egg shells consist mainly of calcium carbonate, which decomposes during firing to form calcium oxide while releasing carbon dioxide. This reaction plays an important role in the densification process and pore structure evolution within the ceramic matrix. Experimental results show that a controlled addition of ESP improves brick performance. Samples containing 10 wt.% ESP achieved the highest bulk density (2.08 g/cm^3) and compressive strength (15.96 N/mm^2) at a firing temperature of 1000 °C, along with a noticeable reduction in porosity. These improvements are associated with better particle packing and the formation of calcium-rich liquid phases that enhance interparticle bonding during sintering. However, higher ESP contents (15 wt.% and above) led to increased pore interconnectivity caused by gas release during thermal decomposition, which negatively affected strength. Overall, the findings demonstrate that

eggshell waste can be effectively incorporated into fire clay ceramic bricks to enhance material performance while contributing to sustainable construction practices.

Keywords: Fire clay, Eggshell powder, Compressive strength, Firing shrinkage, Density, Water absorption, Sustainable construction materials.

INTRODUCTION

Fire clay ceramics are widely used in construction and thermal applications due to their stability at high temperature, availability, and reliable mechanical behaviour. Nevertheless, improving performance while reducing environmental impact remains a continuing challenge in ceramic engineering. One promising approach is the incorporation of calcium-rich waste materials into clay-based systems. Eggshell waste generated by food processing industries consists predominantly of calcium carbonate. During firing, calcium carbonate decomposes within the temperature range of approximately 700–900 °C, producing calcium oxide and releasing carbon dioxide gas. The generated CaO can influence verification and sintering behaviour, whereas CO_2 evolution contributes to pore formation. As a result, eggshell powder incorporation simultaneously modifies densification kinetics and microstructural development. [1] reported that incorporation of ESP in clay bricks reduced bulk density and increased open porosity due to thermal decomposition of $CaCO_3$. The released CO_2 gas created controlled pore structures, improving thermal insulation. Similarly, [7] observed that ESP addition increased water absorption and porosity in fired clay bricks. However, excessive additive content resulted in interconnected pore networks, leading to structural weakening. [5,13] confirmed that increasing $CaCO_3$-based additive concentration reduces density and modifies shrinkage behaviour. Controlled pore formation was found beneficial for lightweight ceramic applications. [4]The incorporation of sawdust as a pore-forming material increases porosity and reduces density due to burnout during firing, thereby significantly enhancing the thermal insulation properties of clay bricks.

[10] Emphasized that mechanical performance strongly depends on pore size distribution rather than only total porosity. Uniform pore distribution contributes to better strength retention.[3]reported that $CaCO_3$ decomposition occurs between 700–900 °C, governing pore development and shrinkage behaviour. Higher sintering temperatures enhanced vitrification of the ceramic matrix. [8] through FTIR and XRD analysis, confirmed progressive decomposition of $CaCO_3$ with increasing temperature. Gas evolution during firing altered pore morphology and internal structure. [6] Demonstrated that CaO formed after decomposition reacts with silica phases, influencing densification and phase evolution. [14] further explained that CaO contributes to liquid-phase formation at elevated temperatures, modifying densification kinetics. [11] Concluded that firing temperature plays a dual role: improving matrix densification while stabilizing pore networks formed during decomposition. [2] Highlighted that sintering temperature determines densification and dimensional stability in calcium-modified ceramics. Increased additive content promoted gas evolution, which may compromise structural integrity if not optimized. [9]Emphasized that excessive porosity negatively affects mechanical strength, while controlled densification enhances performance. [15] reported that moderate bio-waste incorporation improves thermal resistance, but excessive levels reduce compressive strength. [16]Demonstrated that carbonate decomposition significantly affects shrinkage and densification behaviour, requiring temperature optimization for stable microstructure.[12] used SEM analysis to show that moderate additive levels produce uniform pore distribution, while higher levels increase pore connectivity.[6] observed CaO–SiO_2interactions affecting phase transformation and mechanical behaviour.

Previous investigations have shown that calcium carbonate additives may increase porosity because of gas release during decomposition. However, moderate additive levels can improve bonding and promote densification through liquid-phase formation. The mechanical response of clay ceramics is closely linked to pore structure, firing temperature, and densification efficiency. Despite existing studies on lightweight clay systems, comprehensive investigations addressing mechanical behaviour across a broad sintering range in fire clay matrices remain limited.

Therefore, the present study examines the combined influence of ESP content and firing temperature on densification characteristics and compressive strength.

MATERIALS AND METHODS

Eggshells were collected from local food vendors (domestic waste) in Cuddalore town, Tamil Nadu, India. The shells were thoroughly washed distilled water and acetone and sun dried for 48 h. Commercial fire clay was used as the base material. The fire clay samples collected from Government ceramic institute, virudhachalam. The dried shells were ground into a fine powder using a laboratory. ESP was incorporated into fire clay at 0, 5, 10, 15, and 20 wt.% and dry-mixed for 30 min to ensure homogeneity, water (10 wt.%) was added to form a mixture. Appropriate personal protective equipment including gloves and masks, was worn throughout the preparation process. The mixture was molded into brick specimens (l X b X h mm). The samples were are dried of 48 hrs and at fired at 900**°C** – 1200**°C** with 2 hour soaking period before colling to room temperature for firing . Figure 1: illustrate the preparation of the egg shell powder and its incorporation into the brick mixture. Five specimens were tested for each condition, and average values were reported.

Parameters Studied

Firing Shrinkage

Firing shrinkage test considered as an important characteristic to access the suitability of burning temperature of samples. This test gives idea and evidence of the quality of change occurring during burning process. The length of clay bricks sample was measure before and after burning and calculating firing shrinkage. The following equation was applied to determined the firing shrinkage**:** [3].

$$\text{Firing shrinkage (\%)} = \frac{L_d - L_f}{L_d} \text{ X 100} \qquad (1)$$

where L_d - Dried length L_f - Fired length

Bulk Density

The density of the bricks was determined by measuring the dry mass and geometric dimensions (length=13cm, width=3cm, and height=3cm) of each specimen. This test was conducted on bricks containing space varying percentage of eggshell powder (ESP), including the control sample (0%ESP). For each ESP percentage (0%,5%,10%,15% and 20%),five specimens were tested and their average densities are calculated.[1].

The volume of V of each brick was calculated using the formulas:

$$V = L \text{ X } W \text{ X } H \qquad (2)$$

Where L is length in cm, W is width in cm and H, is height in cm.

$$\rho = \frac{M}{V} \quad (g/cm^3) \qquad (3)$$

Where **ϱ** is density in (g/cm^3) M is mass in grams and V is volume in cm^3

Compressive strength

The compressive strength of both the control and ESP modified bricks was evaluated to assess their structural performance. The test determines the maximum uni axial stress the bricks can endure before failure. Rectangular specimen with a length 13 cm and a height 3 cm were used, prepared from mixes containing 0% 5% 10% 15% and 20% ESP as a partial replacement for fireclay. Three specimens were tested for each mix proportion, and the average compressive strength was recorded to ensure accuracy and repeatability. The test was conducted in accordance with

ASTM C39 / C39M standards using a Universal Testing Machine. the setup and testing procedure are shown in fig.3. [7,21]

$$\text{Compressive strength (N/mm}^2) = \frac{\text{Maximum load at failure (N)}}{\text{Area (mm}^2)} \quad (4)$$

Water absorption test

The water absorption test was conducted to evaluated the ability of the bricks to absorb water over a specified period. In this study, bricks containing varying percentage of eggshell powder (ESP) were submerged water for 24h to assess their absorption capacity. As illustrated in fig.3, the procedure involved measuring the dry mass of each specimen (W_d) submerging it in water for 24 h, and then recording the wet mass (W_s) immediately after removal. Three specimen were tested for each ESP level (0%5%10%15% and 20%) and the average absorption value was calculated for each group. The percentage water absorption (WA) was determined using the following equation:[4]

$$W = \frac{W_s - W_d}{W_d} \text{ X } 100 \quad (5)$$

Where W_s represents the weight of the saturated brick W_d is the weight of the dry brick and WA is the water absorption rate in percentage (%).

Water absorption was calculated using Eq. (5) in accordance with ASTM C373 standards [4, 2,7,12].

Apparent Porosity (%)

Porosity is the volume of the pores within a brick, expressed as a percentage of the total volume of the brick. Porosity is an important characteristic of brick. The porosity of the samples were determined by using the following formulas:

$$\text{Porosity (\%)} = \frac{W_s - W_d}{W_s - W_{sus}} \text{ X } 100 \quad (6)$$

Where W_s saturated weight W_d dry weight and W_{sus} suspended weight in water

The apparent porosity was calculated using the Archimedes principle in accordance with ASTM C373 standards, which has been widely adopted in ceramic studies [7,9,11].

RESULTS AND DISCUSSION

Influence of Eggshell Powder Addition

Eggshell powder primarily consists of calcium compounds, mainly calcium carbonate ($CaCO_3$)**.** During firing, this compound undergoes thermal decomposition, releasing carbon dioxide gas and forming calcium oxide. The decomposition process significantly influences the microstructure and physical properties of the bricks (Fig.1). At low ESP contents (5–10%)**,** the pores generated during decomposition remain limited and relatively well distributed. In some cases, these pores may assist in sintering by facilitating particle rearrangement and improving bonding between clay particles. As a result, moderate ESP incorporation can enhance or maintain the mechanical performance of the bricks. At higher ESP contents (15–20%)**,** excessive gas release during decomposition leads to the formation of a large number of pores. This increased porosity reduces the density of the bricks and significantly decreases compressive strength while also lowering firing shrinkage. Furthermore, at very high firing temperatures such as 1200 °C, excessive Verification may occur. This can lead to deformation or over-firing, particularly in highly porous samples, which may further weaken the brick structure.

Linear Shrinkage

In this study, linear shrinkage slightly decreased with the increase in eggshell powder (ESP) content (as shown in table. 2.). This behaviour can be attributed to the non-plastic nature of ESP, which reduces the overall plasticity of the clay mixture. As the plasticity decreases, the contraction that normally occurs during the drying stage is also reduced. Consequently, samples containing higher percentages of ESP showed lower drying shrinkage compared with the control sample prepared without ESP. [6] A reduction in linear shrinkage is considered beneficial in brick production because it minimizes the possibility of drying cracks and warping, thereby improving dimensional stability during the manufacturing process (Fig.2.).

Effect of Firing Temperature

Firing temperature plays a critical role in determining the micro structural development and final properties of fired clay bricks. As the firing temperature increases, several thermal processes such as dehydration, decomposition, sintering, and verification occur within the ceramic body. At around 800 °C, the bonds formed between particles remain relatively weak and the structure still contains a considerable number of open pores. When the temperature increases to approximately 900–1000 °C, improved particle rearrangement takes place and solid-state sintering begins to occur. This stage leads to better densification of the material, a reduction in pore volume, and stronger bonding between particles. At higher temperatures, around 1100 °C, partial verification occurs. During this stage, a glassy phase forms within the matrix, which fills the firing pores and contributes to the strengthening of the brick structure. Overall, increasing the firing temperature improves the mechanical strength and durability of fire clay–eggshell bricks while also reducing permeability. In most cases, optimal performance is achieved within the firing range of 1000–1100 °C, where sufficient densification occurs without causing structural damage.

$$CaCO_3 \longrightarrow CaO + CO_2$$

$$CaO + SiO_2 \longrightarrow CaSiO_3 \text{ Wollastonite (calcium silicate)}$$

Firing Shrinkage

Firing shrinkage generally increased with increasing firing temperature for all brick compositions. This behaviour is mainly attributed to enhanced densification and stronger particle bonding that occur during the sintering and Verification processes at elevated temperatures. The control sample containing 0% eggshell powder exhibited relatively consistent and moderate shrinkage across all firing temperatures (as shown in fig.6.). When eggshell powder was added to the clay mixture, a gradual reduction in firing shrinkage was observed with increasing ESP content. Samples containing 10%, 15%, and 20% ESP showed lower shrinkage values compared with the control sample (as shown in table 3). This reduction can be explained by the decomposition and burnout of calcium-based components in the eggshell powder during firing. The release of gases during this process creates internal pores within the brick body, which reduces the overall densification and consequently lowers the shrinkage. Although higher firing temperatures promote shrinkage through improved densification, increased ESP content (particularly above 10%) counteracts this effect by generating additional porosity. While this reduces shrinkage, it negatively affects the compressive strength due to the weakening influence of the increased pore volume.

Density

Bulk density is an important physical property that reflects the compactness and internal structure of fired clay bricks. Density has a direct influence on the strength, durability, and load-bearing capacity of the brick. In fire clay bricks incorporated with eggshell powder, the bulk density is influenced by both the firing temperature and the ESP content. Generally, increasing the percentage of ESP tends to reduce the bulk density. During firing, the decomposition of calcium carbonate ($Ca\ CO_3$) present in the eggshell powder releases carbon dioxide (CO_2), which creates additional pores within the brick matrix [3]. The formation of these internal voids increases the overall porosity and reduces the density of the brick. As a result, bricks containing higher amounts of ESP become lighter but also more porous. However, moderate incorporation of ESP, particularly in the range of 5–10 %, results in only a slight reduction in density while maintaining acceptable structural integrity (as shown in fig.7). Such compositions

may therefore be suitable for lightweight construction applications. In general, density shows a direct relationship with firing temperature and an inverse relationship with increasing ESP content.

Water Absorption and Apparent Porosity

Water absorption and apparent porosity are important parameters used to evaluate the durability and permeability of fired clay bricks. These two properties are closely related because both depend on the total volume and connectivity of pores within the brick structure. In bricks containing eggshell powder, water absorption tends to increase with increasing ESP content (as shown in table 3). During firing, the decomposition of calcium carbonate releases CO_2 gas, [2] which forms additional pores within the brick matrix. The presence of these pores allows the brick to absorb more water. Therefore, samples with higher ESP percentages generally exhibit higher water absorption values (as shown in fig. 8 & 10). On the other hand, increasing the firing temperature leads to a reduction in porosity due to improved particle bonding and densification. Between 1000 °C and 1200 °C, significant densification occurs, resulting in a decrease in pore volume. However, excessive addition of ESP can increase porosity because the decomposition of Ca CO_3 generates numerous voids, some of which may become interconnected. This interconnection of pores increases permeability and can reduce the mechanical strength of the bricks. Overall, water absorption and apparent porosity tend to decrease with increasing firing temperature [8,12]. Moderate incorporation of ESP (around 5–10 %) combined with appropriate firing temperatures can produce bricks with controlled porosity and acceptable water absorption, [12,10, 15] making them suitable for practical construction applications.

Compressive Strength

The compressive strength of the bricks increased progressively with increasing firing temperature for all compositions. The improvement in strength observed between 900 °C and 1200 °C can be attributed to enhanced sintering, improved inter-particle bonding, and the reduction of open porosity within the ceramic matrix. As the temperature rises, the clay particles undergo stronger bonding due to solid-state diffusion and partial verification, which results in a denser and stronger brick structure. In most cases, the maximum compressive strength was obtained at 1100 °C or 1200 °C, where the sintering process becomes more effective [15, 11, 21] in fig. 9. With respect to eggshell powder (ESP) incorporation, the addition of 5% ESP showed an improvement in compressive strength compared with the control sample. This improvement may be associated with better microstructural bonding and the partial fluxing effect of calcium compounds present in the eggshell powder. When the ESP content increased to 10%, the compressive strength remained comparable to or slightly higher than that of the 5% sample, indicating that moderate ESP addition can be beneficial for strength development [3]. However, further increase in ESP content beyond 10% resulted in a noticeable reduction in compressive strength. Excessive ESP leads to the formation of additional pores during firing due to the decomposition of calcium carbonate, which weakens the overall structure of the brick. Therefore, high ESP incorporation levels are not recommended for structural brick production because of the associated reduction in mechanical performance.

Overall Correlation between Properties

The experimental results show a clear relationship among the measured properties. Bulk density and compressive strength exhibit a direct relationship, meaning that higher density generally leads to higher strength. In contrast, porosity and water absorption show an inverse relationship with strength, as increased pore volume tends to weaken the brick structure. These properties are strongly interconnected through the micro structural changes that occur during the firing process. Optimal performance is observed when moderate amounts of ESP (5–10 %) are incorporated and the bricks are fired at temperatures between 1000 °C and 1100 °C. Under these conditions, sufficient densification occurs to enhance strength while maintaining a controlled level of porosity. In general, the mechanical strength of the bricks increases with densification and decreases as the pore volume becomes larger.

CONCLUSION

Eggshell powder can be successfully incorporated into fire clay bricks up to about 10% without causing a significant loss in mechanical properties. Increasing the firing temperature improves densification, particle bonding, and compressive strength of the bricks. Higher ESP contents **(**above 10%**)** significantly increase porosity, which leads to reduced density and lower mechanical strength. Bricks containing 5–10% ESP and fired at 1000–1100 °C meet the general requirements for structural brick applications. The utilization of eggshell waste in brick production contributes to sustainable waste management and the development of environmentally friendly building materials**.**

ABSTRACT

To study adverse reactions on blood donors, its risk factors and management strategies. Patients had to fill donor screening form on coming for the donation and after donor testing and counselling, the donation process was explained and blood donation taken. Observations were made and refreshments given after donation. Mild reactions were the most prevalent, accounting for 87.5% of the cases, with 15 occurring in 2022 (31.25%) and 27 in 2023 (56.25%). Moderate reactions represented 8.33% of the total, with all 4 cases occurring in 2023. Severe reactions were the least common, making up 4.17% of the total, with 2 cases reported in 2023 and none in 2022. The results of this study shed light on the prevalence of adverse reactions in blood donors and the factors that contribute to their occurrence. Additionally, donors with a history of adverse reactions should be closely monitored and provided with personalized care to prevent future incidents. In terms of management strategies, the findings suggest that a proactive approach is key to reducing adverse reactions in blood donors. While adverse reactions in blood donors are relatively rare, they represent a significant concern for donor safety and retention. Identifying the risk factors and implementing effective management strategies are crucial steps to ensure a positive donation experience and maintain a steady supply of blood for medical needs. Through continued research and improvement of donation protocols, the safety and well-being of blood donors can be further enhanced, ultimately benefiting the broader healthcare system.

Keywords: management strategies, blood donation, donor testing and counseling

INTRODUCTION

Blood transfusion is a process used for recovering lost blood after bleeding or to treat a variety of diseases involving abnormalities in the quantity or function of blood cells. Blood helps save human lives and treat various diseases. Blood and blood products for the treatment of patients are prepared from the blood of voluntary donors. Blood from eligible donors is processed to make blood and its components for patient treatment. Any healthy individual who is able to donate 350–450 millilitres of blood without risk or financial reward is eligible to donate blood. A new voluntary blood donor is a person who has never previously given blood. A regular voluntary donor is someone who voluntarily gives blood on a regular basis without taking a significant pause from blood donation each year. A family or replacement blood donor is a person who donates blood when someone in the patient's community or family needs it. A medical examination is conducted on donors prior to blood donation in order to ascertain their current health status. The physician determines whether the donor is eligible to donate blood after the examination. The physician complies with the established standards for donor selection and the standards for both temporary and permanent postponements of blood donation.(1) In any case, a few donors may have experienced an unfavourable response some time recently, amid and after giving blood. The aetiology of these responses is diverse. In common, it is considered that fear is the most common cause of these responses, and the greatest rate shows up with first-time blood givers, and it decreases with each subsequent blood donation. How diverse etiological components influence the appearance of these responses in donors can be seen by the fact that the donor collapses some time recently or appears to have any undesirable response after giving blood, in case blood is drawn without strong earlier psychological preparation in conditions of crowding and improvisation.

Adverse reactions during or after blood donation are relatively rare but can vary in severity from mild symptoms, such as dizziness and bruising, to more severe complications, including fainting and, in extreme cases, cardiac issues. According to the American Red Cross, less than 1% of blood donors experience significant adverse reactions, yet these events can affect donor retention and overall donation rates. Understanding the types and causes of these reactions is crucial for improving donor safety and the donation experience.(2) Common reactions are usually due to vasovagal response (VVR) or hyperventilation. VVR represents the response of the neuro vegetative system to stress, which, in addition to passionate excitement, can also be caused by intense blood loss. The central thalamic pathways within the central nervous system are stimulated by emotions and hyperventilation. Within the first stage, there's an increase in stroke volume and fringe vascular resistance, and hence an increment in blood vessel pressure, and within the second phase, a decrease in peripheral vascular sympathetic activity, vasodilatation, hypotension, and a decrease in the blood stream to the brain.

Adverse reactions can be categorized into mild, moderate, and severe. Mild reactions include symptoms such as light-headedness, bruising at the needle site, and minor pain. Moderate reactions may involve more pronounced dizziness, nausea, and fainting spells. Severe reactions, though extremely rare, can include seizures, arterial puncture, and cardiac events. Several risk factors contribute to the likelihood of experiencing adverse reactions. These include donor demographics (age, gender, weight), medical history, hydration status, and the donation process itself (e.g., volume of blood donated, needle insertion technique). For instance, younger and first-time donors are statistically more prone to adverse reactions. Additionally, donors with lower body weight or those who are dehydrated at the time of donation may have a higher risk of fainting or experiencing related symptoms. To manage and mitigate these adverse reactions, blood donation centres implement various strategies. Pre-donation screening is essential to identify high-risk individuals and ensure they are well-hydrated and healthy on the day of donation. During the donation process, trained staff monitor donors closely for any signs of distress and provide immediate intervention when necessary. Post-donation care, such as providing refreshments and a resting area, helps stabilize donors and reduce the risk of delayed adverse reactions.(3)

All potential blood donors fill out and sign the Blood Donor Questionnaire (personal anaesthetic information on health status, habits, and travel) for each blood donation, which is standardized and created based on the

recommendations of the NBTC national blood transfusion council. There's a positive relationship between the occurrence of acute and late complications during blood donation and age, gender, weight, and psychological factors (fear, nervousness, complications during previous blood donations).

METHODOLOGY

The actual process of blood donation is relatively simple and typically takes about 10-15 minutes. Patients had to fill donor screening form on coming for the donation and after donor testing and counselling, the donation process was explained and blood donation taken. Donors were asked to lie down on a comfortable chair, and a healthcare technician would clean the donation site and insert a sterile needle into a vein, usually in the arm. Observations were made and refreshments given after donation. After donating blood, donors were advised to rest for a few minutes and consume fluids and snacks provided by the hospital to help replenish their blood volume and prevent light-headedness or dizziness also donors were told to avoid strenuous physical activity for the rest of the day and to keep the donation site clean and dry to prevent infection

- **Sample size**: 50 subjects
- **Data Collection**: The data is collected from Fortis Flt. Lt. Rajan Dhall Hospital, Vasant Kunj
- **Period of data collection:** Year 2022 to 2023
- Inclusion Criteria: Include the donors who weigh more than 55kg, Haemoglobin more than 12.5 and less than 18, regular donor (18-65 years), irregular donor (18-60 years)
- Exclusion Criteria: Subjects excluded are people who have undergone any type of surgery in last 6 months and any pathological infection in last 1 year

DISCUSSION

In 2022 and 2023, a total of 48 adverse reactions were recorded among blood donors. Mild reactions were the most prevalent, accounting for 87.5% of the cases, with 15 occurring in 2022 (31.25%) and 27 in 2023 (56.25%). Moderate reactions represented 8.33% of the total, with all 4 cases occurring in 2023. Severe reactions were the least common, making up 4.17% of the total, with 2 cases reported in 2023 and none in 2022. Overall, 31.25% of the reactions occurred in 2022, while 68.75% were reported in 2023, indicating an increase in reported adverse reactions over the two years. Among 48 adverse reactions, 93.75% occurred with whole blood donations and 6.25% with apheresis. Mild reactions were most common (87.5%), with 85.42% from whole blood and 2.08% from apheresis. Severe and moderate reactions both accounted for 4.17%, with a similar distribution between whole blood and apheresis. In 2022 and 2023, out of 48 total donations, 34 (70.83%) were from replacement donors and 14 (29.17%) from voluntary donors. In 2022, replacement donors contributed 14 donations, while voluntary donors contributed 1. In 2023, replacement donors made 20 donations, and voluntary donors made 13.

The high rate of adverse reactions among young donors highlights the need for targeted interventions to reduce the risk in this population. Education campaigns aimed at young donors could help increase awareness of the potential risks and encourage them to take precautions before and after donation. The gender disparity in adverse reactions also warrants further investigation. Hormonal factors may play a role in increasing the risk for female donors, and more research is needed to understand how these factors can be mitigated By implementing thorough screening processes, providing adequate education and support to donors, and ensuring proper monitoring during and after donation, healthcare providers can help minimize the risk of adverse reactions. Collaboration between blood donation centers, healthcare professionals, and donors themselves is essential to create a safe and supportive environment for blood donation. Risk Factors for Adverse Reactions in Blood Donors are needle-related factors, donor-related factors, donation frequency, donor hydration and nutrition,etc. The size and type of needle used for blood donation can impact the likelihood of adverse reactions, such as pain, bruising, or nerve injury. Individual characteristics of donors, such as age, weight, and health status, can influence their susceptibility to adverse

reactions. Donors who donate blood frequently may be at higher risk for adverse reactions due to the cumulative effects of multiple donations. Donor anxiety or fear of needles can contribute to adverse reactions, such as fainting or vasovagal reactions. Dehydration and poor nutrition can increase the risk of adverse reactions. Types of Adverse Reactions in Blood Donors: Vasovagal reactions are the most common adverse event in blood donors, characterized by symptoms such as fainting, dizziness, and sweating, Hematomas can occur when there is bleeding under the skin at the venipuncture site, resulting in pain and bruising, Nerve damage can occur if the needle is inserted incorrectly or if there is prolonged pressure on a nerve during blood donation. Some donors may experience allergic reactions to anticoagulants or other components of the blood collection system. Some Management Strategies followed for Adverse Reactions in Blood Donors were like pre-donation screening which included screening donors for risk factors and ensuring they are well-hydrated and well-nourished can help prevent adverse reactions. Proper training of phlebotomists in needle insertion techniques can reduce the risk of adverse reactions, such as hematoma or nerve injury. Providing a comfortable and supportive environment for donors, including reclining chairs and access to water and snacks, can help prevent vasovagal reactions. Post-donation monitoring: Monitoring donors after donation for any signs of adverse reactions and providing prompt medical attention if needed is crucial for their safety.

CONCLUSION

Adverse reactions in blood donors, although infrequent, present significant challenges for donor safety and retention. These reactions range from mild, such as dizziness and bruising, to severe, including fainting and cardiac complications. Understanding the risk factors, such as donor demographics, medical history, and hydration status, is crucial for predicting and preventing these reactions. Younger and first-time donors, as well as those with lower body weight or inadequate hydration, are particularly susceptible. Effective management strategies play a vital role in mitigating these adverse effects. Pre-donation screening helps identify high-risk donors, ensuring they are in optimal health for donation. During the donation process, close monitoring and immediate intervention by trained staff are essential to address any signs of distress. Post-donation care, which includes providing refreshments and advising on fluid intake and activity limitations, further helps stabilize donors and minimize delayed reactions. In summary, enhancing donor safety through comprehensive risk assessment and management strategies is imperative. By doing so, we can ensure a positive donation experience, encourage donor retention, and maintain a reliable blood supply, ultimately supporting the healthcare system's needs. Continued research and protocol improvements will further safeguard donor health and well-being.

Limitation

The literature gap in this study is the absence of discussion on specific strategies or interventions to mitigate adverse reactions to blood donation and improve donor retention. The female donors as subject were less in number as compared to the males due to menstruation and pregnancy.

Recommendation

To minimize adverse reactions in blood donors, it is essential to implement robust pre-donation screening to identify high-risk individuals. Enhancing donor education on hydration and health requirements can further reduce risks. During donation, trained staff should closely monitor donors and provide immediate care if needed. Post-donation, ensure donors receive adequate rest and hydration advice. Additionally, continuous research to refine protocols and understand emerging risk factors is crucial. By adopting these strategies, we can improve donor safety, enhance the donation experience, and maintain a reliable blood supply for medical needs.

ABSTRACT

Ribonucleases are hydrolytic enzymes that cleave the phosphodiester backbone of ribonucleic acid, and for much of the twentieth century they were regarded chiefly as housekeeping catalysts and as workhorse reagents of the molecular biology laboratory. That view has changed. Over the past two decades a substantial body of evidence has established that ribonucleases drawn from mammalian, amphibian, bacterial and fungal sources possess anti proliferative, antiangiogenic, antiviral and immune modulatory properties, and that these properties can be engineered, delivered and, in a small number of cases, tested in human beings. The present review synthesises twenty primary and secondary sources published between 2015 and 2026 in order to map the current therapeutic landscape of ribonuclease biology. A structured narrative methodology was adopted: sources were assembled, screened against defined eligibility criteria, charted against a common extraction framework, and synthesised thematically. The evidence converges on several points. First, the cytosolic ribonuclease inhibitor remains the principal obstacle to the clinical use of mammalian ribonucleases, and three distinct strategies have emerged to circumvent it, namely rational mutagenesis, recourse to inhibitor-insensitive microbial enzymes, and nanoparticle-mediated delivery. Second, the antitumour action of at least one bacterial ribonuclease, binase, is not confined to catalysis but extends to direct interference with oncogenic signalling and to reorganisation of the microRNA network. Third, endogenous ribonuclease pathways such as OAS-RNase L and IRE1α are themselves druggable, and their manipulation modifies the response to established chemotherapeutic and antiangiogenic agents. Fourth, the two completed

randomised trials of an RNase-Fc fusion protein indicate that therapeutic benefit is real but confined to defined patient subgroups, a finding with direct implications for trial design. The review closes by identifying the standardisation of activity assays, the resolution of catalytic from non-catalytic mechanisms, and systematic in vivo safety evaluation as the priorities for the next phase of work.

Keywords: Ribonuclease; RNase A; binase; ribonuclease inhibitor; antitumour enzymes; RSLV-132; nanobiomedicine; microbial enzymes; targeted therapy.

INTRODUCTION

Ribonuclease, abbreviated RNase, is the collective name for a large and functionally heterogeneous class of nucleases that catalyse the degradation of ribonucleic acid into smaller nucleotide fragments. The conventional taxonomy divides them by site of attack: endoribonucleases cleave internally, whereas exoribonucleases progressively remove residues from a terminus, characteristically in the 3′ to 5′ direction[1]. Enzymes of both kinds are indispensable to the maturation of messenger RNA, ribosomal RNA and transfer RNA, and to the regulated turnover that determines how long a transcript persists and therefore how strongly a gene is expressed[2]. They occur across the whole of the living world, from bacteria and viruses to plants and mammals, an ubiquity that is itself an argument for their functional centrality[3]. The therapeutic interest in these enzymes rests on a straightforward but consequential observation. A ribonuclease that gains access to the cytosol of a living cell will degrade that cell's RNA, and a cell deprived of intact transcripts cannot sustain protein synthesis. Cytotoxicity follows. What distinguishes ribonucleases from conventional cytotoxic chemotherapy is that their action is non-mutagenic, since the target is RNA rather than DNA, and that certain members of the family display a marked preference for malignant over normal cells[4]. Onconase, an amphibian homologue of the pancreatic enzyme, remains the only ribonuclease to have progressed to clinical evaluation, and the range of malignancies against which it has shown activity, encompassing prostate, cervical, colonic, breast and ovarian tumours as well as lymphocytic leukaemia, indicates that the therapeutic principle is a broad one[3].

Progress has nevertheless been slower than the underlying biology would predict, and the reason is well understood. Mammalian cells express a cytosolic ribonuclease inhibitor, a leucine-rich repeat protein that binds members of the RNase A superfamily with femtomolar affinity and neutralises them almost completely. Any pancreatic-type ribonuclease that reaches the cytosol of a human tumour cell is therefore likely to be inactivated before it can do useful work [4,5]. The literature of the last decade can, to a considerable extent, be read as a sustained attempt to solve this single problem, and the solutions proposed fall into three broad families: engineer the enzyme so that it no longer presents a recognisable inhibitor interface; abandon mammalian enzymes altogether in favour of bacterial or fungal ribonucleases against which the inhibitor has no activity; or leave the enzyme unchanged and change instead the way it is delivered. Alongside this pharmacological line of enquiry, a second and initially separate literature has examined the ribonucleases that cells already possess. The OAS-RNase L axis of the interferon response and the IRE1α endoribonuclease of the unfolded protein response are both endogenous RNA-cleaving systems whose activity shapes the fate of tumour cells, and both have proved to be tractable drug targets[6,7]. A third strand concerns the enzymological and process-engineering questions that any eventual therapeutic would have to answer, namely how the enzyme is to be produced, purified, stabilised and formulated[2,8].

These strands are rarely brought together. Reviews of ribonuclease biology tend to concentrate either on the fundamental enzymology or on a single therapeutic application, and the clinical trial literature sits largely apart from the preclinical work that preceded it. The present review was undertaken to address that gap. Its objectives are fourfold: to characterise the range of ribonucleases currently under investigation as therapeutic agents and the biological sources from which they derive; to compare the strategies that have been devised to overcome the

ribonuclease inhibitor barrier and to assess the evidence supporting each; to examine the mechanisms, catalytic and otherwise, through which these enzymes exert their effects on malignant, virally infected and immunologically dysregulated cells; and to evaluate what the available clinical evidence permits one to say about therapeutic translation. The intended readership comprises researchers in enzyme biotechnology, cancer pharmacology and biopharmaceutical development.

METHODOLOGY

Review Design

This work is a structured narrative review. The narrative form was chosen deliberately in preference to a systematic review or meta-analysis, for reasons intrinsic to the evidence base. The included studies differ radically in design, ranging from molecular dynamics simulations through cell-line cytotoxicity assays and murine xenograft experiments to randomised controlled trials in human patients; they employ incommensurable outcome measures, since an IC50 value, a percentage reduction in viral titre and a CLASI score cannot meaningfully be pooled; and they address a set of related but distinct research questions. Statistical synthesis would in these circumstances be misleading. A structured narrative approach preserves the methodological transparency of a systematic review, in that the search, screening, extraction and synthesis procedures are all specified in advance and reported, while permitting the interpretive breadth that a heterogeneous evidence base requires.

Sources and Search Strategy

The evidence base for this review consists of twenty peer-reviewed publications assembled through a literature survey conducted as part of an ongoing doctoral research programme at the Rajiv Gandhi Biotechnology Centre, L.I.T. Campus, Nagpur. Bibliographic databases consulted included PubMed, Scopus, Web of Science, ScienceDirect and Google Scholar. Search terms were combined using Boolean operators and covered the enzyme and its variants (“ribonuclease”, “RNase”, “RNase A”, “binase”, “onconase”, “ribotoxin”), the biological activity of interest (“antitumour”, “anticancer”, “cytotoxicity”, “antiviral”, “apoptosis”), and the translational context (“ribonuclease inhibitor”, “nanoparticle delivery”, “immobilisation”, “clinical trial”). The reference lists of retrieved articles were hand-searched for further relevant material. The retrieval window extends from 2015 to 2026, a span selected to capture the period in which engineered and microbially derived ribonucleases moved decisively from proof of concept towards translational evaluation.

Eligibility Criteria

Studies were admitted to the review if they satisfied the following conditions:

- Publication in a peer-reviewed journal in the English language between 2015 and 2026.
- A primary focus on ribonuclease structure, function, production or therapeutic application; or, alternatively, on a cytotoxic or delivery strategy that furnishes a direct comparator for ribonuclease-based therapy.
- Presentation of original experimental or clinical data, or of a substantive scholarly synthesis in the case of review articles.
- Reporting of a defined biological endpoint, whether enzymatic, cellular, molecular or clinical.

Excluded were conference abstracts, unpublished theses, editorials, commentaries lacking original data, and studies in which ribonucleases were mentioned only incidentally as laboratory reagents without therapeutic or mechanistic analysis.

Data Extraction and Charting

A standard extraction framework was applied to every included source. The fields recorded were: full bibliographic citation; study design and type; the ribonuclease or comparator agent examined and its biological source; the experimental system, including cell lines, animal models or patient cohorts; the interventions and concentrations or doses employed; the analytical techniques used; the principal quantitative and qualitative findings; and the authors’

stated conclusions together with any limitations they acknowledged. Extraction was performed by the first author and verified against the source abstracts. The charted data are presented in Table 1.

Approach to Synthesis

Thematic synthesis proceeded in three stages. In the first, each extracted record was assigned one or more descriptive codes reflecting its substantive concern, for example "inhibitor evasion", "microbial source", "non-catalytic mechanism", "nanocarrier" or "clinical endpoint". In the second, related codes were grouped into higher-order analytical themes, each of which corresponds to a subsection of the Discussion. In the third, the themes were interrogated against one another in order to identify convergences, contradictions and gaps, an exercise reported in discussion section. Where studies reported findings that were in tension, the discrepancy has been stated rather than smoothed over.

Methodological Limitations

Three limitations of the method should be recorded at the outset. The evidence base of twenty sources, while representative of the principal lines of contemporary enquiry, is not exhaustive, and a broader search would certainly identify further relevant work. Second, extraction was based principally on published abstracts and summary data rather than on full-text re-analysis of primary datasets, which restricts the depth at which methodological quality could be appraised. Third, no formal risk-of-bias instrument was applied, a consequence of the design heterogeneity noted in review design section, since no single instrument accommodates simulations, cell-culture experiments, animal studies and randomised trials alike. These constraints are revisited in discussion section.

Overview of the Included Literature

The twenty included sources comprise fourteen primary experimental studies, four narrative reviews and two randomised controlled clinical trials. Publication dates span 2015 to 2026, with a marked concentration in the period from 2019 onwards, which contains thirteen of the twenty sources and reflects the recent intensification of interest in the field. By biological source, the ribonucleases examined divide into mammalian pancreatic enzymes and their engineered derivatives, represented by bovine RNase A and the ovine variant[4,5]; bacterial enzymes, dominated by binase from *Bacillus pumilus*[9–12] together with an RNase from *Bacillus* sp. RB-3 [8]; fungal ribotoxin-like proteins, represented by Ageritin[13]; endogenous human ribonuclease systems, namely RNase L and IRE1α [6,7]; and the engineered human RNase-Fc fusion protein RSLV-132 evaluated in the clinic[14,15]. By therapeutic domain, oncology predominates, accounting for thirteen sources; autoimmune disease accounts for two, antiviral application for one, and general enzymology, production science and comparator strategies for the remainder. The cell lines most frequently employed are HeLa cervical carcinoma, which appears in five studies, followed by colorectal lines SW-480 and HCT-116, breast lines BT-20 and MCF-7, and the lung adenocarcinoma line A549. Table 1 charts the full evidence base.

DISCUSSION

The discussion that follows is organised into eleven thematic subsections, each addressing a distinct analytical dimension of the evidence, followed by a consideration of the limitations of the review itself.

From Housekeeping Enzymes to Therapeutic Molecules

The conceptual reframing of ribonucleases as candidate drugs rather than as metabolic accessories is documented most clearly in the review literature. Kanwar et al. (2016) trace the widening application of these enzymes beyond molecular biology into medicinal, clinical and analytical chemistry, and note that mammalian and certain fungal ribonucleases carry antiproliferative, antiangiogenic and antitumour activities. Their observation that RNase 6 and RNase 7, members of the same superfamily, function as evolutionarily conserved antimicrobial peptides maintaining sterility in the urinary tract is important, because it establishes that cytotoxic activity is not an artefact of laboratory manipulation but a physiological property that natural selection has preserved [1].

Shruti et al. (2016) extend the catalogue to antifungal, antiviral and immunosuppressive functions and identify the enzymes that have attracted the greatest attention as antitumour agents: bovine pancreatic RNase A, bovine seminal RNase, onconase and angiogenin. Their account of eosinophil-derived neurotoxin and eosinophil cationic protein, designated RNases 2 and 3, is of particular interest, since these enzymes display broad antiviral activity against RNA viruses including HIV-1, and recombinant constructs derived from EDN retain cytotoxicity against leukaemia cells and respiratory syncytial virus. The implication is that the antiviral and antitumour activities of the RNase A superfamily are not separate phenomena requiring separate explanations but expressions of a single underlying capacity to destroy RNA in a context where its destruction is lethal [3]. Hameş and Demir (2015) contribute the argument on which much of the subsequent microbial literature depends: that the cytotoxic potency of particular microbial ribonucleases is comparable to that of animal-derived counterparts, and that microbial sources avoid the safety and regulatory difficulties attending bovine or other animal-derived material. This is not merely a manufacturing convenience. It removes an entire class of regulatory objection from the development pathway, and it goes some way towards explaining why bacterial enzymes have come to occupy so prominent a place in recent work [2].

The Ribonuclease Inhibitor Barrier and Strategies for Its Evasion

The cytosolic ribonuclease inhibitor is the single most consistently cited obstacle in this literature, and the three principal responses to it are worth setting out in comparative terms because they represent genuinely different engineering philosophies.

Rational mutagenesis of the enzyme

The most direct approach is to alter the enzyme so that the inhibitor no longer recognises it. Zabetian et al. (2026) provide the most complete illustration. Working with ovine pancreatic RNase A, itself a variant of the bovine enzyme distinguished by four substitutions (A19S, K37Q, V46F and N103E), the authors introduced a further four mutations selected from the literature for their demonstrated capacity to disrupt the inhibitor interface: D38R, R39D, N67R and G88R. The design was validated computationally before being tested experimentally, and the results are unusually clean. Native ovine RNase A displayed an activity of 558 ± 22 U/mol; the engineered variant reached 674 ± 15 U/mol, exceeding the 656 ± 23 U/nmol reported for the bovine enzyme. More significantly, in the presence of 50 ng/µl of ribonuclease inhibitor the engineered enzyme retained an activity of 168 ± 19 U/nmol, whereas both native ovine and bovine enzymes were inactive. MTT assay confirmed that this biochemical advantage translated into greater cytotoxicity against HeLa cells [5]. Two features of this result deserve emphasis. The first is that inhibitor evasion was achieved without loss of catalytic efficiency; indeed catalytic activity improved, which is not the usual outcome when a protein surface is extensively remodelled. The second is the sequence of the work, in which computational prediction preceded and directed the experimental programme rather than being invoked afterwards to rationalise it. This is a template that could be applied to other members of the superfamily [5].

Recourse to inhibitor-insensitive microbial enzymes

An alternative is to sidestep the problem entirely by using enzymes that the mammalian inhibitor does not recognise. The extensive binase literature rests on this premise, as does the work on the fungal ribotoxin-like protein Ageritin[13]. The advantage is that no engineering is required and the natural enzyme can be used as isolated. The corresponding disadvantage, which the literature acknowledges less often than it should, is immunogenicity: a bacterial protein administered repeatedly to a human patient is a strong candidate for neutralising antibody responses, and none of the studies reviewed here addresses this question directly.

Delivery-based circumvention

The third strategy leaves the enzyme untouched and modifies its route of entry. Khiavi et al. (2019) conjugated bovine RNase A covalently to gold nanoparticles stabilised with polyethylene glycol, producing a construct characterised by scanning electron microscopy, dynamic light scattering and ultraviolet-visible spectroscopy. Against SW-480 colorectal carcinoma cells the nanoconjugate induced apoptosis and reduced viability substantially, with maximal reactive oxygen species generation at the IC50 dose. The mechanistic interest of this result lies in the

coupling of two distinct killing mechanisms: the catalytic degradation of RNA contributed by the enzyme, and oxidative stress contributed by the nanoparticle. Whether the observed cytotoxicity should be attributed principally to enzymatic action, to inhibitor sequestration by the carrier, or to the nanoparticle itself is not resolved by the data presented, and this ambiguity recurs throughout the nanomedicine literature [4]. Considered together, the three strategies are complementary rather than competing, and the most promising direction may well be their combination, for instance the delivery of an engineered inhibitor-evading variant on a targeted nanocarrier.

Microbial Ribonucleases as Antitumour Agents: The Binase Paradigm

Binase, the ribonuclease of *Bacillus pumilus*, is the most thoroughly characterised microbial enzyme in this literature, and four of the included studies address it. Their collective contribution is to demonstrate that a bacterial ribonuclease can act against tumours in vivo, and that its mechanism is more complex than simple RNA degradation. Mohamed et al. (2020) provide the most complete in vivo dataset. In the murine RLS40 lymphosarcoma model, intraperitoneal binase retarded primary tumour growth by up to sixty per cent and inhibited hepatic metastasis by up to eighty-six per cent, with histological evidence of reduced inflammatory infiltration and diminished mitotic activity in tumour tissue. In vitro, cytotoxicity proceeded through caspase-3 and caspase-7 activation, confirming an apoptotic rather than necrotic mode of death. The disparity between the primary tumour and metastasis figures is striking and suggests that the enzyme is more effective against disseminating cells than against established tumour mass, a property of obvious clinical interest if it is confirmed in other models [10]. Ulyanova et al. (2020) took the analysis in a different direction by asking which parts of the binase molecule are responsible for its cytotoxicity. Of five designed peptides, two, corresponding to residues 21–50 and 74–94, carried most of the activity against HeLa, BT-20 and MCF-7 cells. Neither peptide entered A549 lung adenocarcinoma cells, which explains their failure to inhibit proliferation in that line and confirms that cellular uptake, rather than intrinsic potency, is the rate-limiting step. The observation that the 74–94 fragment shares similarity with epidermal growth factor, and may therefore engage the EGF receptor over expressed on BT-20 cells, is a substantial finding: it suggests that selectivity for tumour cells is receptor-mediated rather than an incidental consequence of altered membrane composition, and it opens the possibility of developing short tumour-targeting peptides that dispense with the enzyme altogether [12].

Lampitella et al. (2021) offer a contrasting account of selectivity derived from a fungal enzyme. Ageritin, the prototype of a ribotoxin-like protein family identified in basidiomycetes, cleaves a single phosphodiester bond in the sarcin/ricin loop of the large ribosomal RNA, arresting protein synthesis at an early stage; unusually among ribotoxins, its activity requires divalent cations. Liposome experiments showed interaction with DPPC/DPPS/cholesterol vesicles modelling cancer cell membranes and with DPPC/DPPG vesicles modelling bacterial membranes, indicating a preference for anionic lipids, while the differential perturbation of the two models, mediated by cholesterol redistribution, was proposed as the basis of selectivity. The juxtaposition of these two studies is instructive: the binase work locates selectivity in a specific protein–receptor interaction, the Ageritin work in the general biophysics of the membrane. Both mechanisms may operate, and distinguishing between them in any given case will be necessary before either can be exploited rationally [13].

Beyond Catalysis: Ribonucleases as Modulators of Signalling and microRNA Networks

The assumption that the therapeutic effect of a ribonuclease follows from its catalytic activity is challenged by two of the included studies, and the challenge has significant implications. Dudkina et al. (2024) report that binase inhibits mitogen-activated protein kinase signalling through direct interaction with the EGFR and RAS proteins. Given that aberrant MAPK activation occurs in more than eighty-five per cent of cancers and that no effective targeted therapy against these two oncogenes has been established, a molecule capable of engaging both simultaneously is of considerable interest. The authors' argument that this multitargeted action would impede the development of drug resistance is plausible, since resistance to single-target agents typically arises through mutation of that target, a route unavailable where several targets are engaged at once [9]. The crucial point, however, is that this activity is described as contributing to antitumour potential *alongside* enzymatic activity. If binase is simultaneously an RNA-degrading enzyme and a protein–protein interaction inhibitor, then the peptide fragments identified by Ulyanova et al. (2020)

may be acting through the second mechanism rather than the first, and structure–activity relationships developed on the assumption of catalysis may require revision.

Mohamed et al. (2020) add a further layer. Binase treatment altered the levels of the oncogenic microRNAs miR-21a, miR-31 and miR-155 and of the tumour suppressor let-7g, and did so in opposite directions in serum and in tumour tissue: circulating levels of most species fell, whereas within the tumour the oncomirs miR-21, miR-10b, miR-31 and miR-155 together with let-7g were upregulated. Network analysis indicated that the principal modulated processes were transcriptional and translational control, cell cycle progression, proliferation, adhesion and invasion, apoptosis and autophagy. The compartmental divergence is a genuine puzzle and the authors do not fully resolve it. One reading is that the enzyme degrades circulating extracellular microRNA directly while triggering a compensatory intracellular response; another is that tissue-level changes reflect the altered cellular composition of a regressing tumour rather than a direct enzymatic effect [10]. Discriminating between these accounts would require time-resolved measurement, which the study did not undertake.

Endogenous Ribonuclease Pathways as Therapeutic Targets

A conceptually distinct line of work concerns the ribonucleases that human cells already express, and here the therapeutic intervention consists not in administering an enzyme but in manipulating one. Banerjee et al. (2019) established that the cytotoxicity of the DNA methyltransferase inhibitor 5-azacytidine, a drug approved for myelodysplastic syndromes and acute myeloid leukaemia, is mediated by the 2′,5′-oligoadenylate synthetase–RNase L pathway. Demethylation permits transcription of repetitive elements, generating self double-stranded RNA; this activates OAS enzymes, which synthesise 2-5A, which in turn activates RNase L. Cells deficient in RNase L or in OAS1 to OAS3 were highly resistant to the drug, as were wild-type cells exposed to a small-molecule RNase L inhibitor. Sensitivity was increased by transfection of 2-5A, by deficiency in ADAR1, PDE12 or AKAP7, and by ionising radiation. The correlation between OAS1 expression and azacytidine sensitivity across the NCI-60 panel points towards a clinically usable predictive biomarker. The wider significance of the finding is that an established drug turns out to kill cells through a ribonuclease pathway, which suggests that the therapeutic reach of ribonuclease biology extends well beyond agents explicitly designed as ribonucleases [6].

Harnoss et al. (2020) examined IRE1α, the endoplasmic reticulum sensor of the unfolded protein response, whose cytoplasmic kinase–endoribonuclease module activates the transcription factor XBP1s. Using an XBP1s-dependent gene signature the authors demonstrated pathway activation across multiple solid cancers including triple-negative breast cancer. Knockout of IRE1α reversed the ultrastructural expansion of the endoplasmic reticulum that accompanies in vivo growth and remodelled the tumour microenvironment, increasing pericyte numbers while reducing cancer-associated fibroblasts and myeloid-derived suppressor cells. Pharmacological inhibition of the IRE1α kinase attenuated the growth of both cell-line and patient-derived xenografts and synergised with anti-VEGFA treatment to produce tumour stasis or regression. The clinical relevance is considerable, since antiangiogenic therapy has previously proved ineffective in triple-negative breast cancer; the implication is that its failure reflected an adaptive response that IRE1α inhibition can abolish. This is combination therapy predicated on mechanism rather than on empirical trial and error, and it represents the more sophisticated end of the field [7].

Antiviral Applications of Ribonucleases

Only one included study addresses antiviral activity directly, but its findings are germane to the wider argument. Shah Mahmud et al. (2017) tested binase against a negative-sense and a positive-sense single-stranded RNA virus, influenza A and human rhinovirus respectively, in A549 cells. A single concentration reduced influenza A (H1N1pdm) titres by forty per cent and human rhinovirus serotype 1A titres by sixty-five per cent while leaving the cellular protein spectrum and housekeeping gene expression unaltered, which is the essential control for a nonspecific RNA-degrading agent. Preincubation of the virus with binase before infection significantly reduced titre after a single replication cycle, and a minigenome system showed reduced GFP reporter signal, indicating action on viral messenger RNA expression; accumulation of H1N1pdm NP mRNA in A549 cells fell by twenty per cent [11].

The demonstration of activity against viruses of both polarities at the same concentration argues for a mechanism operating on viral messenger RNA, which is common to both replication strategies, rather than on the genome itself. This is a therapeutically attractive property because it predicts breadth of coverage, and it is particularly relevant for pathogens characterised, as the authors note, by high contagiousness, rapid mutation and antigenic variability, where conventional antivirals are quickly outrun by escape mutation. The evidence remains confined to cell culture, and no animal or human data are presented [11].

Clinical Translation: Lessons from RSLV-132

The two randomised controlled trials in the evidence base concern RSLV-132, a catalytically active human ribonuclease fused to human IgG1 Fc and designed to digest circulating extracellular RNA, which is the principal trigger of type I interferon in several autoimmune conditions. Read together, the two trials constitute the most instructive material in this review, because they illustrate both the promise and the difficulty of clinical translation.

Posada et al. (2021) randomised thirty patients with primary Sjögren's syndrome to RSLV-132 at 10 mg/kg or placebo. Patients receiving active treatment showed clinically meaningful improvement from baseline to day 99 on the ESSPRI, FACIT-F, ProF and DSST instruments, with the DSST reaching $P = 0.02$ and FACIT-F $P = 0.05$, while the placebo group showed no change on any measure. Improvement correlated significantly with expression of selected interferon-inducible genes. That four independent patient-reported measures of fatigue moved in the same direction is a meaningful pattern even where individual P values are modest, and the correlation with interferon gene expression supplies mechanistic corroboration that the drug acted as designed [15]. Burge et al. (2024) conducted a larger and more demanding trial in systemic lupus erythematosus. Sixty-five patients with a baseline CLASI score of ten or greater and at least one of five autoantibodies to RNA-binding proteins were randomised two-to-one to thirteen doses of RSLV-132 at 10 mg/kg or placebo over twenty-four weeks.

The primary endpoint was not met: mean CLASI change at day 169 was −6.2 ± 8.5 with active treatment against −5.7 ± 7.0 with placebo. Prespecified subgroup analyses, however, told a different story. Among patients with baseline SLEDAI of nine or above, BICLA response rates were sixty-two per cent against forty-four per cent and SRI-4 rates twenty-three per cent against eleven per cent; among those with baseline CLASI of twenty-one or above, BICLA rates were twenty-eight per cent against eight per cent and SRI-4 rates thirty-nine per cent against eight per cent [14]. The authors' own diagnosis of the failure is convincing and important. The entry criteria required moderate to severe cutaneous activity but set no minimum SLEDAI score, admitting a cohort whose systemic disease ranged from inactive to severe. In patients whose systemic disease was quiescent there was little for an anti-inflammatory mechanism to improve, and their inclusion diluted any true effect. The negative primary result is therefore better understood as a failure of patient selection than as a refutation of the mechanism. For a field in which biomarker-guided enrolment is technically feasible, given that the relevant autoantibodies and interferon signatures can be measured before randomisation, the lesson is direct: future trials of ribonuclease therapy should enrol on the basis of demonstrated pathway activation rather than on organ-specific severity alone [14].

Nanotechnology-Enabled Delivery

Delivery recurs throughout this literature as the limiting factor, and three included studies address it from different directions. Khiavi et al. (2019), discussed above, provide the direct case of a ribonuclease-nanoparticle conjugate [4]. Dubey et al. (2022) supply the general argument, reviewing nano-enabled CRISPR-Cas strategies and identifying the unresolved problems of viral vector delivery, namely immunogenicity, insertional on cogenesis, poor retention and inadequate targeting, against which tailored polymeric nanoparticles are proposed as an alternative. Although CRISPR-Cas systems are not ribonucleases in the sense used elsewhere in this review, the delivery problem is formally identical: a large, charged, membrane-impermeant biomolecule must be brought intact to an intracellular target in a specific tissue. Advances in one domain should transfer readily to the other [16]. Roy et al. (2025) describe the most unconventional approach, functionalising living *Lactobacillus rhamnosus* with gold nanoclusters and quercetin-loaded magnetic nanoparticles. Against HeLa monolayers and three-dimensional spheroids, a low dose of 5×10^5 CFU/mL produced approximately eighty-four per cent cytotoxicity, rising above ninety-one per cent under an external magnetic field, with reactive oxygen species increasing 1.8- to 2.3-fold, reduced lipid droplet content, altered

cell cycle distribution and necroptosis in an average of seventy-four per cent of cells. The synergy is genuine, in that the combined construct exceeded the effect of either quercetin or bacteria alone, and the magnetic responsiveness offers a form of spatial control that chemical targeting cannot provide. Whether a living bacterial vector is a plausible clinical proposition is a separate question, and the study does not engage with it; but the demonstration that the carrier itself can contribute to killing rather than merely transporting a payload is conceptually relevant to ribonuclease delivery, and the use of spheroids alongside monolayers is a methodological strength that much of the cell-culture literature in this field lacks [19].

Production, Purification and Immobilisation

Therapeutic promise is of little consequence if the enzyme cannot be manufactured reproducibly, and two included sources address this squarely. Hameş and Demir (2015) survey the determination of optimum fermentation conditions for maximising RNase yield from bacterial and fungal producers, together with immobilisation and strain development work, and note the additional demand created by the growth of DNA vaccine and gene therapy programmes, both of which require ribonucleases in downstream processing. They also record applications outside medicine, in single-cell protein preparation for the food industry and in the synthesis of specific nucleotides [2]. Priyanka et al. (2022) supply the corresponding experimental detail. RNase purified from *Bacillus* sp. RB-3 resolved as a single 28 kDa band on SDS-PAGE, and FTIR spectroscopy confirmed both the synthesis of the Moringa gum–polyvinyl alcohol hydrogel and the successful immobilisation of the enzyme upon it. Optima for both free and hydrogel-bound preparations were 37 °C, thirty minutes and pH 7.4, with substrate optima of 150 μg/mL for the bound and 200 μg/mL for the free enzyme. The purified enzyme was cytotoxic against Hep-2C cells. Two aspects merit comment. That optimal temperature and pH coincide with physiological values is convenient for therapeutic application, since no compromise between activity and tolerability is required. That the immobilised preparation achieved its optimum at a lower substrate concentration than the free enzyme suggests that immobilisation improved rather than impaired substrate accessibility, which is not the usual result and warrants further investigation. The use of a plant-derived gum as the matrix is also of interest from the standpoint of cost and biocompatibility in a resource-constrained manufacturing setting [8].

Comparative Context: Natural Product and Small-Molecule Strategies

Three included studies do not concern ribonucleases but furnish comparators against which ribonuclease-based approaches can be judged, and their inclusion is deliberate. El-Garawani et al. (2020) examined a hydromethanolic extract of the lichen *Candelariella vitellina*, which proved almost inert towards normal human peripheral blood lymphocytes, with an IC50 exceeding 1000 μg/mL, while exerting antigenotoxic effects against mitomycin C, normalising cell cycle distribution and restoring the mitotic index, and displaying dose- and time-dependent scolicidal activity against *Echinococcus granulosus*. The therapeutic index implied by so high an IC50 in normal cells is the property that ribonuclease-based agents must ultimately match [17]. Jinu and Jayabaskaran (2015) screened thirty-seven endophytic fungal species isolated from *Saracaasoca*, distributed across twenty-two genera dominated by *Camarosporium*, *Pestalotiopsis* and *Fusarium*, against HeLa, HepG2 and PC3 cells. Eighteen isolates showed appreciable cytotoxicity, and the ethyl acetate extract of *Pestalotiopsis* sp. 6 induced mitochondria-dependent apoptosis in HeLa cells in a dose-dependent manner. The relevance to ribonuclease research is twofold: fungi are established producers of cytotoxic ribonucleases, as the Ageritin work confirms, and the bioprospecting methodology employed here is directly transferable to the search for novel microbial ribonucleases [18]. Mandi et al. (2022) describe a mechanistically elegant small-molecule strategy in which a nitro-containing monoquinoxaline DNA intercalator is reduced by intracellular glutathione to a fluorescent amine that selectively cleaves abasic sites in DNA at approximately 100 nM. The design exploits the elevated glutathione levels of colorectal cancer cells, converting a recognised mechanism of chemoresistance into the trigger for drug activation, and the compound potentiated chlorambucil in HCT-116 cells, producing double-strand breaks and arrest at G0/G1 and G2/M. The lesson for ribonuclease therapeutics is one of design philosophy. Where the ribonuclease literature treats the cytosolic inhibitor as an obstacle to be overcome, this work treats an analogous resistance mechanism as an activation switch. An enzyme prodrug that required the ribonuclease inhibitor for its own activation would be a genuinely novel construct, and nothing in the present evidence base suggests it has been attempted [20].

Convergent Themes and Points of Divergence

Reading the evidence base as a whole, four convergences and three unresolved tensions stand out. The convergences are these. Selectivity for malignant over normal cells is a recurrent and reproducible observation across enzymes of quite different provenance, reported for engineered ovine RNase A, for binase and its derived peptides, and for Ageritin, which argues that it reflects general features of the transformed phenotype rather than the idiosyncrasies of any one molecule. Apoptosis, rather than necrosis, is the dominant mode of cell death, documented through caspase-3/-7 activation, mitochondrial involvement and cell-cycle analysis in several independent systems. Delivery, rather than intrinsic potency, is repeatedly identified as the rate-limiting step, most explicitly in the failure of binase peptides to enter A549 cells. And combination approaches consistently outperform single agents, whether the combination is enzymatic with oxidative, IRE1α inhibition with anti-VEGFA therapy, or bacterial carrier with quercetin payload.

The tensions are equally instructive. First, the relative contribution of catalytic and non-catalytic mechanisms is unresolved; the direct binding of binase to EGFR and RAS reported by Dudkina et al. (2024) is difficult to reconcile with a purely enzymatic account, and no study in the evidence base employs a catalytically dead mutant as a control, which is the obvious experiment [9]. Second, the compartmental divergence in microRNA levels reported by Mohamed et al. (2020) has no settled explanation [10]. Third, and most consequentially, there is a persistent gap between *in vitro* potency and *in vivo* or clinical efficacy. Cell-culture cytotoxicity in the eighty to ninety per cent range is routine in this literature, yet the two clinical trials produced a modest positive result in a small cohort and a negative primary endpoint in a larger one. This gap is not peculiar to ribonucleases, but its magnitude here is a reminder that cell-line data, however striking, forecast clinical performance poorly.

Limitations of the Present Review

The constraints noted in Section 2.6 bear on the confidence that can be placed in these conclusions. The evidence base of twenty sources, though it spans the principal lines of current enquiry, was assembled purposively rather than through an exhaustive systematic search, and publication bias towards positive findings is likely, particularly in the preclinical literature where negative cytotoxicity results are seldom reported. Extraction relied principally on published abstracts and summary data, which limited appraisal of methodological quality; no formal risk-of-bias assessment was applied, for the reasons of design heterogeneity already given. The synthesis is qualitative and interpretive, and different reviewers might reasonably weight the same studies differently. Finally, several of the included sources are single-laboratory reports whose findings await independent replication, a caveat that applies with particular force to the binase literature, in which a substantial proportion of the work originates from a small number of related research groups.

Future Perspectives

Several priorities follow directly from the analysis above. The most urgent is methodological. Comparison across studies is at present severely hampered by the absence of standardised activity units and assay conditions; activities are variously reported in U/mol and U/nmol, and cytotoxicity endpoints are measured by different assays at different time points. Adoption of a common reporting framework would materially improve the interpretability of the field.

Second, the catalytic and non-catalytic contributions to ribonuclease cytotoxicity must be disentangled. The experiment required is straightforward, namely parallel evaluation of active enzyme and a catalytically inactivated point mutant of identical sequence and fold, and its absence from the current literature is conspicuous. Third, the in vitro to in vivo gap demands attention. Three-dimensional spheroid models of the kind employed by Roy et al. (2025), together with patient-derived xenografts of the kind used by Harnoss et al. (2020), should become standard intermediate steps rather than optional refinements, and systematic toxicological and immunogenicity evaluation of microbial enzymes in animal models is a precondition of any clinical programme [7,19]. Fourth, clinical trial design should be reconstructed around biomarker-guided enrolment. The RSLV-132 experience indicates that ribonuclease therapy benefits patients with demonstrable pathway activation, and the relevant markers, including autoantibody status, interferon-inducible gene signatures and, in oncology, OAS1 expression, are measurable before randomisation.

Fifth, the combination strategies that recur throughout the preclinical literature should be pursued deliberately rather than opportunistically. Engineered inhibitor-evading variants delivered on targeted nanocarriers, ribonuclease therapy combined with agents that up regulate endogenous ribonuclease pathways, and receptor-targeted peptide conjugates derived from the binase 74–94 region all represent well-founded next steps. Finally, continued bioprospecting for novel ribonucleases from underexplored microbial and fungal sources, using the screening methodology exemplified by Jinu and Jayabaskaran (2015), remains a rational investment, given that the enzymes currently under study were themselves identified serendipitously [18].

CONCLUSION

The twenty studies synthesised in this review establish that ribonucleases have moved decisively beyond their traditional role as housekeeping enzymes and laboratory reagents to become credible candidates for therapeutic development in oncology, virology and autoimmune disease. The evidence supports four principal conclusions.
The cytosolic ribonuclease inhibitor, long the defining obstacle to the clinical use of mammalian ribonucleases, is now demonstrably surmountable. Rational mutagenesis has produced an engineered ovine enzyme that retains substantial activity under inhibitor concentrations that abolish the activity of native mammalian enzymes entirely, and it has done so without sacrificing catalytic efficiency. Microbial and fungal enzymes bypass the problem constitutively, and nanoparticle conjugation offers a third route that leaves the enzyme itself unaltered. The mechanisms through which these enzymes act are broader than RNA degradation alone. Binase interferes directly with EGFR and RAS signalling, reorganises tumour-associated microRNA networks, and exerts antiviral activity against RNA viruses of both polarities; peptide fragments derived from it retain cytotoxicity and appear to engage tumour-associated receptors. This mechanistic breadth is a therapeutic advantage, since agents acting simultaneously on several targets are less readily defeated by single-point resistance mutations, but it also means that the field cannot continue to reason as though catalysis were the whole story.

Endogenous ribonuclease pathways are themselves therapeutic targets of proven tractability. The dependence of 5-azacytidine cytotoxicity on the OAS-RNase L axis identifies OAS1 expression as a candidate predictive biomarker, while IRE1α inhibition reverses the adaptive response that has hitherto rendered antiangiogenic therapy ineffective in triple-negative breast cancer. Both findings extend the therapeutic reach of ribonuclease biology well beyond enzymes administered as drugs. Clinical translation, finally, is neither established nor refuted by the available trials. RSLV-132 improved fatigue across four independent measures in primary Sjögren's syndrome, yet failed its primary endpoint in systemic lupus erythematosus while showing consistent benefit in the subgroups with the most active disease. The most defensible reading of this pattern is that ribonuclease therapy works within a defined therapeutic window and that identifying patients who occupy it is now the central task of clinical development. Taken together, the evidence describes a field that has resolved its principal biochemical obstacle and accumulated substantial preclinical support, but that has not yet built the translational infrastructure of standardised assays, mechanistically informative controls, physiologically faithful models and biomarker-guided trials on which clinical success will depend. Building it is the work of the next decade.

Table 1: Characteristics and principal findings of the twenty studies included in the review

S. No.	Author(s) and Year	Enzyme / Model System	Principal Findings
1	Zabetian et al. (2026)	Engineered ovine pancreatic RNase A; in silico + in vitro; HeLa	Four rational mutations (D38R, R39D, N67R, G88R) conferred ribonuclease-inhibitor evasion; catalytic activity rose from 558 ± 22 to 674 ± 15 U/mol and retained 168 ± 19 U/nmol under 50 ng/µl RI, where native ovine and bovine enzymes were inert; greater cytotoxicity in MTT assay [5].
2	Harnoss et al. (2020)	IRE1α endoribonuclease in triple-negative breast	An XBP1s-dependent signature indicated pathway activation across solid tumours; IRE1α loss reversed endoplasmic

		cancer; xenografts	reticulum expansion and remodelled the tumour microenvironment; kinase inhibition synergised with anti-VEGFA therapy to produce stasis or regression [7].
3	Posada et al. (2021)	RSLV-132 (RNase–Fc fusion); phase II RCT; primary Sjögren's syndrome (n = 30)	Treated patients showed clinically meaningful gains in ESSPRI, FACIT-F, ProF and DSST from baseline to day 99, with the DSST reaching P = 0.02; improvement correlated with interferon-inducible gene expression; placebo group unchanged [15].
4	Banerjee et al. (2019)	OAS–RNase L pathway and 5-azacytidine cytotoxicity; NCI-60 panel	Cell death after demethylating-drug exposure proceeded through OAS–RNase L; RNase L- or OAS1-3-deficient cells were markedly resistant; OAS1 expression tracked drug sensitivity, suggesting a predictive biomarker [6].
5	Khiavi et al. (2019)	AuNPs–PEG–RNase A nanoconjugate; SW-480 colorectal carcinoma	Covalent conjugation to PEGylated gold nanoparticles delivered RNase A past the cytosolic inhibitor barrier; the construct triggered reactive oxygen species generation, apoptosis and a marked fall in viability at the IC50 dose [4].
6	Shah Mahmud et al. (2017)	Binase (*Bacillus pumilus*) antiviral action; A549 cells	Titres of influenza A (H1N1pdm) and human rhinovirus 1A fell by 40 % and 65 % respectively at a concentration that left host protein spectra and housekeeping gene expression intact; NP mRNA accumulation dropped by 20 % [11].
7	Dudkina et al. (2024)	Binase interaction with EGFR and RAS; MAPK cascade	Binase suppressed MAPK signalling through direct binding to two principal oncoproteins, adding a non-catalytic dimension to its antitumour action; multitargeting was proposed as a safeguard against acquired resistance [9].
8	Mohamed et al. (2020)	Binase and the miRNA network; RLS40 lymphosarcoma, murine model	In vitro apoptosis proceeded via caspase-3/-7 with reduced miR-21a, let-7g, miR-31 and miR-155; in vivo, primary tumour growth was retarded by up to 60 % and hepatic metastasis inhibited by up to 86 %[10].
9	Ulyanova et al. (2020)	Binase-derived synthetic peptides; HeLa, BT-20, MCF-7, A549	Peptides spanning residues 21–50 and 74–94 carried most of the cytotoxic potential; failure to enter A549 cells explained the absence of antiproliferative effect there; the 74–94 fragment resembles EGF, implying receptor-mediated selectivity [12].
10	Burge et al. (2024)	RSLV-132; phase 2a RCT; systemic lupus erythematosus (n = 65)	The primary CLASI endpoint was not met (−6.2 ± 8.5 versus −5.7 ± 7.0 for placebo); subgroups with high baseline SLEDAI or CLASI scores showed higher BICLA and SRI-4 response rates, indicating that patient selection governs benefit [14].
11	Kanwar et al. (2016)	Narrative review; classification and applications of RNases	Sets out the endoribonuclease/exoribonuclease division, the central place of the pancreatic RNase A superfamily, and the widening reach of these enzymes into medicinal, clinical and analytical chemistry; notes antimicrobial roles for RNase 6 and 7 [1].
12	Hameş and Demir (2015)	Narrative review; microbial RNase production and application	Argues that microbial enzymes match animal-derived counterparts in cytotoxic potency while avoiding their safety and regulatory burden; surveys fermentation optimisation, immobilisation and strain development for scale-up [2].
13	Shruti et al. (2016)	Narrative review; therapeutic effects of ribonucleases	Catalogues antitumour, antifungal, antiviral and immunosuppressive activities; identifies onconase as the only ribonuclease to have reached clinical evaluation, and EDN and ECP (RNases 2 and 3) as effectors of antiviral immunity [3].
14	Dubey et al. (2022)	Narrative review; nano-enabled CRISPR-Cas	Frames the delivery problem shared by all nucleic-acid-directed therapeutics and proposes tailored polymeric nanoparticles as

		diagnostics and therapy	an alternative to viral vectors, avoiding immunogenicity and insertional oncogenesis [16].
15	El-Garawani et al. (2020)	*Candelariella vitellina* lichen extract; HPBL, *Echinococcus granulosus*	The hydromethanolic extract was near-inert towards normal lymphocytes (IC50 > 1000 μg/mL) yet antigenotoxic against mitomycin C and scolicidal in a dose- and time-dependent manner; GC-MS and HPLC identified phenolic acids and light flavonoids [17].
16	Jinu and Jayabaskaran (2015)	Endophytic fungi of *Saracaasoca*; HeLa, HepG2, PC3	Thirty-seven isolates across 22 genera were screened; 18 showed appreciable cytotoxicity, and the *Pestalotiopsis* sp. 6 ethyl acetate extract induced mitochondria-dependent apoptosis in HeLa cells in a dose-dependent fashion [18].
17	Priyanka et al. (2022)	Purification and immobilisation of *Bacillus* sp. RB-3 RNase; Hep-2C	A single 28 kDa band confirmed purity; FTIR verified immobilisation on Moringa gum–polyvinyl alcohol hydrogel; optima were 37 °C, 30 min and pH 7.4, with substrate optima of 150 and 200 μg/mL for bound and free enzyme [8].
18	Lampitella et al. (2021)	Ageritin, a fungal ribotoxin-like protein; liposome models	Cleaves a single phosphodiester bond in the sarcin/ricin loop, arresting translation early; interaction with DPPC/DPPS/Chol and DPPC/DPPG vesicles indicated preference for anionic lipids, with cholesterol redistribution underlying tumour selectivity [13].
19	Roy et al. ABSTRACT

Syndet (synthetic detergent) bars are gaining popularity as alternatives to conventional alkaline soaps in which surfactant chemistry, formulation pH, and functional excipients can be adjusted to balance cleansing performance and skin compatibility. This review offers a detailed examination of syndet bars, focusing on their chemistry, skin physiology related to cleansing, surfactant systems, functional ingredients, manufacturing processes, and evaluation metrics. It discusses the structural and functional aspects of the stratum corneum, acid mantle, skin microbiome, natural moisturizing factors, and sebum in connection to how cleansing might impact skin-barrier. The chemistry of conventional soaps is compared with syndet systems, followed by discussion of anionic, amphoteric, nonionic, and cationic surfactants and the principles governing surfactant selection. Functional ingredients, including humectants, emollients, occlusives, barrier-supportive materials, chelating agents, preservatives, antioxidants, fragrances, and colourants, are considered in relation to their formulation roles and limitations. Manufacturing approaches and key quality attributes for syndet bars include physical integrity, pH, moisture, foaming, cleansing efficiency, stability, and skin tolerability are also explained. Recent literature supports continued development of mild cleansing systems, but also shows that claims of superior mildness, biodegradability, or dermatological benefit must be supported by evidence for the complete formulation. Future development of cleansing bars necessitates a balanced approach that considers cleansing effectiveness, skin compatibility, formulation stability, consumer preferences, safety, and sustainability.

Keywords: Syndet bars; synthetic detergents; skin cleansing; surfactants; skin barrier; functional ingredients; cosmetics.

INTRODUCTION

The skin is the body's largest organ and acts as the main barrier between our internal and external environments. It fulfills various critical physiological roles, such as protecting against physical, chemical, and microbial damage, regulating body temperature, enabling sensory perception, preventing transepidermal water loss (TEWL), and maintaining immune balance. The integrity of the skin barrier, especially the stratum corneum, is crucial for sustaining these functions. The stratum corneum is made up of corneocytes held within a lipid-rich extracellular matrix mainly composed of ceramides, cholesterol, and free fatty acids, often illustrated by the "brick-and-mortar" model of skin barrier structure. [1,2] Skin cleansing is a key aspect of personal hygiene and dermatological care. An effective cleanser should adequately remove dirt, sweat, excess oil, microorganisms, pollutants, and cosmetic residues without compromising the skin barrier's structural and functional integrity. However, frequent use of harsh cleansing products can deplete essential lipids and natural moisturizing factors in the epidermis, increase transepidermal water loss, disrupt the skin's surface pH, and lead to dryness and irritation, especially for those with sensitive or barrier-impaired skin. [4,5,11] For centuries, conventional soaps have been favored for their effective cleansing properties, ease of production, and relatively low cost. These soaps are created through the saponification of fats or oils with an alkali, resulting in an alkaline pH. However, frequent usage of these alkaline soaps can disturb the skin's natural acidic pH, weaken the epidermal barrier, denature skin proteins, remove intercellular lipids, and elevate transepidermal water loss. These effects are particularly significant in individuals with sensitive skin or with conditions like acne vulgaris, atopic dermatitis, xerosis, psoriasis, and other inflammatory skin disorders.[3-5,7,8]

The drawbacks of traditional soaps have led to the rise of synthetic detergent bars, known as syndet bars. These are created with synthetic surfactants chosen for their gentleness, high cleansing capability, and dermatological friendliness. Syndet bars typically have a neutral to mildly acidic pH, making them less likely to disturb the skin barrier compared to alkaline soaps. Their gentleness depends on the surfactant types and concentrations, as well as the other ingredients used in the formulation. Innovations in surfactant technology have allowed for the combination of gentle anionic, amphoteric, and nonionic surfactants with humectants, emollients, moisturizers, and conditioning agents, resulting in multifunctional cleansing systems that combine effective cleansing with skin hydration and barrier protection. Growing interest in skin-barrier health has increased attention to mild cleansing products, particularly for individuals with sensitive or barrier-impaired skin. As a result, mild, low-pH cleansing products are often preferred for individuals with sensitive or barrier-impaired skin because they may reduce irritation and minimize disruption of the skin barrier. Furthermore, recent formulation research has explored the incorporation of herbal extracts, naturally derived bioactive compounds, antioxidants, ceramides, and other functional ingredients into syndet systems. However, the dermatological benefits and ecological advantages of these products are contingent on the specific surfactants, excipients, packaging materials, and production techniques employed. [4-10]
Therefore, this review aims to provide a comprehensive overview of syndet bars, including their formulation strategies, surfactant systems, functional ingredients, manufacturing technologies, and evaluation parameters.

Skin Physiology Relevant To Cleansing

Structure of the Skin:

The skin is the largest organ in the body and serves as a critical interface between the internal body and the external environment. It provides protection against mechanical, chemical, immunological, and microbial threats; helps regulate body temperature; enables sensory perception; facilitates vitamin D synthesis; prevents excessive water loss; and plays a role in maintaining homeostasis. Structurally, the skin is primarily composed of the epidermis and dermis, layered over the subcutaneous tissue or hypodermis. The epidermis features a stratified squamous epithelium largely made up of keratinocytes, while the dermis contains connective tissue, blood vessels, lymphatic vessels, nerves, and skin appendages. The hypodermis, which consists mainly of fat and connective tissue, provides cushioning, insulation, and energy reserves. The epidermis is divided into several layers: the stratum basale, stratum

spinosum, stratum granulosum, and stratum corneum. Among these, the stratum corneum is crucial for cleansing as it acts as the primary barrier between the skin and cleansing agents.[1,2,3]

Stratum Corneum

The stratum corneum, the outermost layer of the epidermis, serves as the main barrier to skin permeability. It comprises terminally differentiated keratinocytes known as corneocytes that are embedded within a structured extracellular lipid matrix. This matrix is often described using the "brick-and-mortar" model, where corneocytes act as bricks and the lipid matrix serves as the mortar. The primary intercellular lipids include ceramides, cholesterol, and free fatty acids. The organized makeup of the stratum corneum is vital for regulating transepidermal water loss (TEWL), maintaining skin hydration, and preventing harmful substances and microorganisms from penetrating the skin. Frequent exposure to harsh or highly alkaline cleansers can extract intercellular lipids, alter corneocyte proteins, induce corneocyte swelling, and disturb the lipid matrix organization. These changes may lead to dryness, roughness, irritation, increased TEWL,and impaired barrier function.
[1-5]

Acid Mantle

The surface of the skin is covered with a thin, slightly acidic hydrolipidic film commonly known as the acid mantle. This film consists of sebum, sweat, epidermal lipids, components of the natural moisturizing factor, and other acidic metabolites. In healthy adult skin, the surface pH typically remains acidic, around 4.0–6.0, although it can vary based on location, age, body area, health status, and measurement conditions. This acidic environment contributes to the epidermal barrier's integrity, regulates the desquamation, facilitates the activity of lipid-processing enzymes, and enhances the skin's antimicrobial defense. It also influences the composition and behavior of resident microorganisms. Conventional alkaline soaps may temporarily raise the skin's surface pH after washing, which can cause corneocyte swelling, disrupt enzyme activity, affect lipid organization, and hinder the recovery of the barrier. Syndet formulations can be adjusted to have a pH more aligned with that of healthy skin, making them preferable for regular cleansing, especially for individuals with sensitive or diseased skin. However, the impact of a cleanser is influenced by several factors, including not only pH but also surfactant type and concentration, duration of contact, washing frequency, water temperature, and the condition of the skin barrier. Consequently, simply having a near-skin pH does not guarantee that a formulation is mild. [5-9,14,15]

Skin Microbiome

The skin microbiome comprises a diverse array of bacteria, fungi, viruses, and microscopic eukaryotes that inhabit various skin regions. Its composition is influenced by local factors such as moisture, temperature, sebum production, pH, age, body area, and environmental exposure. Common bacterial species include those from the genera Staphylococcus,Cutibacterium, and Corynebacterium, with their presence varying between oily, moist, and dry areas. The resident microbiota plays a vital role in preventing pathogen colonization, regulating the immune system, producing microbial metabolites, and maintaining the cutaneous ecosystem. Changes in microbial composition and function are linked to inflammatory and dermatological conditions such as atopic dermatitis, acne, psoriasis, and rosacea. Nevertheless, many reported relationships are associative, and the direction of causality between microbiome alterations and disease is not always established. Excessive cleansing, repeated exposure to harsh surfactants, the use of alkaline products, and inappropriate use of antimicrobial agents can disrupt the skin microbiome and barrier function. Therefore, mild syndet formulations may provide a gentler cleansing method that minimizes unnecessary disruption of skin pH, barrier lipids, and resident microbiota.[16,17]

Natural Moisturizing Factor

Natural moisturizing factor (NMF) is a collection of low-molecular-weight, water-soluble, hygroscopic substances primarily found within corneocytes. NMF is largely formed through the enzymatic breakdown of filaggrin and comprises free amino acids, pyrrolidone carboxylic acid, urocanic acid, lactate, urea, electrolytes, and sugars. NMF plays a crucial role in binding water within the stratum corneum, contributing to hydration, flexibility, and the optimal functioning of enzymes essential for corneocyte maturation and shedding. A reduction in NMF can lead to

decreased hydration and impaired barrier function, particularly in dry skin and certain inflammatory conditions. Harsh cleansing can remove water-soluble components of NMF from the skin, resulting in roughness, scaling, tightness, and increased TEWL. For this reason, syndet bars and similar cleansing products often include humectants like glycerol, sorbitol, urea, or sodium PCA, which aid in hydration, although their effectiveness is influenced by concentration, formulation design, rinsing exposure, and the overall state of the skin barrier.[18,19]

Sebum Physiology

Sebum is an oily substance secreted by holocrine sebaceous glands associated with hair follicles. It consists primarily of triglycerides, fatty acids, wax esters, squalene, cholesterol, cholesterol esters, and cellular debris. Sebum helps lubricate the skin and hair, contributes to the formation of a hydrolipidic film on the surface, decreases water loss, and provides antimicrobial and antioxidant properties. Sebum production is influenced by factors such as age, hormonal levels, genetics, anatomical site, and other physiological factors. Increased sebum production and changes in its composition are significant contributors to acne development, while reduced sebum production in older adults can lead to dry skin and increased skin fragility. [20,21] An effective cleanser should effectively remove excess sebum, dirt, and environmental debris without excessively extracting protective skin lipids. Mild syndet formulations may achieve a better balance than traditional alkaline soaps, as their surfactant systems and pH can be selected to reduce lipid removal and irritation. However, assessing a cleanser's mildness should be based on parameters like skin pH, TEWL, hydration, erythema, irritation, and lipid removal, rather than relying solely on its classification as a syndet.

Soap and Syndet: Chemistry and Comparison

Chemistry of Soap

Soap is a cleansing agent created through the process of saponification, which involves reacting fats or oils with a strong alkali, typically sodium hydroxide or potassium hydroxide. This reaction hydrolyzes triglycerides to yield glycerol and the sodium or potassium salts of fatty acids, resulting in soap. Sodium-based soaps tend to be harder and are often used in solid cleansing bars, while potassium-based soaps are softer and more soluble in water. The physicochemical properties of soap are influenced by the fatty-acid composition of the fats or oils used in its production. The final product's characteristics can also be influenced by the manufacturing process, formulation composition, residual alkali, water hardness, and specific usage conditions. Soap molecules exhibit amphiphilic properties, and contain a hydrophobic hydrocarbon chain and a hydrophilic ionic carboxylate group. When present in sufficient concentrations in water, these molecules can form micelles or other aggregate structures that promote the interaction with and removal of oily substances during rinsing. The cleansing efficacy of soap is linked to its ability to reduce surface tension and emulsify or disperse oils, sebum, and other impurities on the skin. The level of cleansing achieved depends on factors such as soap composition, concentration, washing duration, frequency, and usage conditions.Typically, conventional soaps have an alkaline pH ranging from approximately 8.5 to 11.0, although this can vary among products. Because the surface of healthy skin is acidic, repeated exposure to alkaline cleansers may increase skin-surface pH and influence the structure and function of the stratum corneum. Alkaline or harsh cleansing systems can damage the proteins and lipids in the stratum corneum, leading to dryness, irritation, increased transepidermal water loss (TEWL), and compromised barrier function, especially with repeated use or on sensitive skin. An in-use study indicated that alkaline soap increased TEWL and skin pH, resulting in greater erythema compared to other cleansing products. However, these findings should not suggest that all soaps produce the same effects, as they depend on the specific formulation and usage conditions. Additionally, soap can react with calcium and magnesium ions present in hard water, forming poorly soluble fatty-acid salts known as soap scum. This can affect rinsability and lead to residue on cleaned surfaces. [22]

Chemistry of Syndets

The term "syndet" is derived from "synthetic detergent." Unlike conventional soap, syndet bars are mostly made using synthetic surfactants instead of the fatty-acid salts derived from triglycerides via saponification. Syndet

formulations can incorporate anionic, amphoteric, nonionic, or cationic surfactants, with anionic and amphoteric types frequently found in skin-cleansing products. Examples of surfactants used in syndet formulations include sodium cocoyl isethionate, sodium lauroylsarcosinate, and cocamidopropyl betaine. The choice and combination of surfactants in syndet formulations aim to strike a balance between cleansing efficacy, foaming ability, processing characteristics, formulation stability, and skin tolerance.[23–25] Similar to soap molecules, syndet surfactants are also amphiphilic and can form micelles or other aggregates in an aqueous environment, which aids in emulsifying and dispersing oily and particulate materials on the skin. Syndet bars can be formulated to have a range of pH values, often reported to be slightly acidic to neutral, between 5.5 to 7.0. This pH range aligns more closely with the normal acidic condition of healthy skin compared to the alkaline nature of conventional soap. The use of a mildly acidic or neutral pH helps minimize the impact of cleansing on skin pH and barrier function. However, it's important to note that pH alone does not determine gentleness of a cleanser; factors such as surfactant type, concentration, formulation, exposure duration, and frequency of use also affect skin tolerance. Syndet bars may include additional components such as humectants, emollients, fillers, preservatives, and skin-conditioning agents.

Comparison Between Soap and Syndet

Both soap-based and syndet cleansers contain surfactants and serve to remove dirt, sebum, and impurities from the skin. The key chemical distinction lies in that traditional soap is primarily composed of fatty-acid salts from saponification, while syndets include synthetic surfactants produced through various chemical methods. A significant difference between these two categories is their pH. Conventional soaps are usually alkaline, while syndets are typically formulated to be slightly acidic to neutral. The commonly reported ranges of approximately 8.5–10.0 for soaps and 5.5–7.0 for syndets are general values and should not be assumed to apply to every product [28]. The higher alkalinity of conventional soap can elevate skin-surface pH and potentially alter the proteins, lipids, and barrier function of the stratum corneum, especially with frequent use or in individuals with sensitive skin. Syndets can be designed for effective cleansing with a lower risk of irritation or barrier disruption compared to highly alkaline soaps. In a comparative in-use study, alkaline soap produced increases in TEWL and skin pH, while the tested syndet produced different effects on these parameters. Because the study examined specific products under specific conditions, its results should not be interpreted as proof that all syndet bars are milder than all soaps. Syndets may have an advantage in hard water because synthetic surfactants do not generally form the same insoluble calcium and magnesium fatty-acid salts characteristic of conventional soap. Nevertheless, the performance of a particular syndet in hard water depends on its complete formulation. [22]

Syndets also provide greater formulation flexibility because the surfactant system, pH, and other excipients can be selected to modify cleansing performance and tolerability. However, the term “syndet” does not guarantee that a product will be non-irritating or barrier-protective, because the tolerability of a syndet depends on its specific composition and conditions of use, However, a carefully formulated mild syndet may be preferred over a strongly alkaline soap when the aim is to minimize dryness or maintain skin barrier function. This is a formulation-dependent preference rather than as an absolute statement that all syndets are superior to all soaps. Ultimately, the choice of cleanser should take into account the product’s composition, pH, intended purpose, frequency of use, water conditions, and individual skin tolerance. Conventional soaps remain valuable cleansing options, while syndet bars offer increased flexibility for creating formulations with optimized surfactant systems and pH levels that enhance skin compatibility.

Surfactants Utilized in Syndet Bars

Surfactants serve as the primary cleansing agents in syndet bars. They lower interfacial tension and aid in the emulsification, dispersion, and removal of sebum, dirt, and other impurities from the skin. Structurally, surfactants are amphiphilic molecules that consist of a hydrophilic (water-attracting) part and a hydrophobic (water-repelling) part. When the concentration of surfactants exceeds the critical micelle concentration, they can form micelles or aggregates that help in incorporating and washing away oily substances during rinsing. The choice of surfactants for syndet formulations is influenced by various factors such as cleansing efficiency, foaming properties, skin

compatibility, interplay with other ingredients, manufacturing capabilities, formulation stability, and the intended application of the product. Environmental impact and biodegradability are also considerations, although these properties should be evaluated based on the specific surfactant and its production method rather than merely on its nomenclature or natural origin. Unlike traditional soaps that are created from fatty-acid salts through saponification, syndet bars utilize synthetic surfactants manufactured by different processes. Formulations can include a single surfactant or a blend of several, allowing for a balanced approach to cleansing, foaming, gentleness, bar integrity, and stability.

Classification of Surfactants:

Surfactants are commonly classified according to the electrical charge of their hydrophilic group as anionic, amphoteric, nonionic, or cationic surfactants. Anionic surfactants carry a negative charge and are widely used as primary cleansing agents because they generally provide effective detergency and foaming. Amphoteric surfactants may carry either a positive or negative charge, depending on the molecular structure and pH, and are frequently used in combination with anionic surfactants. Nonionic surfactants have no electrical charge and may contribute to cleansing, emulsification, and formulation compatibility. Cationic surfactants carry a positive charge. They are generally used more often for conditioning, antistatic, or antimicrobial functions than as the principal cleansing surfactant in skin-cleansing products. Their suitability depends on the specific compound, concentration, and formulation.

Anionic Surfactants: Anionic surfactants possess a negatively charged hydrophilic group and are commonly found in cleansing products because they effectively remove oily and particulate soil and can generate substantial foam. However, their skin compatibility can vary significantly depending on their chemical structure, combination with other surfactants, and the conditions of use. [26]

Amphoteric Surfactants: Amphoteric surfactants contain molecular groups that can exhibit positive or negative charge depending on their chemical structure and the pH of the formulation. They are commonly used with anionic surfactants to modify foaming, cleansing performance, viscosity, and skin tolerability.

Nonionic Surfactants: Nonionic surfactants contain hydrophilic groups that do not carry a formal electrical charge. They are generally compatible with a range of other surfactants and may contribute to cleansing, emulsification, solubilisation, and formulation stability.

Cationic Surfactants: Cationic surfactants contain positively charged groups, commonly quaternary ammonium groups. They are used primarily for conditioning, antistatic, or antimicrobial functions rather than as the principal cleansing agents in most skin-cleansing products. [26]

Functional Ingredients in Syndet Bars

Functional ingredients are added to syndet bars to enhance their performance beyond cleansing, aiming to boost skin hydration, strengthen barrier protection, improve product stability, refine sensory attributes, and ensure overall dermatological compatibility. These components work synergistically with surfactants to minimize any disruption to the skin barrier and maintain its physiological condition during frequent cleansing. Modern syndet formulations are thus crafted as multifunctional cleansing systems designed not only to eliminate dirt and oils but also to safeguard the skin barrier and promote skin health.

Humectants

Humectants are substances that draw moisture into the stratum corneum and help retain it, thereby enhancing skin hydration and reducing transepidermal water loss (TEWL). Their incorporation into syndet bars compensates for the drying effect associated with cleansing and helps maintain skin softness and elasticity. Commonly used humectants include glycerin, sorbitol, sodium pyrrolidone carboxylate (sodium PCA), propylene glycol, urea, and hyaluronic

acid, with glycerin being the most popular due to its excellent compatibility with surfactants and its ability to enhance skin hydration and sensory characteristics.[18]

Emollients

Emollients contribute to smoothness and flexibility to the skin by filling in spaces between desquamating corneocytes and reinforcing the lipid matrix of the stratum corneum. They help reduce roughness and improve the feel of the skin after cleansing. Commonly used emollients include fatty alcohols (like cetyl and stearyl alcohols), caprylic/capric triglycerides, mineral oil, squalane, shea butter, and various plant oils such as coconut, jojoba, sunflower, and almond oils. The presence of emollients is particularly advantageous in syndet bars aimed for dry and sensitive skin types. [29]

Occlusive Agents

Occlusive agents create a thin hydrophobic layer on the skin's surface that minimizes water evaporation and helps retain moisture. These agents are particularly beneficial in syndet formulations designed for conditions like xerosis and atopic dermatitis. Commonly utilized occlusives include petrolatum, dimethicone, lanolin derivatives, and squalane. Silicone-based occlusives like dimethicone not only provide a protective layer but also enhance the sensory experience of the product.

Barrier

Protective Ingredients: Preservation of the skin barrier has become a primary objective in modern cleanser formulation. As a result, syndet bars increasingly incorporate ingredients that aid in barrier repair and hydration. Topical formulations that contain ceramides, cholesterol, and free fatty acids have been investigated to support the function of the skin barrier. These barrier-supportive formulations are especially beneficial for individuals with sensitive skin or inflammatory conditions like atopic dermatitis and psoriasis.[28,29]

Chelating Agents

Chelating agents enhance formulation stability by binding to polyvalent metal ions such as calcium and magnesium, which can interfere with surfactant efficacy in hard water. Disodium EDTA, tetrasodium EDTA, sodium phytate, and citric acid are commonly used for this purpose. Besides enhancing cleansing effectiveness, chelating agents help reduce oxidative degradation and contribute to overall formulation stability.

Preservatives

Although many syndet bars typically have lower water activity than liquid cleansers, preservatives are sometimes necessary to prevent microbial contamination during manufacturing, storage, and consumer use. Common preservatives include phenoxyethanol, sodium benzoate, potassium sorbate, and ethylhexylglycerin. Selection of preservatives is based on formulation pH, compatibility with surfactants, antimicrobial spectrum, and regulatory acceptance. There is also increasing interest in multifunctional ingredients and naturally derived preservation systems that provide antimicrobial activity while minimizing irritation.

Antioxidants

Antioxidants are included to protect both the formulation and the skin from oxidative damage, preventing the oxidation of lipids and fragrances to enhance product stability and shelf life. Frequently used antioxidants include tocopherol (vitamin E), ascorbyl palmitate, rosemary extract, and green tea polyphenols.

Fragrances and Colourants:

Fragrances and colourants enhance the aesthetic appeal and consumer acceptance of the product. When formulating for sensitive or compromised skin, it is essential to consider potential allergic reactions and irritations caused by fragrances. Only safe, approved cosmetic-grade colourants should be used to ensure regulatory compliance and product safety. [28]

Manufacturing Technologies of Syndet

The production of syndet bars is distinct from that of traditional soap, as syndets are not primarily made through the saponification of fats or oils. Instead, syndet bars are created by blending synthetic surfactants with structural components, processing aids, humectants, emollients, fragrances, colorants, preservatives, and various functional ingredients. This mixture is then transformed into a uniform solid product using processes like mixing, refining or milling, extrusion or plodding, cutting, and stamping. The manufacturing sequence is formulation-dependent. Some syndet bars are processed through a conventional finishing line involving refining, vacuum plodding, cutting, and stamping, whereas other formulations may be produced by hot mixing, moulding, compression, or alternative extrusion processes.[30–34]

Quality Assessment of Syndet Bars

Quality control of syndet bars should include evaluation of their physical characteristics, physicochemical properties, cleansing performance, durability and skin compatibility. Relevant parameters may include appearance, weight variation, hardness, friability, pH, moisture content, foamability, foam stability, cleansing efficiency, washability, rate of wear, mush formation, stability and skin irritation. The selection of tests should be based on the intended formulation, manufacturing process and product claims**.**

CONCLUSION

Syndet bars signify a significant leap in skin-cleansing technology, providing more formulation versatility compared to traditional alkaline soaps. Their ability to incorporate carefully selected surfactants, functional ingredients, and skin-conditioning agents allows the formulation of cleansing products with an appropriate balance of cleansing efficacy, skin tolerability, sensory properties, and product stability. Nonetheless, the effect of a syndet bar on the skin arises from its entire formulation which includes the type and concentration of surfactants, pH, functional ingredients, manufacturing conditions, and frequency of use. Therefore, a thorough understanding of the stratum corneum, acid mantle, skin microbiome, natural moisturizing factor, and sebum physiology is crucial for effective formulation development.

ABSTRACT

Secularism is a cornerstone of India's Constitution, safeguarding equality, liberty, and religious freedom. Yet, contemporary India faces rising communal polarization, political exploitation of religion, and targeted violence against minorities, particularly Christians and Muslims. Incidents such as the Gujarat riots, church attacks in Odisha, harassment of Christian nuns in Chhattisgarh, and the custodial deaths illustrate the erosion of constitutional guarantees. At the same time, civil society movements, volunteer initiatives, Tamil Nadu's social justice programs, and the advocacy of social activists demonstrate persistent resistance. This study examines the acceptance and challenges of secularism in India through a constitutional and human rights lens, analyzing both fundamentalist aggression and civic counter-movements. It argues that safeguarding secularism is both a legal duty and a moral necessity to preserve India's pluralistic heritage and the democratic promise of unity in diversity.

Keywords: Indian secularism - Human rights and Constitution - Religious violence in India - Minority rights - Political voices for secularism - Civic movements and social justice

INTRODUCTION

The national identity of India and the philosophical foundations of the Indian Constitution rest upon the principle of coexistence, where diverse religions, languages, and cultural traditions are accommodated within a democratic framework of equality and freedom. This constitutional vision, articulated through the doctrine of secularism,

represents not merely a political arrangement but a normative commitment to pluralism and mutual respect among communities. Unlike the strict separation of religion and state found in certain Western models, Indian secularism has evolved as a distinctive constitutional framework that recognizes religious diversity while ensuring state neutrality and equal protection of all faiths. The framers of the Constitution envisioned secularism as an essential component of democratic governance, safeguarding both individual religious freedom and collective harmony within a plural society. As emphasized by B. R. Ambedkar during the Constituent Assembly debates, the success of the Constitution ultimately depends on the practice of constitutional morality and the protection of minority rights within democratic institutions.

The framers of the Constitution envisioned secularism as an essential component of democratic governance, safeguarding both individual religious freedom and collective harmony within a plural society. Constitutional provisions such as Articles 14, 15, 25, and 26 guarantee equality before law and freedom of religion, there by establishing the legal foundation for a secular state committed to protecting the rights and dignity of every citizen. Over the decades, the Indian judiciary has played a significant role in interpreting these constitutional guarantees and in reinforcing secular principles through landmark judgments. Despite this constitutional framework, contemporary India has witnessed increasing debates regarding the practice and sustainability of secularism. Incidents of communal tension, religious polarization, and challenges to minority rights have generated widespread scholarly and public discussion concerning the resilience of secular values within democratic institutions. Reports of communal violence in several regions, attacks on religious institutions, and controversies surrounding the treatment of minority communities have raised concerns regarding the effective implementation of constitutional protections. These developments highlight the tension that sometimes emerges between constitutional ideals and socio-political realities. In recent years, several incidents across different states have drawn attention to the vulnerability of religious minorities and the contested nature of secular governance. Instances such as communal violence in parts of northern and western India, attacks on Christian institutions in Odisha, and the arrest of Christian nuns in Chhattisgarh have sparked debates within civil society and international human rights circles. Similarly, the arrest and subsequent death in custody of the Jesuit priest and human rights activist Father Stan Swamy in Maharashtra generated significant concern regarding civil liberties and the protection of dissent in democratic societies. These developments demonstrate the continuing challenges faced by constitutional secularism when confronted with political mobilization based on religious identity.

Nevertheless, Indian democracy continues to witness significant efforts by civil society organizations, academic communities, and constitutional institutions to uphold secular values and protect minority rights. Public intellectuals, social movements, and legal scholars have repeatedly emphasized the importance of preserving India's pluralistic heritage and ensuring that democratic institutions function in accordance with constitutional morality. As noted by the economist and philosopher Amartya Sen, India's democratic resilience depends not only on formal institutions but also on the willingness of its citizens to defend traditions of dialogue, tolerance, and inclusivity. This article seeks to examine the evolving role of the Indian judiciary in interpreting and safeguarding the constitutional principle of secularism within a human rights framework. While the normative importance of secularism has been widely acknowledged in Indian constitutional scholarship, this study contributes to the literature by analyzing how contemporary judicial interventions, constitutional doctrines, and socio-political developments interact in shaping the operational meaning of secularism in India. By integrating doctrinal constitutional analysis with selected contemporary case studies, the article evaluates whether judicial reasoning continues to function as a protective mechanism for pluralism, minority rights, and constitutional morality in contemporary India.

Research Question and Objectives

The central research question guiding this study is:

- How does the constitutional framework of India interpret and safeguard secularism in the context of contemporary social and political challenges?

- How has the Indian judiciary interpreted and operationalized the constitutional principle of secularism in contemporary India, and to what extent does judicial intervention function as an effective safeguard for religious freedom and minority rights within the framework of constitutional human rights protections?

To address this question, the study pursues the following objectives:

- To examine the constitutional foundations of secularism in India.
- To analyse the relationship between secularism and human rights protections.
- To explore contemporary challenges to secular constitutional values in India.
- To evaluate the role of civic movements and constitutional institutions in preserving secular democratic principles.
- To read in what extent judicial decisions reinforce or reinterpret the basic structure doctrine in relation to secularism?
- To reveal how the recent socio-political developments challenge the constitutional understanding of secularism?

Conceptual Definition of Secularism

In the Indian constitutional context, secularism does not imply a rigid separation between religion and the state, as observed in certain Western constitutional models. Rather, the Indian model is characterized by a principle of principled equidistance or equal respect for all religions, whereby the state maintains neutrality among religious communities while simultaneously safeguarding religious freedom, equality, and the dignity of all citizens. Scholars of Indian constitutionalism have argued that this model reflects a historically grounded and context-sensitive approach to managing religious diversity within a democratic framework. The Supreme Court of India has repeatedly affirmed that secularism forms an integral part of the basic structure of the Constitution, thereby placing it beyond the scope of constitutional amendment. This position was authoritatively articulated in the landmark judgment of S.R. Bommai v. Union of India where the Court held that secularism constitutes a foundational principle of the Indian constitutional order and that the state must remain neutral in matters of religion while guaranteeing equal protection to all religious communities. Indian secularism therefore embodies a constitutional commitment to pluralism, minority protection, and equal respect for all faith traditions, emphasizing the state's duty to maintain neutrality while protecting the fundamental rights of citizens irrespective of their religious affiliation.

LITERATURE REVIEW

The study of secularism in India has attracted wide scholarly attention across disciplines. Rajeev Bhargava (2010) argues that Indian secularism is distinct from its Western counterpart, as it is based on the principle of "principled distance" rather than strict separation, thereby allowing for state engagement with religion when necessary to uphold justice. Neera Chandhoke (2019) extends this argument by highlighting the anxieties of pluralism, where secularism and tolerance must constantly negotiate the pressures of majoritarian politics. From the perspective of human rights and minority protection, Anto Akkara (2019) documents the violence faced by Christians in Kandhamal and beyond, framing them as the "early Christians of 21st century India". Human Rights Watch (2021) similarly notes the deteriorating conditions for religious minorities, particularly Muslims and Christians, under contemporary state and societal pressures. Christophe Jaffrelot (2021) provides a broader political reading, analyzing how Hindu nationalism has transformed India into a form of "ethnic democracy". Classical constitutional perspectives remain central to the discourse. Granville Austin (2005) underscores secularism as a "cornerstone of the nation", while Bipan Chandra et al. (2008) trace how post-independence politics attempted to balance unity with diversity. The Indian Constitution itself, through Articles 14, 15, 19, and 25-28, provides the framework for equality, non-discrimination, and freedom of religion. Ambedkar's speeches in the Constituent Assembly (1949) and his writings, such as *Annihilation of Caste* (2014), remain essential to understanding the ethical basis of secularism and human rights in India. Global human rights frameworks also support this inquiry. The Universal Declaration of Human Rights (1948) and the International Covenant on Civil and Political Rights (1966) both guarantee freedom of religion under Article 18. Amartya Sen (2000) and Martha

Nussbaum (2011) further enrich the debate by linking secularism with freedom, capabilities, and the ethical obligations of democratic societies (Sen 2000, Nussbaum 2011). At the level of state initiatives, the Government of Tamil Nadu (2022) has introduced educational policies that actively promote pluralism and social justice. John Harriss (2016) and Zoya Hasan (2009) also demonstrate how affirmative action and social justice policies contribute to sustaining secular values in diverse societies. Taken together, this body of literature illustrates that secularism in India is not merely a constitutional principle but also an ethical and human rights imperative, continuously challenged and reshaped by political power, societal conflict, and civil society movements.

METHODOLOGY

This study adopts a qualitative, doctrinal, and analytical research approach. The selection of sources in this study follows three principal criteria. First, primary constitutional sources such as the Constitution of India, Constituent Assembly Debates, and landmark judicial decisions were selected because they define the normative framework of secularism in India. Second, scholarly works by leading constitutional theorists and political philosophers were chosen based on their academic influence in debates on secularism, democracy, and pluralism. Third, contemporary journal articles, human rights reports, and policy documents published after 2000 were included in order to analyse recent developments and socio-political challenges affecting secular values in India. This approach ensures both historical depth and contemporary relevance in the study.

Sources of Information

Primary Sources

- The Constitution of India, parliamentary debates, reports of the National Human Rights Commission, Supreme Court and High Court judgments (e.g., *Kesavananda Bharati v. State of Kerala, S.R. Bommai v. Union of India*).
- Government policy documents such as the Policy Note on Higher Education (Government of Tamil Nadu, 2022) and reports of social justice initiatives.

Secondary Sources

- Books and writings of Ambedkar, Nehru, Tagore, and Bipan Chandra, alongside contemporary analyses by Rajeev Bhargava, Neera Chandhoke, Christophe Jaffrelot, Amartya Sen, and Ashis Nandy.
- Scholarly articles on secularism, human rights, and religious violence (e.g., John Dayal, Saba Naqvi, Subramaniyan J., Gino Battaglia, Sunil Dutta, Arun V. Unnithan).
- Reports of civil society movements and international human rights organizations (Human Rights Watch, 2021).

Analytical Framework

The analysis is guided by three constitutional interpretive frameworks commonly employed in Indian constitutional jurisprudence:

- Basic Structure Doctrine- which recognizes secularism as an essential feature of the Constitution that cannot be altered even by constitutional amendment.
- Constitutional Morality- a principle emphasized by the Supreme Court in interpreting fundamental rights in a manner that promotes dignity, equality, and pluralism.
- Proportionality and Reasonableness Tests- used by courts to balance religious freedom with other constitutional interests.

Delimitations of the Study

- The research is confined to the Indian context of secularism and does not extend to comparative studies with Western or Islamic secular models.
- Focus is given to selected states (Uttar Pradesh, Gujarat, Odisha, Tamil Nadu, Bihar, and Chhattisgarh) as case studies, rather than an exhaustive nationwide survey.
- The time frame emphasizes contemporary challenges (post-2000), while classical sources are used mainly for theoretical grounding.

- The study prioritizes qualitative analysis of constitutional and ethical dimensions, rather than statistical or survey-based quantitative methods.

Case Selection Criteria

The case studies examined in this research were selected based on three criteria:

- Their relevance to constitutional interpretation of secularism and religious freedom.
- Their impact on public discourse and minority rights in contemporary India.
- Their judicial significance in shaping constitutional jurisprudence.

The selected cases include landmark judicial decisions such as S.R. Bommai v. Union of India (1994), Indian Young Lawyers Association v. State of Kerala (Sabarimala case, 2018), and other contemporary judicial interventions involving religious freedom and minority protection.

Significance of the Study

This research holds significance both in the academic field and in public life:

- It contributes to constitutional and political theory by analyzing Indian secularism not only as a political principle but also as an ethical and human rights mandate.
- By integrating works of Ambedkar, Nehru, Tagore, and contemporary thinkers like Rajeev Bhargava, Neera Chandhoke, Christophe Jaffrelot, and Amartya Sen, the study enriches the interdisciplinary scholarship on secularism.
- The study emphasizes secularism as part of the basic structure of the Constitution, strengthening debates on judicial interpretations and parliamentary practices.
- Case law analysis (e.g., *S.R. Bommai*, *Kesavananda Bharati*) helps clarify the judicial role in defending pluralism.
- By framing secularism as a human rights concern, the research demonstrates its role in safeguarding freedom of religion, equality, and dignity, thus connecting constitutional values with international human rights standards.
- The study is timely in the context of rising religious nationalism and the politicization of faith.
- By studying grassroots initiatives and Tamil Nadu's social justice educational policies, the research highlights the role of citizens and movements in sustaining secular democracy.
- It underscores that secularism is not merely a state principle but a shared ethical responsibility of society.
- The findings of the study may inform policymakers, educators, and human rights advocates in strengthening secular and pluralistic practices in governance, law, and civil society.
- It also provides critical insights for students and researchers exploring the intersections of law, politics, and human rights in India.

Findings

The doctrinal and case-based analysis undertaken in this study reveals three principal findings.

- First, Indian constitutional jurisprudence consistently recognizes secularism as an integral component of the Constitution's basic structure. Judicial decisions have repeatedly affirmed that state institutions must maintain religious neutrality while protecting minority rights.
- Second, contemporary socio-political developments have generated new challenges to the practical implementation of secular constitutional principles, particularly in contexts involving religious polarization and majoritarian political mobilization.
- Third, judicial interventions continue to play a crucial role in reaffirming constitutional commitments to pluralism and religious freedom, although the effectiveness of such interventions often depends on broader political and institutional contexts.

A Relevant and Responsible Academic Touch on Secularism

The academic discourse on secularism in contemporary research reflects the *signs of the times*, as it re-examines India's socio-political realities through a critical and authentic lens. The scope of this study is firmly rooted in the Indian Constitution and the framework of human rights, ensuring that its perspective remains both legal and ethical. The

very choice of this theme signals a deep social concern, one that resonates strongly within the present educational and civic discourse. To study secularism in light of the contemporary context is not a mere intellectual exercise, but a serious academic and civic responsibility. As one of the fundamental spirits of the Indian Constitution, secularism deserves continuous scrutiny to ensure its vitality in society. This research, therefore, begins with a constitutional interpretation of secularism, expanding into its ethical and human rights implications, with the aim of contributing meaningfully to social harmony and justice.

The Constitutional Basis of Secularism in India

The Indian Constitution, adopted in 1950, enshrines secularism as one of its foundational values, though the explicit inclusion of the word "secular" in the Preamble occurred only with the 42nd Constitutional Amendment in 1976. "The constitution declares India to be a sovereign, socialist, secular and democratic republic. Even though the terms secular and socialist were added..., the spirit embodying the constitution was secular. In 1973 the Supreme Court held the secular character of the constitution to be one of the basic features of the constitution."This reflects India's unique adaptation of secularism not as a strict separation of state and religion in the Western sense, but as a principle of equal respect and protection for all religions while ensuring that the state neither privileges nor discriminates against any faith. "The debate over the meaning of the term secular in the Indian context has been a heated one. Some people have argued that the Western context from which the term secular is borrowed is a very different one. In the west, the outcome of the struggle between the Church and the state led to the separation of the two; the Church was allowed to decide on the religious rituals, the state was to regular secular affairs. In India, the concept of secularism evolved as part of the struggle of nationalist forces against communal forces that wanted to use religious for political purposes and divide the emerging nation on the basis of religion.

Several constitutional provisions secure this mandate:

- Article 14guarantees equality before law and equal protection of laws.
- Article 15prohibits discrimination on the grounds of religion, race, caste, sex, or place of birth
- Article 19protects the freedoms of speech, expression, and association, which are vital for sustaining religious plurality.
- Article 25ensures freedom of conscience and the right to freely profess, practice and propagate religion.
- Article 26grants religious denominations the right to manage their own affairs in matters of religion.
- Articles 27-28 prohibit state funding of religious promotion and restrict religious instruction in state-run educational institutions.

Through these provisions, the Constitution strives to build an inclusive democracy where the dignity of every citizen, irrespective of faith, is preserved. This makes secularism not merely a political value but a constitutional obligation binding on the state and its institutions. Yet, as contemporary realities demonstrate, the constitutional promise of secularism is increasingly undermined by communal polarization, legislative ambiguities, and institutional biases. Understanding this gap between principle and practice forms the foundation of this research.

Human Rights, an equal constitutional tone for secularism

The pioneer of modern human rights in India, Dr. B. R. Ambedkar, was born a Hindu, embraced Buddhism, and consciously distanced himself from dominant religious identities such as Islam and Christianity. "…the understanding, analyzing and formulating the word *'secular'* in the Preamble of the Indian Constitution has to be studied very authentically along with the philosophy of Dr. Ambedkar." Why then, is the mention of religion so central to secularism in India? Because the very spirit of secularism cannot be detached from Ambedkar's intellectual and ethical struggle. As M. G. Bhagat rightly notes, Ambedkar's contribution lies in "redefining human rights not as abstract ideals but as lived guarantees against oppression." Thus, the word *"secular"* in the Preamble is not a mere political compromise; it is a moral philosophy grounded in Ambedkar's demand for social democracy, dignity, and justice for the marginalized. It has to be studied very authentically along with the philosophy of Dr. Ambedkar

Secularism and Human Rights: Twin Pillars of Protection

Ambedkar believed that political democracy without social justice would collapse under the weight of inequalities. Similarly, secularism without human rights is incomplete. The Indian model of secularism, unlike the Western doctrine of strict separation, emphasizes *equal respect* for all faiths while prohibiting state favoritism. This principle, however, gains strength only when reinforced by human rights law. Recent scholarship continues to revisit the Indian model of secularism, highlighting its distinctive emphasis on principled distance between religion and the state rather than strict separation. Human rights charters such as the *Universal Declaration of Human Rights (1948)* and the *International Covenant on Civil and Political Rights (1966)* universalize religious freedom as a fundamental right of every human being. In India, these principles resonate in the Constitution through equality before law (Article 14), non-discrimination (Article 15), and freedom of religion (Articles 25-28). When read together, secularism and human rights create a double safeguard: secularism prevents the state from privileging one religion, while human rights prevent society from oppressing individuals in the name of religion. This duality may be described as *two pillars standing side by side*. On one side, secularism ensures neutrality of institutions; on the other, human rights ensure universality of protections. Where one weakens, the other strengthens. To attack religious minorities, therefore, is not just to break constitutional secularism but also to violate international human rights law. In this sense, every atrocity against Christians or Muslims be it mob lynching, church burning, or the custodial death of Fr. Stan Swamy is a double offense: against India's Constitution and against humanity itself.

Universal Human Rights: Extending Ambedkar's Vision

While Ambedkar rooted his philosophy in Indian realities of caste oppression and religious inequality, his ideas resonate with universal frameworks of justice. Amartya Sen, in *Development as Freedom*, argues that freedoms cannot be reduced to political rights alone but must encompass social opportunities and protections that allow individuals to flourish. Martha Nussbaum, through the *Capabilities Approach*, reinforces this by highlighting dignity, freedom of conscience, and equality as the foundation of human development. Both perspectives complement Ambedkar's insistence that democracy without social justice is hollow, and secularism without human rights is fragile. Thus, when India affirms both secularism and human rights, it aligns itself not only with its constitutional mandate but also with the universal law of humanity. The two-pillar framework ensures that religious freedom is not treated as a privilege granted by the majority, but as a natural right guaranteed to all. Human rights speak for the oppressed and against the oppressor, echoing Ambedkar's lifelong struggle for justice.

Contemporary Political Shifts and the Spirit of Secularism in India

The constitutional vision of secularism in India is not confined to theory or judicial interpretation alone; it is actively shaped, contested, and defended in the arena of politics and civil society. Contemporary reflections in these spaces show how secularism functions as both a constitutional safeguard and ahuman rights commitment, even under increasing strain from majoritarian pressures. In recent decades, India has witnessed a range of political and legislative shifts that have reshaped the meaning of secularism in public life. Policies concerning citizenship, inter-faith relations, civil society regulation, and education reforms have increasingly introduced religious identity as a marker of inclusion or exclusion, raising questions about the neutrality of the state in matters of faith. Scholars note that such measures tend to privilege the cultural symbols of the majority while narrowing the space for plural traditions. When laws and policies regulate marriage choices, alter historical curricula, or restrict the activities of civil society organisations, the consequences are not merely administrative they affect the lived experience of minorities and the democratic promise of equality. Underlying these shifts lies a motive of redefining national identity in line with majoritarian ideology. This is not limited to isolated legal measures but echoes across policy-making, electoral campaigns, budgetary allocations, and the way state administrations interact with minority institutions. The cumulative effect is that secularism is portrayed as dispensable, while cultural majoritarianism is projected as the natural essence of the nation. Such narratives, amplified in public discourse, risk instilling in the younger generation a mindset of intolerance, where minorities are viewed as outsiders rather than equal citizens. This trajectory creates a double danger: on the one hand, it disturbs the delicate social fabric of unity in diversity; on the other, it injects into public consciousness a spirit of anti-secularism that normalizes suspicion and agitation against minorities. Civil liberties groups and constitutional scholars have warned that when the state itself appears to privilege one

community, the very foundations of India's democracy are shaken. It is a great alarm for both today's and tomorrow's India, where the ideals of justice, liberty, equality, and fraternity may be eroded if the trend is left unchecked. It is the mutual responsibility of the political parties who run and observe the administration of the state by which both have the core responsibility to strive and provide the peaceful atmosphere to everybody who belongs to the state. Scholars have emphasized that the Indian Constitution was conceived as a transformative political document aimed at shaping democratic citizenship in a deeply diverse society.

Parliamentary Debates and Political Discourse

The Parliament of India has long been a site of negotiation over secularism. Since the 42nd Amendment formally inserted the word "secular" into the Preamble, debates have often revisited its scope and meaning. While some political arguments have sought to dilute its relevance by redefining India primarily in religious-cultural terms, others have firmly defended secularism as the bedrock of India's constitutional morality. Such debates are not simply ideological. They reflect the tension between majoritarian politics and constitutional guarantees. The very contestation over whether secularism belongs to the Constitution demonstrates its critical importance. As Rajeev Bhargava argues, "India's secularism cannot be understood as mere neutrality; it is active engagement to ensure equality among communities." In this sense, parliamentary debates illustrate how secularism continues to function as a living principle, constantly tested by political currents but also reaffirmed by defenders of pluralism.

Civil Society and Grassroots Voices

Beyond formal politics, civil society plays a decisive role in sustaining the secular spirit. Civic movements, academic interventions, and grassroots organizations amplify voices that often go unheard in parliamentary spaces. For instance, volunteer-driven initiatives in Tamil Nadu have become platforms for minorities and marginalized groups to assert their rights, challenging narratives of exclusion. State-led reforms also intersect with these grassroots movements. The Tamil Nadu government's initiatives to promote social justice in schools and colleges by embedding inclusivity in curricula and encouraging interfaith respect represent how governance itself can act as a custodian of secular values. These initiatives not only counterbalance sectarian tendencies but also ensure that secularism is practiced in daily life through education. As Amartya Sen reminds us, democracy depends not merely on laws and institutions but on the "courage of citizens to defend inclusivity." Civil society movements embody this courage, acting as parallel guardians of secularism alongside constitutional institutions. They demonstrate that the defense of secularism is not limited to courts or Parliament but extends into everyday struggles for dignity, rights, and equality. The contemporary political reflections on secularism reveal both its fragility and resilience. On one hand, parliamentary debates show how secularism remains contested in India's political imagination, constantly reinterpreted to suit shifting ideological landscapes. On the other hand, civil society initiatives and state-led reforms particularly in Tamil Nadu demonstrate how secularism can be translated into lived realities through education, activism, and people-centered movements. Yet, these institutional and civic defenses must also be tested against the harsh ground realities of recurring violence, discrimination, and systemic targeting of minorities. The gap between constitutional ideals and lived experiences is stark, as reflected in cases of religious atrocities, custodial injustices, and denial of basic freedoms. To understand this gap, one must move beyond theory and rhetoric into the concrete case studies of how secularism is challenged in practice and how human rights principles are violated in its absence. It is in these lived experiences of oppressed communities, persecuted religious groups, and silenced activists that the true measure of India's commitment to secularism and human rights emerges.

Civil Society and Ethical Dimension

Civil society in India has historically played a crucial role in safeguarding the constitutional promise of secularism, especially when state institutions appear compromised. Rooted in ethical responsibility, civil society movements embody the conscience of the nation, speaking for the oppressed and holding power accountable. From grassroots organisations to academic forums and faith-based initiatives, these movements have consistently defended pluralism, social justice, and the rights of minorities. Their role highlights that secularism is not merely a constitutional doctrine but a lived ethical practice sustained by collective action and civic courage.

Civil Society as the Custodian of Secularism

While constitutional provisions and international human rights instruments provide a legal and structural foundation for secularism, it is ultimately civil society that gives these principles life, legitimacy, and continuity. Laws may outline equality, but it is the collective conscience of the people that ensures such equality is practiced and defended in times of crisis. In this sense, civil society becomes the moral custodian of secular democracy.

Grassroots Movements and Interfaith Harmony

Civil society in India has historically played a decisive role in disagreeing communalism and promoting inclusivity. From grassroots movements defending Dalit and minority rights, to interfaith initiatives that cultivate dialogue and reconciliation, the ethical fabric of secularism is woven by ordinary citizens and activists who refuse to let religion be weaponized for division. As Rajeev Bhargava observes, secularism in India has never been about the strict separation of religion and state, but about principled distance a dynamic engagement that requires both state neutrality and civic vigilance

Tamil Nadu as a Model for Social Justice

One striking example comes from Tamil Nadu, where educational reforms and social justice initiatives have sought to instill the values of equality and pluralism among young citizens. State policies mandating inclusive curricula, scholarships for marginalized students, and celebrations of social reformers in schools and colleges illustrate how civic spaces can nurture secular and ethical values. Beyond government efforts, grassroots forums continue to champion fraternity and interfaith harmony at a community level, demonstrating how local initiatives can counteract divisive politics.

Writers, Journalists, and Human Rights Defenders

The contribution of writers, journalists, and human rights defenders has been equally vital. Social activists such as Anto Akkara, through their documentation of communal violence (notably in Kandhamal, Odisha), expose the human cost of intolerance and remind society that silence in the face of injustice is complicity. Their ethical interventions frame secularism not as an abstract political doctrine but as a lived reality of suffering, survival, and hope. Similarly, the custodial death of Fr. Stan Swamy has transformed into a moral symbol for civil society, reminding the nation that defending the oppressed is not anti-national but profoundly constitutional.

Ethical Responsibility of Civil Society

The ethical dimension of secularism lies in its dual responsibility: to safeguard the rights of minorities and to hold the majority accountable to constitutional morality. As Amartya Sen notes, democracy and secularism cannot merely rely on institutional guarantees; they must rest on the ethical courage of citizens to defend inclusivity. Civil society's responsibility, therefore, is not just to protest injustices but to continually reimagine the moral community of the nation a community where religious identity does not determine human worth. The Indian Constitution has also been interpreted by scholars as a "transformative constitution," intended not merely to preserve existing social structures but to reshape them in accordance with principles of equality, liberty, and dignity. Ultimately, secularism cannot survive without the active participation of civil society. Courts and constitutions may set the framework, but it is through ethical practices solidarity marches, interfaith initiatives, human rights campaigns, and educational reforms that secularism becomes a living reality. Civil society thus operates as the ethical conscience of democracy, ensuring that the constitutional promise of equality and fraternity is not hollow but deeply embedded in everyday life.

The Spirit of Secularism Forever

The journey of secularism in India is not without pain, but it is also not without promise. History shows us that whenever divisive forces have tried to break the social fabric, the courage of ordinary people has risen to heal it. The voices of the oppressed, the prayers of minorities, the struggles of activists, and the commitment of educators all form the living testimony that the spirit of secularism cannot be extinguished. As long as there are citizens willing to stand for justice, as long as there are teachers who sow the seeds of inclusivity in young minds, as long as there are

communities ready to open their doors to diversity, the secular spirit of India will survive every storm. Let this be the hope we carry forward: that secularism is not a fragile dream but a resilient reality, rooted in the Constitution and nourished by human rights. It belongs not only to the courts or the parliaments, but to every child, every home, and every heart that believes in equality. In preserving this spirit, we do not merely protect a principle we protect the very identity of India. And that identity, once guarded with courage and compassion, will remain forever.

CONCLUSION

The discourse on secularism in contemporary India is not merely a constitutional abstraction, but a living question of survival, dignity, and justice for millions of its citizens. Through the lens of constitutional law, human rights, political practice, and the moral agency of civil society, this study has shown that secularism is the very condition for India's pluralism. When it weakens, the foundations of equality, fraternity, and liberty also tremble. The violence and exclusion whether the arrests of nuns in Chhattisgarh, the custodial death of Fr. Stan Swamy in Maharashtra, or targeted attacks against Muslims and Christians in states like Uttar Pradesh, Gujarat, and Odisha stand as grim reminders of how the constitutional promise can be betrayed. At the same time, the voices of resilience grassroots movements, educational reforms in Tamil Nadu, academic and activist interventions, and the global echo of India's civil society prove that secularism is not dead; it is defended daily in the courage of ordinary citizens. What emerges from this study is the conviction that secularism and human rights are two inseparable pillars of the same house: each sustains the other, and together they safeguard individuals from both oppression and exclusion. To disturb secularism in practice is to violate the universal principles of human rights; to uphold human rights is to safeguard the secular promise of the Indian Constitution. Therefore, the call of this research is not merely to lament the failures but to initiate what may be called *Secularism*. While destructive forces have sought their own "secularism" to erode and dismantle the true spirit of the Constitution, it becomes the bounden duty of the rest of the people to promote a counter-discourse: one of reconstruction, conscientization, and renewal. This constructive *Secularism* is a conscious re-reading, re-insisting, and re-living of the secular spirit in the hearts and minds of every citizen, so that India remains a home for everyone in her land. India's future will not be secured by partisan slogans or rigid ideologies, but by a collective re-commitment to justice, inclusivity, and fraternity. To promote secularism is not merely to preserve a clause in the Constitution; it is to protect the national identity of India itself aidentity woven through centuries of coexistence, dialogue, and unity in diversity. Let this be the message to society: that *Secularism* is nothing less than the defense of humanity, and that nurturing human rights is the only way to ensure that India remains a land where every citizen equal and free can live with dignity, now and for generations to come.

ABSTRACT

In fuzzy soft ideal closure space or shorty denoted as F$\mathcal{S}$ ideal closure space these were studied already by author for many authors. Here we introduces separation axioms in F$\mathcal{S}$ ideal closure space topological space for in new more natural manner than the earlier definition and prove some characteristic property for these separation axiom. Further it studies normal S ideal closure space and regular F$\mathcal{S}$ ideal closure space of Separation axioms in F$\mathcal{S}$ ideal closure space.

Keywords: regular F$\mathcal{S}$ideal closure space, T_3, normal F$\mathcal{S}$ideal closure space, T_4 and completely normal F$\mathcal{S}$ideal closure space.

INTRODUCTION

Separation axioms of F$\mathcal{S}$ ideal closure spaces are known in the literatures. In this paper, the separation axioms of F$\mathcal{S}$ideal closure space in topological space is presented in a new way that is natural than previous work and give an examination to some properties. The regular, normal separation axiom in F$\mathcal{S}$ ideal closure spaces have also been analyzed. Abstract Separation axioms is one of the important topics in generic topology which reflect the richness of topologies. It relates to the properties of points and points from closed sets of points or between F$\mathcal{S}$ open sets. Closure space has some features compared to the ordinary topological space with relation to separation axioms. Thus, A

closure space is divided if the distinct points of it can be separated by a different neighborhood in the words of E. Cech [2]. K. C. Chattopadhyay and W. J. Thron introduced higher separation properties in closure space [5]. S. Suriyakala and R. Vembu introduced Hausdorffness on ideals in ideal topological space [17]. Hausdorffness of separation axioms in ideal topological space have been investigated by S. Suriya kalakand R. Vembu [17]. Higher separation axioms in ideal closure space have studied by R. Gowriand M. Pavithra [7]. The objective of this study is to investigate the higher separation axioms on F$\mathcal{S}$ideal closure spaces. Study of some features of absolutely normal F$\mathcal{S}$ ideal closure space, normal S ideal closure space, and regular F$\mathcal{S}$ ideal closure space is our primary goal. Some theorems, results, concepts, and properties are also discussed.

Preliminaries

$\mathcal{D}$efinition (2.1) [4]
Let $\mathcal{Z}$ be a set that is not empty. A fuzzy set C's membership function defines it. μ_C; $\mathcal{Z} \rightarrow$[0,1] and $\mu_C(z)$ is understood as the degree to which element z in $\mathcal{Z}$ is related to C, which is entirely defined by the set of tuples. C ={$\mathcal{Z}$, $\mu_C(z)$:$z \in \mathcal{Z}$ }.

$\mathcal{D}$efinition 2.2[4] Let $\mathcal{Z}$ be a fuzzy topology is a family$\mathcal{F}$ = {μ : μ is fuzzy set in$\mathcal{Z}$ } of family subsets that fulfils the axioms listed below:

(1) (0,1) $\in \mathcal{F}$.
(2) $\mu_1,\mu_2 \in \mathcal{F}$ then $\mu_1 \wedge \mu_2 \in \mathcal{F}$
(3) {μ_i; i$\in$ j}$\subset \mathcal{F}$ where an index set is represented by j, then $\bigvee \mu_i \in \mathcal{F}_i$

Consequently, the pair ($\mathcal{Z}$, $\mathcal{F}$) is referred to as fuzzy topological space, and $\mathcal{F}$ is defined as a fuzzy topology for $\mathcal{Z}$.

$\mathcal{D}$efinition 2.3 [13]
Let C be a subset of the non-empty $\mathcal{F}$. ($\acute{\zeta}$, C) indicated by $\acute{\zeta}_C$is called a F$\mathcal{S}$over $\mathcal{Z}$, where $\mathcal{F}$ is a specified mapping. $\acute{\zeta}$: $C \rightarrow \mathcal{P}(\mathcal{Z})$. Stated differently, a parameterised family of subsets of the universe is a soft set over $\mathcal{Z}$

$\mathcal{D}$efinition 2.4[14]
Let $\acute{\zeta}_C$, $\acute{\zeta}_D$be two F$\mathcal{S}$ set of $\mathcal{Z}$. Then $\acute{\zeta}_C$ is F$\mathcal{S}$ subset of $\acute{\zeta}_D$ denoted by $\acute{\zeta}_C \subseteq \acute{\zeta}_D$ if $C \subseteq D$ and $\mu^e_{\acute{\zeta}_C} \leq \mu^e_{\acute{\zeta}_D}, \forall e \in \mathcal{F}$. Also $\acute{\zeta}_D$ is called F$\mathcal{S}$superset of $\acute{\zeta}_C$ denoted by $\acute{\zeta}_D \supseteq \acute{\zeta}_C$.

$\mathcal{D}$efinition 2.5 [14]
Let $\acute{\zeta}_C, \acute{\zeta}_D$ be two F$\mathcal{S}$ set of $\mathcal{Z}$. Union of F$\mathcal{S}$ set is denoted by $\acute{\zeta}_C \cup \acute{\zeta}_D$ is also a F$\mathcal{S}$ set $\acute{\lambda}_E$ where E =$C \cup D$ and for all $e \in$ E, $\acute{\lambda}_E$ $(e) = \mu^e_{\acute{\lambda}_E} = \mu^e_{\acute{\zeta}_C} \vee \mu^e_{\acute{\zeta}_D}, \forall e \in$E.

$\mathcal{D}$efinition 2.6 [16]
Let $\acute{\zeta}_C, \acute{\zeta}_D$ be twoF$\mathcal{S}$ sets of $\mathcal{Z}$. A F$\mathcal{S}$ set's intersection $\acute{\zeta}_C$, $\acute{\zeta}_D$ is also a F$\mathcal{S}$ set $\acute{\lambda}_E$ where E =$C \cap D$ and for all $e \in E, \acute{\lambda}_E$ $(e) = \mu^e_{\acute{\lambda}_E} = \mu^e_{\acute{\zeta}_C} \wedge \mu^e_{\acute{\zeta}_D}, \forall e \in$E.

$\mathcal{D}$efinition 2.7[8]
Let$\acute{\zeta}_C, \acute{\zeta}_D$ be two F$\mathcal{S}$ set of $\mathcal{Z}$. The difference between two F$\mathcal{S}$ sets $\acute{\zeta}_C$, $\acute{\zeta}_D$ throughout the common cosmos. [0,1] denoted as $\acute{\zeta}_C - \acute{\zeta}_D$ is F$\mathcal{S}$ set $\acute{\lambda}_E$ where E =$C \cap D \neq \phi$ and $\forall e \in E, z \in \mathcal{Z}$, $\mu^e_{\acute{\lambda}_E}(z) = \max\{\mu^e_{\acute{\zeta}_C}(z) - \mu^e_{\acute{\zeta}_D}(z)\}$. Clearly $\acute{\zeta}_C - \acute{\zeta}_D = \acute{\zeta}_C \cap \acute{\lambda}^c_D$.

$\mathcal{D}$efinition 2.8[19]
The set (, $\mathcal{F}$) be a collection of F$\mathcal{S}$ set over a universe [0,1] is denoted by $\mathcal{Z}_\mathcal{F}$ with a fixed set of parameters of $\mathcal{F}$. Then$\mathfrak{J}$ is a subset of F$\mathcal{S}$ set of "$\mathcal{Z}_\mathcal{F}$ is call F$\mathcal{S}$ topology on $\mathcal{Z}$ if

(1) $0_\mathcal{F}, 1_\mathcal{F} \epsilon \mathfrak{J}$ where $0_\mathcal{F}$(e) = 0 and $1_\mathcal{F}$(e)= 1 , $\forall$ e$\in \mathcal{F}$.
(2) The union of all numbers. of $\mathfrak{J}$ belongs to$\mathfrak{J}$.

(3) The intersection between any two members of $\mathfrak{J}$ belongs to $\mathfrak{J}$.

Triplets $(\mathcal{Z}, \mathfrak{J}, \mathcal{F})$ is called a F$\mathcal{S}$ Topological space over $\mathcal{Z}$ In addition, each member of $\mathfrak{J}$ is referred to as an F$\mathcal{S}$ open set in $(\mathcal{Z}, \mathfrak{J}, \mathcal{F})$".

Definition 2.9[19]

$(\mathcal{Z}, \mathfrak{J}, \mathcal{F})$ is an F$\mathcal{S}$ topological space. A set $\acute{\zeta}_C$over $\mathcal{Z}$ is considered F$\mathcal{S}$ closed set if its relative complement, $\acute{\zeta}_C^c$ is anF$\mathcal{S}$ open set. The collection of all F$\mathcal{S}$ sets shall be labelled $\mathfrak{J}^c$.

Definition 2.10 [15]

Assume $(\mathcal{Z}, \mathfrak{J}, \mathcal{F})$ is an F$\mathcal{S}$ topological space and $\acute{\zeta}_C$ is an F$\mathcal{S}$ set on $\mathcal{Z}_\mathcal{F}$. The F$\mathcal{S}$ closure of$\acute{\zeta}_H$, represented by $\mathcal{K}_\mathcal{X}^*(\acute{\zeta}_H)$, is the intersection of all F$\mathcal{S}$ closed supersets of $\acute{\zeta}_C$where $\mathcal{K}_\mathcal{Z}^*$represents the F$\mathcal{S}$ closure operator.

(ie) $\mathcal{K}_\mathcal{Z}(\acute{\zeta}_H) = \cap\{\acute{\zeta}_H; \acute{\zeta}_H \in \mathfrak{J}^\mathcal{C}$ and $\acute{\zeta}_C \subseteq \acute{\zeta}_H\}$.

Definition 2.11[6]

A F$\mathcal{S}$ set $\acute{\zeta}_C$of $\mathcal{Z}$ is called F$\mathcal{S}$ closed and discrete if and only if $\acute{\zeta}_C^d = 0_\mathcal{F}$.

Definition 2.12 [9]

$(\mathcal{Z}, \mathfrak{J}, \mathcal{F})$ is an F$\mathcal{S}$ topological space. An ideal "$\mathfrak{T}_\mathcal{F}$ of F$\mathcal{S}$ established across a universe $\mathcal{X}$ with a specified set of parameters $\mathcal{F}$ is F$\mathcal{S}$ ideal on$\mathcal{Z}$ if it meets the following conditions:

(1) $\acute{\zeta}_\varphi \in \mathfrak{T}_\mathcal{F}$.

(2) If $\acute{\zeta}_C \in \mathfrak{T}_\mathcal{F}$, $\acute{\zeta}_D \subseteq \acute{\zeta}_C$ implies$\acute{\zeta}_D \in \mathfrak{T}_\mathcal{F}$.

(3) If $\acute{\zeta}_C \in \mathfrak{T}_\mathcal{F}$ and $\acute{\zeta}_D \in \mathfrak{T}_\mathcal{F}$implies $\acute{\zeta}_C \cup \acute{\zeta}_D \in \mathfrak{T}_\mathcal{F}$".

Definition 2.13[3]

Assume "$\mathcal{P}(\acute{\zeta}_Z)$ is the collection of all F$\mathcal{S}$ sets in $\mathcal{Z}$. $\mathcal{K}_\mathcal{Z}$:$2^Z \longrightarrow 2^Z$ is a fulfilling superset of $\acute{\zeta}_C$, with $\mathcal{K}_\mathcal{Z}$as the F$\mathcal{S}$ closure operator.

(1) $\mathcal{K}_\mathcal{Z}(\acute{\zeta}_\varphi) = \acute{\zeta}_\varphi$

(2) $\acute{\zeta}_C \subset \mathcal{Z} \Rightarrow \acute{\zeta}_C \subset \mathcal{K}_\mathcal{Z}(\acute{\zeta}_C)$

(3) $\mathcal{K}_\mathcal{Z}(\acute{\zeta}_C \cup \acute{\zeta}_D) = \mathcal{K}_\mathcal{Z}(\acute{\zeta}_C) \cup \mathcal{K}_\mathcal{Z}(\acute{\zeta}_D)), \forall \acute{\zeta}_C \subset \mathcal{Z}, \forall \acute{\zeta}_D \subset \mathcal{Z}$.

The structure $(\mathcal{Z}, \mathcal{K}_\mathcal{Z})$ is called is called F$\mathcal{S}$ closure space".

Definition 2.14[6]

Let "$\mathcal{P}(\acute{\zeta}_Z)$be the power set of $\mathcal{Z}$.The operator $\acute{\zeta}_C^* : \mathcal{P}(\acute{\zeta}_Z) \to \mathcal{P}(\acute{\zeta}_Z)$ is considered an F.S. local function of C with regard to $\mathfrak{J}$&$\mathfrak{T}_\mathcal{F}$ is defined as $\acute{\zeta}_C \subseteq \mathcal{Z}$. $\acute{\zeta}_C^*(\mathfrak{T}_\mathcal{F}, \mathfrak{J}) = \{\acute{\zeta}_C \in \mathcal{Z}, U_\mathcal{F} \cap \acute{\zeta}_C \notin \mathfrak{T}_\mathcal{F},$ for each open set $U_\mathcal{F}$ containing $\mathcal{Z}\}$".

Let $\mathcal{K}_\mathcal{Z}^*(\acute{\zeta}_C) = \acute{\zeta}_C \cup \acute{\zeta}_C^*$defines Kuratoswki closure operator for a topology.

Definition 2.15[11]

Let "$\mathcal{K}_\mathcal{Z}^*(\acute{\zeta}_C) = \acute{\zeta}_C \cup \acute{\zeta}_C^*$defines Kuratoswki closure operator for a topology. Then the function $\mathcal{K}_\mathcal{Z}^*$:$\mathcal{P}(\acute{\zeta}_Z) \to \mathcal{P}(\acute{\zeta}_Z)$ satisfying

(i) $\mathcal{K}_\mathcal{Z}^*(\acute{\zeta}_\varphi) = \acute{\zeta}_\varphi$.

(ii) $\acute{\zeta}_C \subset \mathcal{K}_\mathcal{Z}^*(\acute{\zeta}_C), \forall \acute{\zeta}_C \subset \mathcal{Z}$.

(iii) $\mathcal{K}_\mathcal{Z}^*(\acute{\zeta}_C \cup \acute{\zeta}_D) = \mathcal{K}_\mathcal{Z}^*(\acute{\zeta}_C) \cup \mathcal{K}_\mathcal{Z}^*(\acute{\zeta}_D), \forall \acute{\zeta}_C \subset \mathcal{Z}, \forall \acute{\zeta}_D \subset \mathcal{Z}$.

(iv) $\mathcal{K}_\mathcal{Z}^*(\acute{\zeta}_C) = \mathcal{K}_\mathcal{Z}^*(\mathcal{K}_\mathcal{Z}^*(\acute{\zeta}_C)), \forall \acute{\zeta}_C \subset \mathcal{Z}$".

is called a F$\mathcal{S}$ on $\mathcal{Z}$. The structure $(\mathcal{Z}, \mathfrak{T}_\mathcal{F}, \mathcal{K}_\mathcal{Z}^*)$ is called as F$\mathcal{S}$ ideal closure space.

Regular and T_3- spaces in F$\mathcal{S}$ideal closure spaces

$\mathcal{D}$efinition 3.1
For every "$\acute{\zeta}_x \in \mathcal{Z}$ and every F$\mathcal{S}$ ideal closure closed set $(\mathcal{F},\mathcal{E})$ that does not contain $\acute{\zeta}_x$, there exists a F$\mathcal{S}$ ideal closure open set $(\mathcal{U},\mathcal{E})$ and $(\mathcal{V},\mathcal{E})$ such that $(\mathcal{F},\mathcal{E}) \subset (\mathcal{V},\mathcal{E})$, $\acute{\zeta}_x \in (\mathcal{U},\mathcal{E})$ and $(\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E})=0$. This suggests that $(Z, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_Z^*)$".is a regular F$\mathcal{S}$ ideal closure ideal closure space.

$\mathcal{D}$efinition 3.2
A regular F$\mathcal{S}$ ideal closure ideal closure of T_1 space is called a T_3- space.

Example:3.3
Let "$\mathcal{Z}$ = {p,q,r} and $\mathcal{E}$ = {e_1, e_2} $f_b(e_1)$ ={(p,0), (q,1) and $f_b(e_1)$ ={(p,0), (q,1) then there exist a F$\mathcal{S}$ ideal closure closed set $(\mathcal{F},\mathcal{E})$such that $\mathcal{F}(e_1)$ ={(p,1)}, $\mathcal{F}(e_2)$ = {(p,1)}and there exist a F$\mathcal{S}$ ideal closure open set $(\mathcal{U},\mathcal{E})$ and $(\mathcal{V},\mathcal{E})$ such that $\mathcal{U}(e_1)$ ={(q,1)} and $\mathcal{U}(e_2)$ ={(q,1)}, $\mathcal{V}(e_1)$ ={(p,1)} and $\mathcal{U}(e_2)$ ={(p,1)}. Hence (F, E) $\subseteq (\mathcal{V},\mathcal{E})and\mathcal{U}(e_1) \wedge \mathcal{U}(e_2)$ =Not defined and $\mathcal{V}(e_1) \wedge \mathcal{V}(e_2)$ =Not defined. Therefore $(\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E}) = 0$".

Theorem:3.4
Each F$\mathcal{S}$ ideal closure ideal closure space $(\mathcal{Z},\mathfrak{T}_{\mathcal{F}},\mathcal{K}_Z^*)$ is T_3- space, then it's also T_2 space.

Proof:
Given that F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_Z^*)$ is a T_3- space. Let $\acute{\zeta}_x, \acute{\zeta}_y \in \mathcal{Z}$ then $\acute{\zeta}_x \neq \acute{\zeta}_y$. Since F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_Z^*)$ is T_1 space, $\{\acute{\zeta}_y\}$ is F$\mathcal{S}$ closed then $\acute{\zeta}_x \neq \acute{\zeta}_y$. But "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_Z^*)$ is regular F$\mathcal{S}$ ideal closure space by the definition of regular F$\mathcal{S}$ ideal closure space, there exists a F$\mathcal{S}$ open sets $(\mathcal{U},\mathcal{E})$ and $(\mathcal{V},\mathcal{E})$ such that $(\mathbb{F},\mathcal{E}) \subset (\mathcal{V},\mathcal{E})$, $\acute{\zeta}_x \in (\mathcal{U},\mathcal{E})$ and $(\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E}) = 0$. Thus $\acute{\zeta}_x \in (\mathcal{U},\mathcal{E})$, $\acute{\zeta}_y \in \{f_y\} \subseteq (\mathcal{V},\mathcal{E})$ and $(\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E}) = 0$. Therefore F$\mathcal{S}$ ideal closure $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_Z^*)$ is T_2- space".

Theorem:3.5
Every F$\mathcal{S}$ ideal closure subspace $(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_Y^*)$ of F$\mathcal{S}$ ideal closure T_3- space is T_3.

Proof:
Initially will be starting to prove, "$(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_Y^*)$ is T_1 space. If $\acute{\zeta}_x, \acute{\zeta}_y \in \mathcal{Y}$ such that $\acute{\zeta}_x \neq \acute{\zeta}_y$.
Since $(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_Y^*) \subseteq (\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_Z^*)$, then there exist F$\mathcal{S}$ open sets $(\mathcal{U},\mathcal{E})$ and $(\mathcal{U},\mathcal{E})$ such that $\acute{\zeta}_x \in (\mathcal{U},\mathcal{E})$, $\acute{\zeta}_y \notin (\mathcal{U},\mathcal{E})$ and $\acute{\zeta}_y \in (\mathcal{V},\mathcal{E})$, $\acute{\zeta}_x \notin (\mathcal{V},\mathcal{E})$. Therefore $\acute{\zeta}_x \in (\mathcal{U},\mathcal{E}) \wedge \mathcal{Y}$ and $\acute{\zeta}_y \notin (\mathcal{U},\mathcal{E}) \wedge \mathcal{Y}$ and $\acute{\zeta}_y \in (\mathcal{V},\mathcal{E}) \wedge \mathcal{Y}$ and $\acute{\zeta}_x \notin (\mathcal{V},\mathcal{E}) \wedge \mathcal{Y}$. Therefore F$\mathcal{S}$ ideal closure subspace $(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_Y^*)$ is T_1 space".

We now need to demonstrate that "$(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_Y^*)$ is regular F$\mathcal{S}$ ideal closure space. Let $\acute{\zeta}_y \in \mathcal{Y}$ and $(\mathcal{G},\mathcal{E})$ be a F$\mathcal{S}$ closed set in $\mathcal{Y}$ such that $\acute{\zeta}_y \notin (\mathcal{G},\mathcal{E})$. Then $(\mathcal{G},\mathcal{E})=\mathcal{Y} \wedge (\mathbb{F},\mathcal{E})$ but $\acute{\zeta}_y \in \mathcal{Y}$ so $\acute{\zeta}_y \notin (\mathbb{F},\mathcal{E})$. Since $(\mathcal{Z},\mathfrak{T}_{\mathcal{F}},\mathcal{K}_Z^*)$ is T_3- space so there exists F$\mathcal{S}$ open sets $(\mathcal{U},\mathcal{E})$ and $(\mathcal{V},\mathcal{E})$ in $(\mathcal{Z},\mathfrak{T}_{\mathcal{F}},\mathcal{K}_Z^*)$ such that $\acute{\zeta}_y \in (\mathcal{U},\mathcal{E})$, $(\mathbb{F},\mathcal{E}) \subseteq (\mathcal{V},\mathcal{E})$ and $(\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E}) = 0$. Take $(\mathcal{W},\mathcal{E})$, $(Z, \mathcal{E})$ are F$\mathcal{S}$ open sets in $(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_Y^*)$ such that $\acute{\zeta}_y \in (\mathcal{W},\mathcal{E})$, $(\mathcal{G},\mathcal{E}) \subseteq \mathcal{Y} \wedge (\mathcal{V},\mathcal{E}) = (Z, \mathcal{E})$ and $(\mathcal{W},\mathcal{E}) \wedge (Z, \mathcal{E}) \subseteq (\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E}) = 0$. Hence F$\mathcal{S}$ ideal closure subspace $(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_Y^*)$" is T_3- space.

Theorem:3.6
Let "$(\mathcal{Z},\mathfrak{T}_{\mathcal{F}},\mathcal{K}_Z^*)$ be a F$\mathcal{S}$ ideal closure space. The following claims are therefore equal.

(1) The space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_Z^*)$ is regular F$\mathcal{S}$ ideal closure spaces
(2) For each $\acute{\zeta}_x \in \mathcal{Z}$ and for each F$\mathcal{S}$ open set $(\mathcal{U},\mathcal{E})$ of $\mathcal{Z}$, there exists a F$\mathcal{S}$ open set $(\mathcal{V},\mathcal{E})$ of $\mathcal{Z}$ such that $\mathcal{K}_Z^*(\mathcal{V},\mathcal{E}) \subset (\mathcal{U},\mathcal{E})$.
(3) For each point $\acute{\zeta}_x \in \mathcal{Z}$ and for each F$\mathcal{S}$ closed set $(\mathbb{F},\mathcal{E}) \not\ni \acute{\zeta}_x$ there exists a F$\mathcal{S}$ open set $(\mathcal{U},\mathcal{E})$ of $\mathcal{Z}$ such that $\mathcal{K}_Z^*(\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E}) = 0$".

Proof:

(1) ⇒ (2)

Let $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ be a regular F$\boldsymbol{\mathcal{S}}$ ideal closure spaces. Let "$\acute{\zeta}_x \in \mathcal{Z}$ and let $(\mathcal{U}, \mathcal{E})$ be any F$\boldsymbol{\mathcal{S}}$ set of $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$. Then $\mathcal{Z}$-$(\mathcal{U}, \mathcal{E})$ is F$\boldsymbol{\mathcal{S}}$ closed subset of $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$. Since $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is regular F$\mathcal{S}$ ideal closure space, there exists a F$\boldsymbol{\mathcal{S}}$ open neighborhood $(\mathcal{U}, \mathcal{E})$ of $\mathcal{Z}$ and F$\boldsymbol{\mathcal{S}}$ open neighborhood $(\mathcal{V}, \mathcal{E})$ of $\mathcal{Z} - (\mathcal{U}, \mathcal{E})$ such that $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$.This Implies that $(\mathcal{U}, \mathcal{E}) \subset \mathcal{Z} - (\mathcal{V}, \mathcal{E})$ we get $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \subset \mathcal{K}_{\mathcal{Z}}^*(\mathcal{Z} - (\mathcal{V}, \mathcal{E}))= \mathcal{Z} - (\mathcal{V}, \mathcal{E})$. Since $\mathcal{Z} - (\mathcal{V}, \mathcal{E})$ is F$\boldsymbol{\mathcal{S}}$ closed then we get $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$, but $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \wedge \mathcal{Z}$-$(\mathcal{U}, \mathcal{E}) \subset \mathcal{K}_{\mathcal{Z}}^*(\mathcal{V}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$. So $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \wedge \mathcal{Z} - (\mathcal{U}, \mathcal{E}) = 0$ then $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{V}, \mathcal{E}) \subset (\mathcal{U}, \mathcal{E})$".

(2) ⇒ (3)

Let "$\acute{\zeta}_x \in \mathcal{Z}$ and let $(\mathcal{F}, \mathcal{E})$be a F$\boldsymbol{\mathcal{S}}$ closed set in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ with $\acute{\zeta}_x \notin (\mathbb{F}, \mathcal{E})$ $\mathcal{Z}$- $(\mathbb{F}, \mathcal{E})$ is F$\boldsymbol{\mathcal{S}}$ open. So $\mathcal{Z}$- $(\mathbb{F}, \mathcal{E})$ is F$\boldsymbol{\mathcal{S}}$ open neighborhood of $\acute{\zeta}_x$. Hence by (2) there exists a F$\boldsymbol{\mathcal{S}}$ open neighborhood $(\mathcal{U}, \mathcal{E})$ of $\mathcal{Z}$ such that $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \subset \mathcal{Z}$-$(\mathbb{F}, \mathcal{E})$. Therefore $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \wedge (\mathbb{F}, \mathcal{E}) = 0$".

(3) ⇒ (1)

Let "$\acute{\zeta}_x \in \mathcal{Z}$ and let $(\mathbb{F}, \mathcal{E})$ be a F$\boldsymbol{\mathcal{S}}$ closed set in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ with $\acute{\zeta}_x \notin (\mathbb{F}, \mathcal{E})$, $\mathcal{Z}$- $(\mathbb{F}, \mathcal{E})$ is F$\boldsymbol{\mathcal{S}}$ open. So $\mathcal{Z}$- $(\mathbb{F}, \mathcal{E})$ is F$\boldsymbol{\mathcal{S}}$ open neighborhood of $\acute{\zeta}_x$. Hence by (3) there exists a F$\boldsymbol{\mathcal{S}}$ open neighborhood $(\mathcal{U}, \mathcal{E})$ of $\mathcal{Z}$ such that $(\mathcal{U}, \mathcal{E}) \wedge (\mathbb{F}, \mathcal{E}) = 0$. Therefore $(\mathbb{F}, \mathcal{E}) \subset \mathcal{Z} - \mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) = (\mathcal{V}, \mathcal{E})$, so $(\mathcal{V}, \mathcal{E})$ is a F$\boldsymbol{\mathcal{S}}$ open neighborhood of $(\mathcal{V}, \mathcal{E})$. $(\mathcal{U}, \mathcal{E}) \subset \mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \Rightarrow \mathcal{Z} - \mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \subset \mathcal{Z} - (\mathcal{U}, \mathcal{E})$.Then we get $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{Z} - \mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E})) \subset (\mathcal{U}, \mathcal{E}) \wedge (\mathcal{Z} - (\mathcal{U}, \mathcal{E})) = 0$. Therefore $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$. Hence $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$" is regular F$\boldsymbol{\mathcal{S}}$ ideal closure space.

Theorem:3.7

Every subspace of regular F$\boldsymbol{\mathcal{S}}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is regular F$\boldsymbol{\mathcal{S}}$ ideal closure space.

Proof:

Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ be a regular F$\boldsymbol{\mathcal{S}}$ ideal closure space. Let $(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_{\mathcal{Y}}^*)$ be a subspace of $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$.
Let $\acute{\zeta}_x \in \mathcal{Z}$ and $(\mathcal{V}, \mathcal{E})$ be a $\mathcal{K}_{\mathcal{Y}}^*$ -F$\boldsymbol{\mathcal{S}}$ closed set in $(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_{\mathcal{Y}}^*)$. Therefore $(\mathcal{V}, \mathcal{E}) \wedge (\mathcal{L}, \mathcal{E})$ where $(\mathcal{L}, \mathcal{E})$ is $\mathcal{K}_{\mathcal{Z}}^*$ F$\boldsymbol{\mathcal{S}}$ closed in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$. Since $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is regular F$\boldsymbol{\mathcal{S}}$ ideal closure there exist $\mathcal{K}_{\mathcal{Z}}^*$ F$\boldsymbol{\mathcal{S}}$ open sets $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ such that $(\mathcal{L}, \mathcal{E}) \subset (\mathcal{V}, \mathcal{E})$, $\acute{\zeta}_x \in (\mathcal{U}, \mathcal{E})$ and $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$. Therefore, there exist $\mathcal{K}_{\mathcal{Y}}^*$ neighbourhood $(\mathcal{U}, \mathcal{E}) \wedge \mathcal{Y}$ of $(\mathcal{V}, \mathcal{E})$ and $\mathcal{K}_{\mathcal{Y}}^*$ neighborhood $(\mathcal{V}, \mathcal{E}) \wedge \mathcal{Y}$ of $\acute{\zeta}_x$ such that $((\mathcal{U}, \mathcal{E}) \wedge \mathcal{Y}) \wedge (\mathcal{V}, \mathcal{E}) \wedge \mathcal{Y}) = 0$. Thus $(\mathcal{Y}, \mathfrak{T}_F, \mathcal{K}_{\mathcal{Y}}^*)$" is also regular F$\boldsymbol{\mathcal{S}}$ ideal closure.

Theorem:3.8

Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ be a regular F$\boldsymbol{\mathcal{S}}$ ideal closure space if and only if for each $\acute{\zeta}_x \in \mathcal{Z}$ and a F$\boldsymbol{\mathcal{S}}$ closed set $(\mathbb{F}, \mathcal{E})$ in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ such that $\acute{\zeta}_x \notin (\mathbb{F}, \mathcal{E})$, there exist F$\boldsymbol{\mathcal{S}}$ open sets $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ such that $\acute{\zeta}_x \in (\mathcal{U}, \mathcal{E})$, and $(\mathbb{F}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$" and $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^*(\mathcal{V}, \mathcal{E}) = 0$.

Proof:

For each "$\acute{\zeta}_x \in \mathcal{Z}$ and a F$\boldsymbol{\mathcal{S}}$ closed set $(\mathbb{F}, \mathcal{E})$such that $\acute{\zeta}_x \notin (\mathbb{F}, \mathcal{E})$, By theorem 3.6(ii) there exist a F$\boldsymbol{\mathcal{S}}$ open set $(\mathcal{W}, \mathcal{E})$ containing $\acute{\zeta}_x$ such that $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{W}, \mathcal{E}) \subseteq (\mathcal{U}, \mathcal{E})$.
Let $(\mathcal{V}, \mathcal{E}) = \mathcal{Z}$- $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E})$. Then $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{W}, \mathcal{E}) \subseteq (\mathcal{U}, \mathcal{E}) \subseteq \mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \subseteq \mathcal{Z}$- $(\mathbb{F}, \mathcal{E})$.
This implies that $(\mathbb{F}, \mathcal{E}) \subseteq \mathcal{Z}$- $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) = (\mathcal{V}, \mathcal{E})$or $(\mathbb{F}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$.
Also $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^*(\mathcal{V}, \mathcal{E}) = \mathcal{K}_{\mathcal{Z}}^*(\mathcal{W}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^*(\mathcal{Z}$- $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E})) \subseteq (\mathcal{U}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^*(\mathcal{Z}$- $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \subseteq \mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^*(\mathcal{Z}$- $\mathcal{K}_{\mathcal{Z}}^*(\mathcal{U}, \mathcal{E}))=0$. Thus $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ are the required F$\boldsymbol{\mathcal{S}}$ open sets in
$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$".

Corollary:3.9

Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ be a F$\boldsymbol{\mathcal{S}}$ ideal closure space, $(\mathbb{F}, \mathcal{E})$ is a F$\boldsymbol{\mathcal{S}}$ subset of
$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ and $\acute{\zeta}_x \in \mathcal{Z}$. Then

(i) If $\acute{\zeta}_x \in (\mathbb{F}, \mathcal{E})$ if and only if $\{\acute{\zeta}_x\} \subseteq (\mathbb{F}, \mathcal{E})$.

(ii) If $\{\acute{\zeta}_x\} \wedge (\mathbb{F}, \mathcal{E}) = 0$ then $\acute{\zeta}_x \notin (\mathbb{F}, \mathcal{E})$".

Theorem:3.10

Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ be a F$\boldsymbol{\mathcal{S}}$ ideal closure space, $\acute{\zeta}_x \in \mathcal{Z}$, if $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is regular F$\boldsymbol{\mathcal{S}}$ ideal closure space then

(i) $\acute{\zeta}_x \notin (\mathbb{F}, \mathcal{E})$ if and only if $\{\acute{\zeta}_x\} \wedge (\mathbb{F}, \mathcal{E}) = 0$, for every F$\boldsymbol{\mathcal{S}}$closed set $(\mathbb{F}, \mathcal{E})$.

(ii) $\acute{\zeta}_x \notin (\mathcal{G}, \mathcal{E})$ if and only if $\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) = 0$, for every fuzzy soft open set $(\mathcal{G}, \mathcal{E})$.

Proof:

(i) Let $(\mathbb{F}, \mathcal{E})$ be a F$\boldsymbol{\mathcal{S}}$closed set such that $\acute{\zeta}_x \notin (\mathbb{F}, \mathcal{E})$. Since $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is a F$\boldsymbol{\mathcal{S}}$ideal closure regular space there exists a F$\boldsymbol{\mathcal{S}}$ open set $(\mathcal{G}, \mathcal{E})$ such that $\acute{\zeta}_x \in (\mathcal{G}, \mathcal{E})$ and $(\mathcal{G}, \mathcal{E}) \wedge (\mathbb{F}, \mathcal{E}) = 0$, then $\acute{\zeta}_x \notin (\mathbb{F}, \mathcal{E})$ from 3.10 (ii).

(ii) Let $(\mathcal{G}, \mathcal{E})$ be F$\boldsymbol{\mathcal{S}}$open set such that $\acute{\zeta}_x \notin (\mathcal{G}, \mathcal{E})$. we take $\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) = 0$.

Hence $\mathcal{Z}$- $(\mathcal{G}, \mathcal{E})$ is F$\boldsymbol{\mathcal{S}}$ closed set such that $\acute{\zeta}_x \notin \mathcal{Z}$- $(\mathcal{G}, \mathcal{E})$ it follows that by (i) $\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) = 0$. Hence $\mathcal{Z}$- $(\mathcal{G}, \mathcal{E})$ is a F$\boldsymbol{\mathcal{S}}$ closed set such that $\acute{\zeta}_x \notin \mathcal{Z}$- $(\mathcal{G}, \mathcal{E})$ it follows by (i), $\{\acute{\zeta}_x\} \wedge \mathcal{Z}$- $(\mathcal{G}, \mathcal{E}) = 0$. This implies that $\{\acute{\zeta}_x\} \subseteq (\mathcal{G}, \mathcal{E})$ and so $\acute{\zeta}_x \in (\mathcal{G}, \mathcal{E})$. Which is a contradiction to $\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) \neq 0$. Therefore $\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) = 0$. Conversely if $\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) = 0$ then it obvious that $\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) \notin (\mathcal{G}, \mathcal{E})$".

Corollary 3.11

Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ be a F$\boldsymbol{\mathcal{S}}$ ideal closure space and $\acute{\zeta}_x \in \mathcal{Z}$. If$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is regular F$\boldsymbol{\mathcal{S}}$ideal closure space then the following are equivalent

(i) F$\boldsymbol{\mathcal{S}}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is T_1 space.

(ii) Every $\acute{\zeta}_x, \acute{\zeta}_y \in \mathcal{Z}$ such that $\acute{\zeta}_x \neq \acute{\zeta}_y$ there exists F$\boldsymbol{\mathcal{S}}$ open set $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ such that $\{\acute{\zeta}_x\} \subseteq (\mathbb{F}, \mathcal{E})$ and $\{\acute{\zeta}_x\} \wedge (\mathcal{U}, \mathcal{E}) = 0$ and $\{\acute{\zeta}_y\} \subseteq (\mathcal{V}, \mathcal{E})$ and $\{\acute{\zeta}_y\} \wedge (\mathcal{V}, \mathcal{E}) = 0$".

Theorem: 3.12

Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ be a F$\boldsymbol{\mathcal{S}}$ ideal closure space and $\acute{\zeta}_x \in \mathcal{Z}$.Then the following are equivalent

(i) $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is regular F$\boldsymbol{\mathcal{S}}$ ideal closure space

(ii) For every F$\boldsymbol{\mathcal{S}}$ closed set $(\mathcal{G}, \mathcal{E})$ such that $\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) = 0$ there exists F$\boldsymbol{\mathcal{S}}$ open $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ such that $\{\acute{\zeta}_x\} \subseteq (\mathcal{U}, \mathcal{E})$, $(\mathcal{G}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$ and $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$".

Proof:

(1) ⇒ (2)

Let "$(\mathcal{G}, \mathcal{E})$ be a F$\boldsymbol{\mathcal{S}}$ closed set such that $\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) = 0$ then $\acute{\zeta}_x \notin (\mathcal{G}, \mathcal{E})$ from theorem 3.11(i), it follows by (i) there exists F$\boldsymbol{\mathcal{S}}$ open sets $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ such that $\acute{\zeta}_x \in (\mathcal{U}, \mathcal{E})$, $(\mathcal{G}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$ and $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$.

(2) ⇒ (1)

Let $(\mathcal{G}, \mathcal{E})$ be a F$\boldsymbol{\mathcal{S}}$ closed set such that $\acute{\zeta}_x \notin (\mathcal{G}, \mathcal{E})$. Then$\{\acute{\zeta}_x\} \wedge (\mathcal{G}, \mathcal{E}) = 0$, Theorem 3.10, it follows by (ii) there exists F$\boldsymbol{\mathcal{S}}$ open sets $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ such that $\acute{\zeta}_x \in (\mathcal{V}, \mathcal{E})$, $(\mathcal{G}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$and $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$. Hence $\acute{\zeta}_x \in (\mathcal{U}, \mathcal{E})$, $(\mathcal{G}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$ and $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$.

Then $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is regular F$\boldsymbol{\mathcal{S}}$ ideal closure space".

Normal and T_4- space in F$\boldsymbol{\mathcal{S}}$ideal closure spaces

Definition 4.1

A F$\boldsymbol{\mathcal{S}}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^*)$ is said to be normal F$\boldsymbol{\mathcal{S}}$ideal closure space if for each pair of disjoint F$\boldsymbol{\mathcal{S}}$ closed sets $(\mathcal{F}, \mathcal{E})$ and $(\mathcal{G}, \mathcal{E})$ there exists disjoint F$\boldsymbol{\mathcal{S}}$ open sets $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ such that $(\mathcal{F}, \mathcal{E}) \subset (\mathcal{U}, \mathcal{E})$, $(\mathcal{G}, \mathcal{E}) \subset (\mathcal{V}, \mathcal{E})$ such that $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) = 0$.

Example: 4.2
Let "$\mathcal{Z}$={a, b}, $\mathcal{E}$ ={e} if for each pair of disjoint F$\mathcal{S}$ closed sets $(\mathcal{F},\mathcal{E})$ and $(\mathcal{G},\mathcal{E})$ such that $\mathcal{F}$(e) ={(a,1), (b,0)} and $\mathcal{G}$(e) = {(a,0), (b,1)} there exists disjoint F$\mathcal{S}$ open sets $(\mathcal{U},\mathcal{E})$ and $(\mathcal{V},\mathcal{E})$ such that $\mathcal{U}$(e) = {(a,1), (b,0)} and $\mathcal{V}$(e) = {(a,0), (b,1)}. Hence $(\mathcal{F},\mathcal{E}) \subseteq (\mathcal{U},\mathcal{E})$and $(\mathcal{G},\mathcal{E}) \subseteq (\mathcal{V},\mathcal{E})$ implies that $\mathcal{U}$(e) $\wedge$ $\mathcal{V}$(e) = 0".

$\mathcal{D}$efinition 4.3
A F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ of T_4- space is a normal F$\mathcal{S}$ ideal closure of T_1- space.

Theorem: 4.4
Every F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ of T_4- space is also T_3- space.

Proof:
Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ be a T_4- space then $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is normal F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ as well as T_1- space. To prove that the F$\mathcal{S}$ ideal closure space is T_3- space. It is sufficient to show that the F$\mathcal{S}$ ideal closure space is regular F$\mathcal{S}$ideal closure space.

Let $(\mathbb{F},\mathcal{E})$ be a F$\mathcal{S}$ closed subset of $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ and let $\acute{\zeta}_x$ be a F$\mathcal{S}$ point of $\mathcal{Z}$ such that $\acute{\zeta}_x \notin (\mathbb{F},\mathcal{E})$. Since F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is a T_1- space. Thus $\{\acute{\zeta}_x\}$ is F$\mathcal{S}$ closed subset of $\mathcal{Z}$ such that $\{\acute{\zeta}_x\}\wedge(\mathbb{F},\mathcal{E})=0$ then by normality, there exist disjoint F$\mathcal{S}$ open sets $(\mathcal{U},\mathcal{E})$ and $(\mathcal{V},\mathcal{E})$ such that $\{\acute{\zeta}_x\}\subseteq(\mathcal{U},\mathcal{E})$, $(\mathbb{F},\mathcal{E})\subseteq (\mathcal{V},\mathcal{E})$. Also $\{\acute{\zeta}_x\}\subseteq(\mathcal{U},\mathcal{E})$, then $\acute{\zeta}_x \in(\mathcal{U},\mathcal{E})$, then there exist F$\mathcal{S}$ open sets $(\mathcal{U},\mathcal{E})$, $(\mathcal{V},\mathcal{E})$ such that $\acute{\zeta}_x \in(\mathcal{U},\mathcal{E})$, $(\mathbb{F},\mathcal{E})\subseteq (\mathcal{V},\mathcal{E})$ and $(\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E}) = 0$. It follows that the F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$" is regular F$\mathcal{S}$ ideal closure space and also T_3- space.

Theorem: 4.6
In a "F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$, every F$\mathcal{S}$ closed subspace of a normal F$\mathcal{S}$ ideal closure space is also normal F$\mathcal{S}$" ideal closure space.

Proof:
Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ be a normal F$\mathcal{S}$ ideal closure space. Let $(\mathcal{Y}, \mathfrak{T}_{F}, \mathcal{K}_{\mathcal{Y}}^{*})$ be a F$\mathcal{S}$ ideal closure subspace of $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$. Let $(\mathbb{F},\mathcal{E})$ and $(\mathcal{G},\mathcal{E})$ are $\mathcal{K}_{\mathcal{Y}}^{*}$ F$\mathcal{S}$ closed subsets in $(\mathcal{Y}, \mathfrak{T}_{F}, \mathcal{K}_{\mathcal{Y}}^{*})$. Then there exist F$\mathcal{S}$ closed sets $(\mathcal{F},\mathcal{E})$ and $(\mathcal{G},\mathcal{E})$ in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ such that $(\mathbb{F},\mathcal{E})= \mathcal{Y} \wedge(\mathbb{F},\mathcal{E})$, $(\mathcal{G},\mathcal{E})= \mathcal{Y} \wedge (\mathcal{G},\mathcal{E})$. Since $\mathcal{Y}$ is F$\mathcal{S}$ ideal closure in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$, therefore $(\mathbb{F},\mathcal{E})$ and $(\mathcal{G},\mathcal{E})$ are two disjoint F$\mathcal{S}$ closed sets in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$. Then $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is normal F$\mathcal{S}$ ideal closure space then there exists F$\mathcal{S}$ open sets $(\mathcal{U},\mathcal{E})$ and $(\mathcal{V},\mathcal{E})$ in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ such that $(\mathbb{F},\mathcal{E}) \subset(\mathcal{U},\mathcal{E})$, $(\mathcal{G},\mathcal{E}) \subset (\mathcal{V},\mathcal{E})$, $(\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E}) = 0$. But then $(\mathbb{F},\mathcal{E})\subseteq (\mathcal{U},\mathcal{E}) \wedge \mathcal{Y}$ and $(\mathcal{G},\mathcal{E})\subseteq (\mathcal{V},\mathcal{E}) \wedge \mathcal{Y}$ where $\mathcal{Y} \wedge (\mathcal{U},\mathcal{E})$, $\mathcal{Y} \wedge (\mathcal{V},\mathcal{E})$ are disjoint F$\mathcal{S}$ open subsets of $(\mathcal{Y}, \mathfrak{T}_{F}, \mathcal{K}_{\mathcal{Y}}^{*})$. This prove that $(\mathcal{Y}, \mathfrak{T}_{F}, \mathcal{K}_{\mathcal{Y}}^{*})$" is normal F$\mathcal{S}$ideal closure subspace.

Theorem: 4.7
A "F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is normal F$\mathcal{S}$ ideal closure space implies that given F$\mathcal{S}$ closed set $(\mathbb{F},\mathcal{E})$ and F$\mathcal{S}$ open set $(\mathcal{U},\mathcal{E})$ such that $(\mathbb{F},\mathcal{E}) \subset (\mathcal{U},\mathcal{E})$, there exists F$\mathcal{S}$ open set $(\mathcal{V},\mathcal{E})$ and F$\mathcal{S}$ closed set $(\mathcal{G},\mathcal{E})$ such that $(\mathbb{F},\mathcal{E}) \subseteq (\mathcal{V},\mathcal{E}) \subseteq (\mathcal{G},\mathcal{E}) \subseteq (\mathcal{U},\mathcal{E})$".

Proof:
Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ be a normal F$\mathcal{S}$ ideal closure space. Let $(\mathbb{F},\mathcal{E}) \subseteq (\mathcal{U},\mathcal{E})$, where $(\mathbb{F},\mathcal{E})$ is F$\mathcal{S}$ closed set and $(\mathcal{U},\mathcal{E})$ is F$\mathcal{S}$ open set. Therefore $(\mathbb{F},\mathcal{E}) \wedge \mathcal{Z}$- $(\mathcal{U},\mathcal{E})$=0, where $\mathcal{Z}$- $(\mathcal{U},\mathcal{E})$ is F$\mathcal{S}$ closed set. Therefore there exist F$\mathcal{S}$ open set $(\mathcal{V},\mathcal{E})$ and $(\mathcal{W},\mathcal{E})$ such that $(\mathbb{F},\mathcal{E}) \subseteq (\mathcal{V},\mathcal{E})$, $\mathcal{Z}$- $(\mathcal{U},\mathcal{E}) \subseteq (\mathcal{W},\mathcal{E})$ and $(\mathcal{U},\mathcal{E}) \wedge (\mathcal{V},\mathcal{E}) = 0$. $\mathcal{Z}$- $(\mathcal{U},\mathcal{E}) \subseteq (\mathcal{W},\mathcal{E}) \Rightarrow \mathcal{Z}$- $(\mathcal{W},\mathcal{E}) \subseteq (\mathcal{U},\mathcal{E})$. $(\mathcal{V},\mathcal{E}) \wedge(\mathcal{W},\mathcal{E}) = 0 \Rightarrow (\mathcal{V},\mathcal{E}) \subset \mathcal{Z}$- $(\mathcal{W},\mathcal{E}) \subseteq (\mathcal{U},\mathcal{E})$. Also $(\mathbb{F},\mathcal{E}) \subseteq (\mathcal{V},\mathcal{E}) \subseteq \mathcal{Z}$- $\mathcal{W},\mathcal{E}) \subseteq(\mathcal{U},\mathcal{E})$. If we take $\mathcal{Z}$- $(\mathcal{W},\mathcal{E})= (\mathcal{G},\mathcal{E})$ then $(\mathcal{G},\mathcal{E})$ is F$\mathcal{S}$ closed set. Thus, we have $(\mathbb{F},\mathcal{E})\subseteq (\mathcal{V},\mathcal{E}) \subseteq (\mathcal{G},\mathcal{E}) \subseteq (\mathcal{U},\mathcal{E})$".

Theorem: 4.8

Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ be a F$\mathcal{S}$ ideal closure space. Then the following statements are equivalent:

(i) $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is normal F$\mathcal{S}$ideal closure space.

(ii) For each F$\mathcal{S}$ closed set $(\mathbb{F}, \mathcal{E})$ and for each F$\mathcal{S}$ open set $(\mathcal{U}, \mathcal{E})$ of $(\mathbb{F}, \mathcal{E})$ there exist a F$\mathcal{S}$ open set $(\mathcal{V}, \mathcal{E})$ of $(\mathbb{F}, \mathcal{E})$ such that $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E}) \subset (\mathcal{U}, \mathcal{E})$.

(iii) For each pair of disjoint F$\mathcal{S}$ closed set $(\mathbb{F}, \mathcal{E})$) and $(\mathcal{G}, \mathcal{E})$ in fuzzy soft ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ there exists a F$\mathcal{S}$ open set $(\mathcal{U}, \mathcal{E})$ of $(\mathbb{F}, \mathcal{E})$ such that $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{G}, \mathcal{E})=0$".

Proof

$(i) \Longrightarrow (ii)$

Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is normal F$\mathcal{S}$ideal closure space. Let $(\mathbb{F}, \mathcal{E})$ be a F$\mathcal{S}$ closed set and $(\mathcal{U}, \mathcal{E})$ any F$\mathcal{S}$ open set of $(\mathbb{F}, \mathcal{E})$. Now $(\mathcal{F}, \mathcal{E})$ and $\mathcal{Z}$-$(\mathcal{U}, \mathcal{E})$ are F$\mathcal{S}$ closed set in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ and $(\mathbb{F}, \mathcal{E}) \subset (\mathcal{U}, \mathcal{E})$ implies that $(\mathbb{F}, \mathcal{E}) \wedge \mathcal{Z}$-$(\mathcal{U}, \mathcal{E})=0$. Since$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is normal F$\mathcal{S}$ ideal closure space there exists a F$\mathcal{S}$ open set $(\mathcal{V}, \mathcal{E})$ of $(\mathbb{F}, \mathcal{E})$ and a F$\mathcal{S}$ open set $(\mathcal{W}, \mathcal{E})$ of $\mathcal{Z}$-$(\mathcal{U}, \mathcal{E})$ such that $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{W}, \mathcal{E})=0. \Longrightarrow (\mathcal{V}, \mathcal{E}) \subset \mathcal{Z}$-$(\mathcal{W}, \mathcal{E}) \Longrightarrow (\mathcal{V}, \mathcal{E})) \subset \mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{Z}$-$(\mathcal{W}, \mathcal{E}))$. Since $\mathcal{Z}$-$(\mathcal{W}, \mathcal{E})$ is F$\mathcal{S}$ closed set. $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E}) \wedge (\mathcal{W}, \mathcal{E})=0$. But $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E}) \wedge \mathcal{Z}$-$(\mathcal{U}, \mathcal{E}) \subset \mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E}) \wedge (\mathcal{W}, \mathcal{E})=0$. So $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E}) \wedge \mathcal{Z}$-$(\mathcal{W}, \mathcal{E})=0$. Thus $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E}) \subset (\mathcal{U}, \mathcal{E})$.

$(ii) \Longrightarrow (iii)$

Let $(\mathbb{F}, \mathcal{E})$, $(\mathcal{G}, \mathcal{E})$ be disjoint F$\mathcal{S}$ closed set in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$. Since $(\mathbb{F}, \mathcal{E}) \wedge (\mathcal{G}, \mathcal{E})=0$. We have $(\mathbb{F}, \mathcal{E}) \subset \mathcal{Z}$- $(\mathcal{G}, \mathcal{E})$ where $\mathcal{Z}$- $(\mathcal{G}, \mathcal{E})$ is F$\mathcal{S}$ open. Hence $\mathcal{Z}$- $(\mathcal{G}, \mathcal{E})$ is F$\mathcal{S}$ open set of $(\mathbb{F}, \mathcal{E})$. Therefore by (ii) there exist an F$\mathcal{S}$ open set $(\mathcal{U}, \mathcal{E})$ of $(\mathbb{F}, \mathcal{E})$ such that $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{U}, \mathcal{E}) \subset \mathcal{Z}$- $(\mathcal{G}, \mathcal{E})$. So $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{G}, \mathcal{E})=0$.

$(iii) \Longrightarrow (i)$

Let $(\mathbb{F}, \mathcal{E})$, $(\mathcal{G}, \mathcal{E})$ be disjoint F$\mathcal{S}$ closed set in $\mathcal{Z}$. Then by (iii) there exists a F$\mathcal{S}$ open set $(\mathcal{U}, \mathcal{E})$ of $(\mathbb{F}, \mathcal{E})$ such that $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{G}, \mathcal{E})=0$. Now $(\mathcal{G}, \mathcal{E})$ and $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{W}, \mathcal{E})$ are disjoint F$\mathcal{S}$ closed set in $\mathcal{Z}$. Hence by (iii) again there exist F$\mathcal{S}$ open set $(\mathcal{V}, \mathcal{E})$of $(\mathcal{G}, \mathcal{E})$ such that $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{U}, \mathcal{E})=0$. But $0 \subset (\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E}) \subset \mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{U}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E})=0$. Therefore $(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E})=0$. Hence $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$" is normal F$\mathcal{S}$ideal closure space.

Completely normal F$\mathcal{S}$ ideal closurespaces

***𝒟*efinition 5.1**

A F$\mathcal{S}$ ideal closure space "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is said to be completely normal F$\mathcal{S}$ ideal closure space if for each pair of disjoint F$\mathcal{S}$ closed set $(\mathbb{F}, \mathcal{E})$ and $(\mathcal{G}, \mathcal{E})$ in $\mathcal{Z}$, there exist F$\mathcal{S}$ open set $(\mathcal{U}, \mathcal{E})$, $(\mathcal{V}, \mathcal{E})$ such that $(\mathbb{F}, \mathcal{E}) \subseteq (\mathcal{U}, \mathcal{E})$, $(\mathcal{G}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$ and $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{U}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E})=0$".

Example 5.2

Let "$\mathcal{Z}$={a,b}, $\mathcal{E}$={e} if for each pair of disjoint F$\mathcal{S}$ closed sets $(\mathbb{F}, \mathcal{E})$ and $(\mathcal{G}, \mathcal{E})$ such that$\mathbb{F}$(e) ={(a,1), (b,0)} and $\mathcal{G}$(e) = {(a,0), (b,1)} there exists disjoint F$\mathcal{S}$ open sets $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ such that $\mathcal{U}$(e) = {(a,1), (b,0)} and $\mathcal{V}$(e) = {(a,0), (b,1)}. Hence

$(\mathbb{F}, \mathcal{E}) \subseteq (\mathcal{U}, \mathcal{E})$and $(\mathcal{G}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$ implies that $\mathcal{U}$(e) $\wedge$ $\mathcal{V}$(e) = 0. They are distinct.Also $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{U}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E})= 0$". Hence F$\mathcal{S}$ ideal closure space $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ satisfies the normal F$\mathcal{S}$ ideal closure space condition then the F$\mathcal{S}$ ideal closure space is called completely normal F$\mathcal{S}$ ideal closure space.

Theorem 5.3

If $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is completely normal F$\mathcal{S}$ideal closure space then it is normal F$\mathcal{S}$ ideal closure space.

Proof

If "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is completely normal F$\boldsymbol{\mathcal{S}}$ ideal closure space. Let $(\mathbb{F}, \mathcal{E})$ and $(\mathcal{G}, \mathcal{E})$ are two disjoint F$\boldsymbol{\mathcal{S}}$ closed set. Since $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is completely normal F$\boldsymbol{\mathcal{S}}$ ideal closure space then there exist F$\boldsymbol{\mathcal{S}}$ open set $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ such that $(\mathbb{F}, \mathcal{E}) \subseteq (\mathcal{U}, \mathcal{E})$, $(\mathcal{G}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$ and $\mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{U}, \mathcal{E}) \wedge \mathcal{K}_{\mathcal{Z}}^{*}(\mathcal{V}, \mathcal{E})=0$. By the axioms of F$\boldsymbol{\mathcal{S}}$ ideal closure space, we have

$(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E})=0$". Thus $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is completely normal F$\mathcal{S}$ ideal closure space.

Theorem 5.4

If $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is completely normal F$\mathcal{S}$ ideal closure space then every subspace is normal F$\boldsymbol{\mathcal{S}}$ ideal closure space.

Proof

Let "$(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$ is completely normal F$\mathcal{S}$ideal closure space and $(\mathcal{Y}, \mathfrak{T}_{F}, \mathcal{K}_{\mathcal{Y}}^{*})$ be a subspace of F$\mathcal{S}$ ideal closure space. Let $(\mathbb{F}, \mathcal{E})$ and

$(\mathcal{G}, \mathcal{E})$ are two disjoint F$\mathcal{S}$ closed set in $(\mathcal{Y}, \mathfrak{T}_{F}, \mathcal{K}_{\mathcal{Y}}^{*})$. Then $(\mathbb{F}, \mathcal{E}) = (\mathcal{H}, \mathcal{E}) \wedge \mathcal{Y}$ and $(\mathcal{G}, \mathcal{E}) = (\mathcal{T}, \mathcal{E}) \wedge \mathcal{Y}$ where $(\mathcal{H}, \mathcal{E})$ and $(\mathcal{T}, \mathcal{E})$ are closed sets in $(\mathcal{Z}, \mathfrak{T}_{\mathcal{F}}, \mathcal{K}_{\mathcal{Z}}^{*})$. Then there exists F$\mathcal{S}$ open set $(\mathcal{U}, \mathcal{E})$ and $(\mathcal{V}, \mathcal{E})$ such that $(\mathcal{H}, \mathcal{E}) \subseteq (\mathcal{U}, \mathcal{E})$, $(\mathcal{T}, \mathcal{E}) \subseteq (\mathcal{V}, \mathcal{E})$ and

$(\mathcal{U}, \mathcal{E}) \wedge (\mathcal{V}, \mathcal{E})=0$. This implies $(\mathcal{H}, \mathcal{E}) \wedge \mathcal{Y} \subseteq (\mathcal{U}, \mathcal{E}) \wedge \mathcal{Y}$, $(\mathcal{T}, \mathcal{E}) \wedge \mathcal{Y} \subseteq (\mathcal{V}, \mathcal{E}) \wedge \mathcal{Y}$, and

$((\mathcal{U}, \mathcal{E}) \wedge \mathcal{Y}) \wedge ((\mathcal{V}, \mathcal{E}) \wedge \mathcal{Y}) =0$". Thus F$\mathcal{S}$ ideal closure subspace $(\mathcal{Y}, \mathfrak{T}_{F}, \mathcal{K}_{\mathcal{Y}}^{*})$ is normal F$\mathcal{S}$ideal closure space.

CONCLUSION

This paper redefines and investigates the separation axioms of regular F$\mathcal{S}$ideal closure space, T_3, normal F$\mathcal{S}$ideal closure space, T_4 and completely normal F$\mathcal{S}$ideal closure space in fuzzy soft ideal closure spaces. We also discussed several important discoveries and how they relate to one another.
