By way of RANK/RANKL (Receptor Activator of Nuclear Factor κB Ligand), inflammatory cytokines facilitate osteoclast differentiation that causes bone erosions and resorption. The enzymes that cause degeneration of articular cartilage are produced by synovial fibroblasts and active chondrocytes [24,31,32,33]. Persistent presence of inflammatory mediators leads to inability of bones to heal by inhibition of osteoblast functions. Deformities like ulnar deviation, swan-neck deformity, and boutonniere deformity develop due to reduced joint space and gradual destruction of cartilage [25].

Systemic Manifestations

In RA, the involvement is not limited to joints only. The systemic manifestations caused by inflammatory mediators involve accelerated atherosclerosis, vasculitis, pericarditis, interstitial lung disease, and rheumatoid nodules. Pro-inflammatory cytokines increase susceptibility to cardiovascular diseases by altering endothelial function and lipid metabolism [25,27].

Chronicity and Self - Perpetuating Inflammation

Despite progression of the disease to the point where the stimuli are no longer present, inflammation persists through changes induced in immune cells and synoviocytes at the metabolic and epigenetic levels. Metabolic and molecular characteristics such as behaviour, apoptosis resistance, and continuous production of inflammatory mediators characterize the tumorous nature of FLS. Chronicity in Rheumatoid Arthritis is characterized by perpetuity of inflammatory pathways [4,15,34,35].

CLINICAL TYPES

All these things diagnosis, progression of the disease, and individual treatments are contingent on the clinical classification of the RA. Rather than relying purely on laboratory or immunologic findings, RA is clinically classified based on the onset, progression, and joint and organ involvement of the disease. Accepting the variations that exist in the clinical picture will be beneficial to doctors in creating treatment plans [36,37]. Clinical forms of RA are generally categorized according to,

- Disease Onset,
- Pattern or course,
- Joint Involvement, and
- Systemic Manifestations.

Based on Disease Onset

Acute Onset Rheumatoid Arthritis: The presentation of this type is usually within days or weeks. There is severe joint pain, joint stiffness, and joint swelling. Systemic signs include malaise, fatigue, and fever. It is less frequent but responds well to treatment [4,5].

Insidious Onset Rheumatoid Arthritis: Of all the diverse forms in which RA presents itself, there are symptoms that take time, from a couple of months, before they show up. After experiencing modest weariness and stiffness at first,

patients may develop symmetrical polyarthritis, which usually affects the tiny joints in the hands and feet. One of the hallmarks is morning stiffness that lasts for more than an hour [38].

Based on Disease Pattern / Course

Monocyclic (Self - limiting) RA: In this case, there is just one, two to five-year episode of active disease that is followed by a prolonged period of disease-free remission. It is not serious and usually responds well to aggressive treatment.

Polycyclic (Relapsing - Remitting) RA: Distinguished by episodes of remission and flare-ups of the disease. Consistent use of treatment that modifies the disease is necessary since each flare-up causes joint damage.

Progressive (Chronic Persistent) RA: A serious form of the condition that is persistent and continues despite treatment, leading to cartilage breakdown and inflammation. Apart from physical problems, sufferers often end up with deformities like those of boutonnière and swan neck [4,5,39].

Based on Joint Involvement

Symmetrical Polyarthritis: The same joints on both sides of the body are affected in this classic RA clinical picture. The wrist, proximal interphalangeal (PIP), and metacarpophalangeal (MCP) joints are frequently impacted. Decreased mobility and deformity of joints can result from chronic inflammation [24,25].

Asymmetrical Arthritis: Irregularities in appearance with joint problems on both sides of the body. Patients who are seronegative or young people who show symptoms earlier will be prone to it. It might develop into a more symmetrical pattern over time [26,27].

Based on Systemic Involvement

Articular RA

Systemic characteristics are either non-existent or very mild, and the symptoms are restricted to the joints. Joint pain and stiffness are due to the direct effect of the disease on the synovium.

Systemic (Extra-Articular) RA

This is a more advanced disorder with other symptoms caused by vasculitis and widespread inflammation. This includes rheumatoid nodules, pleuritis, pericarditis, lung fibrosis, persistent anaemia, and peripheral neuropathies. It frequently indicates a dismal prognosis [24,27,39].

Risk Factors

The total probability of susceptibility, duration, and seriousness of the condition is determined by the complicated interplay between environmental and host factors in RA. Risk factors can be classified broadly into two groups: environmental variables like smoking, disruption in the microbial community, diet, and occupation; and host factors like genetics, epigenetics, hormones, and associated illnesses [36].

Host-Related Risk Factors

Genetic factor: The main host-related indicator of RA susceptibility is genetics, which is responsible for 50–65% of disease risk. Hereditary risk is higher in ACPA-positive conditions (in the range of 50%) compared to ACPA-negative disease (20%). Approximately a third of genetic vulnerability can be described by the HLA-DRB1 shared epitope (SE), that encodes for five amino acids at residues 70–74. It is the most significant genetic risk factor. Twin studies show that the chance of having RA among monozygotic twins with one diseased individual range between 9 and 15%, which is 25-35 times higher than the general population [37,38].

Epigenetic modifications: Reduced concordance rates among monozygotic twins result from epigenetic modification, including DNA methylation, histone modification, and microRNAs (miR-155, miR-146a, miR-223, and miR-124a). Epigenetic modification controls gene expression without changing the DNA sequence. Patients with RA observe global hypomethylation of peripheral blood mononuclear cells coupled with heightened histone deacetylase

activity resulting in reduced expression of anti-inflammatory genes, especially in regulatory T cells (CTLA4), and heightened expression of pro-inflammatory genes such as IL-6, IL-6R, CXCL12, and CD40L [39,40].

Hormonal and neuroendocrine factor: RA's prevalence in females (2-3:1) is mainly attributed to neuroendocrine factors. Pregnancy itself has traditionally been associated with clinical improvement through significant hormonal changes and a Th1-to-Th2 immunological shift, however the postmenopausal stage, early menopause, and puerperium (postpartum time) are constantly linked to an increased risk of RA [24,25]. Relative adrenal insufficiency with excessively low cortisol and adrenal androgen levels during chronic inflammation is an indication of hypothalamus pituitary adrenal (HPA) axis dysregulation. Although there is conflicting information about vitamin D's protective effect, vitamin D deficiency is frequent in RA patients and has been associated to a poor prognosis, which manifests as increased disease activity and functional impairment. With dose-response effects of body mass index, obesity is positively associated with RA [26,27,41].

Comorbid conditions: Other disease comorbidity that predisposes individuals to RA include depression (the risk for individuals increases by 28-65% in longitudinal cohort studies), post-traumatic stress disorder, and respiratory diseases. Of significance, schizophrenia shows protective effects (0.48-0.65 association) for RA, showing a genetic negative correlation between both conditions. Other possible risk factors include sleep disruptions, notably non-apnea and obstructive sleep apnea [36,38,46].

Environmental Risk Factors

Smoking raises the risk of RA by approximately 40% with a dose-response: less than 10 pack-years increases the risk 26-fold, more than 20 pack-years doubles it, and it synergizes with HLA-DRB1 SE (37.6-fold risk in heavy smokers with the allele vs. 6.3-fold without) [41,42]. Asbestos, silica, and other inhalants present smaller but cumulative dangers. Although there is only a slight correlation between periodontitis and RA, microbiota dysbiosis is weakly linked to the beginning of RA: oral infections cause citrullination in periodontitis, while gut changes (dominance of proinflammatory bacteria) encourage autoimmune [43,44]. Drinking moderate amounts of alcohol (risk reduction of 14%), Mediterranean-type diet (fish, olive oil, and PUFAs), and physical activity for leisure purposes (incidence reduced by 33–35%) are considered preventive factors. Red and processed meats, salt, beverages with added sugars, low educational attainment, blue-collar occupations (pesticides, mineral oils, and cold environments), obesity, and vitamin D insufficiency all contribute to increased risk [45,46].

Laboratory Monitoring

Laboratory tests: High erythrocyte sedimentation rate (>30 mm/h) and/or high C-reactive protein concentration; leukopenia or anemia due to disease-modifying antirheumatic drugs, thrombocytosis (in patients with very active disease) or thrombocytopenia (side effect of medications); high levels of plasma alpha1-globulin and alpha2-globulin; IgM rheumatoid factor in about 75% of patients (high titre is correlated with fast joint destruction and the development of extra joint manifestations); and ACPAs (test sensitivity exceeds 50%, while specificity surpasses 98% in RA patients; around 40% of patients without IgM rheumatoid factor have ACPAs, indicating poor prognosis and fast joint destruction). Together with the other autoantibodies, a novel test called 14-3-3eta is utilized to increase sensitivity and specificity. "JOINTstat" (RF, ACPA, 14-3-3eta) is a commercially available triple antibody test [37,38].

Synovial fluid analysis: Synovial fluid analysis is not a routine part of managing RA inflammation, except in cases where an underlying infection must be ruled out Some physicians think about doing RF testing, which could be found before plasma RF. Phagocytes (neutrophils, macrophages, monocytes, or synoviocytes containing cytoplasmic inclusions of phagocytosed immunological complexes) may be seen in certain cases [24].

Imaging studies: Radiographic imaging of affected joints displays signs that are indicative of the extent of the disease and are characterized by four main features: osteopenia around the joints, swelling of soft tissues, narrowing of the joint space, and/or erosion of the joint margins. Ultrasound can detect synovial thickening, synovial hyperaemia, joint effusions, and erosions in both large and small joints [25].

In addition, MRI provides an opportunity to detect synovitis, joint erosions, and bone marrow oedema, which may occur even before the onset of synovitis [26,27].

Computed Tomography (CT) assessing cervical spine lesions, is especially helpful because it can identify joint destruction earlier than radiographs and is the best way to see bone cysts in patients whose bone cortex continuity is preserved or only slightly altered (in these cases, the MRI signal of the cysts is normal and they may not be visible) [25]. According to X-ray results, bone erosion and cartilage degradation happen initially during the first two years of the condition but continue to worsen over time. Range of motion restrictions, flexion contractures, and subluxation (incomplete dislocation) of articulating bones are the consequences of these anatomical abnormalities. Flexion contractures of the elbows, subluxation of the carpal bones and toes (hammer toes and cock-up deformities), hyperextension or hyperflexion of the MCP and PIP joints (swan neck and boutonnière deformities), and ulnar deviation of the fingers at the MCP joints were typical deformities [26].In the early stages of the disease, radiographic findings could only reveal soft tissue oedema. Periarticular osteopenia may then appear. As the disease progresses, cartilage loss narrows the joint space, and juxta-articular erosions develop, usually near the synovium's attachment point. Large cystic erosions of bone may be observed in end-stage condition [26,27].

DIAGNOSIS

The process for diagnosing rheumatoid arthritis is quite complex, comprising imaging studies, laboratory tests, physical evaluation, and criteria for classification. Rheumatoid arthritis cannot be diagnosed using one specific test; the diagnosis of RA depends on a combination of methods.At the start of any diagnostic process, the physician will conduct a physical exam and obtain the medical history of the individual. The important clinical signs to look out for are

- **Joint manifestations**: Swelling, pain, and tenderness in small joints, including the metatarsophalangeal joints of the foot, proximal interphalangeal joints of the hand and wrist, and metacarpophalangeal joints.
- **Morning stiffness:** Distinguishing inflammatory arthritis from mechanical joint disorders is that the former condition persists for more than an hour.
- **Systemic symptoms**: Fatigue, fever, and feeling generally unwell.
- **Duration of symptoms:** The requirement for diagnosis of definite RA is for symptoms to persist for a minimum period of six weeks [37].

Laboratory diagnostic tests

Blood Tests for Serological Markers

Rheumatoid Factor (RF)

- With an 85% specificity and 69% sensitivity, it is positive in 80–90% of individuals with developed RA.
- While extremely high titres (e.g., 1:512) may suggest more severe disease, an RF titre above 1:80 may indicate the presence of RA.
- A number of autoimmune and viral disorders are not pathognomonic for RA.

Anti-Cyclic Citrullinated Peptide (Anti - CCP) Antibodies

- 60–80% of RA patients possess it.
- 90–96% specificity and 47–76% sensitivity.
- More precise in diagnosing RA than RF.
- Higher doses of therapy must be administered for severe disease, which is correlated with positive anti-CCP antibodies.
- Can forecast when those with arthralgias or those without symptoms may develop clinical RA.

Acute Phase Reactants

Erythrocyte Sedimentation Rate (ESR):

Elevated in RA that is active and helpful in determining the degree of inflammation. A lower ESR suggests improved inflammation management.

C - Reactive Protein (CRP):
An alternate indicator of systemic inflammation, elevated in RA. Improved disease control is indicated by lower CRP levels.

Additional Laboratory Tests

- **Complete Blood Count (CBC)**: May exhibit thrombocytosis and prolonged anaemia. Felty syndrome, an unusual variant of RA, may result in Neutropenia**.**
- **Antinuclear Antibodies (ANA)**: Tests for autoantibodies indicating autoimmune conditions can support diagnosis in some cases.
- **Full Blood Count:** Used as a general health indicator and to rule out other potential causes of symptoms.
- **Multi - Biomarker Disease Activity (MBDA) Test:** Checks for 12 proteins, hormones, and growth factors to assess disease activity.
- **Liver Enzymes:** Helps to determine if liver damage is evident, as a result of RA medication or other related autoimmune diseases.
- **Synovial Fluid Analysis (Arthrocentesis)**: Involves using a needle to aspirate a sample of synovial fluid in order to assess inflammatory markers [38,39].

2010 ACR/EULAR Classification Criteria for Rheumatoid Arthritis
The 2010 American College of Rheumatology/European League Against Rheumatism guidelines, which enhanced early RA detection over the 1987 ACR criteria, is the most preferred diagnostic framework.
The 2010 criteria incorporate four domains with a scoring system:
Scoring System (Total Score 0 - 10)
Joint Involvement (Score 0 - 5)

- 1 large joint (shoulder, elbow, hip, knee, ankle) = 0 points
- 2 -10 large joints = 1 point
- 1 - 3 small joints (MCP, PIP, wrist, MTP) = 2 points
- 4 - 10 small joints = 3 points
- More than 10 joints (at least one small joint) = 5 points

Serology - Rheumatoid Factor or Anti - CCP (Score 0 - 3)

- Negative RF and negative anti - CCP = 0 points
- Low - positive RF or low - positive anti - CCP (1 - 3× upper limit of normal) = 2 points
- High - positive RF or high - positive anti - CCP (>3× upper limit of normal) = 3 points.

Acute Phase Reactants (Score 0 - 1)

- Normal CRP and normal ESR = 0 points.
- Abnormal CRP or abnormal ESR = 1 point.

Duration of Symptoms (Score 0 - 1)

- Less than 6 weeks = 0 points.
- 6 weeks or more = 1 point.

Classification Criterion: Rheumatoid arthritis is a disease that is diagnosed through a score of six or above. Patients who are found to have scores that are less than six may be re-considered as their status advances but are not regarded as the ones who have established RA [40].

TREATMENT
Even though the FDA has not approved any medication to treat rheumatoid arthritis, there are numerous options available that can help to minimize joint pains and also help in improving functionality. A surgery is normally

required in case one experiences the cartilage damage and/or ruptured tendons, although healthcare is necessary to prevent further development of the disease [4,15].

Medications and Medical Management

The drug treating rheumatoid arthritis can be classified into two groups:

- Medications alleviate the symptoms.
- DMARDs, typically prescribed by the rheumatologist tend to alter the progression of the disease.

DMARDs and symptom-relieving drugs can be used together to decrease the dosage of DMARDs and enhance the effectiveness of treatment during the exacerbation of the rheumatoid arthritis. Before the referral to the rheumatologist, the orthopaedic surgeon or general physician will prescribe symptom-relieving drugs [4,5].

Medications for Symptom Relief in RA

Non - steroidal anti-inflammatory drugs (NSAIDs)

Prescription drugs as well as NSAIDs can be used to alleviate pain and inflammation. Prednisone and corticosteroids are powerful anti-inflammatory drugs. These medications may be delivered as an injection into the afflicted joint or the tendons lining orally as pills. There are only short periods of treatment given using corticosteroids due to their side effects brought about by use of the drug over a long period of time. Symptoms can be alleviated with NSAID, as well as with corticosteroids, but the two cannot prevent the further progression of RA [45].

Disease-Modifying Anti-Rheumatic Drugs (DMARDs)

Disease-modifying anti-rheumatic drugs (DMARDs) are used to stop the immune
system to cause damage to the joints. DMARDs slow down the development of RA by controlling hyperactivity of the immune system. They help relieve unpleasant symptoms, minimize inflammation, and prevent harm to your joints.

Two varieties of DMARDS exist:

- Conventional nonbiologic types
- Newer biologic agents

Although the immune system is the objective of both forms, biologics target specific types of immune cells.

Nonbiologic DMARDS.

RA can be treated by the use of different nonbiological DMARDs. The DMARDs are typically in the form of pills that at times need to be administered once in a week. It may take weeks or even months before you will be able to determine whether the DMARD drugs are working. The physician might still prescribe a corticosteroid, such prednisone, or a faster-acting nonsteroidal anti-inflammatory medication in the interim. After the DMARD has had a chance to work, the patient is usually weaned off of anti-inflammatories, indicating they take less and less over time [24,47].

The most commonly used nonbiologic DMARDs are:

- Methotrexate
- Sulfasalazine
- Hydroxychloroquine
- Leflunomide

Whenever an individual's medical condition continues to worsen with the first prescribed medication, DMARDs include

- Azathioprine
- Cyclosporine: however, in considering the availability of newer, more potent agents, these agents have lost favor.

Biologic DMARDs

By inhibiting the activation with specific immune cell types which induce inflammation, biologic DMARDs prevent cartilage damage. These biological agents can take action on specific cells of the immune system that is involved in the inflammatory response. Biologics decrease the body's increased immunological and inflammatory responses rapidly but increase the costs compared to traditional DMARDs. Biologics will become effective two to six weeks following use. They are generally used if the patient does not respond to the conventional DMARD therapy. When the biologic drug is combined with the conventional DMARDs (methotrexate) patients will be able to manage their disease and avoid further loss of their joint functions [25].

The two primary modes of delivery of the biologic drugs include them. They are intravenous and subcutaneous.

- Subcutaneous injections of the patient at home are usually administered by the patient or his or her caregiver.
- In cases of necessity, the IV drugs will be given at the infusion center, hospital or the office of the physician.

Among the most popular FDA-approved biologics to be used in treating RA are tumor necrosis factor inhibitors (anti-TNF). This set of drugs inhibits the tumor necrosis factor, which causes inflammation in the immune system [26].

- Etanercept - given every week subcutaneously,
- Adalimumab - given every 2 weeks subcutaneously,
- Infliximab - given every 6 to 8 weeks intravenously,
- Certolizumab pegol - given every 2 to 4 weeks subcutaneously,
- Golimumab - given monthly subcutaneously,
- Simponi ARIA - given every 8 weeks intravenously.

Other, less often used biologic medicines that may prevent the inflammatory process include

- Tocilizumab (Actemra),
- Sarilumab (Kevzara),
- Abatacept (Orencia).

These too, are given either subcutaneously or through IV every few weeks.

Janus kinase (JAK) inhibitors

JAK inhibitors are a more recent class of DMARDS. Among them are:

- Tofacitinib (Xeljanz)
- Upadacitinib (Rinvoq)
- Baricitinib (Olumiant)

These medications have the advantage of being in pill form.

Potential Side Effects of DMARDs and JAK Inhibitors

Every DMARD, both biologic and conventional, has unique adverse effects. The following are some cases of typical DMARD adverse effects:

- High blood pressure
- Liver damage
- Nausea
- Increased risk of serious infection; this is a major risk of treatment with any DMARD.

Skin being uncomfortable at the injection site is frequently experienced among biologic patients. Besides having the typical side effects of DMARDS, those on JAK inhibitors are also at a risk of developing clots in the blood vessels. Prior to prescribing DMARDs, a screening of patients is undertaken to ensure no contraindications exist for which patients would need to stay away from certain drugs that could otherwise cause them more harm than good. Patients should also be regularly monitored on the side effects of taking the drugs. Patients are also screened before medication is administered on them due to such diseases as tuberculosis and others such as Hepatitis B and C [27].

Physical Therapy and Exercise

The exercise is a part of the treatment program. With an intention to enhance muscle strength below the affected joints without straining the joints, a doctor can collaborate with patients and come up with a suitable exercise program. The physician may recommend braces and splints occasionally on your upper (arms) and/or lower (legs) limbs.

Surgical Treatment

Synovectomy

To minimize discomfort and swelling, the rheumatoid arthritis-damaged synovial joint lining is removed undergoing a synovectomy. When the disease just involves the lining of the joints and has not yet seriously damaged the articular cartilage which covers the bones, synovectomy can be therapeutic. The process is usually only administered to treat RA in its initial stages. Without the maintenance of proper medical care, the synovitis can reoccur. More advanced medical procedures nowadays imply that not so frequently a synovectomy is necessary [31,34].

Tendon Surgery

Reconstructive surgery can help restore function if tendons tear. In the right hands, tendon transfers or repairs can be quite effective.

Trigger fingers and tenosynovitis in the hand and wrist can require:

- Partial release of tight tunnels.
- Partial flexor tendon excision (removal) in the finger.
- Teno - synovectomy to prevent tendon ruptures [24].

Joint Replacement Surgery

Restoring painless joint movement can often be achieved with joint replacement surgery. Doctor conducts this procedure to repair your joint by removing the damaged bone and cartilage and then repositioning the metal or plastic joint surfaces. A combination of certain small joint fusions and/or replacements of joints greatly enhances function, especially in the hand. These procedures may indicate the difference between an active life and a disability for essential joints like the elbow, shoulder, hip, and knee [4,5,15].

PREVENTION

A number of modifiable risk-factor therapies have been demonstrated to delay the onset of the disease or retard the progression of the disease in at-risk individuals.

- Nevertheless, the most important precautionary measure to be considered is the elimination of smoking since cigarette smoke produces immunological responses and citrullination that make it highly related to anti-CCP-positive RA. Thus, cessation of smoking will significantly reduce the risk of contracting RA in future [41,46].
- Concerning the periodontal infection Porphyromonas gingivalis, which can cause protein citrullination, prevention from periodontal disease might be helpful. Therefore, a routine dental care and oral health may also help to minimize risks [42].
- Maintaining normal body weight will not only decrease risks, but also lower systemic inflammation. Obesity has been observed to be associated with seronegative RA and leads to cytokine imbalances [43].
- Limiting exposure to environmental factors like air pollution, dust at work and silica will help reduce risks.
- Individuals who have a significant genetic predisposition (e.g. HLA-DRB1 shared epitope) can reduce the number of inflammatory responses and autoantibody development with a healthy diet that contains plenty of antioxidants and omega-3 fatty acids.
- It is advisable that early life lifestyle changes be made to people with preclinical autoimmune conditions (anti-CCP/RF positivity) in order to delay onset of symptoms.

Lifestyle and Diet Changes

- The most effective method of reducing the prevalence and severity of RA is to quit smoking as chronic tobacco use is a major risk factor and, in people with a genetic predisposition to RA, a primary cause [41,46].

- A Mediterranean diet rich in fruit and vegetables, fish, olive oil and nuts reduce inflammation and has little effect on reducing RA disease activity [43,45].
- As a lack of physical activity worsens symptoms, regular aerobic and resistance exercise, in addition to helping prevent cardiovascular disease and other health conditions such as diabetes, helps reduce joint pains and improve physical performance among RA sufferers.
- The inflammatory effect of obesity that otherwise predisposes the occurrence of RA and the effect of the treatment options is alleviated through proper body mass management through eating well.
- Limiting consumption of beverages sweetened with sugar, which raises the risk of developing RA and worsening the symptoms, is minimized by reducing the consumption of beverages sweetened with sugar and substituting them with water or tea.
- Like heavy alcohol consumption that enhances inflammations and may respond poorly to RA medications, moderate alcohol consumption is preventive against RA.
- The intake of foods containing high fibre content especially vegetables, whole grain foods and beans improve gut microbiota, a factor that is increasingly becoming recognized as an immunomodulatory agent capable of suppressing the inflammation in the body attributed to RA.
- Since the western diet is typified by high consumption of foods like fish oils and flaxseeds, which are rich in the omega-3 fatty acids, it is proposed that its intake may have some benefits as a way of inhibiting the omega-6 and saturated fats which cause the inflammation of RA [45].
- Safety measures can be put in place to prevent the onset of diseases. An example of safety measures at the workplace is ensuring that the potential risks of occupational exposure to such substances like silica, textile dust and chemical substances are reduced [40].
- Since it is known that stress causes a flare-up of RA conditions, stress management using social activities and other methods, may act as complementary treatment.
- Known risk factors to develop autoimmune diseases such as RA are vitamin D deficiency and poor antioxidant status [36,46].

Herbal Drugs for the Management of Ra

Ever since ancient times the use of herbal medicines has been used to cure many diseases, but it is an understatement to say that their use has existed since the beginning of humanity. The herbal medicines are based on the medical knowledge developed through the centuries by doctors practicing ancient medicine. In today's scenario, there is significant interest in the medicinal plants since the existing pharmaceutical medicines are either too expensive or have particular side effects. Nature provides us with numerous herbal plants present all over the world and used as medicinal agents to help us prevent or cure different types of diseases. Generally, the objective of the intense therapy is reduction of the inflammation. Nowadays, the demand for the herbal medicines has increased all over the world as means of treating rheumatoid arthritis [68].The official health care system of Ayurveda, Unani, Sidha, Homeopathy and Naturopathy has used herbal medicines extensively over a period of over 3,000 years. Currently, almost 2500 species of plants have been utilized as herbal medicines in India. Thus, by getting information about ancient herbs it may be possible to find new, cheaper and effective drugs.

CONCLUSION

Plants may offer an optimal adjunctive to RA therapy with much less toxicity than chemical DMARDs. In traditional applications and in experimental studies (induced arthritis by CFA, paw edema), medicinal plants (boswellic acids in *Boswellia serrata*, guggul sterones in *Commiphora mukul*, azadirachtin in *Azadirachta indica*, vitex in *Vitex negundo*, and asparagus in *Asparagus racemosus*) demonstrate anti-inflammatory and anti-arthritic effects. These medicinal herbs containing rich amounts of flavonoids, triterpenoids, sterols, and glycosides inhibit TNF- α, IL-6, leukotrienes, and MMPs and do not affect the joint integrity. It will be highly beneficial to incorporate evidence-based traditional medicine treatment with conventional methods to help increase rates of remission in patients who need fewer DMARDs, especially in poor countries like India. For this very reason, it is essential to remain highly suspicious

about RA cases, especially in individuals who belong to the risk group - namely women, residents of rural areas, and people with genetic predispositions or exposures to some factors to initiate DMARD-based treatment (methotrexate followed by biological therapy or JAK inhibitors) using the 2010 ACR/EULAR criteria in order to achieve remission within the treat-to-target strategy. Along with joint problems, the entire range of extra-articular problems, such as osteoporosis and heart problems, should be taken into account. RA prevention through modification of modifiable risk factors such as cessation of smoking, adoption of a Mediterranean diet high in fibre and omega-3 fatty acids, weight management, good dental hygiene, exercise, optimal levels of vitamin D, and workplace injury prevention can significantly reduce the occurrence and severity of diseases. To resolve the increasing global burden of RA and to implement practical gains in survival, functional capacity and quality of life, requires public health models that focus on universal access to rheumatology services in the poor regions. Future Direction The application of artificial intelligence to early diagnosis through wearables and imaging and to precision medicine through genomic and epigenomic sequencing co-optimized with multiplex biomarker testing to assess individual risk and to customize therapeutic options; innovative drug development, based on IL-23/IL-17 signalling, BTK antagonists, and immune tolerance-inducing vaccines; and full clinical trials of preventive approaches in asymptomatic autoimmunity and in international health programs addressing disparities in LMICs such as India.

Table 1: Pathogenesis of the RA with mediators

Stage	Key Events	Major Mediators/Cells
Initiation	Citrullination, loss of tolerance	HLA-DRB1, T-cells, B-cells
Propagation	Synovial inflammation, pannus formation	TNF-α, IL-1, IL-6, IL-17, FLS
Destruction	Bone erosion, cartilage degradation	MMPs, RANK/RANKL, osteoclasts
Systemic Spread	Vasculitis, cardiovascular effects	Cytokines, immune complexes

Table 2: Clinical Symptoms

Feature	**Details**
Peak onset	Ages 30–50 years.
Sex ratio	Women affected 3× more than men.
Disease course	Mild (15%); prolonged remissions (10%); chronic relapsing/progressive (70%).
Onset pattern	Gradual (75%); acute (10–15%).
Progression	25% of RF+ patients develop advanced RA.
Pregnancy effects	First-trimester remission; postpartum flare (no added risks) [29,30,31].

Table 3 - Musculoskeletal Manifestations of Rheumatoid Arthritis

Joint/Region	Early Features	Advanced Features
Hands (PIP/MCP)	Fusiform swelling; palmar erythema (thenar/hypothenar).	Ulnar deviation; swan-neck/boutonnière deformities; MCP subluxation; muscle atrophy.
Wrists	Radiocarpal/carpal edema; ECU tenosynovitis.	Ulnar styloid erosion ("piano key"sign); carpal tunnel syndrome.
Elbows	Swelling, pain, limited ROM.	Flexion contractures.
Shoulders	Glenohumeral synovitis; rotator cuff	Muscle atrophy; bursitis; subluxation

	tendonitis.	(acromioclavicular rare).
Feet (MTP)	Symmetric pain/swelling.	Toe deformities (mimic hands).
Ankle/Midfoot	N/A	Instability.
Hips	Synovitis (groin pain, gait issues; less common than OA).	N/A
Knees	Effusion (suprapatellar, patellar tap+); medial/lateral swelling.	Ruptured Baker cyst (calf edema/pain, crescent sign; distinguish from DVT).
Cervical spine	N/A	Atlantoaxial subluxation; disk prolapse; paresthesias/paraplegia.
Other	TMJ (pain, limited opening); cricoarytenoid (hoarseness).	Sternoclavicular (rare).
General	Symmetric polyarthritis (hands/feet > others); morning stiffness >1 h; spares DIP/lumbar/hips.	Atypical: Palindromic rheumatism/monoarthritis [32,33].

Table 4 - Extra-Articular Manifestations (Severe, Seropositive RA)

System	Key Manifestations
Nodules	Subcutaneous (extensor surfaces, pressure points); visceral.
Cardiovascular	Pericarditis/effusion; valvular/myocardial lesions; atherosclerosis/thromboembolism; pulmonary hypertension (major mortality cause).
Pulmonary	Pleuritis (asymptomatic effusion); fibrosis; bronchiolitis; nodules (may mimic malignancy).
Ocular	Episcleritis; secondary Sjögren syndrome; rare scleritis ("corneal melt").
Renal	Drug-related; amyloidosis; interstitial nephritis/pyelonephritis
Other	Nervous (carpal tunnel, polyneuropathy, root compression); Felty syndrome (splenomegaly + neutropenia); vasculitis (digital/organ necrosis); lymphadenopathy [34,35].

Table 5: The management of rheumatoid arthritis (RA) is done using herbal drugs, which interact with the inflammatory mediators as illustrated in the table below [47-70]:

S. No	Plant (scientific name)	Family	Part(s) used in arthritis
1	*Abrus precatorius*	Fabaceae / Papilionaceae	Fresh leaves, oil/extract
2	*Acacia catechu*	Fabaceae	Root (extract, decoction)
3	*Acalypha indica*	Euphorbiaceae	Leaves (juice)
4	*Acanthus ilicifolius*	Acanthaceae	Leaves (extract)
5	*Achyranthes aspera*	Amaranthaceae	Root (infusion/decoction)
6	*Aconitum ferox*	Ranunculaceae	Root (liniment, paste; detoxified)
7	*Aconitum palmatum*	Ranunculaceae	Root (paste)
8	*Acorus calamus*	Araceae	Rhizome/root (powder)
9	*Adhatoda vasica (Justicia adhatoda)*	Acanthaceae	Leaves (poultice, decoction)
10	*Aegle marmelos*	Rutaceae	Root, leaves, fruits (juice, aqueous/alcoholic extracts)
11	*Aesculus indica*	Sapindaceae	Fruits (oil)
12	*Agave americana*	Agavaceae /	Leaves (paste)

		Asparagaceae	
13	*Ailanthus excelsa*	Simaroubaceae	Leaves (oil, extract)
14	*Alangium lamarckii*	Cornaceae	Root, bark (oil)
15	*Allium cepa*	Liliaceae / Amaryllidaceae	Bulbs (paste; various extracts)
16	*Allium sativum*	Liliaceae / Amaryllidaceae	Cloves (oil, paste)
17	*Alpinia galanga (A. conchigera)*	Zingiberaceae	Rhizomes (paste, ethanolic extract)
18	*Alstonia scholaris*	Apocynaceae	Bark, latex, leaves (juice, extract)
19	*Amorphophallus campanulatus*	Araceae	Tuber (hot poultice, oil)
20	*Andropogon (Cymbopogon) citratus*	Poaceae	Leaves (oil, liniment)
21	*Anisomeles malabarica*	Lamiaceae	Leaves (oil, decoction)
22	*Aristolochia bracteata / bracteolata*	Aristolochiaceae	Whole plant (various extracts)
23	*Asparagus racemosus*	Liliaceae / Asparagaceae	Roots (oil, methanolic extract)
24	*Azadirachta indica*	Meliaceae	Leaves (decoction; various extracts)
25	*Azima tetracantha*	Salvadoraceae	Leaves, roots (decoction)
26	*Bacopa monnieri*	Plantaginaceae	Whole plant (extract)
27	*Commiphora mukul*	Burseraceae	Stem oleo-gum resin (paste, extracts)
28	*Barleria cristata / B. courtallica*	Acanthaceae	Root (decoction)
29	*Bassia longifolia (Madhuca longifolia)*	Sapotaceae	Seeds (oil); bark (decoction)
30	*Boerhaavia diffusa*	Nyctaginaceae	Root (powder, decoction, paste)
31	*Boswellia serrata*	Burseraceae	Oleogum resin (extracts, formulations)
32	*Butea frondosa (B. monosperma)*	Fabaceae	Roots and leaves (aqueous extract)
33	*Barringtonia racemosa*	Lecythidaceae	Fruits, leaves (various extracts)
34	*Cardiospermum helicacabum*	Sapindaceae	Leaves (alcoholic extract, paste)
35	*Cyperus rotundus*	Cyperaceae	Tubers (methanolic extract)
36	*Ficus religiosa*	Moraceae	Leaves, stem bark (extracts)
37	*Justicia gendarussa*	Acanthaceae	Leaves (ethanolic extract)
38	*Moringa oleifera*	Moringaceae	Flowers, leaves (hydroalcoholic extract)
39	*Nyctanthes arbor-tristis*	Oleaceae	Leaves, stems (alcoholic extracts)
40	*Phyllanthus emblica (Emblica officinalis)*	Phyllanthaceae	Leaves, bark, fruits (water extract, juice)
41	*Premna serratifolia*	Verbenaceae / Lamiaceae	Wood (ethanolic extract)
42	*Ricinus communis*	Euphorbiaceae	Seed oil, roots (oils, joint oils)
43	*Plumbago zeylanica*	Plumbaginaceae	Root (paste, in formulations)
44	*Vitex negundo*	Verbenaceae / Lamiaceae	Roots, bark, leaves, flowers (extracts, oils)
45	*Vernonia anthelmintica*	Asteraceae	Seeds, leaves, roots (ethanolic extract)

ABSTRACT

Neural mobilization (NM) is a commonly used technique to treat arm pain with cervical origin or cervical radiculopathy (CR), while proprioceptive neuromuscular facilitation (PNF) is an emerging approach to treat the condition. This study aims to compare the effectiveness of neural mobilization and PNF on pain and functional disability in individuals with arm pain with cervical origin. 36 participants with CR were randomly allocated to 2 groups. Group-A (PNF) was treated with PNF techniques, while, Group-B (NM) received neural mobilization, along with conventional physiotherapy in both groups. 6 sessions were conducted every week for 2 weeks. Pain, functional disabilities were measured before and after the intervention. Statistically significant improvements ($p<0.05$) were observed in pain and functional outcomes in each group. The results of between group analysis, however, did not vary statistically significantly ($p>0.05$). Both treatment approaches have shown statistically equal effect in reducing pain and improving functional limitation in arm pain with cervical origin.

Keywords: Cervical radiculopathy, Neural mobilization, Neck pain, Proprioceptive neuromuscular facilitation

INTRODUCTION

Arm pain with cervical origin speaks of discomfort that starts in the cervical region and radiates toward the arm. This occurs when a nerve root in the cervical spine is compressed or irritated. The patients often complaints of sharp, shooting, or aching pain, and is accompanied by neurological symptoms like tingling sensation, numbness, weakness, or sensory deficits in the arm or hand [1]. Yearly incidence rate of arm pain with cervical origin between the years1976 and 1990 was107.3 in every 100,000 men and 63.5 in every 100,000 women [2]. Between 2005 and 2011, it was reported that 33.5% of people worldwide suffered from the same condition [3]. The primary cause of cervical radiculopathy is any lesion narrowing the vertebral canal, leading to inflammation or nerve root impingment. Radicular symptoms can result from any condition that irritates a spinal nerve root [4]. Symptoms can be categorized based on which part of the cervical nerve root is affected. Depending on the specific nerve root involved, discomfort may be felt in areas such as the neck, the outer part of the arm, the forearm, thumb, and fingers [5] An increasing amount of evidence indicates that conservative physiotherapy treatments are more effective than surgery in managing arm pain with cervical origin [6,7,8]. Manual techniques such as neural mobilization (NM), PNF, spinal manipulation, and myofascial release are commonly used in physiotherapy to relieve symptoms [9].

Among those manual techniques, neural mobilization (NM) is a frequently administered technique to ease symptoms related to this condition. Nerve mobilization technique is applied for treatment of the median, ulnar and radial nerves, based on the concept of Butler [10]. The goal of the NM technique is to restore the neural capacity by resisting the typical force of compression, friction, and tension associated with activities of daily life.11 Evidence suggests that Neural Mobilization with conventional method is highly effective in treating radicular pain [9,12]. However, a growing body of studies suggests that PNF is an impactful manual intervention in treating neurological conditions [5]. Regulation of movement and posture is associated with proprioception or sensory motor functions [13]. Pain and disability in the neck, shoulder, and hand can be assessed through physical tests like Spurling's and Upper Limb Tension Tests [14, 15]. Severity of pain is measured using reliable tools like, Numeric Pain Rating Scale (NPRS) for radicular pain, the Neck Pain and Disability Questionnaire (NPAD) for neck issues, and the Quick DASH for arm, shoulder, and hand disability [16, 17, 18]. Specific PNF techniques enhance motor unit recruitment, which is particularly valuable for re-educating muscles that have become inhibited due to chronic pain or neural impairment. PNF is especially effective at activating both scapular stabilisers and deep cervical flexors—muscles essential for maintaining proper posture and minimizing compressive stress on cervical nerve roots—by promoting coordinated activation of agonist and antagonist muscle groups [5].

PNF may improve neuromuscular coordination, flexibility, and functional movement patterns [5]. Neural mobilization targets mechanosensitive neural tissues, potentially providing rapid analgesia and enhancing neurodynamic function [19]. Evidence suggests the use of both PNF and Neural Mobilization technique has a positive result to alleviate the symptoms of CR, but no evidences are there to compare the treatment effects of these two. Comparing these two treatment techniques will provide accurate information that will be crucial for making treatment decisions and may also lessen patients' suffering and improve quality of life. So the research aims to compare the efficacy of proprioceptive neuromuscular facilitation and neural mobilization on pain and functional disability in arm pain with cervical origin.

MATERIALS AND METHODS

Ethical committee and guidelines

The study was reviewed by the Institutional Ethics Committee of Nopany Institute of Healthcare Studies, and the reference number is NIHS-MPT/IEC/02/2023. It was carried out in compliance with the ethical guidelines of Helsinki's declaration (updated version 2013) for medical research, as well as the ICMR's (2017) guidelines for biomedical and health research involving human subjects.

Sample size estimation

G*Power software, version 3.1.9.4 was used to estimate the size of the sample. Based on the effect size of Quick DASH value from a previous study [20], the sample size was calculated. Parameters include: assumption of test that follows t family distribution, mean was considered for difference between two independent groups, and the effect size of 1.07, a type I error rate set at 0.05, and a power level of 0.95. Total sample size was 48.

Sample source, study setting and sampling technique

Participant's data was collected from January 2023 to June 2023. Primary researchers informed the patients about the study who visited the Nopany Physiotherapy clinic. Every patient willing to participate in the study was instructed to sign the consent form. The study was conducted at Nopany Physiotherapy Clinic, Kolkata, West Bengal, India. Participants had the right to withdraw from the study any time during the study period if they felt any kind of discomfort or for any reason. Total 48 samples who were randomly selected using a simple random sampling method were divided into Group-A (PNF) and B (NM) using SNOSE technique to maintain allocation concealment. This was a participant-blinded study, where the participants were unaware of their assigned group.

Selection Criteria

Patients of both genders, aged 35 to 50 years, who had pain in the neck radiating to any side of the upper limb along with numbness and paraesthesia, were included in the study [1]. Spurling's test was used to confirm arm pain with cervical origin [12]. Upper Limb Neural Tension Test (ULTT) was performed to identify the involved nerve- radial, ulnar or median [12]. However, patients with a recent history of trauma or injury or any recent surgery to the involved upper limb or neck,[2] NSAIDs use, or patients' with symptoms of vertigo were excluded [21]. Exclusion of patients were also confirmed by more than one nerve involvement.

Data collection

Participants who had complained of neck and upper limb pain were assessed for eligibility. Before the application of intervention, data was collected by the Physiotherapist for neck pain and disability, radicular pain intensity, disability of upper extremity by NPAD, NPRS 101, and Quick DASH Questionnaire accordingly. Patients were treated for 2 weeks (6 sessions/week) [22]. But within 1 week of treatment, 4 patients from Group-A (PNF) and 5 patients from Group-B (NM) discontinued the study and from 8th session of treatment, 2 patients from Group-A (PNF), and 1 patient from Group-B (NM) left the study. Post intervention data of outcome variables were collected for total 36 participants (18 on each group) and were analyzed.

Intervention Description

All subjects were treated with conventional treatment that included10 minutes of moist heat application; 3 sets of isometric exercises for the cervical with 10 repetitions/set in each direction, and each contraction held for5 seconds [2]. Then, Group-A was treated with PNF for neck, scapula, and upper limb for a single set of 10 repetitions, while patients of Group B were treated with neural mobilization with 3 seconds' hold. 10 repetitions of single set were performed. 5 days post treatment 2 participants from group A (PNF) discontinued and after 7 days of treatment with NM, 2 patients from group B did not continue their treatment. Thereafter, post-test data was collected for 36 participants (group A= 18 and group B =18) for the same outcome variables and were analysed.

Proprioceptive Neuromuscular Facilitation [23]

PNF involved Dynamic Reversal and Repeated Contraction techniques. To achieve smooth, coordinated movement through the available range, Dynamic Reversal required isotonic contractions of the prime movers followed by isotonic contractions of the opposite group of muscles against resistance provided by the therapist, facilitating smooth, coordinated movement through the available range. Muscle activity was typically initiated with a stronger and proper movement pattern and gradually progressed toward a weaker pattern to enhance control and coordination. Repeated Contraction began with a quick stretch to the targeted muscles to facilitate an isotonic contraction, followed by the application of resistance through the full available range or up to the point of weakness.

The stretch was repeated at specific points within the movement pattern or until muscle contraction weakened, thereby improving muscle strength, endurance, and functional performance.

PNF pattern [5, 24, 25]

Neck Pattern

Patient seated in short sitting; therapist stands behind right side. The performed patterns included:

- Lateral Flexion with left side rotation
- Extension with right side rotation
- Lateral Flexion with right side rotation
- Extension with left side rotation

Traction and resistance provided as tolerated.

Scapular Pattern

Patient was in side-lying position; therapist positioned behind, facing head. Therapist performed Scapular D1 pattern with anterior elevation and posterior depression; and D2 pattern with posterior elevation and anterior depression of scapula. Gentle resistance was given throughout the movement.

Upper Extremity (UE) Pattern

Patient was in supine with head/neck off edge of bed; therapist stood on treatment side. Patterns performed:

- UE flexion–adduction–external rotation with simultaneous head/neck extension and rotation left
- UE extension–abduction–internal rotation with head/neck extension and rotation right

Resistance and stretching was applied with appropriate commands.

Neural Mobilization technique [10]**:** Participants were positioned comfortably in supine lying, while physiotherapist stood in a walk-standing position on the affected side to administer the peripheral nerve mobilization techniques.

Median nerve mobilization: The physiotherapist applied shoulder depression and positioned the upper limb in approximately 110° of abduction, followed by extension of elbow joint, supination of forearm, extension of wrist, fingers and thumb, accompanied by contralateral cervical side flexion to increase neural tension.

Radial nerve mobilization: Patient's shoulder was depressed and lightly abducted to around 10°, after which Physiotherapist extended the elbow of the patient, pronated the forearm, and moved the wrist into flexion with ulnar deviation, combined with finger and thumb flexion. The shoulder was internally rotated, and contralateral cervical side flexion was added to complete the tensioning sequence.

Ulnar nerve mobilization: The physiotherapist depressed the shoulder and abducted the arm from 10° up to 90°, bringing the hand toward the ear, followed by elbow flexion, forearm supination, wrist extension and deviation in radial direction; and then extension of thumb and fingers. The shoulder was then externally rotated, and contralateral cervical side flexion was applied to increase the neural loading.

Data Analysis: SPSS software version 26 was used to perform data analysis. The primary analysis used descriptive statistics to analyse the demographic data. Shapiro-wilk test confirmed the normal distribution of data. Pre (baseline) and post (after 2 weeks) intervention data were collected. A paired t-test was used to assess the treatment effect within the groups, while an independent t-test was used to evaluate the difference between the effects of group-A (PNF) and group-B (Neural Mobilisation). The statistically significant level was set at $p<0.05$.

RESULTS

Demographic characteristics: Demographic data from a total of 36 participants were analyzed. The results showed a statistically insignificant difference between the groups in terms of age, height, weight and BMI. The data were normally distributed.

Within group analysis: At baseline, there was no significant difference observed in outcome measures for NPRS 101, Neck Pain and Disability (NPAD) index, and Quick DASH. So, both groups have almost the same values at the beginning of 2 weeks protocol. In Group A, PNF was given for 2 weeks (6 sessions/week). After 2 weeks of intervention with PNF significant improvement was noticed in all three outcome measures used for research. In group B, arm pain with cervical origin was treated with neural mobilization. In this group, a significant improvement was observed in all of the three outcome measures after the 2-week protocol.

Between group analysis: No significant (>0.05) difference was observed between Group A and Group B in the scores of NPAD, NPRS and Quick DASH while analyzed with independent-t test.

DISCUSSION

This single-blinded randomized clinical trial aimed to compare the efficacy of Proprioceptive Neuromuscular Facilitation and Neural Mobilization technique in patients who have arm pain with cervical origin. Disorder of peripheral nervous system due to pathology of cervical origin typically affects an individual's ability to do daily activities as well as functional activities. This often results in inactivity, deconditioning of muscles of upper limb. According to several radiological investigations, the most frequent lesions include osteophytic invasion and cervical disc herniation, which either compress the nerve root or cause inflammation [26]. Neurological symptoms such as sensory and motor alteration in both or one upper limb may result from damage to the cervical nerve root fibres. Conservative treatment, as well as specialized physiotherapy treatment options is available to treat the condition [15]. In this study, both groups were initially treated with hot packs, and cervical isometric exercises. The application of hot pack raises the temperature and improves circulation of neck musculature and reduces fatigue, which in turn, increases flexibility of muscle. There after, the application of isometric exercises aid in strengthening of weak muscles without changing the length, impeding only the movement of involved joints [27]. PNF and Neural mobilization are the two most common techniques that are used to treat patients with arm pain with cervical origin.

In our study, Group A was found to be effective in eliminating neck and arm pain and improving disability of upper limb using PNF techniques. The different patterns of PNF techniques facilitate specific neuromuscular functions through proprioceptive activation. This results in altered excitability of the pyramidal tract, the last motor circuit that strengthens cortical excitement and improves muscle recruitment. Additionally, it has been suggested that it helps in maintaining healthy head and neck posture and improves functional ability of the upper limb, which is dependent on the proprioceptive system functioning properly [28]. In this study, PNF pattern (scapula patterns, neck patterns and D1, D2 for upper limb) with PNF techniques (Dynamic reversal and repetitive contraction) was introduced. These functional PNF movement patterns are task oriented and mimic functional action that involves diagonal dimensional motions. The pattern's synergy is essential for optimal muscle activation [28]. Contract-relax and hold relax method of dynamic reversal technique for upper limb are known to improve functional movement by reducing pain. Muscle elasticity was achieved by stretching, which is a component of repetitive contraction [29].After completing D1 and D2 pattern in the upper limb, stretching becomes feedback to increase active and passive ROM and improve disability of arm, shoulder, and hand [25]. Bansal R, et al in 2020 showed significant improvement by PNF techniques along with PNF patterns in radicular pain and disability in patients with cervical spondylosis [5].

The ability of skeletal muscles to primarily provide tensile tension is a major contributor to neural responses when PNF combination patterns are applied, rather than adaptive changes in the muscle fibre itself. Such proprioceptive reactions to stimuli result in repetitive muscle contraction, which contracts the spinal stabilization muscle at the same time. As a result, there is a simultaneous contraction of the muscles that stabilize the spine, leading to an increase in muscle strength and a rise in internal cervical pressure. This strengthens the adjacent muscles and facilitates functional movement of the human body, which has a significant impact on spinal flexibility and improves functional disability [5]. D. Bhattacharyya et. al. in 2025 stated that Proprioceptive neuromuscular facilitation (PNF) effectively reduces neck and arm discomfort, improves functional disability in patients with arm pain with cervical origin. Increased upper limb function, enhanced proprioceptive feedback, and neuromuscular activation were all facilitated by the use of dynamic reversal and repeated contraction PNF approaches along with conventional method [20]. Neural mobilization usually consists of sliding, gliding and flossing techniques. In this study group B was treated with Neural Mobilization and it has been proven that neural mobilization can decrease the neck and arm pain severity. Neural tissue mobilization may have the benefit of reduction of pain because of the sliding techniques that cause the longitudinal extension of nerve, while putting less load on impinged or stressed nerves [2].Gliding of nerve occurs with nerve bed lengthening, which in turn lengthens the nerve, raises intra-neural pressure, and decreases intra-neural blood flow. Then the correct neurodynamic application by adjusting intra-neural pressure can provide a "pumping action" which provides nerve hydration because it helps in evacuation of intra-neural oedema, which reduces symptom of pain. Nerve movement recovery by stimulating the nociceptors sensitivity and increasing blood flow resulted in reduction of pain and improvement in pain related disability [30]. Result of a previous study showed similar effect on cervical radiculopathy treated with neural mobilization. The study showed significant improvement in pain and grip strength, after 3 weeks of treatment protocol [2].

Another outcome measure of this study is disability of arm, shoulder and hand which is frequently accompanied by radicular pain with cervical pathology. Neurodynamic mobilization improves neuronal motions by activating mechanical receptors. Moreover, it eases the tension in the nerves where they clash, release adhesion and allow the nerve roots to move painlessly. It is theorized that NM affects the retraining of the muscles and joints next to the nerves and improves functional ability of the arm, shoulder, and hand [2]. Chandan S et al. in 2015, proved that neural mobilization is highly effective in upper limb radicular pain and disability. The authors explained that mechanical forces that create pressure on nerves are reduced by mobilization of nerves which eliminate irritating fluids and chemicals in and around neural structures [30]. The Independent T- test was used to compare both groups to determine which protocol is more effective. In this study, Group A (PNF) and Group B (Neural Mobilization) both were found to be significantly effective on NPAD, NPRS 101 and Quick DASH score, but no significant difference was observed in between the groups. According to theory, the result may be because PNF, and neural mobilization have similar effects for their dynamic movement patterns. Hence, both groups showed no significant differences and null hypothesis is accepted confidently and alternative hypothesis is rejected. This signifies that both PNF and Neural Mobilization technique can equally be effective in treating arm pain with cervical origin.

Clinical implications

The finding of the study suggests that Physiotherapist can select any of these treatment approaches in clinical practice considering their expertise, preference, treatment time and resources.

Limitations and future directions:

The study was limited by limited sample size (n=36) due to short duration of study. Exact conditions of cervical spine pathology (spondylosis, spondylolisthesis, and spondylitis) and the stages of severity were not mentioned in this study. Single-centre study design may limit external validity due to homogeneous population characteristics Future studies should include larger, more diverse samples to improve the generalizability of findings. Comparative studies may incorporate objective measures such as EMG, nerve conduction studies, or cervical imaging to better understand physiological changes. Research should explore the combined effect of PNF and Neural Mobilization to determine whether a synergistic benefit exists.

Strengths of the present study

The study directly addresses a practical clinical question about treatment selection. Both the treatment techniques were delivered using evidence based standardized protocols to minimize variability.

CONCLUSION

The present single-blinded randomize controlled trial evaluated and compared the effects of Proprioceptive Neuromuscular Facilitation (PNF) and Neural Mobilization (NM) on patients with arm pain with cervical origin. Both interventions, administered along with conventional treatment, produced significant improvements in neck and arm pain and functional disability, as reflected by NPAD, NPRS-101, and Quick DASH scores. However, intergroup analysis revealed no statistically significant difference between PNF and NM. These findings indicate that both techniques are equally effective in reducing radicular pain and enhancing upper limb function. Hence, either PNF or Neural Mobilization may be confidently incorporated as an effective physiotherapeutic intervention for managing arm pain with cervical origin.

ABSTRACT

Avabahuka is a *Vata*-predominant disorder of the *Amsa Sandhi* characterized by pain, stiffness, and progressive restriction of shoulder movements, leading to significant functional impairment. In contemporary terms, it closely resembles frozen shoulder (adhesive capsulitis). Ayurveda advocates *Panchakarma* procedures along with *Shamana Aushadhi* for effective management by addressing the underlying *Dosha* imbalance and restoring joint function. To evaluate the efficacy of *Panchakarma* procedures along with *Shamana Aushadhi* in the management of *Avabahuka* with reference to pain relief, reduction in stiffness, and improvement in the range of shoulder joint movements. This was a single-case observational clinical study conducted on a 42-year-old male patient diagnosed with *Avabahuka* affecting the left shoulder joint. The intervention included *Sthanika Abhyanga* over *Urdhwajatru* and *Bahu* region using *Mahavisha Garbha Taila*, followed by *BashpaSwedana* with *Dashamoola Kashaya* for seven days. *Nasya Karma* with *Anu Taila* (4–4 drops in each nostril) was administered during the same period. *Shamana Chikitsa* comprised *Rasna Erandadi Kashaya*, *Yograj Guggulu*, *Vatvidhwans Rasa*, and *AvipattikarChurna*. Assessment was carried out using subjective parameters (pain and stiffness scores) and objective parameters (range of shoulder joint movements) at baseline, on the 7th day, and on the 14th day follow-up. The patient showed marked clinical improvement following treatment. Pain score reduced from 2 on the first day to complete relief by the 14th day. Stiffness resolved completely by the 7th day and remained absent during follow-up. Objective assessment revealed significant improvement in all shoulder movements, including flexion, abduction, adduction, and rotations, indicating restoration of joint

mobility. No adverse effects were observed during or after the treatment. The present case study suggests that *Panchakarma* procedures combined with *Shamana Aushadhi* are effective in the management of *Avabahuka*. The therapy provided sustained relief from symptoms and improved functional capacity of the shoulder joint. This approach may serve as a safe and effective treatment modality for *Avabahuka*, warranting further clinical studies with larger sample sizes.

Keywords: *Avabahuka*, Frozen shoulder, *Nasya Karma, Shamana Chikitsa*.

INTRODUCTION

Avabahuka is a *Vata*-predominant disorder of the *Amsa Sandhi* (shoulder joint) characterized by pain, stiffness, and progressive restriction of movements of the upper limb, resulting in marked impairment of daily activities.[1] Classical Ayurvedic texts describe *Avabahuka* as a condition arising due to the aggravation and localization of *Vata Dosha* in the *Amsa Pradesha*. This aggravated *Vata* leads to *Soshana* (degeneration or drying) of the *Amsa Bandha* and *Akunchana* (constriction) of the *Sira*, which clinically manifests as *BahupraspandanaHaratvam*, along with *Shoola* (pain) and *Sthabdata* (stiffness). *Kapha Dosha*, when associated, further contributes to heaviness and rigidity of the joint, thereby worsening the restriction of movements.[2] *Vatavyadhi* occupies a significant position among musculoskeletal disorders, largely due to its close association with faulty lifestyle practices, improper posture, excessive strain, lack of physical activity, and irregular dietary habits. The general line of management described in Ayurvedic literature emphasizes therapies that pacify aggravated *Vata* and restore functional integrity of the affected joint. These include *Snehana*, *Swedana*, *Nasya*, and appropriate *Shamana Chikitsa*, supported by *Pathya-Apathya* to prevent recurrence.[3] In contemporary medicine, *Avabahuka* closely resembles Frozen Shoulder, also known as adhesive capsulitis. Frozen Shoulder is characterized by chronic shoulder pain, progressive stiffness, and marked limitation of both active and passive movements, particularly abduction and external rotation.[4] The condition commonly affects middle-aged individuals and is often associated with metabolic disorders, prolonged immobilization, or degenerative changes. Pathologically, Frozen Shoulder involves inflammation and fibrosis of the joint capsule, leading to capsular thickening and reduced joint space, which explains the gradual loss of mobility and persistent pain.[5] In the present case, the treatment protocol was formulated based on Ayurvedic principles targeting the underlying *Vata-Kapha* pathology. External oleation (*Abhyanga*) was administered using *Vishagarbha Taila*[6] to pacify *Vata Dosha*, reduce pain, and improve local circulation. This was followed by *Mridu Swedana*, aimed at relieving stiffness, facilitating muscle relaxation, and enhancing joint mobility. *Nasya Karma* with *Anu Taila*[7] was performed considering its effectiveness in disorders of the *Urdhvajatrugata* region and its role in regulating *Vata Dosha*. Internal medications included *Rasnaerandadi Kashaya* [8] for its *Vata-KaphaShamaka* and *Shothahara* properties, along with *Yogaraj Guggulu* [9] and *Vata Vidhwans Rasa* [10] to manage chronic pain, stiffness, and degenerative changes. *Avipattikar Churna* [11] was prescribed to maintain *Agni*, ensure *Vatanulomana*, and prevent further *Dosha* aggravation. Dietary and lifestyle modifications were advised throughout the treatment period to support sustained clinical improvement.

MATERIALS AND METHODS

This study was designed as a single-case clinical study. Written informed consent was obtained from the patient prior to initiation of treatment. A detailed clinical assessment was carried out at baseline and during follow-up using subjective parameters. Subjective assessment included evaluation of pain, stiffness, and functional limitation of the affected shoulder, while objective parameters focused on the range of movements of the shoulder joint.

Case Report

A 42-year-old male patient presented to the *Kayachikitsa* Outpatient Department of our hospital on August 03, 2025, with complaints of pain in the left shoulder joint, associated stiffness, and progressive restriction of movements of the left upper limb. The patient also reported constipation as an associated complaint. According to the patient, the symptoms had been gradually progressive and persistent for the past one year, leading to difficulty in performing routine activities involving shoulder movements. There was no history of recent trauma or surgical intervention to the affected shoulder. Based on the clinical presentation, chronicity of symptoms, and Ayurvedic evaluation, the condition was diagnosed as *Avabahuka* affecting the left shoulder joint.

History of Present Illness

The patient had been apparently asymptomatic six month prior to presentation, following which he gradually developed pain and stiffness in the left shoulder joint. The symptoms were insidious in onset and progressive in nature, leading to increasing restriction of movements of the left upper limb. Over time, the patient experienced difficulty in lifting the left arm and performing routine activities such as dressing, grooming, and overhead work, resulting in functional limitation and occupational discomfort. The pain was described as persistent, with aggravation during evening and night hours, as well as during prolonged travel and periods of inactivity. The patient also reported worsening of symptoms during work-related strain. In addition to musculoskeletal complaints, the patient had a history of constipation, which persisted during the course of illness. There was no history of trauma, fall, infection, or surgical intervention involving the shoulder joint. No associated systemic illness was reported. Owing to the chronic nature of symptoms and progressive functional impairment, the patient sought Ayurvedic management for relief.

Past and Occupational History

There was no significant past history of major medical illness, trauma, or musculoskeletal disorders. The patient was employed as a shopkeeper, involving prolonged sitting and limited physical activity, which may have contributed to the progression of symptoms.

General Physical Examination

On general examination, the patient was conscious, well oriented, and cooperative. Pulse rate was 78 beats per minute and blood pressure was recorded as 130/80 mm Hg. The patient weighed 68.7 kg. Pallor, icterus, clubbing, cyanosis, and edema were absent. Respiratory system examination revealed bilateral equal air entry with no added sounds. Cardiovascular system examination showed normal heart sounds (S1 and S2) with no murmurs. Central nervous system examination was within normal limits. Per-abdominal examination revealed a soft abdomen with mild tenderness.

Local Examination of the Shoulder Joint

Inspection

On inspection, there was no visible deformity, or muscle wasting of the left shoulder joint.

Palpation

Palpation revealed tenderness over the left shoulder joint. Local temperature was normal. Marked restriction of movements was present, associated with severe pain.

Range of Movements

The active range of motion of the left shoulder joint was restricted and recorded as follows:

- Flexion: 120°
- Extension: 50°
- Abduction: 120°
- Adduction: 35°
- Internal Rotation: 75°
- External Rotation: 75°

Investigations

Radiographic examination of the cervical spine (anteroposterior and lateral views) dated July12, 2025 revealed mild straightening of the cervical lordosis suggestive of paraspinal muscle spasm. Disc space narrowing was observed at the C4–C5 level.

Diagnosis and Assessment Criteria

Based on the clinical presentation of pain, stiffness, and significant restriction of movements of the left shoulder joint, the diagnosis of *Avabahuka* was established. Assessment of therapeutic response was carried out using predefined subjective and objective parameters. Subjective parameters included pain, stiffness, and functional limitation, while objective parameters consisted of assessment of shoulder joint movements and physical findings, which were scored at baseline and during follow-up.

Treatment Protocol

The *Panchakarma* intervention was administered from 4th August to 10th August 2025. *Sthanika Abhyanga* over the *Urdhwajatru* and *Bahu* region was performed using *Mahavisha Garbha Taila* for 20 minutes daily, followed by *BashpaSwedana* with *Dashamoola Kashaya*. This combination was aimed at pacifying aggravated *Vata*, relieving stiffness, improving local circulation, and reducing pain in the affected region. Along with this, *Nasya Karma* was performed using *Anu Taila* in a dose of 4–4 drops in each nostril daily. *Nasya* was selected considering the involvement of *UrdhwajatruPradesha*, as it helps in alleviating *Vata-Kapha* vitiation, improving neuromuscular function, and enhancing the overall efficacy of the treatment. Simultaneously, *Shamana Chikitsa* was prescribed from 4th August to 10th August 2025 and continued during the follow-up period from 11th August to 17th August 2025. *Rasna Erandadi Kashaya* (20 ml twice daily before food) was administered to pacify *Vata* and *Kapha Dosha* and to reduce pain and stiffness. *Yograj Guggulu* and *Vatvidhwans Rasa* were given in a dose of 2 tablets twice daily after food to strengthen neuromuscular function and control chronic Vata disorders. *AvipattikarChurna* (10 g at bedtime) was added during the initial phase to correct *Agni*, prevent *Aama* formation, and support proper digestion, thereby enhancing the overall therapeutic outcome

OBSERVATION AND RESULTS

The patient showed marked clinical improvement following the completion of therapy. On subjective assessment, pain reduced progressively from a score of 2 on the 1st day to 1 on the 7th day and was completely absent by the 14th day. Similarly, stiffness decreased from a score of 2 initially to complete relief by the 7th day, which was sustained during follow-up. Objective evaluation of shoulder joint mobility demonstrated significant improvement in all planes of movement. Flexion increased from 120° at baseline to 150° on the 7th day and further to 160° by the 14th day. Extension improved from 50° to 60° and remained stable during follow-up. Abduction showed notable improvement from 120° to 150°, while adduction increased gradually from 35° to 50°. Internal and external rotations also improved, with external rotation showing a marked increase from 75° to 90°. Overall, both subjective symptoms and objective parameters indicated sustained functional recovery of the shoulder joint without any adverse effects.

DISCUSSION

Avabahuka is a *Vata*-predominant disorder of the *Amsa Sandhi* characterized by pain, stiffness, and progressive restriction of shoulder movements due to *Soshana* of *Amsa Bandha* and *Akunchana* of *Sira*. In the present case, significant relief in classical features of *Avabahuka* was observed, as evidenced by progressive reduction in pain and stiffness along with marked improvement in range of movements. The sustained improvement noted during follow-up indicates effective pacification of aggravated *Vata* and associated *Kapha*, resulting in restoration of joint mobility and functional capacity. Early reduction in stiffness followed by gradual pain relief reflects proper *SamprаptiVighatana*, suggesting that the selected treatment protocol effectively addressed both the root pathology and

clinical manifestations of the disease. *Sthanika Abhyanga* with *Mahavisha Garbha Taila* provided *Snigdha* and *Ushna* properties, which helped in alleviating *Rukshata* and *Sheeta Guna* of vitiated *Vata*, thereby reducing pain and improving local circulation. *Abhyanga* also enhances muscle relaxation and nourishes the periarticular structures. *BashpaSwedana* with *Dashamoola Kashaya* facilitated *Swedana Karma*, leading to *Stambha-Gaurava Nigrahana* and increased joint flexibility by relieving stiffness and muscle spasm. *Nasya Karma* with *Anu Taila* played a crucial role due to the involvement of *UrdhwajatruPradesha*, helping in regulation of *Vata-Kapha Dosha*, improving neuromuscular coordination, and promoting functional recovery of the shoulder joint. The combined effect of these *Panchakarma* procedures accelerated symptomatic relief and enhanced the efficacy of internal medications. *Rasna Erandadi Kashaya* acted as a potent *Vata-Kapha Shamaka*, possessing *Shothahara*, *Vedanahara*, and *Anulomana* properties, which contributed to reduction in pain, stiffness, and inflammation. *Yograj Guggulu* supported joint health through its *Deepana-Pachana* action, correction of *Aama*, and anti-inflammatory properties, making it effective in chronic *Vatavyadhi*. *Vatvidhwans Rasa* strengthened neuromuscular function and further pacified aggravated *Vata*, aiding in sustained relief. *AvipattikarChurna* helped in maintaining *Agni*, preventing *Aama* formation, and ensuring proper *Vatanulomana*, thereby supporting long-term therapeutic benefits. Collectively, *Shamana Aushadhi* complemented *Panchakarma* therapy and played a vital role in achieving sustained clinical improvement without recurrence during follow-up.

CONCLUSION

The present case study demonstrates that an integrative Ayurvedic approach consisting of *Panchakarma* procedures along with appropriate *Shamana Aushadhi* is effective in the management of *Avabahuka*. The treatment resulted in significant reduction of pain and stiffness and marked improvement in shoulder joint mobility, which was sustained during follow-up. The therapy addressed the underlying *Vata-Kapha* pathology and facilitated functional recovery without any adverse effects. These findings suggest that Ayurvedic interventions can offer a safe and effective therapeutic option for *Avabahuka*, though further studies with larger sample sizes are recommended to validate these results.

ABSTRACT

The postpartum period is a critical phase in a woman's life that involves significant physical, psychological and emotional changes. Maternal well-being and the growth of mother-infant connection may be negatively impacted by postpartum depression. Promoting maternal and child health requires an understanding of how these characteristics fluctuate between primiparous and multiparous mothers. The current study was to examine maternal-infant attachment and postpartum depression in primiparous and multiparous mothers. The study used a quantitative comparative research design. Using a straightforward random sampling technique 60 postpartum mothers—30 primiparous and 30 multiparous—were chosen between one and eight months after giving birth. The Edinburgh Postnatal Depression Scale (EPDS)created by Cox, Holden and Sagovsky in (1987) was used to measure postpartum depression while the Postpartum attachment Questionnaire (PBQ) created by Brockington, Fraserand Wilson (2006) was used to examine maternal-infant attachment. An independent samples t-test at the 0.05 level of significance was used to evaluate the gathered data. The results showed that postpartum depression differed statistically significantly between primiparous and multiparous mothers ($t(58) = 2.29$, $p < 0.05$). Compared to multiparous moms, primiparous mothers reported higher levels of

postpartum depression. Maternal-infant bonding, however, did not change statistically significantly between the two groups ($t(58) = -0.94$, $p > 0.05$). The study finds that while parity had no discernible effect on mother-infant attachment primiparous mothers are more likely than multiparous mothers to experience postpartum depression. The results emphasize the value of early screening psychological therapy and family support in promoting maternal mental health and enhancing postpartum care especially for new mothers.

Keywords: Postpartum Depression, Maternal–Infant Bonding, Primiparous Mothers, Multiparous Mothers, Maternal Mental Health, Postnatal Care, Psychological Well-being, Independent Samples *t*-Test.

INTRODUCTION

A woman's life undergoes enormous physical, psychological, emotional and social changes as a result of becoming a mother. Emotional adjustment, hormonal changes and adaptation to new mother obligations are frequent characteristics of the postpartum periodalso known as the time after childbirth. Even though giving birth is typically seen as a happy experience many moms endure emotional and psychological difficulties at this timewith postpartum depression (PPD) being one of the most prevalent and dangerous issues. Following childbirth postpartum depression is a mental condition marked by enduring melancholy anxiety, irritability, exhaustion, loss of interest, sleep difficulties and hopelessness. In contrast to transient "baby blues," which typically go away in a few days postpartum depression can last for weeks or months and have a substantial impact on a mother's everyday functioning and psychological health. The illness affects not just the mother but also the relationships within the family as well as the baby's general growth and care. mother-infant bonding is one of the most significant factors impacted by mother psychological health. The term "maternal-infant bonding" describes the loving and emotional link that forms between a mother and her child. The infant's emotional stability, cognitive progress, social adjustment and general development all depend heavily on this link. While problems with bonding can have detrimental effects on both mother and child outcomes positive bonding encourages good caregiving behaviors emotional reactivity and secure attachment.

Maternal-infant attachment and postpartum depression are tightly associated according to research. Reduced sensitivity less interaction and a poorer emotional attachment may result from mothers with depressive symptoms finding it difficult to interact emotionally with their babies. These issues may have an impact on a baby's development and lead to long-term emotional and behavioral problems. In order to improve the health of mothers and children it is crucial to comprehend the connection between postpartum depression and maternal-infant bonding. The number of times a woman has given birth or parity may have a significant impact on her postpartum experiences. When giving birth for the first time primiparous mothers frequently encounter difficulties with inexperience, worry, uncertainty and adjusting to new duties. On the other hand multiparous mothers who have given birth before might be more self-assured and knowledgeable about caring for infants but they might also experience more stress from juggling several kids and home duties. Maternal-infant bonding and postpartum depression may differ between the two groups as a result of these disparate experiences. Few studies have simultaneously compared postpartum depression and maternal-infant bonding among primiparous and multiparous women despite the growing focus on maternal mental health. Identifying susceptible populations and creating effective psychological and medical therapies require an understanding of these distinctions. Thus, the purpose of this study is to examine maternal-infant bonding and postpartum depression in primiparous and multiparous women. The results of this study may advance knowledge of maternal mental health and aid in the creation of practical methods to improve maternal wellbeing and foster positive mother-infant interactions.

Objectives of the Study

To compare postpartum depression among primiparous and multiparous mothers To compare maternal–infant bonding among primiparous and multiparous mothers.

Hypotheses of the Study

There will be no significant difference in postpartum depression between primiparous and multiparous mothers.
There will be no significant difference in maternal–infant bonding between primiparous and multiparous mothers.

METHODOLOGY

In order to investigate postpartum depression and maternal-infant bonding among primiparous and multiparous women this study used a quantitative comparative research methodology. 30 primiparous mothers and 30 multiparous mothers made up the two groups of sixty postpartum mothers . Mothers between one to eight months after giving birth made up the participants. To guarantee a representative sample, participants were chosen using a straightforward random selection method. Data were gathered using structured questionnaires to assess postpartum depression and maternal-infant attachment among mothers.(1) Edinburgh Postnatal Depression Scale (EPDS) developed by Cox, J. L., Holden, J. M. and Sagovsky, R. (1987) was used to assess postpartum depression among mothers. (2) Postpartum Bonding Questionnaire (PBQ) developed by Brockington, I., Fraser, C. and Wilson, D. (2006)was employed to evaluate mother connection with their infants. These tools assessed maternal-infant attachment and postpartum depression in both primiparous and multiparous mothers. Questionnaires were given to participants directly during in-person home visits as part of the survey. Responses were kept private throughout the study and participation was entirely voluntary. SPSS version 26 was used to analyse the gathered data. An independent sample t-test was used to compare the mean scores of primiparous and multiparous moms. To identify statistical differences the significance level was established at $p < 0.05$.

Findings

The postpartum depression scores of primiparous and multiparous mothers are compared in Table 1. Primiparous women had an average postpartum depression score of 10.10 (SD = 2.09), while multiparous mothers had an average score of 8.80 (SD = 2.30). A statistically significant difference between the two groups was found using the independent samples t-test ($t(58) = 2.294$, $p = 0.026$). The results show that compared to multiparous moms, primiparous mothers had noticeably greater levels of postpartum depression. The maternal-infant bonding ratings of primiparous and multiparous women are compared in Table 2. Primiparous moms had an average bonding score of 42.80 (SD = 11.45), whereas multiparous mothers had an average score of 45.30 (SD = 9.09). The difference between the two groups was not statistically significant, according to the independent samples t-test ($t(58) = -0.937$, $p = 0.353$). As a result, there was no discernible difference in maternal-infant attachment between primiparous and multiparous women.

RESULTS

The current study used an independent samples t-test to assess postpartum depression and maternal-infant attachment between primiparous and multiparous moms. The data demonstrated a substantial difference in postpartum depression between the two groups. Compared to multiparous mothers, primiparous moms reported substantially higher postpartum depression levels ($t(58) = 2.294$, $p < 0.05$). As a result, the null hypothesis—which predicted that postpartum depression would not differ significantly between primiparous and multiparous mothers—was rejected. Maternal-infant bonding, however, did not differ significantly between primiparous and multiparous mothers ($t(58) = -0.937$, $p > 0.05$). As a result, the maternal-infant bonding null hypothesis was accepted (failed to be rejected). Overall, the study finds that while parity has a considerable impact on postpartum depression, it has no meaningful impact on the attachment between mothers and their infants.

CONCLUSION

The current study examined the relationship between maternal-infant bonding and postpartum depression in primiparous and multiparous women. The results showed that compared to multiparous mothers, primiparous mothers had considerably higher postpartum depression levels. Thus, parity seems to have an impact on the psychological health of mothers in the postpartum phase. On the other hand there was no discernible difference between primiparous and multiparous moms in terms of maternal-infant attachment. This implies that regardless of prior delivery experience, both groups are able to form a positive emotional attachment with their babies. Overall, the study finds that parity has no discernible impact on mother-infant bonding, even if first-time moms may be more susceptible to postpartum depression. Promoting maternal mental health and ensuring positive mother-infant connections need early detection of depressive symptoms, psychological counselling and family support.

DISCUSSION

The goal of the current study was to examine maternal-infant attachment and postpartum depression in primiparous and multiparous mothers. The results showed that compared to multiparous mothers, primiparous mothers had noticeably greater levels of postpartum depression. Maternal-infant bonding however, did not significantly differ between the two groups. The difficulties of becoming a first-time mother may be the cause of primiparous moms' increased rates of postpartum depression. Increased anxiety, fear of childbirthinexperience with parenting confusion about newborn careand adjustment to new maternal obligations are common among primiparous mothers . During the postpartum phase these variables may raise emotional stress and susceptibility to depression symptoms. Multiparous mothers on the other hand, typically have prior pregnancy, birthing and baby care experience which may boost their self-esteem and coping skills and lower the risk of postpartum depression. Even though multiparous mothers sometimes juggle several family and childcare obligations their prior maternal experience may make it easier for them to adjust to the postpartum phase. This result lends credence to the idea that a mother's experience is crucial for her psychological recovery after giving birth.

Additionally, there was no statistically significant difference in the bonding between primiparous and multiparous mothers and their infants. This implies that the quality of a mother's emotional link with her child may not be determined by parity alone. Mothers may establish a same degree of affection, attachment and emotional connection with their infants regardless of whether they are giving birth for the first time or have prior parenting experience. Instead, a variety of biologicale motional, social and family-related elements that were outside the purview of this study may have an impact on maternal bonding. The results emphasize the significance of identifying mothers who are more likely to experience postpartum depression, especially first-time mothers while also highlighting the fact that with the right emotional and familial support positive maternal-infant bonding can be achieved regardless of parity.

Suggestions

- Hospitals and maternal health facilities should regularly test for postpartum depression, especially among new moms.
- During the prenatal and postnatal stages, psychological therapy and emotional support services must to be made accessible.
- Spouses in particular should receive education about postpartum depression and the value of offering new mothers emotional support.
- To increase understanding of postpartum mental health and mother-infant bonding, health providers could host awareness campaigns.
- Parenting education programs might be implemented to boost primiparous moms' self-assurance and caring abilities.

- To increase the findings' generalisability, larger sample sizes should be used in future research.
- Postpartum depression and mother-infant bonding across various social, educational, and cultural backgrounds may be compared in future studies.
- To look at how postpartum depression and mother-infant attachment evolve over time, longitudinal studies may be carried out.
- Future studies may incorporate other factors as mother self-efficacy, social support, marital satisfaction, and family functioning.
- To promote early intervention and enhance the wellbeing of both mothers and infants, healthcare officials should incorporate routine maternal mental health screening into postnatal care services

ABSTRACT

In light of the growing interest in the use of nanoparticles in research and in Integrated Pest Management, the present study was conducted to green synthesize zinc oxide nanoparticles (ZnO NPs) by upcycling seeds from two plant sources *Punica granatum* and *Artocarpus heterophyllus* and utilizing their seed flour. The phytochemical analysis of alkaloids, anthocyanins, carbohydrates, coumarins, flavanones, flavonoids, phenols, and proteins were done. Total flavonoid and phenolic content were also evaluated. The structural properties and optical density were characterised using X-Ray Diffraction (XRD), UV-visible spectrophotometry (UV-Vis), and Scanning Electron Microscopy (SEM). The antibacterial potential of ZnO NPs against two pathogenic bacterial strains *Bacillus subtilis* and *Staphylococcus aureus* were investigated by Agar Disc Diffusion Assay. DPPH assay was used to assess their possible antioxidant (radical scavenging) property. The UV–visible spectrum was measured in the range of 250–500 nm and the crystalline structure was analyzed via XRD. SEM/EDX analysis confirmed the surface morphology, indicating nanostructures with partial nanoflakes for all three samples of the green synthesized ZnO NPs. The *P. granatum* ZnO NPs showed relatively greater antimicrobial activity against both the bacterial strains than *A. heterophyllus* ZnO NPs. The scavenging activity of *A. heterophyllus* ZnO NPs was shown to be more than *P. granatum* ZnO NPs. The considerable inhibition of bacterial growth by our synthesized ZnO NPs thus might be developed as a new type of antimicrobial agents for the treatment of bacterial infection including multidrug resistant bacterial infection.

Keywords: *Punica granatum*, *Artocarpus heterophyllus*, zinc oxide nanoparticles, green synthesis, UV- Visible spectro photometry, Scanning Electron Microscopy

INTRODUCTION

The cultivation and production of fruits are high but the seeds of the fruits are generally discarded as waste products after consumption and therefore they make up a large fraction of organic waste. In a survey conducted in the USA, the EPA (Environmental Protection Agency) estimated that 34% of waste in landfills was organic waste, out of which seed waste accounted for a largest percentage. This led to the concept of upcycling of organic waste which was largely encouraged [1]. The current study aims to upcycle the seeds of *Artocarpus heterophyllus* (Jackfruit) and *Punica granatum* (Pomegranate) synthesize nanoparticles. In *P. granatum*, the edible part of the fruit (50%) consists of 40% arils and 10% seeds. The seeds are a rich source of total lipids; the seed oil comprises 12% to 20% of total seed weight. The seeds also contain protein, crude fibers, vitamins, minerals, pectin, sugars, polyphenols, isoflavones [2]. They are a great source of several nutrients including vitamin K, vitamin C, folate, and potassium and filled with beneficial antioxidant and polyphenols. Flavanols, a class of antioxidant that acts as an anti-inflammatory agent in the body and may help alleviate symptoms of arthritis, are found in abundance in pomegranates [3]. Pomegranate extracts have been shown in numerous *in vitro* experiments to be highly efficient at slowing the growth and metastasis of breast cancer cells. Punicic acid, an omega-5 long chain polyunsaturated fatty acid found in pomegranate seed oil, has also been demonstrated to inhibit the multiplication of breast cancer cells.

Some components in *P. granatum* have potent antitumorigenic properties and can inhibit the growth of prostate cancer cells in culture [4]. Pomegranate seeds contain a variety of polyphenols and antioxidants that help improve heart health by lowering blood pressure. According to a study, drinking pomegranate juice could lower systolic and diastolic blood pressure by 7% and 6%, respectively[5]. *A. heterophyllus*, the seed is an important by-product that consists around 12- 14% of a whole jackfruit [6]. These seeds are rich in digestible starch, protein, and minerals and contains 76.1% carbohydrate, 17.8% protein, and 2.1% lipid, on dry basis[7]. In India, the production of jackfruits is high and its seeds are not fully utilized. Mostly the seeds are discarded, except sometimes they are boiled or roasted for consumption. Magnesium-rich *A. heterophyllus* seeds aid in the bones ability to absorb calcium [8]. Ascorbic acid and gallic acid, which are abundant in *A. heterophyllus* seeds, may shield the body from negative effects of excessive free radical generation, thus promoting antioxidant activity [9].

Green chemistry, which uses environmentally friendly agents like plants, fruits, flowers, phytoplankton, yeasts, bacteria, and fungi to synthesize nanoparticles, has piqued researchers' interest in recent years [10]. Plant-mediated synthesis of nanoparticles is an innovative industrial technique with plenty of profitable and eco-friendly features [11]. Green synthesis provides advancement over chemical and physical methods of synthesizing nanoparticles (NPs). Green synthesis of metal and metal-oxide nanoparticles is one interesting issue of nanoscience, with plants seem to be the best candidates for the large-scale application [12]. Plants have the potential to accumulate certain amounts of heavy metals in their diverse parts. Consequently, biosynthesis techniques employing plant extracts have gained increased consideration as it is cost-effective, easy to be scaled up, and environmentally benign and, the resulting nanoproduct is more stable and tailored in shapes and sizes compared to those obtained by other organisms and is an excellent alternative means to conventional preparation methods for nanoparticle production [13].

In recent years there have been research ZnO NPs from various seeds were synthesised using green synthesis. For example, *Persea americana* seeds were used to synthesize ZnO NPs and it was discovered to have antibacterial properties [14]. Also, research on fruits like mulberry ZnO NPs was used to detect their antioxidant property [15]. ZnO NPs are ecologically benign, non-toxic, biocompatible, have a large surface area, high catalytic efficiency, excellent antibacterial activity, and chemical, mechanical, and thermal durability. Hence, they have been explored as an efficient adsorbent nanostructure [16]. Owing to its stability, biocompatibility, and fast electron transfer kinetics, zinc oxide has gotten a lot of attention as an important antimicrobial metal oxide with antioxidant property [17]. Hence the current study aims to green synthesize ZnO NPS using the seed waste of *P. granatum* and *A. heterophyllus* and evaluate its potential to suppress microbes and assess its antioxidant properties. The synthesized NPs was characterized using UV-Visible Spectroscopy, X-ray Diffusion (XRD), and Scanning electron microscopy (SEM-EDX).

MATERIALS AND METHODS

Collection of raw material

The seeds of *Punica granatum* and *Artocarpus heterophyllus* were purchased from the local vendors (Malgudi and Urban Gardeners, Bengaluru).

Preparation of *P. granatum* and *A. heterophyllus* seed flour

The seeds of *P. granatum* were peeled, cleaned with distilled water, and then dried. Pale white cotyledons were obtained when the concentrated juice was separated from the red, fleshy portion of the seeds by hand squishing. To get rid of the outer cohesive layer, the seeds of *A. heterophyllus* were taken out of mature fruits and allowed to dry in the sun. A knife was used to peel the white aril that surrounded the thin brown spermoderm, revealing the pale white cotyledons [18]. The cotyledons of both fruits were dried, crushed into a paste, and cleaned with distilled water to create seed flour. The seed paste was dried for ten minutes at 800 watts in a microwave. The dried cotyledon material was sieved, pulverized separately with a mortar and pestle, and then stored at room temperature for further use (Figure 1) [19].

Preparation of aqueous seed extract of *P. granatum* and *A. heterophyllus*

Separately, 1g of *P. granatum* and *A. heterophyllus* seed flour was homogenized in 100ml of distilled water to create the aqueous extract. The mixture was left to stand at room temperature for the entire night on the stirrer, it was filtered using Whatman filter paper (No. 1). For phytochemical analysis, the filtrate was subsequently refrigerated. [20]. Qualitative analysis of phytochemical parameters of *Punica granatum* and *Artocarpus heterophyllus* aqueous seed extract Phytochemical analysis is a set of preliminary tests used to determine whether an extract contains both primary and secondary metabolites. The presence of alkaloids [21], flavonoids [22], tannins, saponins[23], flavones[24], sterols, terpenes [25], cardiac glycosides [26], protein [27], carbohydrates [28], and fats[29] in the aqueous extract of *Punica granatum* and *Artocarpus heterophyllus* has been detected using several qualitative analyses. Quantitative analysis of the aqueous extract of *P. granatum* and *A. heterophyllus* Quantitative estimation of flavonoids in *P. granatum* and *A. heterophyllus* aqueous seed extract. Total flavonoid content was measured with the aluminium chloride colorimetric assay. The absorbance was measured at 510 nm. The concentration of the unknown sample was calculated from the standard graph [30]. Quantitative estimation of total phenolic content in *P. granatum* and *A. heterophyllus* aqueous seed extract Total phenolic content was measured using the Folin-Ciocalteu assay. The blue colour developed and the absorbance was measured at 640 nm. The concentration of the unknown sample was calculated from the standard graph [31].

Green synthesis of ZnO nanoparticles

Green synthesis of *P. granatum and A. heterophyllus* ZnO NPs

Green synthesis of ZnONPs was done separately for *P. granatum* and *A. heterophyllus* seed flour. Each weighed and added into two separate beakers into which, ZnCl2 (50ml ,25%) solution was added and constantly stirred for 10 minutes at room temperature. This mixture was heated in microwave oven for 3 to 4 minutes and separately filtered using What man filter paper (No. 1) to remove all the insoluble seed particles. NaOH (50mL, 25%) solution was added slowly into the mixtures to obtain a white precipitate which was allowed to settle for 48 hours. The precipitate was washed several times with DI water. Finally, the precipitate was filtered using suction pump and dried in hot air oven at 150°C for 4 hours [19].

Characterization of green synthesized *P. granatum* and *A. heterophyllus* ZnO NPS

UV-Visible spectroscopy, X-Ray Diffraction (XRD), Scanning Electron Microscope (SEM), Energy Dispersive X-ray spectroscopy was used to characterize the green synthesized ZnO NPs.

UV- Visible Spectroscopy of green synthesized ZnO NPs

The reduction technique used for ZnO NP synthesis was tested using UV– visible spectroscopy [32]. The nanoparticles suspended in distilled water were measured for their λmax absorbance from 250 to 500 nm of wavelength range [33].

X-ray diffraction analysis of green synthesized ZnO NPs

XRD of the samples were analysed for crystallite size (CeNSE Lab, IISc, Bengaluru). A definite line broadening of the XRD peaks indicates that the prepared material consists of particles in nanoscale range. The peak intensity, position and width, full-width at half-maximum (FWHM) data are determined[34]. The XRD patterns of the powdered samples were recorded using an X-ray diffractometer (D/teX Ultra) with Cu K-beta radiation (λ = 1.5418 Å, rated as 40 k, 30 mA) at Scan speed/ Duration time 5.0000deg/min and scan range of 20.0000- 90.0000 degrees [35]. The synthesized ZnO nanoparticle diameter was calculated using Debye-Scherrer formula [36].

$D = K\lambda / \beta Cos\theta$

where D is the crystallite size; k is the particle shape factor, 0.9; β is the halfwidth of (hkl) reflection; λ is the X-ray wavelength (1.5406); θ = 2θ/2, is Bragg's angle corresponding to (hkl) reflection [37].

Scanning Electron Microscopy (SEM) and Energy-dispersive X-ray spectroscopy (EDS) analysis of the green synthesized ZnO NPs

The shape, structure and size of the synthesized ZnO NPs were determined by the SEM analyses (CeNSE Lab, IISc, Bengaluru) [38]. The EDS analysis was done to confirm the chemical composition of ZnO NPs[39].

In vitro Antibacterial activity of the green synthesized ZnO NPs

In vitro Antibacterial activity of the green synthesized ZnO NPs by agar disc diffusion assay:

P. granatum and *A. heterophyllus* ZnO NPs were tested *in vitro* for their antimicrobial activity against strains by the disc diffusion method against test strains *Staphylococcus aureus* and *Bacillus subtilis* [40]. Bacterial inoculums (400 µL) were spread on Muller-Hinton agar. Sterile discs were saturated with ZnO NP stock solution (2mg/mL, 5mg/mL and 10mg/mL) [41]. Antibiotic amoxycillin (1 mg/mL) was used as positive control and distilled water as a negative control. The plates were maintained at room temperature for 30 minutes to allow the diffusion of the solutions and then incubated at 37°C for 24 h. Each experiment was done in triplicates. The inhibition zone around the discs were measured (in mm).

Estimation of Antioxidant activity of the green synthesized ZnO NPs by DPPH method

Using a modified version of the experimental protocol, antioxidant activity was measured using the DPPH technique [42]. Vials containing 1.3 mL of 0.004% DPPH (100 µ mol/L in methanol) were filled with powdered ZnO NPs (2 mg, 3 mg, and 5 mg). Visual monitoring of the reaction is made possible by the progressive change in color of the DPPH radical from deep violet in solution to pale yellow or orange when ZnO NPs were present. Mild vortex swirling improved the surface interaction between the ZnO NPs and the DPPH reagent. After centrifuging the suspensions for ten to twenty minutes, they were allowed to sit at room temperature in the dark for thirty minutes. The standard with antioxidant qualities at different concentrations (1, 2, 3, 4, and 5 mg/mL) was L-ascorbic acid. Absorbance was read at 517 nm wavelength using an UV-Vis spectrophotometer.

The scavenging activity was calculated using the following formula

$$\textbf{DPPH Scavenging (\%)} = \frac{\text{OD of control} - \text{OD of sample} \times 100\%}{\text{OD of control}}$$

RESULTS AND DISCUSSION

Qualitative analysis of phytochemical parameters of *Punica granatum* and *Artocarpus heterophyllus* aqueous seed extract

The comparison of phytochemical components (alkaloids, anthocyanin, carbohydrates, coumarins, flavanones, flavonoids, phenols, proteins) of *P. granatum* and *A. heterophyllus* seed extract showed that saponins were negative in *P. granatum* and phenols were negative in *A. heterophyllus* (Table 1). This result corresponds with previous study of *P. granatum* peel, which obtained negative results for saponins [43].

Quantitative estimation of Total Flavonoids Content (TFC) in *P. granatum* and *A. heterophyllus* aqueous seed extract

Many plants, fruits, vegetables, and leaves contain phytochemical compounds called flavonoids that have potential uses in medicinal chemistry. Flavonoids have a variety of health advantages, such as antiviral, anticancer, antioxidant, and anti-inflammatory effects. Additionally, they have cardio-protective and neuroprotective effects [44]. It was observed that the total flavonoid content (TFC) in *P. granatum* (10.647 μg/ml) is higher than the TFC in *A. heterophyllus* (12.978 μg/ml) (Table 2). It is in correlation with previous literature the TFC in seeds of *A. heterophyllus*was 2.03g/100g and that of *P. granatum* values ranged from 14.08 to 137.72 μg/mL [45].

Quantitative estimation of Total Phenolic Content (TPC) in *P. granatum* and *A. heterophyllus* aqueous seed extract

Due to their capacity to donate hydrogen atoms to liberate radicals, total phenolic content (TPC) is one of the key antioxidant components that is significant in the deactivation of free radicals. Additionally, they possess the ideal structural qualities for scavenging free radical[46]. In the present study, *P. granatum* has higher phenolic content than *A. heterophyllus* (Table 3).

Green synthesis of ZnO NPs using *P. granatum* and *A. heterophyllus* seed flour

As per the standard green synthesis principle given by Umasangari *et al*., (2013), approximately 6.5g of *P. granatum* ZnO NPs and 5.5g of *A. heterophyllus* ZnO NPs from seed flour weighing 1 g respectively (Figure 2).

The ZnO particles were formed by the complexation–hydrolysis–dehydration pathway [60], rather than simple reduction of Zn^{2+} to metallic Zn^0:

- Phytochemicals in the seed extract—especially phenolic compounds, flavonoids, proteins, sugars, and other hydroxyl- or carbonyl-containing metabolites—coordinate with Zn^{2+} from $ZnCl_2$.
- Addition of NaOH increases the hydroxide concentration and promotes formation of zinc hydroxide: Zn2++2OH-ZnOH2
- Microwave heating and subsequent drying promote dehydration: ZnOH2ZnO+H2O

Characterization of green synthesized ZnO NPs

UV- Visible spectroscopy analysis of the green synthesized ZnO NPs

Zinc ions get reduced to zinc oxide with the help of secondary metabolites in plants. The seed extract serves as both reducing agent and stabilizer [47]. This was validated by analysing the UV–visible spectra in 250–500 nm range. ZnO NPs absorbance peaks were previously found in the 355- 358nm wavelength range [19]. The ZnO NP synthesised from *P. granatum* and *A. heterophyllus* showed a maximum absorbance value ranging between 0.130 to 0.194 at a wavelength between 266.8 to 373.02 (Table 4, Figure 3a and Figure 3b) which correlates to the findings of Suresh *et al*., (2015)[48] where the wavelength of maximum absorbance of ZnO NPs from *Artocarpus gomezianus* was seen at 370nm. Several others have reported the peaks of green ZnO NPs that were synthesized between the 300 to 400 nm range [49,50,51].

XRD analysis of the green synthesized ZnO NPs

The XRD analysis was conducted using Rigaku, Smart lab XRay Diffractometer (CeNSE, IISc, Bengaluru) to observe the crystallite size. The scanning was done in 2θ region from 20˚ to 90. The analysis shows a characteristic broad peak which indicates the prepared zinc oxide nanoparticles of *P. granatum* (Figure 4a) and *A. heterophyllus* (**Figure 4b**) are crystalline. There were several peaks representing the purity of the samples. The 2θ values of *P. granatum* ZnO NPs (Table 5.1) and *A. heterophyllus* ZnO NPs **(**Table 5.2) correspond to the Miller indices of peak regions in the XRD spectrum are comparable to the reports of Faisal *et al*., (2021)[52] where *Myristica fragrans* was used as the raw material and of Shabaani *et al*., (2020)[53] where *Eriobutria japonica* seed extract was used for synthesis.* Applying the Debye-Scherrer equation, it was noticed that the crystallite size of *P. granatum* ZnO NPs corresponding to the intense peak (101) was 23.01832 nm (Table 5.1**)** and *A. heterophyllus* ZnO NPs was 23.15299 nm, corresponding to intense peak (1 0 1) (Table 5.2). Previously conducted studies have shown average crystallite sizes of ZnO NPs synthesized from *Eriobotrya japonica* as 14.81nm (Shabani *et al*., 2012) [53], from *Myristica fragrans* was 29 nm (Faisal *et al*., 2021)[52] and from *Persea americana* was 36.83nm (Saridewi *et al*., 2022)[14]. The average dimension of crystallites of the three synthesized ZnO NPs was calculated (Table 5.3) and discovered to be larger than those of previous reports. It was also noted that the size of crystals of *P. granatum* ZnO NPs was smaller than that of *A. heterophyllus.*

Scanning Electron Microscope (SEM) analysis of the green synthesized ZnO NPs

P. granatum ZnO NPs and *A. heterophyllus* ZnO NPs consisted of spherical nanostructure with nanoflakes along with aggregates. The images were observed under magnifications (5KX, 10KX, 25KX) (Figure 5a and 5b). The average diameter of 52.98 nm was seen *P. granatum* ZnO NPs and 59.13 nm for *A. heterophyllus* (Table 6). Similarly shaped ZnO NPs (spherical) were reported in nanoparticles synthesized from *Persea americana* [14] and *Artocarpus gomezianus* [54]. Aggregation, nanoflake attachment, capping layers, drying-related agglomeration, and the two-dimensional projection of irregular particles can all increase the SEM-measured apparent diameter. A similar distinction has been reported in green ZnO studies in which XRD crystallite sizes were smaller than sizes obtained by electron microscopy or colloidal sizing (61)

Energy Dispersion X-ray Spectroscopy (EDS) analysis of the green synthesized ZnO NPs

The following analysis was carried out to determine the chemical purity, elemental composition and stoichiometry [49]. The EDS analysis proved the elements Zn and O were present in both the samples and in a higher percentage than other elements (Figure 6). *P. granatum* ZnO NPs contained 74.95% weight of Zn and 15.21% weight of O. While *A. heterophyllus* ZnO NPs contained Zn in 68.78% weight and O in 16.56% weight (Table 7). Percentage weight of Zn was greater than O, similar to as reported in several studies [47,55] Current results also indicate that *P. granatum* ZnO NPs contained the higher percentage of Zn. Further few other elements such as Mg, Cl, C, N and Al were in trace amounts, similar to various studies (14,47,55). The carbon detected by EDS most likely originates from residual seed-derived organic compounds adsorbed on or trapped within the ZnO particles. The seed extract contains proteins, carbohydrates, phenolics, flavonoids, and other carbon-containing metabolites that can act as capping or stabilizing agents.

In vitro Antibacterial activity of the green synthesized ZnO NPs by agar disc diffusion assay :

ZnO NPs synthesized using extracts of both *P. granatum* and *A. heterophyllus* demonstrated inhibitory activity against the bacterial pathogens tested. Among the concentrations evaluated, 10 mg/mL *P. granatum*-mediated ZnO NPs exhibited a maximum inhibition zone of 5.5 ± 2.12 mm (mean ± SD) against *B. subtilis*, whereas *A. heterophyllus*-mediated ZnO NPs at 10 mg/mL produced an inhibition zone of 5.0 ± 3.54 mm (mean ± SD). Against *S. aureus*, 10 mg/mL *P. granatum*-mediated ZnO NPs showed a maximum inhibition zone of 6.5 ± 4.59 mm (mean ± SD), while *A. heterophyllus*-mediated ZnO NPs at the same concentration produced an inhibition zone of 4.5 ± 3.18 mm (mean ± SD). The observed inhibition zones are presented in Tables 8 and 9 and Figure 7a and 7b. In comparison to *A. heterophyllus* ZnO NPs, zones of inhibition of *P. granatum* ZnO NPs were larger. This implies *P. granatum* ZnO NPs against Gram-positive pathogens like *B. subtilis* and *S. aureus* pathogens could be more effective than *A. heterophyllus* ZnO NPs. These results coordinate with preceding studies where they performed antibacterial activity ZnO NPs [56].

Antioxidant activity of the green synthesized ZnO NPs by DPPH method

Environmental stress, degrades membrane lipids, plant cells, DNA, and proteins, is to blame for the alteration in metabolic pathways in plants [57]. Many substances with metabolic importance, including terpenoids, flavonoids, and substances that respond to oxidative stress, play a promising function in capping and stabilising the nanoparticles [58]. The concentration of 1mg/mL of *A. heterophyllus* ZnO NPs and 5mg/mL of *P. granatum* ZnO NPs displayed maximum percentage inhibition (Table 10,Figure 8). In our current study, the inhibition percentage of *A. heterophyllus* ZnO NPs was more than that of *P. granatum* ZnO NPs. This is concordant to previous study of *Mangifera indica* [59]. The IC50 value for synthesized *P. granatum* ZnO NPs, *A. heterophyllus* ZnO NPs and Ascorbic acid was 2.0847mg/ml, 2.2421mg/ml and 2.0212mg/ml respectively (Table 10). The extract possessed a good radical scavenging capacity. This corresponds to earlier research performed using *Artocarpus gomezianus* [48] The DPPH showed a non-linear concentration pattern. This can be because the scavenging depends on surface contact between the radical and active surface or capping molecules, not simply on nanoparticle mass. At higher nanoparticle concentrations, aggregation can reduce the accessible surface area. ZnO suspensions can scatter or absorb light at 517 nm, causing spectrophotometric interference.

CONCLUSION

The green-synthesized ZnO nanoparticles demonstrated antibacterial activity against *Bacillus subtilis* and *Staphylococcus aureus*, together with DPPH radical-scavenging activity under the experimental conditions used in this study. These findings suggest that the nanoparticles may have potential for further investigation in biomedical, pharmaceutical, agricultural, food-packaging, and environmental applications. However, their practical use cannot be established from the present in-vitro results alone. Further studies are required to evaluate cytotoxicity toward normal mammalian cells, hemocompatibility, genotoxicity, nanoparticle stability, bioaccumulation, environmental toxicity, and the mechanisms underlying their antimicrobial and antioxidant activities. Application-specific investigations, including drug-delivery efficiency, wound-healing performance, photocatalytic activity, wastewater-treatment efficiency, agricultural efficacy, food-contact safety, scale-up feasibility, and regulatory compliance, are also necessary before these nanoparticles can be considered for biomedical or industrial use.

ABSTRACT

Soil contamination with heavy metals poses a formidable environmental challenge. This pioneering study unlocks the phytoremediation potential of Ananas comosus (pineapple) in mitigating copper (81.2%), lead (87%), chromium (70.4%), arsenic (63.87%), cadmium (75.1%), and nickel (67.4%) pollution. Our findings reveal remarkable reductions in heavy metal concentrations, with Ananas comosus demonstrating exceptional efficiency in removing these toxic pollutants. A comprehensive analysis of soil parameters (pH, organic matter, and nutrient content) sheds light on the intricacies of phytoremediation. This groundbreaking research heralds Ananas comosus as a promising solution for sustainable soil decontamination, paving the way for innovative phytoremediation strategies.

Keywords: Phytoremediation, Ananas comosus, Heavy metal concentration, Soil decontamination, Sustainable soil decontamination

INTRODUCTION

Soil pollution, a clandestine threat to environmental and human well-being, has reached alarming proportions. The unchecked release of heavy metals from industrial and anthropogenic activities has irreparably harmed ecosystems,

compromising soil health and fertility. Conventional remediation methods, often resource-intensive and invasive, have proven insufficient to mitigate this crisis. Phyto remediation emerges as a beacon of hope, offering a sustainable, eco-friendly solution to revitalize contaminated soils. This approach not only promises to restore soil health but also fosters biodiversity and ecosystem resilience, enhances soil structure and fertility, supports plant growth and agricultural productivity, reduces environmental and human health risks, and offers a cost-effective and scalable solution. Furthermore, phyto remediation provides a natural, non-invasive alternative to traditional remediation methods, making it an attractive solution for soil pollution. As the world grapples with the challenges of soil pollution, phyto remediation presents a compelling alternative, warranting further exploration and adoption. By harnessing the power of plants, we can reclaim polluted soils, safeguard ecosystems, and ensure a sustainable future.

MATERIALS AND METHODS

Soil samples were collected from 10 contaminated sites in Kanyakumari District, Tamil Nadu, for analysis. The sites included Alanvilai, Muttom, Kappiyarai, Katimancode, Vellimalai, Manalvalakurichi, Aathivilai, Kothanalloor, Thickenamcode, and Colachel. Soil sampling was carried out using soil sampling augers, and the collected samples were transferred to drums or containers, labeled, and stored in a secure location. The collected soil samples were then used to plant Ananas comosus (Pineapple) in drums. The soil was prepared by mixing and adding water to achieve a moist consistency, and the pineapple plantlets were planted, leaving space for growth. The soil was watered, fertilized with a balanced natural fertilizer, and mulched with organic material to retain moisture and suppress weeds. The planted drums were placed in a location with bright, indirect light and temperatures between 65-95°F (18-35°C). Regular watering, monitoring for pests and diseases, and pruning were performed to ensure the healthy growth of the pineapple plants. This setup allows for the assessment of the phyto remediation potential of Ananas comosus in contaminated soils, providing insights into the plant's ability to absorb and accumulate heavy metals. The analysis of heavy metals in soil involves digesting a 1g soil sample with acid (HCl or HNO3) at 100°C for 30 minutes. After cooling, various reagents are added to the mixture, depending on the metal being analyzed. The mixture is then atomized in an Atomic Absorption Spectrometer (AAS) instrument at specific wavelengths for each metal. The absorbance measured by the AAS instrument is used to calculate the concentration of each metal in the soil sample, expressed in parts per million (ppm). The calculation involves multiplying the absorbance by the concentration of the metal standard, the dilution factor, and dividing by the weight of the soil sample. The specific wavelengths used for each metal are: Arsenic (193.7 nm), Cadmium (228.8 nm), Chromium (357.9 nm), and Lead (283.3 nm). The analysis provides a quantitative measure of the heavy metal content in the soil, which is essential for assessing soil pollution and implementing phyto remediation strategies.

X (ppm) = (Absorbance x Concentration of X standard x Dilution factor) / Weight of soil (g)

Chromium

The initial chromium concentration was highest at Colachel, Thickenamcode, and Kothanalloor, with significantly higher levels than other stations. All stations showed a gradual decrease in chromium concentration over time, with varying percentage decreases, ranging from 67.2% (Kothanalloor) to 73.2% (Colachel). Despite significant decreases, the stations with highest initial concentrations remained relatively high, while those with lower initial concentrations experienced larger percentage decreases, resulting in Manalvalakurichi, Aathivilai, and Kappiyarai having the lowest final concentrations. The overall mean decrease in chromium concentration was approximately 70.4% across all stations, indicating a significant reduction over time.

Cadmium

The initial cadmium concentration was highest at Kothanalloor, Thickenamcode, and Muttom, likely due to industrial or agricultural activities, and these stations had significantly higher concentrations than others. All stations showed a gradual decrease in cadmium concentration over time, with varying percentages of decrease, ranging from 34.6% (Kothanalloor) to 90.5% (Vellimalai). The stations with highest initial concentrations remained relatively high even after significant decreases, while those with lower initial concentrations experienced larger percentage

decreases. The overall mean decrease in cadmium concentration was 57.1%, suggesting a significant reduction over time, likely due to phyto remediation and efforts to reduce pollution.

Copper

The initial copper concentration was highest at Katimancode, Alanvilai, and Vellimalai, with significantly higher levels than other stations. All stations showed a gradual decrease in copper concentration over time, with varying percentage decreases, ranging from 79.5% (Thickenamcode) to 86.5% (Alanvilai). Despite significant decreases, the stations with highest initial concentrations remained relatively high, while those with lower initial concentrations experienced larger percentage decreases, resulting in Thickenamcode, Colachel, and Kothanalloor having the lowest final concentrations. The overall mean decrease in copper concentration was 81.2% across all stations, indicating a significant reduction over time.

Nickel

The study found that the initial nickel concentration was highest at Muttom, Kappiyarai, and Alanvilai, with significantly higher levels than other stations. All stations showed a gradual decrease in nickel concentration over time, with varying percentages of decrease, ranging from 11.4% (Colachel) to 50.9% (Manalvalakurichi). The stations with highest initial concentrations experienced larger decreases, resulting in Muttom, Kappiyarai, and Alanvilai having the highest final concentrations. The overall mean decrease in nickel concentration across all stations was 37.4%, indicating a significant reduction over time, with a clear trend of higher initial concentrations corresponding to larger decreases.

Arsenic

The initial arsenic concentration was highest at Katimancode (152.32 ppm), followed by Vellimalai (136.80 ppm) and Alanvilai (125.24 ppm), which showed significant decreases over time. All stations experienced a gradual decline in arsenic concentration, with varying percentages of decrease, ranging from 56.2% (Aathivilai) to 77.4% (Katimancode). Despite significant reductions, the stations with the highest initial concentrations remained the highest at the end, while Thickenamcode, Colachel, and Kothanalloor had the lowest final concentrations. The mean decrease in arsenic concentration across all stations was 63.2%, indicating a substantial overall reduction in arsenic levels over the months.

Lead

The initial lead concentration was highest at Muttom, Alanvilai, Kappiyarai, and Katimancode, with significantly higher levels than other stations. All stations showed a gradual decrease in lead concentration over time, with varying percentage decreases, ranging from 33.9% (Kothanalloor) to 89.3% (Alanvilai). Despite significant decreases, the stations with highest initial concentrations remained relatively high, while those with lower initial concentrations experienced larger percentage decreases, resulting in Kothanalloor, Aathivilai, and Manalvalakurichi having the lowest final concentrations. The overall mean decrease in lead concentration was 73.5% across all stations, indicating a significant reduction over time.

pH

The soil pH levels at different stations before planting pineapple ranged from 6.3 to 7.9, but decreased slightly after planting, ranging from 5.9 to 7.1, due to nutrient absorption and organic acid release. The largest decrease was observed at Kappiyarai (0.8 units), while Katiman code had the smallest decrease (0.6 units).Despite the decrease, the pH levels remained suitable for pineapple growth, which prefers a slightly acidic to neutral soil pH (5.5-7.0). Overall, the soil pH shifted from neutral to slightly acidic after planting, with most stations experiencing a moderate decrease, emphasizing the importance of monitoring soil pH and nutrient levels for optimal plant growth and soil health.

Electrical conductivity (EC)

The electrical conductivity (EC) of the soil, measuring soil salinity, ranged from 0.2 to 1.9 mmhos/cm before planting pineapple, and increased after planting, ranging from 0.6 to 2.3 mmhos/cm, due to fertilizer or irrigation water

addition. The largest increase was observed at Aathivilai (0.4 mmhos/cm), while Alanvilai had the smallest increase (0.4 mmhos/cm). Most stations had EC levels within the acceptable range for pineapple growth (0.5-2.5 mmhos/cm), but Vellimalai, Aathivilai, and Thick enamcode had relatively high EC levels, indicating higher soil salinity. Regular monitoring of soil EC and salinity is crucial to ensure optimal plant growth and soil health, and appropriate irrigation management and fertilizer application practices are necessary to mitigate soil salinization.

Moisture Content in Soil (%)

The soil moisture content before planting pineapple ranged from 31% to 54%, but increased at all stations after planting, ranging from 45% to 67%, due to irrigation or rainfall. The largest increase was observed at Vellimalai (22%), while Alanvilai had the smallest increase (13%). All stations had moisture content within the acceptable range for pineapple growth (40-70%), indicating optimal soil conditions. However, regular monitoring is necessary to maintain optimal soil moisture levels and avoid waterlogged soil conditions, which can lead to root rot and other problems, ensuring healthy plant growth.

Soil Temperature (℃)

Soil temperature before planting pineapple ranged from 27.2°C to 35.4°C, but decreased at all stations after planting, ranging from 21.5°C to 31.6°C, due to the shading effect of the plants. The largest decrease was observed at Kappiyarai (7.9°C), while Vellimalai had the smallest decrease (3.8°C). All stations had soil temperatures within the acceptable range for pineapple growth (20-30°C) after planting, indicating optimal soil conditions. The decrease in soil temperature suggests a beneficial cooling effect from the plants, which can enhance plant growth and productivity. Regular monitoring of soil temperature is necessary to ensure optimal soil conditions for healthy plant growth.

Bulk density(g/cm^3)

The bulk density of the soil at the stations ranged from 1.5 to 1.7 g/cm^3, indicating a moderate to low density, allowing for adequate water infiltration and aeration. After planting Ananas comosus, the bulk density decreased at all stations, ranging from 1.2 to 1.5 g/cm^3, indicating an improvement in soil structure and porosity. The largest decrease was observed at Katimancode, from 1.5 to 1.2 g/cm^3. The decrease in bulk density suggests an increase in porosity, benefiting root growth and water infiltration, and is attributed to the addition of organic matter and improvement in soil structure.

Cation Exchange Capacity(meq/100g)

The soil's cation exchange capacity (CEC) varied from 18.9 to 31.2 meq/100g, indicating a moderate to high capacity for nutrient exchange, essential for plant growth. After planting Ananascomosus, CEC increased at all stations, with the largest increase at Thickenamcode (from 31.2 to 34.7 meq/100g) and the smallest at Kappiyarai (from 18.9 to 21.3 meq/100g). This increase suggests improved soil fertility and productivity, likely due to added organic matter and improved soil structure and porosity, enabling better nutrient retention and exchange. The higher CEC values indicate a reduced risk of nutrient leaching, making the soil more conducive to plant growth

Organic matter (%)

The organic matter content in the soil increased at all stations after planting Ananascomosus, indicating improved soil fertility and productivity. Initially, the organic matter content ranged from 1.5 to 3.4%, but after planting, it increased to a range of 2.3 to 5.2%. The largest increase was observed at Kappiyarai (from 2.5% to 5.2%), followed by Alanvillai (from 3.2% to 4.3%), and the smallest at Thick enamcode (from 1.5% to 2.3%). This increase is attributed to the addition of organic matter from the pineapple plants, which decomposes and enriches the soil, improving its structure, fertility, and overall health.

Redox potential(mV)

The redox potential of the soil was measured at 10 stations before and after the planting of Ananascomosus. The results show an increase in redox potential at all stations after planting, indicating improved soil conditions. The

redox potential increased from 226-340 mV before planting to 239-363 mV after planting, with the largest increase observed at Manalvalakurichi (23 mV) and the smallest at Kothanallur (13 mV). The increase in redox potential suggests improved soil aeration, fertility, and overall health, likely due to the addition of organic matter and improved soil structure from the pineapple plants.

Soil Texture and Soil Structure

The soil texture at all stations is classified as sandy loam, indicating a consistent geological profile with minimal variation in soil composition, making it suitable for pineapple growth. However, the soil structure varies between blocky and granular, affecting soil aeration, water infiltration, and root growth. Most stations have a granular soil structure, indicating good soil aggregation and porosity, while a few have a blocky structure, potentially leading to reduced soil aeration and water infiltration. Regular monitoring and management practices can help maintain optimal soil conditions, allowing farmers to adjust their practices to ensure healthy pineapple growth.

Nitrogen, Phosphorus, Potassium

Macronutrients: Before planting pineapple, soil nutrient levels varied across stations, with N content ranging from 55-102, P content from 8.7-21and Potassium content from 29.4-59. After planting, all stations showed increased nutrient levels. These increases are attributed to the addition of organic matter from pineapple plants, which enriched the soil through the nitrogen cycle and improved soil structure and fertility. The overall improvement in soil nutrient levels and structure suggests that planting pineapple can have a positive impact on soil health and productivity, highlighting its potential benefits as a cover crop or intercrop in agricultural systems.

ABSTRACT

Health insurance fraud is one of the major issues in healthcare sector, with the effect on economic stability and trust in the patients in the global arena accelerating. The point of entry needs to be identified in time to reduce the financial cost and also to protect the health care systems integrity. Conventional fraud detection approaches rely on centralized data processing, but the rigid data privacy laws, as well as the sensitivity of medical and insurance data, limit the opportunity to share raw data between companies. The given limitation causes a divided data silo, poorer model generalization, and ineffective fraud detection. Machine Learning (ML) is one of the technologies to solve these issues, as it is possible to detect fraud based on the patterns and anomalies in claims data to automate it. However, the traditional ML techniques are based on centralized datasets, need a lot of data privacy, security threats, and scalability. By allowing collaborative training of models across institutions without sharing raw data, Federated Learning (FL) has become an effective way to address these limitations. Local models in FL are trained using decentralized data sources and only model updates are exchanged, thus, maintaining data privacy and enhancing detection performance. This paper provides a literature review and comparison of the current FL solutions to detect health insurance fraud. In comparison to conventional centralized approaches to ML, FL-based systems are more privacy-preserving, more robust in models, and can be used to securely and scalable cooperate between healthcare organizations to produce more accurate and reliable fraud detection outcomes.

Keywords: Fraud detection in health insurance, Federated learning, Privacy preservation, Machine learning, Decentralized learning, Healthcare analytics, Secure data sharing, Anomaly detection.

INTRODUCTION

The healthcare system is vital in the health and wellbeing of society and most nations offer health insurance to their citizens to make sure that they can get medical care when they require it. Both the public and the private entities can offer health insurance and it assists in meeting the cost of medical treatments, procedures and drugs. The system is also useful in safeguarding individuals against the financial risk of unforeseen medical costs that may occur as a result of sickness or accident [1]. False claims, billing manipulations and unnecessary medical practices are some of the frauds that cost billions of dollars annually around the world [2]. As digital healthcare systems and insurance databases swell fast, fraudulent claims have grown more complicated and have become necessary to ensure the integrity of systems [3]. Early and accurate detection of fraudulent cases is critical to minimizing financial damages and enhancing the standard of healthcare services [4]. Health insurance fraud may be categorised into provider fraud, patient fraud and insurer fraud depending on source and nature of manipulation [5]. Overbilling and billing of services not performed are some of the practices that constitute provider fraud whereas misuse of identity or falsifying claims by patients are some of the practices constituting patient fraud [6]. Categories less prevalent, but also included in insurer fraud, are intentional refusal to pay valid claims. A majority of the frauds are hard to track because they are covert in nature and they are similar to the genuine claims [7,8]. Nevertheless, some trends like recurring claims, irregular billing codes or uncommon frequency of treatments can be a sign of fraudulent activity. Various factors such as absence of stringent laws, elaborate steps to claim, huge financial rewards, and inappropriate monitoring systems contribute to the incidence of fraud.

Timely identification of fraudulent claims is essential in reducing the risk of finances and improving trust in healthcare systems [9]. Conventional methods of fraud detection are based on rule-based systems, statistical analysis as well as manual auditing [10]. Despite the fact that these methods have been proven to be effective to a certain extent, these methods are time consuming, not as scalable and have failed to identify more intricate patterns of frauds in large volumes of data. Also, these systems are too dependent on rules and professional expertise that are fixed and can be easily adjusted to new fraud methods. Popular implementations have also been the use of machine learning (ML), approaches to detecting obscured patterns, anomalies, and other subtle patterns in large datasets [11]. It has been demonstrated when using decision tree, random forest, support vector machine, and logistic regression algorithm [12]. However, ML-based solutions are typically linked with central information collection, which can be severely doubted regarding data privacy, security and legislation, especially in the healthcare industry where patient information is sensitive.To address these challenges, FL has emerged as a viable framework to enable collaborative model training without the transfer of raw data between institutions. In FL, healthcare providers or insurance companies in a given area locally train a typical global method on their data and only update them with model updates, thereby ensuring the privacy of their data [13]. This is not only compliant with privacy laws, but also enhances the generalization of models that are trained using different datasets of different types.

The latest developments of FL coupled with Deep Learning (DL) algorithms have enhanced the precision and effectiveness in the detection of fraud. Neural networks and hybrid architectures are DL models that can be automatically trained to acquire complex representations of the fraudulent patterns, whereas FL provides safe and distributed learning [14]. As a result, FL-based fraud detection systems offer a privacy-preserving, scalable, and efficient approach to detecting fraud in a health insurance and are therefore of significant interest to contemporary healthcare analytics. Figure 1 represents the Federated Learning Framework for Health Insurance Fraud Detection. This survey reviews various existing FL models employed for health insurance fraud detection by comparing its datasets used, merits, demerits and performances. The subsequent sections of the paper are as follows: Section 2 reviews various FL models employed for health insurance fraud detection. Section 3 compares the reviewed models and Section 4 evaluates it using common metrics. Section 5 delineates future directions, while Section 6 closes the investigation.

Kotekani and Ilango [15] presented HEMClust, a modern, health insurance fraud detection model combining essential data preprocessing, k-prototype clustering, and a heterogeneous stacking ensemble framework. The model was developed to enhance data quality, then take care of cases involving overlapping provider specialty by clustering and lastly apply multi-level ensemble learning to achieve correct classification of fraud. The combination of clustering and heterogeneous ensemble techniques in HEMClust boosted the fraud detection accuracy and classification of the various types of fraud. However, be more complex to implement and may also demand special parameters to be set so as to achieve the best performance. Arockiam and Pushpanathan [16] suggested MR-ISVM, an iterative MapReduce-based support vector machine model in healthcare insurance fraud detection, which is effectively used with big data infrastructure to handle millions of insurance claims. The model enabled the automation of fraud detection and minimized the time and resources spent on the computational workload of large healthcare datasets by applying the MapReduce framework and use of iterative SVM classification. This hybrid scheme improved scaling capabilities and achieved high levels of classification with respect to traditional SVM variants. However, the model could be less interpretable than more recent DL or graph-based models.

Parthasarathy et al. [17] introduced Bayesian Optimized XGBoost (BOXGBoost) that uses a Bayesian optimizer to optimize XGBoost and improve predictive accuracy over insurance claim on big datasets. The framework was effective to enhance the classification of frauds by maximizing the hyperparameters leading to high detection rates as opposed to the conventional machine learning models like Logistic Regression, Random Forest, and AdaBoost. The model has delivered much accurate and reliable predictions of frauds by using advanced optimization techniques. However, it could be less transparent in practical use when it requires huge labeled datasets and it is less interpretable than simpler models. Nabrawi and Alanazi [18] created a ML-based healthcare insurance fraud detection model by applying Random Forest, Logistic Regression, and Artificial Neural Network on the Saudi Arabian insurance claim data. The framework also used SMOTE to balance the classes and Boruta feature selection that enhanced the predictive accuracy and detected the factors that were considered significant in relation to fraud detection. Random Forest has the bestcapabilities of detecting fraud with a high level of accuracy and good classifications rulesamong the models tested.

Mangharamani and Jain [19] suggested an AI Risk Dashboards to detecting health insurance fraud and to make timely policy adjustments in actual time with assistance of machine-intelligence and real-time. The system facilitated the detection of frauds before they occurred by detecting suspicious behavior in real time and facilitated adaptive changes in policy using dynamic risk profiles. This would enhance efficiency in operations, lessen administration, and make decisions more informed based on predictive insights. However, obstacles associated with dealing with data integration, AI model transparency, and ethical issues in automated decision-making can influence the operation and reliability. Villegas-Ortega et al. [20] developed a six-phase process to detect potential healthcare insurance frauds using supervised machine learning, called PDHIF. The approach combined fraud theory, healthcare stakeholders, types of fraud and the machine learning lifecycle to produce a consistent and flexible process. Using balancing strategies like K-means SMOTE, the framework greatly boosted the ability to detect fraud in highly imbalanced data, as well as improving model trustworthiness. However, the technique is based on preprocessing and balancing algorithms that may contribute to the complexity of the implementation and the resource requirements. Seshagiri & Prema [21] developed a Meta-Reinforcement Learning (Meta-RL) to deal with the data imbalance of detecting health insurance frauds. The Meta-RA took advantage of the principles of meta-learning to acquire the properties of fraudulent cases dynamically. This technique increased effect of samples, flexibility and generalization at imbalanced frauds. But the complexity of the realization of the Meta-R and tuning could be referred to as problems of the practical implementation in the traditional healthcare fraud detection systems.

Survey of Health Insurance Fraud Detection Using Federated Learning

Okeno and Muchemi, [22] introduced a decentralized and confidentiality system for insurance fraud detection utilizing asynchronous FL with adjusted random forest model. This method is a FL that is decently processed with a blockchain system to facilitate safe and decentralized information processing in distributed fog and cloud settings. It

supports both hard constraints and soft constraints with the help of dynamic heuristics that makes sure both hard constraints and soft constraints are well managed in healthcare applications. The framework also improves data security, validation and fraud detection and streamlines performance of the system by minimizing energy usage and delay. However, blockchain processes may impose both calculative and storage overheads, which can impact the efficiency of the systems. Amistapuram [23] presented a cross-carrier insurance detection fraud framework based on FL-based classification models with a closed set of labels for the data being classified. Forming a viable methodology, the methodology supports both horizontal and vertical data partitioning as well as Availing privacy-managing approaches like differential privacy, secure multiparty computation and homomorphic encryption so as to guarantee data confidentiality. It also incorporates data governance data minimization and access control as privacy concerns to address privacy issues in multi-institutional settings. The framework enhances performance on fraud detection by relying on distributed information among carriers and helps prevent such challenges as data insufficiency, noise and mislabelling. However, the model is distrust among the actors, in particular, rival insurers, can restrain effective cooperation.

Ara et al. [24] examined the use of FL and Differential Privacy (DP) in secure prediction modeling in healthcare finance. The model is based on the decentralized training of such models in different institutions such as hospitals, insurance companies and financial organizations without necessarily sharing uncodified sensitive data. The framework benefits main uses including fraud detection, insurance risk assessment, billing optimisation, and cost forecasting. However, it is subject to scaling issues, communication overhead, and trade off of privacy model accuracy that can impact model performance in large, real-world, healthcare financial systems. Raghi et al. [25] introduced FraudNetX, a privacy-preserving health insurance fraud detector based on Vertical FL (VFL). The methodology enables interaction between the parties such as hospitals and insurance companies where different characteristics of similar data are shared across the organizations without necessarily sharing raw data. It has an architecture which is founded on the combination of Feedforward Neural Networks (FFNNs) and transformer encoders which allow successful learning of features that are presented by the heterogenous sources of data. However, this model is limited by the fact that it relies on limited number of entities involved and experimental controlled conditions that may have an implication on generalization and scalability in more complex environments with huge populations.

Rafi et al. [26] suggested a FL based architecture of privacy-aware healthcare analytics to detect fraud. The methodology also enables different healthcare stakeholders to jointly train the models without the exchange of raw data, thereby complying with privacy policies. The framework integrates the notion of Differential Privacy (DP) and that of secure aggregation to make sure that the sensitive information of both patients and providers are not disclosed in the training process. Nevertheless, the framework has shortcomings in the literature through assessment of controlled datasets and might have issues of real-life implementation especially in dealing with heterogeneous data distributions. Jeevarathinam and Kumaravelan [27] introduced a Dynamic Trust-Aware Blockchain FL (DT-BFL) model of medical insurance fraud detection that guarantees privacy and safety of collaboration between parties. The method integrates FL with blockchain technology so as to allow decentralized training of models as well as help to maintain transparent records and tamper-proof record. It uses a dynamically defined trust-based weighting mechanism to assess the reliability of each participant and mitigate impact of malicious or poisoned updates. The framework does a good job in achieving a stronger resistance to data-poisoning attack and also in retaining sensitive medical data. However, the model could become vulnerable regarding greater computational resources, the complexity of incorporating blockchains, and the challenge of scaling it in large-scale real-world implementations.

Sargam and Kalapala [28] developed a federated system of anomaly detectors with differential privacy-preserving autoencoders in detecting large-scale health-fraud. It is a model that integrates client-side deep autoencoders with Federated Averaging (FedAvg) and Differential Privacy (DP) and enables individual institutions to collectively train models without disclosing the raw claims data of individuals. The system runs on cloud infrastructure with local models being trained on inhouse datasets and privacy-preserving updates alone are sent to a central aggregator. However, the approach is based on synthetic augmentation of fraud data and can be challenged to deal with highly

imbalanced real data and the distribution of institutional data. Teki et al., [29] developed FraudBERT-MM, a multimodal FL framework for healthcare insurance fraud detection that integrate s structured claim features with unstructured textual data to improve detection of subtle and emerging fraud patterns. The architecture combines a BERT-based text encoder, an MLP-based structured encoder, and a cross-modal fusion layer, along with a binary classification head to generate comprehensive claim representations. Nonetheless, the model's complex architecture, which combines multimodal learning, few-shot adaptation, and federated differential privacy, leads to high computational and implementation complexity. Table 1 shows the comparison of above reviewed health insurance fraud prediction models using ML and DL models, highlighting their merits and demerits along with their techniquesand datasets used as well as their performance metrics.

Comparative Analysis

Table 2 shows the comparison of above reviewed health insurance fraud prediction models using FL, highlighting their merits and demerits along with their techniques and datasets used as well as their performance metrics.

Performance Evaluation

This section assesses the efficacy of the above-mentioned health insurance fraud prediction models. The discussion of the performance achieved by the proposed models show that they are effective in detecting and fighting fraudulent activities in health insurance systems with the help of FL approaches. The majority of the studies used a mix of publicly-available datasets and non-public-access institution-based healthcare claims, which guaranteed the variety of sources of data without compromising privacy and security. FL facilitates decentralized training of models across multiple organizations without the need to share sensitive patient information and this makes it very applicable in the context of healthcare. This section involves a comparative performance analysis of the FL-based fraud detection models based on the main aspects of detection accuracy, classification performance, preservation of data privacy, and system reliability. Figure 2 shows the graphical form of the various ML & DL based methods of health insurance fraud detection in terms of accuracy metrics. The comparison of results shows that ML and DL models, especially, PDHIF, ANN/LR/RF, BOXGBoost, and HEMClust, resulted in the highest fraud detection rates of about 98%, which are significantly better than traditional ML models, and MR-ISVM demonstrated relatively lower results at about 87.73% in the same study, which demonstrates the relevance of the current AI-based solutions to detect. Figure 3 shows the graphical form of the various FL based methods of health insurance fraud detection in terms of accuracy metrics. Fed Avg [28] model offers the best accuracy of 99.91% thus performing better than various methods which are in use. This improvement is possible because of the incorporation of privacy protection mechanism, decentralized training, and other sophisticated learning methods and strategies which can be more effective in identifying complex pattern of fraud as well as protect the remaining data of distributed healthcare systems.

CONCLUSION

Health insurance fraud is an increasing issue as it has got complicated patterns in claims and huge data. The ancient centralized approaches are contested with such challenges as risks to privacy, lack of scalability, and impoverished flexibility. FL is a method to solve the problem by having several medical institutions jointly train models without the transfer of sensitive data. The FL-based methods enhance fraud detection by detecting suspicious claims and abnormal patterns and maintaining privacy of the data. This paper discusses FL methods of identifying health insurance frauds, strengths, limitations, and performance of the methods. The study helps in making better decisions, saving of costs and safe and healthy working. Future research will be dedicated to the improvement of FL models by adding the possibility to monitor them in real-time to be able to detect fraud in healthcare systems faster and more precisely.

ABSTRACT

In this paper, we investigate the gamma graph associated with the zero-divisor graph of the ring $\mathbb{Z}_n$. We determine the diameter of $\gamma.\Gamma(\mathbb{Z}_n)$ for various classes of integers $n$andobtain a formula for its wiener index when $n = p_1^{k_1}p_2^{k_2}$, $p_1^{k_1}p_2^{k_2}p_3^{k_3}$, $p_1^{k_1}p_2^{k_2}p_3^{k_3}p_4^{k_4}$ where$p_1, p_2, p_3$and $p_4$are distinct primes. In addition, we provide python code for finding wiener index for gamma graph of zero-divisor graph of the commutative ring $\mathbb{Z}_n$ for all n. These results contribute to the understanding of distance based properties ofgamma graphs.

Keywords: Gamma graph, Zero-divisor graph, diameter, wiener index

INTRODUCTION

In recent years, the interaction between algebraic structures and graph theory has received considerable attention, resulting in many significant developments and challenging research problems. Among the various graph-theoretic representations of rings, the zero-divisor graph has emerged as an important area of study. The concept was first

introduced by Beck [3] and was subsequently modified by Anderson and Livingston [1]. For a commutative ring $R$with identity, the zero-divisor graph $G(R)$is the graph whose vertex set consists of the nonzero zero-divisors of R, where two distinct vertices are adjacent if and only if their product is zero. Distance-based graph invariants play a fundamental role in understanding the structural properties of graphs. Let Gbe a graph. The distance between two vertices x and y, denoted by $d(x,y)$, is the length of a shortest path joining them. If no such path exists, then $d(x,y) = \infty$[2]

The eccentricity of a vertex$u \in V(G)$ is defined as $e(u) = \max_{v \in V(G)} d(u,v)$ that is, the greatest distance from $u$to any other vertex of G. The diameter of $G$is the maximum eccentricity among its vertices and is given by $diam(G) = \max_{v \in V(G)} e(u)$. Another important distance-based graph invariant is the Wiener index, which quantifies the total distance between all unordered pairs of vertices in a graph. Introduced by Hosoya [6] in 1976, it has become one ofthe most extensively studied topological indices. For a vertex $u \in V(G)$, the distance sum is defined by

$$d(u \mid G) = \sum_{u \in V(G)} d(u,v)$$

Accordingly, the Wiener index of $G$is $W(G) = \frac{1}{2}\sum_{u \in V(G)} d(u \mid G)$. For more information non zero-divisor graphs and the Wiener index of zero-divisor graphs, the reader is referred to[9,4,11,10,2].

The present work is concerned with the gamma graph associated with the zero-divisor graph of the ring $\mathbb{Z}_n$. The gamma graph, denoted by $\gamma.\Gamma(\mathbb{Z}_n)$, is defined by taking the γ-sets of $\Gamma(\mathbb{Z}_n)$as its vertices. Two vertices of $\gamma.\Gamma(\mathbb{Z}_n)$are adjacent whenever the corresponding γ-sets differ in exactly one element, or equivalently, have precisely $\gamma(\Gamma(\mathbb{Z}_n)) - 1$ elements in common. In this paper, we determine the Wiener index of $\gamma.\Gamma(\mathbb{Z}_n)$for the cases $n = p_1^{k_1}p_2^{k_2}$, $p_1^{k_1}p_2^{k_2}p_3^{k_3}$, $p_1^{k_1}p_2^{k_2}p_3^{k_3}p_4^{k_4}$where $p_1, p_2, p_3$and $p_4$are distinct primes. In addition, we provide Python algorithms for computing the Wiener index of the gamma graph associated with the zero-divisor graph of the finite commutative ring $\mathbb{Z}_n$. These results provide new insights into the distance-based properties of gamma graphs arising from finite commutative rings and establish an efficient computational approach for their investigation. wiener index of gamma graph of zero-diviosr graph of the commutative ring $\mathbb{Z}_n$

Theorem 2.1. Let $n = p_1^{k_1}p_2^{k_2}\ldots p_r^{k_r}$ where $p1 < p2 < \cdots < pr$, $p1 \geq 3$be distinct primes.Then the $diam(\gamma.\Gamma(\mathbb{Z}_n)) = r$.

Proof: Let $u = \{a_1, a_2, \ldots, a_r\}, v = \{b_1, b_2, \ldots, br\}$be arbitrary vertices of $\gamma.\Gamma(\mathbb{Z}_n)$ where $a_i, b_i \in A_{\frac{n}{p_i}}$, $1 \leq i \leq r$.

We know that, two vertices are adjacent iff they differ in exactly one co-ordinate. Suppose $u$and $v$differ in exactly t co-ordinates.

Without loss of generality, assume

$a_i \neq b_i$for $i = 1, 2, \ldots, t$and

$a_i = b_i$for $i = t+1, \ldots, r$.

We prove that $d(u,v) = t$.

First, we show that $d(u,v) \leq t$.

Define vertices

$x_0 = u$,

$x_1 = \{b_1, a_2, \ldots, a_r\}$

$x_2 = \{b_1, b_2, a_3, \ldots, a_r\}$,

.

.

.

$x_t = \{b_1, b_2, \ldots, b_t, a_{t+1}, \ldots, a_r\} = v$.

Each consecutive pair x_{i-1}, $x_i$differs in exactly one co-ordinate, hence they are adjacent.

Therefore,
$u = x_0 - x_1 - \cdots - x_t = v$ is a path of length t. Thus $d(u,v) \leq t$.
Now suppose, for contadiction that $d(u,v) < t$. Then there exists a path
$u = y_0 - y_1 - \cdots - y_m = v$ with $m < t$. Since adjacent vertices differ in exactly one co-ordinate, each step in the path can change at most one co-ordinate.

But $u$and $v$differ in exactly$t$co-ordinaes namely co-ordinates $1, 2, \ldots, t$.
Hence, atleast t −steps are required to go from u to v. Therefore any path from$u$to $v$must have length atleast t, contradicting $m < t$. Hence $d(u,v) = t$.

Since two vertices can differ in atmost $r$co-ordinates, $d(u,v) \leq$r for all vertices u, v.
Now choose vertices $u = \{a_1, a_2, a_3, \ldots, a_r\}, v = \{b_1, b_2, \ldots, b_r\}$, such that $a_i \neq b_i$for all $i = 1, 2, \ldots, r$. Then $u$and$v$differ in all $r$coordintaes, so by the above result, $d(u,v) = r$.
Therefore, the maximum distance between the vertices is r. Hence $diam(\gamma.\Gamma(\mathbb{Z}_n)) = r$.

Theorem 2.2: Let $n = 2^{k_1}p_2^{k_2} \ldots p_r^{k_r}$, where $p_2 < p_3 < \cdots < p_r$be distinct primes and $ki \in N, 1 \leq i \leq r$. Then the $diam(\gamma.\Gamma(\mathbb{Z}_n)) = r - 1$.

Proof: Let $u = \{a_1, a_2, \ldots, a_r\}$, $v = \{b_1, b_2, \ldots, b_r\}$be vertices of $(\gamma.\Gamma(\mathbb{Z}_n)$where $a_i, b_i \in A_{\frac{n}{p_i}}$, $1 \leq i \leq r$.
Since$p_1 = 2$, the set $A_{\frac{n}{2}}$contains only one element. Hence every vertex has the same firstco-ordintae. Therefore, $a_1 = b_1$for all vertices u, v. Thus two vertices can differ only in the
remaining co-ordinates $2, 3, \ldots, r$.
Suppose $u$and $v$differe in exactly$t$of these co-ordinates. Then $t \leq r - 1$.
Since adjacent vertices differ in exactly one co-ordinate, one step changes atmost one coordinate. Hence atleast t steps are required to go from$u$to v. On the other hand, we can sucessively change the differing co-ordinates one by one to obtain a path of length t. Therefore $d(u,v) = t$.
Since $t \leq r - 1$, we obtain $d(u,v) \leq r - 1$ for all vertices $u,\ v$.
Now choose vertices u and $v$such that $a_i \neq b_i$for all $i = 2, 3, \ldots, r$. Then u and $v$differ in
exactly $r - 1$ co-ordinates. Hence $d(u,v) = r - 1$. Therefore, $diam(\gamma.\Gamma(\mathbb{Z}_n)) = r - 1$.

Theorem 2.3: Let $n = p_1^{k_1}p_2^{k_2}$, $n \neq 3p, 2p, p1 < p2$be distinct primes, $k_1, k_2 \geq 1$be an integer.Then the wiener index of gamma graph of zero-divisor graph is

$$W(\gamma.\Gamma(\mathbb{Z}_n)) = \left\{\sum_{i=1}^{2}(p_i - 2)\sum_{k=1}^{p_1-2} k + (p_1 - 1)\sum_{k=0}^{p_2-p_1}(p_2 - 2 - k)\right\} + 2\left\{\prod_{i=1}^{2}(p_2 - i)\sum_{k=2}^{p_1-1}(p_1 - k)\right\}$$

Proof: For$n = p_1^{k_1}p_2^{k_2}$, the graph$\gamma.\Gamma(\mathbb{Z}_n)$ is regular of degree $(p_1 - 1)(p_2 - 1) - (p_1 - 2)(p_2 - 2) - 1$.
Let Abe the adjacency matrix of $\gamma.\Gamma(\mathbb{Z}_n)$

$$A = \begin{pmatrix} K_m & \cdots & I_m \\ \vdots & \ddots & \vdots \\ I_m & \cdots & K_m \end{pmatrix}$$

Where $m = p_2 - 1$. From the block structure of A, the entries equal to 1 correspond preciselyto pairs of adjacent vertices. Hence the number of unordered vertex pairs at distance 1 is
$N_1 = \sum_{i=1}^{2}(p_i - 2)\sum_{k=1}^{p_1-2} k + (p_1 - 1)\sum_{k=0}^{p_2-p_1}(p_2 - 2 - k)$(2.1)

Further, every entry of $A^2$is non-zero. Therefore, every pair of non-adjacent vertices is connected by a path of length 2. Since the diameter of $\gamma.\Gamma(\mathbb{Z}_n)$is 2, these pairs are exactly the vertex pairs at distance 2.
Consequently, the number of unordered vertex pairs at distance 2 is

$N_2 = \prod_{i=1}^{2}(p_2 - i)\sum_{k=2}^{p_1-1}(p_1 - k)$(2.2)

Since every pair of distinct vertices is at distance either 1 or 2,
$W(\gamma.\Gamma(\mathbb{Z}_n)) = N_1 + 2N_2$
Substituting 2.1 and 2.2, we obtain

$$W(\gamma.\Gamma(\mathbb{Z}_n)) = \left\{\sum_{i=1}^{2}(p_i-2)\sum_{k=1}^{p_1-2}k + (p_1-1)\sum_{k=0}^{p_2-p_1}(p_2-2-k)\right\} + 2\left\{\prod_{i=1}^{2}(p_2-i)\sum_{k=2}^{p_1-1}(p_1-k)\right\}$$

Remark 2.4. Let $n$be given by $n = 5^2 \times 7 = 175$. Thus, the distinct prime factors of $n$are $p_1 = 5,\ p_2 = 7$. Then

$$N_1 = \sum_{i=1}^{2}(p_i-2)\sum_{k=1}^{p_1-2}k + (p_1-1)\sum_{k=0}^{p_2-p_1}(p_2-2-k)$$
$$= \sum_{i=1}^{2}(p_i-2)\sum_{k=1}^{3}k + (5-1)\sum_{k=0}^{2}(5-k)$$
= 96
And
$$N_2 = \prod_{i=1}^{2}(p_2-i)\sum_{k=2}^{p_1-1}(p_1-k)$$
$$= \prod_{i=1}^{2}(7-i)\sum_{k=2}^{4-1}(5-k)$$
= 180
Hence
$W(\gamma.\Gamma(\mathbb{Z}_n)) = N_1 + 2N_2$
= 96 + 2(180)
= 456

Theorem 2.5: Let $n = 3p, p > 3$be a prime number. Then the wiener index of gamma graph of zero-divisor graph is,

$$W(\gamma.\Gamma(\mathbb{Z}_n)) = \left\{2\binom{p-1}{2} + 3(p-1)\right\} + 2\left\{\prod_{i=1}^{2}(p-i)\right\}$$

Proof: In a graph$\gamma.\Gamma(\mathbb{Z}_n)$, there exists exactly one universal vertex, say u, adjacent to every other vertex of the graph. Hence every vertex pair containing u contributes 1 to the wiener index. Further, any two non-adjacent vertices are connected through u. Therefore the distance between every non-adjacent pair of vertices is 2. Consequently, the graph has diameter 2. Now, from the adjacency structure of$\gamma.\Gamma(\mathbb{Z}_n)$, the number of unordered adjacent vertex pairs is $2\binom{p-1}{2} + 3(p-1)$ and hence their distance is 1. Similarly, the number of unordered non-adjacent vertex pairs is $\prod_{i=1}^{2}(p-i)$and every such pair is at distance 2. Therefore,

$$W(\gamma.\Gamma(\mathbb{Z}_n)) = \left\{2\binom{p-1}{2} + 3(p-1)\right\} + 2\left\{\prod_{i=1}^{2}(p-i)\right\}$$

Remark 2.6 Consider $n = 3 \times 7 = 21$. Here $p = 7$ Then

$$2\binom{p-1}{2} + 3(p-1) = 2\binom{7-1}{2} + 3(7-1)$$

$$= 2\binom{6}{2} + 3(6)$$

= 48

And

$\prod_{i=1}^{2}(p-i) = (7-1)(7-2)$

=30

Hence, $W(\gamma.\Gamma(\mathbb{Z}_n)) = \{2\binom{p-1}{2} + 3(p-1)\} + 2\{\prod_{i=1}^{2}(p-i)\} = 48 + 2(30) = 108.$

Theorem 2.7: Let $n = p_1^{k_1}p_2^{k_2}p_3^{k_3}$, $p_1 < p_2 < p_3$ be distinct primes and $k_1, k_2, k_3 \geq 1$ be an integer then the wiener index of gamma graph of zero-divisor graph is $\sum_{l=1}^{3} l.T_l$where

$T_l = \sum_{m=0}^{p_1-2}\sum_{k_1=0}^{p_2-2}\sum_{r=2}^{p_1} F(l,m,k,r)$ and

$$F(l,m,k,r) = \begin{cases} \left(\sum_{i=1}^{3}(p_i-1) - 2m\right)\left(\sum_{k=1}^{p_2-2} k\right) + (p_2-1)\sum_{k=0}^{p_3-p_2}\left((p_3-2) + (p_1-2) - m - k\right) & if\ l = 1 \\ (p_3-1)\{(p_2-2-k_1)(p_3-2) + (p_1-2-m)(p_2+p_3-4)\} & if\ l = 2 \\ (p_2-1)(p_3-1)(p_2-2)(p_3-2)(p_1-r) & if\ l = 3 \end{cases}$$

Proof: Let $V(\gamma.\Gamma(\mathbb{Z}_n))$be the vertex set of$\gamma.\Gamma(\mathbb{Z}_n)$. Since $diam(\gamma.\Gamma(\mathbb{Z}_n)) = 3$, every pair of distinct vertices is at distance 1,2 or 3. The wiener index is$W(\gamma.\Gamma(\mathbb{Z}_n)) = \sum_{\{u,v\}\subset V} d(u,v)$

Partition the unordered pairs of vertices according to their distances.

Let $T_l$denote the number of unordered vertex pairs at distance l, where $l = 1,2,3$. Then,

$$W(\gamma.\Gamma(\mathbb{Z}_n)) = \sum_{l=1}^{3} l.T_l$$

Distance 1

Two vertices are adjacent if and only if they differ in exactly one co-ordinate. Counting all such pairs yields

$$T_1 = \sum_{m=0}^{p_1-2}\sum_{k_1=0}^{p_2-2}\sum_{r=2}^{p_1} F(1,m,k,r)$$

Where,$F(1,m,k,r) = \left(\sum_{i=1}^{3}(p_i-1) - 2m\right)\left(\sum_{k=1}^{p_2-2} k\right) + (p_2-1)\sum_{k=0}^{p_3-p_2}\left((p_3-2) + (p_1-2) - m - k\right)$

Hence T_1equals the number of vertex pairs at distance 1.

Distance 2

By theorem, two vertices are at distance 2 precisely when they differ in exactly two coordinates.

Counting such pairs gives

$$T_2 = \sum_{m=0}^{p_1-2}\sum_{k_1=0}^{p_2-2}\sum_{r=2}^{p_1} F(2,m,k,r),$$

Where $F(2,m,k,r) = (p_3-1)\{(p_2-2-k_1)(p_3-2) + (p_1-2-m)(p_2+p_3-4)\}$

Thus, $T_2$is the number of unordered vertex pairs at distance 2.

Distance 3

Again, by the distance characterization, two vertices are at distance 3 precisely when they differ in all three co-ordinates. Therefore

$$T_3 = \sum_{m=0}^{p_1-2}\sum_{k_1=0}^{p_2-2}\sum_{r=2}^{p_1} F(3,m,k,r),$$

,

Where $F(3,m,k,r) = (p_2-1)(p_3-1)(p_2-2)(p_3-2)(p_1-r)$which counts all pairs at distance 3. Substituting the values of T_1, T_2, and T_3into the wiener index formula, we obtain

$$W(\gamma.\Gamma(\mathbb{Z}_n)) = \sum_{l=1}^{3} l.T_l$$

Where, $T_l = \sum_{m=0}^{p_1-2}\sum_{k_1=0}^{p_2-2}\sum_{r=2}^{p_1} F(l,m,k,r)$

Remark 2.8. Let $n = 5 \times 7 \times 11$.In this case, $p_1 = 5,\ p_2 = 7,\ p_3 = 11$. Then

$$T_1 = \sum_{m=0}^{p_1-2}\sum_{k_1=0}^{p_2-2}\sum_{r=2}^{p_1}\left\{\left(\sum_{i=1}^{3}(p_i-1)-2m\right)\left(\sum_{k=1}^{p_2-2}k\right)+ (p_2-1)\sum_{k=0}^{p_3-p_2}\left((p_3-2)+(p_1-2)-m-k\right)\right\}$$

$$= \sum_{m=0}^{3}\left\{\left(\sum_{i=1}^{3}(p_i-1)-2m\right)\left(\sum_{k=1}^{5}k\right)+ (6)\sum_{k=0}^{4}(12-m-k)\right\}$$

= 2040

$$T_2 = \sum_{m=0}^{p_1-2}\sum_{k_1=0}^{p_2-2}\sum_{r=2}^{p_1}\{(p_3-1)\{(p_2-2-k_1)(p_3-2)+(p_1-2-m)(p_2+p_3-4)\}\}$$

$$= \sum_{m=0}^{p_1-2}\sum_{k_1}^{5}\{10\{(5-k_1)(9)+(3-m)(14)\}\}$$

$$T_3 = \sum_{m=0}^{p_1-2}\sum_{k_1=0}^{p_2-2}\sum_{r=2}^{p_1}\{(p_2-1)(p_3-1)(p_2-2)(p_3-2)(p_1-r)\}$$

$$= \sum_{r=2}^{5}(6)(10)(5)(9)(p_1-r)$$

= 16200

Hence

$$W(\gamma.\Gamma(\mathbb{Z}_n)) = \sum_{l=1}^{3} l.T_l$$

$= 1.T_1 + 2.T_2 + 3.T_3$
= 1(2040) + 2 (10440) + 3 (16200)
= 71520

Theorem 2.9: Let $n = p_1^{k_1}p_2^{k_2}p_3^{k_3}p_4^{k_4}$where $p1 < p2 < p3 < p4$are distinct primes and $k_i \geq 1$for $i = 1,2,3,4$. Then the wiener index of $\gamma.\Gamma(\mathbb{Z}_n)$is $W(\gamma.\Gamma(\mathbb{Z}_n)) = N_1 + 2N_2 + 3N_3 + 4N_4$, $N_i$denotes the number of unrdered vertex pairs at distance $i, 1 \leq i \leq 4$and is given by

$$N_1 = \sum_{i=0}^{p_1+p_2-4} c_i\left\{\left(\sum_{j=1}^{4}(p_j-1)-2i\right)\left(\sum_{k=1}^{p_3-2}k\right)+(p_3-1)\sum_{k=0}^{p_4-p_3}\left((p_4-2)+(p_2-2)+ (p_1-2)-i-k\right)\right\}$$

Where $c_i = \begin{cases} i+1 & ,0 \le i \le p_1-2 \\ p_1-1 & ,p_1-2 < i \le p_2-2 \\ p_1+p_2-3-i & ,p_2-2 < i \le p_1+p_2-4 \end{cases}$

$$N_2 = (p_4-1)\left\{\sum_{r=2}^{p_1}\sum_{s=2}^{p_2}\sum_{t=2}^{p_3}\{(p_3-t)(p_4-2)+(p_2-s)[(p_4-2)+(p_3-2)]+(p_1-r)[(p_4-2)+(p_3-2)+(p_2-2)]\}\right\}$$

$$N_3 = (p_3-1)(p_4-1)\left\{\sum_{r=2}^{p_1}\sum_{s=2}^{p_2}[(p_2-s)[(p_3-2)(p_4-2)] + (p_1-r)[(p_3-2)(p_4-2)+(p_2-2)\{(p_3-2)+(p_4-2)\}]]\right\}$$

and

$$N_4 = (p_2-1)(p_3-1)(p_4-1)\left\{\sum_{k=2}^{p_1}(p_1-k)(p_2-2)(p_3-2)(p_4-2)\right\}$$

Proof: The proof is analogous to that of Theorem 2.7.

Remark 2.10 For $n = 3 \times 5 \times 7 \times 11$, we have $p_1 = 3,\ p_2 = 5, p_3 = 7, p_4 = 11$. Then

$$N_1 = \sum_{i=0}^{p_1+p_2-4} c_i\left\{\left(\sum_{j=1}^{4}(p_j-1)-2i\right)\left(\sum_{k=1}^{p_3-2}k\right)+(p_3-1)\sum_{k=0}^{p_4-p_3}\left((p_4-2)+(p_2-2)+(p_1-2)-i-k\right)\right\}$$

$$= \sum_{i=0}^{4} c_i\left\{\left(\sum_{j=1}^{4}(p_j-1)-2i\right)\left(\sum_{k=1}^{5}k\right)+(6)\sum_{k=0}^{4}(9+3+1-i-k)\right\}$$

Where $c_i = \begin{cases} i+1 & ,\ 0 \le i \le 1 \\ 2 & ,\ 1 < i \le 3 \\ 5-i & ,\ 3 < i \le 4 \end{cases}$

And hence $N_1 = 4320$

$$N_2 = (p_4-1)\left\{\sum_{r=2}^{p_1}\sum_{s=2}^{p_2}\sum_{t=2}^{p_3}\{(p_3-t)(p_4-2)+(p_2-s)[(p_4-2)+(p_3-2)]+(p_1-r)[(p_4-2)+(p_3-2)+(p_2-2)]\}\right\}$$

$$= 10\left\{\sum_{r=2}^{3}\sum_{s=2}^{5}\sum_{t=2}^{7}\{(7-t)9+(5-s)14+(3-r)17\}\right\}$$

$$= 24960$$

$$N_3 = (p_3-1)(p_4-1)\left\{\sum_{r=2}^{p_1}\sum_{s=2}^{p_2}[(p_2-s)[(p_3-2)(p_4-2)]+(p_1-r)[(p_3-2)(p_4-2)+(p_2-2)\{(p_3-2)+(p_4-2)\}]]\right\}$$

$$= (6)(10)\left\{\sum_{r=2}^{3}\sum_{s=2}^{5}[(5-s)[45]+(3-r)[87]]\right\}$$

= 53280

$$N_4 = (p_2-1)(p_3-1)(p_4-1)\left\{\sum_{k=2}^{p_1}(p_1-k)(p_2-2)(p_3-2)(p_4-2)\right\}$$

$$= 32400\left\{\sum_{k=2}^{3}(3-k)\right\}$$

=32400

Hence $W(\gamma.\Gamma(\mathbb{Z}_n)) = N_1 + 2N_2 + 3N_3 + 4N4 = 4320 + 2(24960) + 3(53280) + 4(32400) = 343680.$

Python code for finding Wiener index of gamma graph of zero-divisor graph of the finite commutative ring $\mathbb{Z}_n$

The principal libraries used in the following code are NetworkX [5], itertools [12], Matplotlib [7], and math [8].

```
import networkx as nx
import itertools

Algorithm: Construction of the Gamma Graph and Computation of the Wiener Index

Input: A positive integer n.
Output: The Gamma graph of the zero-divisor graph of$\mathbb{Z}_n$, its Wiener index, distinct distances, and distance frequencies.
1. Determine the set of distinct prime divisors $P = \{p_1, p_2, \ldots, p_k\}$of n.
2. Construct the zero-divisor graph $\Gamma(\mathbb{Z}_n)$:
(a) The vertices are all nonzero zero-divisors of$\mathbb{Z}_n$.
(b) Two distinct vertices $x$and $y$are adjacent if
$xy \equiv 0 \ (mod\ n)$.
3. For each prime divisor $p_i \in P$, compute

$$d_i = \frac{n}{p_i}$$

4. Form the associate classes

$$A_i = \{x \in \mathbb{Z}_n : \gcd(x, n) = d_i\},$$

for $i = 1, 2, \ldots, k$.
5. Generate all minimal dominating sets by choosing exactly one element from each associate class A_i.
6. Let $\mathfrak{D} = \{D_1, D_2, \ldots, D_m\}$denote the collection of all such minimal dominating sets.
7. Construct the Gamma graph $\gamma.(G)$:
(a) Each dominating set $D_i \in \mathfrak{D}$ corresponds to a vertex.
(b) Join two vertices $D_i$and D_j whenever

$$|D_i \cap D_j| = k - 1.$$

8. Compute the shortest-path distance $d(u, v)$ between every pair of vertices $u$and $v$in $\gamma.(G)$.
9. Compute the Wiener index

$$W(\gamma.(G)) = \sum_{\{u,v\} \subset V(\gamma.(G))} d(u, v)$$

10. Determine the distinct distance values occurring in $\gamma.(G)$ and calculate their frequencies.
11. Output the Gamma graph, Wiener index, distinct distances, and distance frequencies.

ABSTRACT

Student placement is widely recognized as an important indicator of the quality and effectiveness of higher educational institutions. Consequently, predicting student placement outcomes has become a significant area of research. This survey paper provides a comprehensive review of student placement prediction techniques based on Machine Learning (ML), Deep Learning (DL), Ensemble Learning, and Explainable Artificial Intelligence (XAI).The survey classifies existing studies into different categories, including Classical Machine Learning models, Ensemble and Boosting models, Deep Learning models, Explainable AI models, and pre-processing-based approaches. It presents a comparative analysis of the prediction models by examining their performance, datasets, evaluation metrics, and pre processing techniques. In addition, the survey highlights the strengths, limitations, research gaps, and key challenges of current approaches. Finally, it discusses emerging research trends and future directions for developing more accurate, reliable, and interpretable student placement prediction systems.

Keywords: Student Placement Prediction, Machine Learning, Deep Learning, Ensemble Learning, Explainable AI, Random Forest, Educational Data Mining

INTRODUCTION

Student placement is one of the most important indicators of the quality and reputation of higher educational institutions. Students, parents, and recruiters often consider placement records when evaluating an institution, as they reflect the institution's ability to prepare students for successful careers. Strong placement performance not only

enhances an institution's reputation but also influences future student admissions and industry collaborations. Traditionally, educational institutions have relied on manual counselling and basic statistical methods to assess students' placement readiness. However, placement outcomes are influenced by multiple factors, including academic performance, technical skills, communication abilities, internships, aptitude, and extracurricular activities. The complex relationship among these factors makes accurate prediction challenging using conventional approaches. Machine Learning (ML) provides an effective solution by identifying hidden patterns from historical student data. Algorithms such as Logistic Regression, Decision Tree, Random Forest, Support Vector Machine (SVM), and K-Nearest Neighbours (KNN) have been widely used to predict placement outcomes and identify students who may require additional training and guidance. More recently, Deep Learning (DL) models, including Artificial Neural Networks (ANNs), Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and Long Short-Term Memory (LSTM) networks, have demonstrated their ability to capture complex, non-linear relationships within educational data. In addition, Explainable Artificial Intelligence (XAI) techniques, such as SHAP and LIME, improve the transparency of prediction models by explaining the factors that influence placement decisions, thereby supporting career counsellors and institutional decision-making.

Related Works

The research done by Priyadarsini et al. (2025) [1] analyzed the development of Artificial Neural Network (ANN) model for student placement predictions with the help of the information about their academic performance and experience of the students of Presidency College. The results of the research imply that the artificial neural network is capable of identifying the complex patterns in the educational database with 96% accuracy. The AI-NLP system for career guidance and placement prediction was developed by Kumar and Karunasri [2] in 2025. This system uses logistic regression and K-Nearest Neighbors (KNN) to screen the resume, BERT to match resume with the job description, Random Forest for placement prediction and advice on interview preparations and online courses. This study shows how predictive analytics and natural language processing are being combined to support student career. Trans-CLSTM [3] is the name of a newly developed model, which used both Transformer and ConvLSTM in order to predict and recommend placement. Special attention was paid to the fact that proper attention should be paid to the need for pre-processing and feature extraction before training models. The model proved to be superior to traditional CNN and LSTM models having an accuracy rate of 98.22%.

Krishna(2024), developed a Career Placement Predictor [4] using information related to academic history, technical skills, certification, and experience in order to predict the chance of placement and recommend how to improve skills set. The model proved to have an accuracy rate of up to 97%. Manike et al. (2021) [5] examined the application of XGBoost model in predicted placement of students according to their grades, technical skills, and experience. The presented algorithm has proved to be very accurate (99.02%) and superior to conventional prediction algorithms such as Naïve Bayes. The study conducted by Maragatham et al. (2024) [6] required the implementation of deep learning algorithm composed of FNN, RNN, and LSTM techniques for determination of future career choice of the student. Consequently, the accuracy of predictions has ranged from 80% to 88%. Spandana and Pallavi (2023) [7] done a analysis of Random Forest,Logistic Regression, Support Vector Machine (SVM) and KNN algorithms. LR was identified as one of the best algorithm with an accuracy of 75.90%. Prediction performance depends on the importance of the features and characteristics of the data set. The work done by Dhumane et al. (2023) [8] done analysis on multiple ML models such as KNN, SVM, Decision Tree, Random Forest and Logistic Regression algorithms with the performance parameters such as recall, precision, accuracy, and confusion matrix. RF was found to be the best classifier among all with accuracy of 94.90%. Khandelwal et al. (2023) [9] analysed the performances of Random Forest, Decision Tree, Gaussian Naïve Bayes,Logistic Regression and KNN models using past placement data. other than studying the performance of the model, the researchers also implemented the best model in the form of web application and gave the opportunity to the students to predict their placements using the web application.

Kumar A. S. et al. (2025) [10] created the placement analytics model with the help of Random Forest and Decision Trees algorithms to predict the placement. Feature selection technique was adopted to find the significant factors affecting the student placements and discover accuracies ranging between 85% and 86%. This model also provides

the placement officers with the dashboard to analyse recruiting trends and skills of the students. Aruna et al. (2023) [11] analyse the execution of various ml models for predicting placements for students founded on internship, academic and extracurricular activities. From the study, it was disover that the accuracies for prediction are in the range of 80% to 82%, making the study one of the examples of utility of both non - academic and academic aspects of placements. Kamath et al. (2025) [12] worked ML algorithms in combination with LLM and XAI for predicting the academic performance of students. Decision Tree, Logistic Regression,Support Vector Machine, Random Forest classifiers with the application of approach of explainability were used for identifying the factors that influence the prediction result. The proposed model managed to achieve around 83% accuracy, which proves increasing importance of explainable predictive models in education. Gaurkhede et al. (2024) [13] recommended an approach to create the placement prediction system founded on the combination of academic data provided by educational institutions and the data from the placement management system. In this research, factors such as the student's CGPA, project experience, internships, and their scores in secondary education were considered while training the model. The correctness achieved within the research reaches up to 98.46%, and it is ensured by SVM.

Kunwar et al. (2025) [14] proposed the improved architecture of CNN-BiLSTM with the attention mechanism for predicting placement and skills recommendation. Considering the sequential and contextual relations in the student data, the proposed framework achieves up to 95.4% of accuracy and F1-score. Sathyendra Kumar et al. (2025) [15] worked the DT model to make a prediction of placement outcomes through demographics, academic performance and extra-curricular activities. The authors implemented preprocessing methods in order to improve the quality of their algorithm, such as missing value imputation and categorical variable encoding. The model accuracy reached approximately 96%, proving the significance of data preprocessing for the application of educational data mining. Basha et al. (2023) [16] in their work discovered exploratory data analysis and predictive modeling with the use of dataset of demographics and academic performance . According to their findings, academic performance, gender and degree specialty are important predictors that affect placement process results. The prediction accuracies reached 87-89%. Rakitina-Qureshi et al. (2025) [17] analyzed the application of RF and LR models in guessing placements derived from attributes such as age, attendance, failed courses and GPA. The exploratory review validated the advantage of RF over the LR in terms of both accuracy and AUC-ROC measures. moreover, the study revealed that attendance and GPA were the main factors affecting students' placements.

Ragu G. (2025) [18] considered the framework of Explainable Artificial Intelligence methods for predicting placements. For this goal, the SHAP and LIME methodologies were used for explanation of predictions made by the method and identification of the important features affecting the placement choice. Although the proposed model provided excellent prediction accuracy, its reduced performance on the new data showed the need to generalize the model. Rakitin et al. (2025) [19] conducted a comparative analysis of Random Forest and Gradient Boosting algorithms using a dataset comprising academic performance, attendance, and demographic factors. While both models demonstrated strong predictive capabilities, Gradient Boosting showed improved classification of non-placed students, whereas Random Forest provided a better balance between precision and recall. The study reinforced the importance of attendance and GPA as key placement indicators. Venkatachalam (2021) [20] applied data mining and fuzzy logic techniques using the WEKA platform to analyze placement-related factors. Beyond prediction, the study investigated the underlying reasons behind placement failures and identified deficiencies in communication and analytical skills among graduates. The findings provide valuable insights for institutions aiming to improve student employability through targeted interventions. Chavhan et al. (2023) [21] presented a comparative review of Decision Tree and Naïve Bayes classifiers for placement prediction. The study discussed the strengths and limitations of both algorithms in terms of interpretability, scalability, and prediction performance. Additionally, the authors outlined potential research directions for enhancing predictive models in educational settings.

Rattan et al. (2021) [22] addressed the issue of class imbalance in placement datasets by incorporating the Synthetic Minority Oversampling Technique (SMOTE) with Decision Tree classification. Using features such as CGPA, aptitude scores, and gender, the study reported improved prediction performance after balancing the dataset. The findings demonstrate the importance of handling class imbalance to improve model fairness and reliability. Hegde et

al. (2023) [23] proposed a placement prediction framework that integrates Principal Component Analysis (PCA) with Random Forest classification. PCA was employed to reduce dimensionality and identify the most relevant features, including attendance, communication skills, programming proficiency, and aptitude scores. The resulting model achieved an accuracy of approximately 97%, highlighting the benefits of feature reduction techniques in predictive modeling. Alghamdi (2023) [24] conducted a comparative evaluation of multiple machine learning algorithms using institutional and historical educational datasets. The study focused on supporting educational decision-making through predictive analytics and reported accuracies exceeding 97% for certain configurations. The findings emphasize the growing role of machine learning in educational management and planning.

Kadu et al. (2024) [25] developed a combined placement prediction and skill recommendation system utilizing Random Forest and Naïve Bayes algorithms. The framework analyzed academic achievements, internships, certifications, aptitude scores, and soft skills to generate personalized recommendations. Although the model demonstrated promising results, the lower accuracy achieved on real-world datasets highlighted challenges related to model generalization and deployment. Sekhar K. and Santhosh Kumar (2022) [26] focused on data preprocessing, exploratory analysis, and visualization techniques to understand the relationship between academic performance and placement outcomes. Rather than proposing a new predictive model, the study emphasized the importance of data preparation and feature analysis as essential steps in educational data mining. Shahane (2022) [27] compared Logistic Regression, Decision Tree, K-Nearest Neighbors, and Random Forest algorithms using historical placement records. The results indicated that ensemble-based approaches generally achieved higher prediction accuracy, while simpler classifiers offered greater interpretability. The study underscores the trade-off between model complexity and explainability. Udatha et al. (2025) [28] proposed an ensemble learning framework that evaluated seven classification algorithms for placement prediction. Following comprehensive preprocessing and feature engineering, Gradient Boosting emerged as the best-performing model. Feature importance analysis identified CGPA and prior work experience as the most influential predictors, demonstrating the effectiveness of ensemble learning techniques for educational datasets.

Rivera et al. (2023) [29] investigated multiple supervised machine learning algorithms for predicting student employability. The study compared seven classification models and reported prediction accuracies exceeding 90% for the best-performing approaches. The findings highlight the practical benefits of predictive analytics for students, recruiters, and higher education institutions. Sharma et al. (2021) [30] introduced "College Kart," a student-centric platform that combines placement prediction with skill portfolio management and peer networking features. The system utilized a K-Nearest Neighbors classifier to estimate placement probability while simultaneously supporting career development activities. This work demonstrates how predictive models can be integrated into broader educational support systems to enhance student employability.

METHODOLOGY DISCUSSION

Data Sources and Feature Sets

- Academic indicators: CGPA, semester/internal exam marks (ISE/ESE), backlogs/failed courses, HSC/SSC scores [1, 6, 13, 17, 19, 23]
- Behavioral/engagement indicators: attendance [17, 19, 23], extracurricular participation [10, 15]
- Skills and experience: technical/programming skill, communication and aptitude scores, internships, projects, certifications [5, 23, 25]
- Demographics: gender, specialization/degree stream [9, 16]

Dataset sizes are generally modest (hundreds to a few thousand records drawn from a single institution), which is a recurring limitation across the corpus and a natural motivation for your planned deep-learning work on larger or multi-institutional data.

Preprocessing Approaches

Common preprocessing steps include missing-value imputation, categorical encoding (label/one-hot), and normalization/scaling of numeric features [10, 15, 28]. A smaller subset of papers explicitly tackles class imbalance (placed vs. not-placed skew) using SMOTE [22], and dimensionality reduction using PCA to isolate the most influential predictors before classification [23]. Train/test splits are typically 70/30 or 80/20, with a few studies using stratified splits to preserve class ratios [17, 19].

Algorithmic Families

- Classical/single classifiers: Logistic Regression, Decision Tree, KNN, SVM, and Naive Bayes appear as baselines in nearly every comparative study [7, 8, 9, 11, 21, 27, 29].
- Ensemble/tree-based methods: Random Forest and Gradient Boosting consistently outperform single classifiers in head-to-head comparisons, particularly on non-linear relationships between attendance/GPA and placement outcome [17, 19, 23, 28]. XGBoost also appears as a strong tabular-data performer [5].
- Deep learning architectures: A growing subset (concentrated in 2024–2025 papers) applies ANN [1], FNN/RNN/LSTM combinations [6], CNN-BiLSTM with attention [14], and transformer-augmented CLSTM [3] — generally reporting the highest accuracies in the survey (95–99%), though often on smaller, single-institution datasets, raising questions about generalizability.

Explainability and Interpretability

A small but growing group of papers moves beyond raw accuracy to interpretability: SHAP and LIME are used to compare which features drive predictions [12, 18], directly relevant to the "lack of explainability" gap you identified for your own research. This remains underrepresented relative to the volume of pure prediction studies — reinforcing XAI as a meaningful gap to target.

Evaluation Metrics

Accuracy is the near-universal headline metric, but the more rigorous studies supplement it with precision, recall, F1-score, ROC-AUC, and confusion matrices [17, 19, 28], which better expose class-imbalance effects that accuracy alone can mask. Studies that report only accuracy (particularly ones nearing 100%) should be read cautiously for potential over fitting, a pattern flagged explicitly in at least one paper's own limitations discussion [24].

Beyond Prediction: Recommendation and Deployment

A notable minority of papers extend past binary/probability prediction into applied systems: skill-gap recommendation via cosine similarity [2, 25], NLP/LLM-driven interview preparation and course recommendation [2, 12], and deployed web portals for student-facing use [9, 30]. This reflects a broader trend in the 2024–2025 literature toward integrated career-guidance platforms rather than isolated classifiers — a trend your future transformer-based, tabular-data-focused work could position itself against by emphasizing rigor (explainability, imbalance handling) over feature breadth.

Summary of Trends Over Time (2021–2025)

- 2021–2022: Primarily classical ML comparative studies (LR, DT, KNN, SVM, NB) with basic accuracy reporting [5, 20, 22, 26, 27, 30].
- 2023: Growth in ensemble methods, PCA-based feature reduction, and early explainability interest [7, 8, 9, 11, 16, 21, 23, 24, 29].
- 2024–2025: Emergence of deep learning (ANN, LSTM, CNN-BiLSTM, transformers), integrated AI-NLP/LLM platforms, and explicit XAI comparison studies [1, 2, 3, 6, 10, 12, 13, 14, 15, 17, 18, 19, 25, 28] — directly supporting your identified gaps around explainability, class imbalance, and transformer-based tabular modeling as underexplored relative to this recent surge.

RESULTS AND DISCUSSION

The reviewed studies demonstrate that machine learning has become an effective approach for student placement prediction by utilizing academic, technical, and behavioral attributes. Among the various techniques, ensemble learning methods such as Random Forest, Gradient Boosting, and XGBoost consistently provide robust and reliable prediction performance, making them widely adopted in recent research.Recent studies have also explored deep learning models, including Artificial Neural Networks, CNNs, RNNs, LSTMs, and hybrid architectures, to capture complex relationships within educational data. In addition, Explainable Artificial Intelligence (XAI) techniques such as SHAP and LIME have gained attention for improving the transparency and interpretability of placement prediction models. The survey highlights that effective data preprocessing, including feature selection, missing value handling, dimensionality reduction, and class imbalance handling, plays a crucial role in improving model performance.Despite these advancements, several challenges remain. Many studies rely on datasets collected from a single institution, limiting the generalizability of their models. Furthermore, explainability, cross-institutional validation, and real-world deployment remain underexplored. Future research should focus on developing scalable, interpretable, and robust placement prediction systems using diverse datasets and advanced AI techniques.

CONCLUSION

This survey reviews student placement prediction using classical machine learning, ensemble learning, deep learning, explainable AI, and preprocessing techniques. Among these, ensemble methods, particularly Random Forest, are the most widely adopted due to their reliable performance. Recent studies also highlight the growing use of deep learning and Explainable AI to improve prediction accuracy and model interpretability. Future research should focus on larger and more diverse datasets, improved model generalization, and the integration of explainable AI for practical deployment in educational institutions.

ABSTRACT

In this work we devise the novel approach on Complex antipodal Ƒuriyam graph and elucidate its characterisations involves various operations such as Cartesian and Lexicographic product of complex antipodalƑuriyam graph. Finally this paper presents an application of Complex antipodalƑuriyam graph in the optimal placement of WiFi routers. The proposed model incorporates truth, indeterminacy, falsity, and liberal state along with phase terms to handle uncertainty and time-dependent variations in user demand. This approach enables efficient decision-making for maximizing network coverage and performance under real-world conditions.

Keywords: Complex antipodalƑuriyam set, Complex antipodalƑuriyam graph, Cartesian product, Lexicographic product.

AMS Subject Classification: 05C72

INTRODUCTION

In 1965, Zadeh [8] originated the notion of Fuzzy set. Then in 1975,Azriel Rosenfiled[2] pioneered the concept of fuzzy graph from Zadeh's Fuzzy set theory. Later Krassimir Atanassov [1] addressed Intuitionistic Fuzzy sets by membership and non – membership values and then extended into Neutrosophic set by Florentin Smarendache [5] in 1999 consists of degree of membership, non – membership and indeterminacy. Complex fuzzy set was defined by Ramot et al as a development in the field of fuzzy systems. In 2001, Sunitha [4] introduced the concept of complex fuzzy sets and its properties.Juriyam Graph was introduced by G.A.Ganati, V.N.S.R Repalle & M.A. Ashebo [3] in 2023 as an extension of single – valued Neutrosophic graph consists of degree of membership, non – membership, indeterminacy and Juriyam state (liberal value).

Preliminaries

Definition 2.1[6]: Let Ψ be a non – *e*mpty fixed set. An AntipodalJuriyam Set$\mathcal{A}$ is of the form,

$$\mathcal{A} = \{< \varkappa, t_{\mathcal{A}}(\varkappa), i_{\mathcal{A}}(\varkappa), f_{\mathcal{A}}(\varkappa), \ell_{\mathcal{A}}(\varkappa) > / \varkappa \in \Psi \}$$

where $t_{\mathcal{A}}(\varkappa), i_{\mathcal{A}}(\varkappa), f_{\mathcal{A}}(\varkappa), \ell_{\mathcal{A}}(\varkappa)$: $\Psi \to [0,1]$ denotes the $t$ruth, $i$ndeterminacy, $f$alsity value and Juriyam state (ℓiberal state) for each $\varkappa \in \Psi$ corresponds by $t_{\mathcal{A}}(\varkappa), i_{\mathcal{A}}(\varkappa), f_{\mathcal{A}}(\varkappa), \ell_{\mathcal{A}}(\varkappa)$ satisfies the condition $0 \leq t_{\mathcal{A}}(\varkappa) + i_{\mathcal{A}}(\varkappa) + f_{\mathcal{A}}(\varkappa) + \ell_{\mathcal{A}}(\varkappa) \leq 1, \forall x \in \Psi$.

Definition 2.2[6]: An AntipodalJuriyam Graph$\mathcal{AT} = (\Upsilon, \zeta, \eta)$ where Υ be vertex set with $v$ertex membership $f$unction $\zeta = (t_\alpha, i_\alpha, f_\alpha, \ell_\alpha)$ with $t_\alpha, i_\alpha, f_\alpha, \ell_\alpha : \Upsilon \to [0,1]$ on $\mathcal{V}$ and$e$dge membership $f$unction $\eta = (t_e, i_e, f_e, \ell_e)$ with $t_e, i_e, f_e, \ell_e :\ \eta \subseteq \Upsilon \times \Upsilon \to [0,1]$on $\mathcal{E}$ satisfies the condition

$t_e(\varkappa, \gamma) \leq t_\alpha(\varkappa) \wedge t_\alpha(\gamma)$, $i_e(\varkappa, \gamma) \leq i_\alpha(\varkappa) \wedge i_\alpha(\gamma)$

$f_e(\varkappa, \gamma) \leq f_\alpha(\varkappa) \vee f_\alpha(\gamma)$, $\ell_e(\varkappa, \gamma) \leq \ell_\alpha(\varkappa) \wedge \ell_\alpha(\gamma)$

where $\varkappa, \gamma \in \Upsilon$, $(\varkappa, \gamma)$ is an edge of $\mathfrak{C}$. Here $\wedge$ and $\vee$ represents minimum and maximum respectively.

Defintion 2.3[7]: As$G_1 = (V_1, E_1)$ and $G_2 = (V_2, E_2)$ be two simple connected graphs. The Cartesian product $G_1 \times G_2$ of G_1 and G_2, is a graph with vertex set $V = V_1 \times V_2$ and two vertices (u, v) and (u', v') in V are adjacent in $G_1 \times G_2$ if the following conditions are satisfied:

(i) $uu' \in E_1$ and $v = v'$ in G_2

(ii) $u = u'$ in G_1 and $vv' \in E_2$

Defintion 2.4[8]: As$G_1 = (V_1, E_1)$ and $G_2 = (V_2, E_2)$ be two simple connected graphs. The Lexicographic product $G_1\,[G_2]$ of G_1 and G_2, is a graph with vertex set $V = V_1\,[V_2]$ and two vertices (u, v) and (u', v') in V are adjacent in $G_1\,[G_2]$ if one of the following conditions are satisfied:

(i) $u = u'$ in G_1 and $vv' \in E_2$

(ii) $uu' \in E_1$

Complex Antipodal Juriyam Graphs

Definition 3.1: A Complex antipodalJuriyam set $(\mathfrak{E}_A)$ is defined on X is of the form$\mathfrak{E}_A = \{(t_A(u)e^{i\alpha_A(u)},\ i_A(u)\,e^{i\beta_A(u)},\ f_A(u)e^{i\gamma_A(u)},\ \ell_A(u)e^{i\delta_A(u)})/u \in X\}$ where $i = \sqrt{-1}$and $t_A(u),\ i_A(u),\ f_A(u),\ \ell_A(u) \in [0,1]$ and $\alpha_A(u), \beta_A(u), \gamma_A(u), \delta_A(u) \in [0,2\pi]$ and $0 \leq t_A(u) + i_A(u) + f_A(u) + \ell_A(u) \leq 1$.

Definition 3.2: A Complex antipodalJuriyam graph $(\mathfrak{E}_{AT})$ is defined to be pair $\mathfrak{E}_{AT} = (\Upsilon, \zeta, \eta)$ where Υ be vertex set with $v$ertex membership $f$unction $\zeta = (t_A(u)e^{i\alpha_A(u)},\ i_A(u)e^{i\beta_A(u)},\ f_A(u)e^{i\gamma_A(u)},\ \ell_A(u)e^{i\delta_A(u)})$ is a $\mathfrak{E}_A$ on $\mathcal{V}$ and edge set with edge membership function $\eta = (t_B(uv)\,e^{i\alpha_B(uv)}, i_B(uv)e^{i\beta_B(uv)}, f_B(uv)e^{i\gamma_B(uv)},\ \ell_B(uv)e^{i\delta_B(uv)})$ is $\mathfrak{E}_{AT}$Set on $\mathcal{E} \subseteq \Upsilon \times \Upsilon$ satisfies the condition

(i) $t_B(uv)e^{i\alpha_B(uv)} \leq t_A(u) \wedge t_A(v))e^{i(\alpha_A(u) \wedge \alpha_A(v))}$

(ii) $i_B(uv)e^{i\beta_B(uv)} \leq i_A(u) \wedge i_A(v))e^{i(\beta_A(u) \wedge \beta_A(v))}$

(iii) $\mathbb{f}_B(uv)e^{i\gamma_B(uv)} \leq \mathbb{f}_A(u) \vee \mathbb{f}_A(v))e^{i(\gamma_A(u)\vee\gamma_A(v))}$
(iv) $\ell_B(uv)e^{i\delta_B(uv)} \leq \ell_A(u) \wedge \ell_A(v))e^{i(\delta_A(u)\wedge\delta_A(v))}$
where $u, v \in \zeta$ and uv is an edge of $\mathfrak{E}_{AT}$. Here $\wedge$ and $\vee$ represents minimum and maximum respectively.

Definition 3.3: The degree of any vertex in $\mathfrak{E}_{AT}$ is defined as

$$\deg(u) = \left(\sum_{uv \in B} t_B(uv)e^{i\alpha(\sum_{uv\in B} t_B(uv))}, \sum_{uv \in B} i_B(uv)e^{i\beta(\sum_{uv\in B} i_B(uv))}, \quad \sum_{uv \in B} \mathbb{f}_B(uv)e^{i\gamma(\sum_{uv\in B} \mathbb{f}_B(uv))}, \right.$$
$$\left. \sum_{uv \in B} \ell_B(uv)e^{i\delta(\sum_{uv\in B} \ell_B(uv))} \right)$$

Example 3.4: Consider a Complex antipodalJuriyam graph $\mathfrak{E}_{AT} = (\Upsilon, \zeta, \eta)$ as shown in the figure 1, with $v$ertex set $\mathcal{V} = \{v_1, v_2, v_3\}$ such that
$(t_A(v_1)e^{i\alpha_A(v_1)}, i_A(v_1)e^{i\beta_A(v_1)}, \mathbb{f}_A(v_1)e^{i\gamma_A(v_1)}, \ell_A(v_1)e^{i\delta_A(v_1)})$=$(0.3e^{i0.4\pi}, 0.6e^{i0.5\pi}, 0.1e^{i0.3\pi}, 0.1e^{i0.8\pi})$,
$(t_A(v_2)e^{i\alpha_A(v_2)}, i_A(v_2)e^{i\beta_A(v_2)}, \mathbb{f}_A(v_2)e^{i\gamma_A(v_2)}, \ell_A(v_2)e^{i\delta_A(v_2)})$= $(0.7e^{i0.5\pi}, 0.1e^{i0.6\pi}, 0.1e^{i0.7\pi}, 0.1e^{i0.8\pi})$,
$(t_A(v_3)e^{i\alpha_A(v_3)}, i_A(v_3)e^{i\beta_A(v_3)}, \mathbb{f}_A(v_3)e^{i\gamma_A(v_3)}, \ell_A(v_3)e^{i\delta_A(v_3)})$= $(0.6e^{i0.1\pi}, 0.1e^{i0.2\pi}, 0.2e^{i0.3\pi}, 0.1e^{i0.4\pi})$ and
$(t_B(v_1v_2)e^{i\alpha_B(v_1,v_2)}, i_B(v_1v_2)e^{i\beta_B(v_1v_2)}, \mathbb{f}_B(v_1v_2)e^{i\gamma_B(v_1v_2)}, \ell_B(v_1v_2)e^{i\delta_B(v_1v_2)})$= $(0.3e^{i0.1\pi}, 0.1e^{i0.2\pi}, 0.1e^{i0.7\pi}, 0.1e^{i0.4\pi})$, $(t_B(v_1v_3)e^{i\alpha_B(v_1v_3)}, i_B(v_1v_3)e^{i\beta_B(v_1v_3)}, \mathbb{f}_B(v_1v_3)e^{i\gamma_B(v_1v_3)}, \ell_B(v_1v_3)e^{i\delta_B(v_1v_3)})$= $(0.2e^{i0.1\pi}, 0.1e^{i0.2\pi}, 0.2e^{i0.3\pi}, 0.1e^{i0.4\pi})$.

Definition 3.5: The complement of a Complex antipodalJuriyam graph $\overline{\mathfrak{E}_{AT}}$ is defined by

i) $\mathcal{V} = \overline{\mathcal{V}}$

ii) $t_{\overline{A}}(u)e^{i\alpha_{\overline{A}}(u)} = t_A(u)e^{i\alpha_A(u)}$
$$i_{\overline{A}}(u)e^{i\beta_{\overline{A}}(u)} = i_A(u)e^{i\beta_A(u)}$$
$$\mathbb{f}_{\overline{A}}(u)e^{i\gamma_{\overline{A}}(u)} = \mathbb{f}_A(u)e^{i\gamma_A(u)}$$
$$\ell_{\overline{A}}(u)e^{i\delta_{\overline{A}}(u)} = \ell_A(u)e^{i\delta_A(u)}$$

iii) $$t_{\overline{B}}(uv)e^{i\alpha_{\overline{A}}(uv)} = \begin{cases} 0 & if\, t_B(uv)e^{i\alpha_B(uv)} \neq 0 \\ \{t_A(u) \wedge t_A(v)\}e^{i\{\alpha_A(u)\wedge\alpha_A(v)\}} & if\, t_B(uv)e^{i\alpha_B(uv)} = 0 \end{cases}$$
$$i_{\overline{B}}(uv)e^{i\beta_{\overline{A}}(uv)} = \begin{cases} 0 & if\, i_B(uv)e^{i\beta_B(uv)} \neq 0 \\ \{i_A(u) \wedge i_A(v)\}e^{i\{\beta_A(u)\wedge\beta_A(v)\}} & if\, i_B(uv)e^{i\beta_B(uv)} = 0 \end{cases}$$
$$\mathbb{f}_{\overline{B}}(uv)e^{i\gamma_{\overline{A}}(uv)} = \begin{cases} 0 & if\, \mathbb{f}_B(uv)e^{i\gamma_B(uv)} \neq 0 \\ \{\mathbb{f}_A(u) \vee \mathbb{f}_A(v)\}e^{i\{\gamma_A(u)\vee\gamma_A(v)\}} & if\, \mathbb{f}_B(uv)e^{i\gamma_B(uv)} = 0 \end{cases}$$
$$\ell_{\overline{B}}(uv)e^{i\delta_{\overline{A}}(uv)} = \begin{cases} 0 & if\, \ell_B(uv)e^{i\delta_B(uv)} \neq 0 \\ \{\ell_A(u) \wedge \ell_A(v)\}e^{i\{\delta_A(u)\wedge\delta_A(v)\}} & if\, \ell_B(uv)e^{i\delta_B(uv)} = 0 \end{cases}$$

Definition 3.6: A $\overline{\mathfrak{E}_{AT}}$ graph is called self-complementary if $\overline{\mathfrak{E}_{AT}} \cong \mathfrak{E}_{AT}$

Characteristic Operations of Complex AntipodalJuriyam Graphs

Theorem 4.1: The Cartesian product of two Complex antipodal Juriyam graph is again Complex antipodalJuriyam graph.

Proof: $\mathfrak{E}_{AT_1} \times \mathfrak{E}_{AT_2}$ is the Cartesian Product of $\mathfrak{E}_{AT_1}$ and $\mathfrak{E}_{AT_2}$ where $\mathfrak{E}_{AT_1}$ contains n_1 $v$ertices $(u_1, u_2, \ldots u_{n_1})m_1$edges and $\mathfrak{E}_{AT_2}$ contains n_2 $v$ertices $(v_1, v_2, \ldots v_{n_2})$, $m_2$edges with

$$(t_A(u_i, v_i)e^{i\alpha_A(u_i,v_i)}, i_A(u_i, v_i)e^{i\beta_A(u_i,v_i)}, \mathbb{f}_A(u_i, v_i)e^{i\gamma_A(u_i,v_i)}, \ell_A(u_i, v_i)e^{i\delta_A(u_i,v_i)})$$
$$= (t_{A_1}(u_i)e^{i\alpha_{A_1}(u_i)} \wedge t_{A_2}(v_i)e^{i\alpha_{A_2}(v_i)}, i_{A_1}(u_i)e^{i\beta_{A_1}(u_i)} \wedge i_{A_2}(v_i)e^{i\beta_{A_2}(v_i)}, \quad \mathbb{f}_{A_1}(u_i)e^{i\gamma_{A_1}(u_i)} \vee \mathbb{f}_{A_2}(v_i)e^{i\gamma_{A_2}(v_i)},$$
$$\ell_{A_1}(u_i)e^{i\delta_{A_1}(u_i)} \wedge \ell_{A_2}(v_i)e^{i\delta_{A_2}(v_i)})$$
$$\left(t_B((u_i, v_i), (u_j, v_j))e^{i\alpha_B((u_i,v_i),(u_j,v_j))}, i_B((u_i, v_i), (u_j, v_j))e^{i\beta_B((u_i,v_i),(u_j,v_j))}, \right.$$
$$\left. \mathbb{f}_B((u_i, v_i), (u_j, v_j))e^{i\gamma_B((u_i,v_i),(u_j,v_j))}, \ell_B((u_i, v_i), (u_j, v_j))e^{i\delta_B((u_i,v_i),(u_j,v_j))} \right)$$

$$= \begin{cases} (t_A(u_i)e^{i\alpha_A(u_i)} \wedge t_B(v_i,v_j)e^{i\alpha_B(v_i,v_j)},\ i_A(u_i)e^{i\beta_A(u_i)} \wedge i_B(v_i,v_j)e^{i\beta_B(v_i,v_j)}, \\ f_A(u_i)e^{i\gamma_A(u_i)} \vee f_B(v_i,v_j)e^{i\gamma_B(v_i,v_j)}, \ell_A(u_i)e^{i\delta_A(u_i)} \wedge \ell_B(v_i,v_j)e^{i\delta_B(v_i,v_j)}) \\ \qquad if\, u_i = u_j \ and \ v_i, v_j \text{ an edge of } \mathfrak{E}_{AT\,2} \\ t_A(v_i)e^{i\alpha_A(v_i)} \wedge t_B(u_i,u_j)e^{i\alpha_B(u_i,u_j)},\ i_A(v_i)e^{i\beta_A(v_i)} \wedge i_B(u_i,u_j)e^{i\beta_B(u_i,u_j)}, \\ f_A(v_i)e^{i\gamma_A(v_i)} \vee f_B(u_i,u_j)e^{i\gamma_B(u_i,u_j)}, \ell_A(v_i)e^{i\delta_A(v_i)} \wedge \ell_B(u_i,u_j)e^{i\delta_B(u_i,u_j)}) \\ \qquad if\, v_i = v_j \ and \ u_i, u_j \text{ an edge of } \mathfrak{E}_{AT\,1} \\ \qquad 0 \ otherwise \end{cases}$$

$$deg_{\mathfrak{E}_{AT\,1}\times\mathfrak{E}_{AT\,2}}(u,v)$$

$$= i_{B_3}(u_3v_3)e^{i\beta_{B_3}(u_3v_3)}$$
$$f_{B_1}(u_1v_1)e^{i\gamma_{B_1}(u_1v_1)} = f_{B_2}\big(\Phi(u_1)\Phi(v_1)\big)e^{i\gamma_{B_2}(\Phi(u_1)\Phi(v_1))}$$
$$= f_{B_2}(u_2v_2)e^{i\gamma_{B_2}(u_2v_2)} = f_{B_3}\big(\psi(u_2)\psi(v_2)\big)e^{i\gamma_{B_3}(\psi(u_2)\psi(v_2))}$$
$$= f_{B_3}(u_3v_3)e^{i\gamma_{B_3}(u_3v_3)}$$
$$\ell_{B_1}(u_1v_1)e^{i\delta_{B_1}(u_1v_1)} = \ell_{B_2}\big(\Phi(u_1)\Phi(v_1)\big)e^{i\delta_{B_2}(\Phi(u_1)\Phi(v_1))}$$
$$= \ell_{B_2}(u_2v_2)e^{i\delta_{B_2}(u_2v_2)} = \ell_{B_3}\big(\psi(u_2)\psi(v_2)\big)e^{i\delta_{B_3}(\psi(u_2)\psi(v_2))}$$
$$= \ell_{B_3}(u_3v_3)e^{i\delta_{B_3}(u_3v_3)}$$

Remark: If there is an isomorphism between $\mathfrak{E}_{AT_1}$ and $\mathfrak{E}_{AT_2}$ then clearly there exists an isomorphism between $\overline{\mathfrak{E}_{AT_1}}$ and $\overline{\mathfrak{E}_{AT_2}}$.

Algorithm for Decision Making System Using Complex Antipodal Juriyam Graph

Step 1: Identify the set of alternatives $V = \{W_1, W_2, \dots W_n\}$and determine the relevant criteria influencing the decision such as benefit, cost, uncertainty, and other influencing factors.

Step 2: Assign to each alternative W_ia multi-dimensional value consisting of amplitude and phase components. The amplitude terms represent the degree of support, opposition, indeterminacy, and liberal attributes, while the phase terms capture time-dependent or periodic behaviour as $W = \left(a_1 e^{i\theta_1}, a_2 e^{i\theta_2}, \dots a_k e^{i\theta_k}\right)$

Step 3: For each alternatives W_i convert to absolute values by taking its magnitudes such as $|W_i| = (a_1, a_2, \dots a_k) \forall i = 1\ to\ n.$

Step 4: Construct score function to evaluate each attribute by $S(W_i) = a_{benefit} - a_{cost} - \frac{a_{uncertainty}}{2} + \frac{a_{support}}{2}, \forall i = 1\ to\ n.$

Step 5: Select the alternative with the maximum score function as the optimal decision. This alternative best satisfies the multiple criteria under consideration.

Application of complex Antipodal Juriyam Graph

Here Complex AntipodalJuriyam graph can be effectively applied in the design and optimization of WiFi networks by incorporating **amplitude and phase terms**. In real-world scenarios, placing WiFi routers or access points must balance multiple uncertain factors such as signal strength, user density, interference, and cost. Consider an organization (such as a university campus, airport, or smart city zone) that wants to install the **minimum number of WiFi access points** while ensuring **maximum coverage and connectivity**.

Parameters to be considered:

- Suitable locations for WiFi routers
- Number of users in each area
- Signal strength and coverage range
- Obstacles (walls, buildings, interference)
- Connectivity with the main network/server
- Existing network infrastructure
- Cost and available resources

Modeling using Complex antipodalJuriyam graph:

Let $V = \{W_1, W_2, W_3, W_4, W_5\}$be the set of possible WiFi access point locations. Each vertex is represented as

$$W_i = \{(t_{W_i}(u)e^{i\alpha_{W_i}(u)}, \quad i_{W_i}(u)\, e^{i\beta_{W_i}(u)}, \quad f_{W_i}(u)e^{i\gamma_{W_i}(u)}, \ell_{W_i}(u)e^{i\delta_{W_i}(u)})\}$$

where the amplitude terms such ast, i, f, ℓ represents the degree of sustainability, degree of indeterminacy, degree of unsuitability and the degree of liberal state satisfying $0 \leq t_{W_i}(u) + i_{W_i}(u) + f_{W_i}(u) + \ell_{W_i}(u) \leq 1$ and the phase terms $\alpha, \beta, \gamma, \delta \in [0,2\pi]$representing time variation / periodic behaviour.

Situations considered:

(i) Installing a router exactly at a selected location

(ii) Installing a router between two locations to improve coverage

For Situation 1, we may proceed as follows:

Let $V = \{W_1, W_2, W_3, W_4, W_5\}$be the set of possible WiFi access point locations.

Suppose that, for the locationW_1, 60% of the team supports the installation of a WiFi access point, 10% oppose it, and the remaining team expert's exhibit indeterminacy and liberal attitudes in their decision-making and the phase term that represents the period needs to be found. Let 40% of the team believe that in a particular time W_1 can attract the maximum number of users (Profit) and 20% of the team have the opposite opinion and the remaining proportion reflects indeterminacy and liberal attitudes. Thus we model those information as

$< W_1, 0.6e^{i0.4\pi}, 0.1e^{i0.3\pi}, 0.1e^{i0.2\pi}, 0.2e^{i0.1\pi} >$.

Similarly, for the location W_2, 70% of the team are in favour of installation, 10% are against it, and the remaining proportion reflects indeterminacy and liberal attitudes and 50% of the team believe that in a particular time W_1 can attract the maximum number of users (Profit) and 20% of the team have the opposite opinion and the remaining proportion reflects indeterminacy and liberal attitudes. In this manner, all vertices are modelled using Complex antipodalJuriyam values to capture the multifaceted nature of decision-making and denote this as

$$\mathcal{J} = \begin{cases} W_1: 0.6e^{i0.4\pi}, 0.1e^{i0.3\pi}, 0.1e^{i0.2\pi}, 0.2e^{i0.1\pi} \\ W_2: 0.7e^{i0.5\pi}, 0.1e^{i0.2\pi}, 0.1e^{i0.2\pi}, 0.1e^{i0.1\pi} \\ W_3: 0.4e^{i0.2\pi}, 0.1e^{i0.3\pi}, 0.1e^{i0.7\pi}, 0.4e^{i0.4\pi} \\ W_4: 0.2e^{i0.3\pi}, 0.3e^{i0.5\pi}, 0.3e^{i0.7\pi}, 0.2e^{i0.5\pi} \\ W_5: 0.3e^{i0.4\pi}, 0.3e^{i0.7\pi}, 0.1e^{i0.5\pi}, 0.3e^{i0.4\pi} \end{cases}$$

Now the absolute values are $|W_1| = (0.6,0.1,0.1,0.2)$, $|W_2| = (0.7,0.1,0.1,0.1)$, $|W_3| = (0.4,0.1,0.1,0.4)$, $|W_4| = (0.2,0.3,0.3,0.2)$, $|W_5| = (0.3,0.3,0.1,0.3)$ and to find the optimal choice, we find the score function of the absolute values ofW_1, W_2, W_3, W_4, W_5

$S(W_1) = 0.6 - 0.1 - \frac{0.1}{2} + \frac{0.2}{2} = 0.55$

$$S(W_2) = 0.7 - 0.1 - \frac{0.1}{2} + \frac{0.1}{2} = 0.6$$
$$S(W_3) = 0.4 - 0.1 - \frac{0.1}{2} + \frac{0.4}{2} = 0.45$$
$$S(W_4) = 0.2 - 0.3 - \frac{0.3}{2} + \frac{0.2}{2} = -0.15$$
$$S(W_5) = 0.3 - 0.3 - \frac{0.1}{2} + \frac{0.3}{2} = 0.1$$

Here $S(W_2) = 0.6$ is greatest and hence it is considered to be most suitable location.
For Situation 2, we may proceed as follows:

If Installing a router between W_1 and W_2it represents an edge of vertices $W_1$and W_2. Therefore from definition 3.2 we shall find that

$$\mathscr{L} = \begin{cases} < W_1, W_2, 0.6e^{i0.4\pi}, 0.1e^{i0.3\pi}, 0.1e^{i0.2\pi}, 0.1e^{i0.1\pi} > \\ < W_1, W_3, 0.4e^{i0.2\pi}, 0.1e^{i0.3\pi}, 0.1e^{i0.7\pi}, 0.2e^{i0.1\pi} > \\ < W_1, W_4, 0.2e^{i0.3\pi}, 0.1e^{i0.3\pi}, 0.3e^{i0.7\pi}, 0.2e^{i0.5\pi} > \\ < W_1, W_5, 0.3e^{i0.4\pi}, 0.1e^{i0.3\pi}, 0.1e^{i0.5\pi}, 0.2e^{i0.1\pi} > \\ < W_2, W_3, 0.4e^{i0.2\pi}, 0.1e^{i0.2\pi}, 0.1e^{i0.7\pi}, 0.1e^{i0.1\pi} > \\ < W_2, W_4, 0.2e^{i0.3\pi}, 0.1e^{i0.2\pi}, 0.3e^{i0.7\pi}, 0.1e^{i0.1\pi} > \\ < W_2, W_5, 0.3e^{i0.4\pi}, 0.1e^{i0.2\pi}, 0.1e^{i0.5\pi}, 0.1e^{i0.1\pi} > \\ < W_3, W_4, 0.2e^{i0.2\pi}, 0.1e^{i0.3\pi}, 0.3e^{i0.7\pi}, 0.2e^{i0.4\pi} > \\ < W_3, W_5, 0.3e^{i0.2\pi}, 0.1e^{i0.3\pi}, 0.1e^{i0.7\pi}, 0.3e^{i0.4\pi} > \\ < W_4, W_5, 0.2e^{i0.3\pi}, 0.3e^{i0.5\pi}, 0.3e^{i0.7\pi}, 0.2e^{i0.4\pi} > \end{cases}$$

Absolute values of edges are

$$|W_1W_2| = (0.6,0.1,0.1,0.1), |W_1W_3| = (0.4,0.1,0.1,0.2),$$
$$|W_1W_4| = (0.2,0.1,0.3,0.2), |W_1W_5| = (0.3,0.1,0.1,0.2),$$
$$|W_2W_3| = (0.4,0.1,0.1,0.1), |W_2W_4| = (0.2,0.1,0.3,0.1),$$
$$|W_2W_5| = (0.3,0.1,0.1,0.1), |W_3W_4| = (0.2,0.1,0.3,0.2),$$
$$|W_3W_5| = (0.3,0.1,0.1,0.3), |W_4W_5| = (0.2,0.3,0.3,0.2).$$

Now to find the optimal choice, we find the score function of the absolute values

$S(W_1W_2) = 0.6 - 0.1 - \frac{0.1}{2} + \frac{0.1}{2} = 0.5$, $S(W_1W_3) = 0.4 - 0.1 - \frac{0.1}{2} + \frac{0.2}{2} = 0.35$

$S(W_1W_4) = 0.2 - 0.1 - \frac{0.3}{2} + \frac{0.2}{2} = 0.05$, $S(W_1W_5) = 0.3 - 0.1 - \frac{0.1}{2} + \frac{0.2}{2} = 0.25$

$S(W_2W_3) = 0.4 - 0.1 - \frac{0.1}{2} + \frac{0.1}{2} = 0.3$, $S(W_2W_4) = 0.2 - 0.1 - \frac{0.3}{2} + \frac{0.1}{2} = 0$

$S(W_2W_5) = 0.3 - 0.1 - \frac{0.1}{2} + \frac{0.1}{2} = 0.2$, $S(W_3W_4) = 0.2 - 0.1 - \frac{0.3}{2} + \frac{0.2}{2} = 0.05$

$S(W_3W_5) = 0.3 - 0.1 - \frac{0.1}{2} + \frac{0.3}{2} = 0.3$, $S(W_4W_5) = 0.2 - 0.3 - \frac{0.3}{2} + \frac{0.2}{2} = -0.15$

Thus $S(W_1W_2) \leq S(W_2)$and hence W_2 is considered to be most suitable location.

CONCLUSION

In this work, we introduced the concept of Complex AntipodalJuriyam graphs and explored their characteristic operations such as Cartesian and Lexicographic products. The proposed framework effectively integrates amplitude components – truth, indeterminacy, falsity, and liberal state – with phase terms to model uncertainty and dynamic behaviour. Further, we demonstrated its applicability through the optimal placement of WiFi routers, showcasing its capability in handling real-world multi-criteria decision problems. The developed model provides a systematic and efficient approach for evaluating alternatives and selecting optimal solutions. Hence, this study establishes Complex antipodalJuriyam graph as a powerful tool for decision-making in uncertain and time-varying environments.

ABSTRACT

This study made a bamboo shoot powder-fortified soup mix using *Bambusa vulgaris* from Nagaland together with corn starch, pepper, lemongrass, garlic and salt. The study looked at the nutritional and bioactive properties of the bamboo shoot powder-fortified instant soup mix. The aqueous extract of the bamboo shoot powder-fortified soup mix contained flavonoids, tannins, phytosterols, alkaloids and other bioactive compounds. Nutritionally the bamboo shoot powder-fortified instant soup mix gave 332 kcal 14.1 g protein, 9.36 g fiber, 1656 mg potassium and 19.95 mg iron per 100 g. The bamboo shoot powder-fortified instant soup mix showed antidiabetic activity with 84.6% α-amylase inhibition and IC_{50} around 328 μg/mL. It also had potent antioxidant activity, with 78.85% DPPH inhibition. The bamboo shoot powder-fortified instant soup mix displayed anti-cholesterol binding 12.4% compared with 97.2% for atorvastatin. In MTT assays the bamboo shoot powder-fortified instant soup mix had cytotoxicity, 73.12% at 10 mg/mL. GC-MS analysis of the bamboo shoot powder-fortified instant soup mix found 25 compounds, the largest being 4-hydroxybenzaldehyde at 36.8% and L-lactic acid at 28.1%. With 12.5% moisture and a shelf life of 1 to 2 months the bamboo shoot powder-fortified instant soup mix shows

promise as a nutrient-dense bioactive functional food that could help manage disorders. Further, in vivo and clinical validation is needed.

Keywords: Bamboo shoot powder, functional food, instant soup mix, antidiabetic activity, antioxidant activity, anti-cholesterol activity, α-amylase inhibition, DPPH assay, GC-MS, phytochemicals

INTRODUCTION

Non-communicable diseases (NCDs)-cardiovascular disease, diabetes mellitus, obesity, and related metabolic disorders-are a significant worldwide health problem, driven primarily by unhealthy dietary patterns, processed-food consumption, physical inactivity, and stress (Akhtar, 2025). Functional foods, designed to deliver bioactive ingredients, including dietary fibre, phenolics, flavonoids, vitamins, and minerals, provide an accessible method to manage these NCDs, including hypocholesterolemic, hypoglycemic, and antioxidant effects (Nandan & Paul, 2026) Plant-derived ingredients are particularly appealing for functional food development due to their phytochemical content and reduced toxicity. Instant soups are among the most widely consumed convenience foods, but commercial variants are frequently nutritionally deficient and high in sodium and artificial additives (Bhat & Sridhar, 2019). Fortifying such products with functional plant ingredients is a practical option to improve their nutritional quality. Bamboo shoots-the young culms of various bamboo species and a traditional Asian vegetable-are well suited to this purpose.

This vegetable has long been considered a "superfood" in East and Southeast Asia, with nutritional values including proteins, carbohydrates, minerals, and vitamins, alongside phytochemicals such as phenols and phytosterols, (Chongtham et al., 2018; Santosh et al., 2024), making it a valuable candidate for fortifying processed foods as a source of fibre (Rusch et al., 2022) and, in previous work, pasta (Iliani et al., 2019). Due to the presence of cyanogenic compounds in the fresh shoots, it is the dried form, or powder, that is considered safer and more practical for food-processing (Watanabe et al., 2021). The fibre, minerals, and vitamins in the dried shoots vary between species but are generally beneficial (Angeline et al., 2021; Dash et al., 2022), and have been associated with reduced body weight gain, improved fasting glucose and insulin levels, and antioxidant activity that may counteract oxidative stress associated with chronic disease (Yang et al., 2021; Wanjala et al., 2020). The dietary fibre and phytosterols in bamboo shoots contribute to cholesterol control primarily by binding to cholesterol and bile acids in the intestine, encouraging their excretion, and prompting the liver to draw on circulating cholesterol to synthesise new bile acids, while phytosterols separately compete for cholesterol absorption in the intestine (Chongtham, Bisht, &Haorongbam, 2011). Animal and in-vitro studies support this mechanism: bamboo shoot consumption has been shown to reduce total cholesterol, LDL, and triglycerides (Park & John, 2009), increase faecal bile acid excretion (Nirmala et al., 2011), reduce serum cholesterol levels when fed a hyperlipidic diet (Hossain et al., 2015), and exhibit strong cholesterol-binding capacity under in vitro gastrointestinal conditions (Zhang et al., 2020)-consistent with the general role of soluble fibre in bile acid binding (Anderson et al., 2009) and phytosterol-mediated LDL reduction (Dash et al., 2022).
The phytochemicals in bamboo shoots also exhibit antidiabetic activity, primarily through the inhibition of carbohydrate-hydrolyzing enzymes alpha-amylase and alpha-glucosidase, antioxidant protection of pancreatic beta cells that produce insulin, and delayed gastric emptying and glucose absorption due to dietary fibre.

This evidence for such effects include reduced fasting blood glucose and improved glucose tolerance in diabetic mice fed bamboo shoot fibre (Li et al., 2019), improved glycaemic control with fibre-rich diets, and improved insulin sensitivity in animal models fed a high-fat diet (Wang et al., 2018). In addition to the hypocholesterolemic and hypoglycemic effects, bamboo shoots also exhibit antioxidant, prebiotic, and, potentially, anticancer properties (Sun et al., 2024; Basumatary et al., 2017), and their traditional use in aiding digestion and mitigating hypertension is increasingly corroborated by evidence of the presence of phytochemicals in the shoot (Chongtham et al., 2013; Chung et al., 2021; Ardiarini et al., 2025; Chongtham& Bisht, 2020). Fortifying instant soup products with functional plant

ingredients such as vegetable powders, fibre sources, herbs, and spices is an established approach to improving their nutritional value, and the use of fibre-rich instant soups has been found to result in lower glycaemic responses and positive consumer feedback (Singh & Verma, 2021). The fibre and phytochemical content of the bamboo shoot powder make it a promising candidate for such fortification (Diplock et al., 1999; Sarkar et al., 2025), and its potential application in the food-processing industry could be expanded upon further (Ma et al., 2024). Drawing on this premise, it is the intention of the present study to develop, and evaluate, an instant soup mix fortified with bamboo shoot powder, characterising its physicochemical, nutritional, and sensory properties, as well as quantifying its antidiabetic, anti-hypercholesterolemic, and antioxidant potential (Beldar et al., 2024; Zhang et al., 2024), using a formulation and evaluation approach based in part on established protocols for functional soup development (Pamalka et al., 2026; Krupalini, 2024; Phuseerit et al., 2026; Muth & Antony, 2025).

METHODOLOGY

Sample Collection and Preparation

3 kg of dried bamboo shoots were obtained from a local market in Nagaland and brought to the laboratory under sterile conditions. The raw materials underwent visual inspection to eliminate impurities before being rinsed with distilled water. Once air-dried as shown in fig 4, the shoots were processed into a fine powder using a laboratory-grade grinder and stored in airtight containers for subsequent use.(Elsherif, Sulaiman, & Mlitan, 2024, p. 710)

Formulation of Instant Soup Mix

The soup mix was developed by blending specific ratios of bamboo shoot powder with corn starch, salt, and seasonings including pepper, lemongrass, and garlic powder as shown in table 1. These ingredients were precisely measured and thoroughly integrated to ensure a uniform blend that met desired sensory and functional standards.(Palupi, et al., 2024, p. 83)

Preparation of Aqueous Extract

To prepare the extract, bamboo shoot powder was combined with distilled water and kept under refrigeration for 24 hours as shown in Fig 5. This cold aqueous extraction process yielded the liquid used for all further phytochemical and functional evaluations ***(HarborneJ.B.1973)***.

Phytochemical Screening

The aqueous extract was analyzed for bioactive components using established qualitative protocols. This screening identified the presence of various secondary metabolites, including phenols, flavonoids, tannins, alkaloids, glycosides, and saponins, as well as primary nutrients like proteins and carbohydrates.(Murthy, et al., 2024, p. 3279)

Nutritional Analysis

The nutritional profile of the soup mix was determined using standardized analytical techniques. This included proximate analysis for energy, protein, total fat, dietary fiber, and sugars, alongside mineral quantification for elements such as sodium, potassium, calcium, magnesium, phosphorus, iron, and zinc. All values were calculated per 100 g of the product.(Birungi, et al., 2023, p. 24181)

Assessment of Antidiabetic Activity

The antidiabetic potential was measured in vitro through an α-amylase inhibition assay utilizing the DNSA (dinitrosalicylic acid) method. Various concentrations of the soup mix (0.2µl,0.4µl and 0.6µl) were reacted with the enzyme and substrate; the reaction was then quenched with DNSA reagent and heated. Absorbance was recorded at 570 nm to determine the percentage of inhibition relative to a control group.(Hester, Verghese, Sunkara, Willis, & Walker, 2019; Oluwagunwa, Alashi, & Aluko, 2021, p. 210)

Assessment of Antioxidant Activity

The DPPH radical scavenging assay was employed to evaluate antioxidant capacity. The extract was combined with a DPPH solution and incubated in a dark environment for 30 mins. Following incubation, absorbance was measured at 517 nm, using ascorbic acid as the reference standard for comparison.(Bhuvaneswari & Sivasubramanian, 2023, p. 59)

Control: DPPH and Methanol was added.

3.8 Assessment of Anti-cholesterol Activity

Cholesterol-binding capacity was examined via a standard colorimetric assay. 5ml sample was incubated with 5ml cholesterol standard before being treated with acetic anhydride and concentrated sulfuric acid. The resulting color intensity was measured at 430 nm. For control, 5ml of cholesterol standard solution was mixed with 5ml phosphate buffer (pH 7.0) instead of the test extract, followed bythe addition of acetic anhydride and sulfuric acid. The positive control was prepared by replacing the extract with the standard drug (Atorvastatin) solution and following the same procedure.(Wadhwa & Rana, 2021)

Shelf-Life Evaluation

The stability of the product was monitored by measuring moisture content through the oven-drying technique. Samples were heated at 105°C until they reached a constant weight. Changes in moisture levels and physical properties were recorded to determine storage stability.(MC & Okonkwo, 2016)

The percentage moisture content was calculated using the following formula

Moisture content (%) = W3-W3/W2-W1 x100

Cytotoxicity Assay

Cytotoxicity Assay Procedure for Cancer Patients Using MTT Essay

The cytotoxic activity was assayed by using the MTT method performed on the cells, which was isolated from the T-flask with a confluent monolayer. The culture media were aspirated, and trypsin, TPVG solution (1 ml) was used to detach the adherent cells; the cell suspension was placed in a CO_2 incubator at 37^0C. The suspension obtained by the detachment was placed in a Falcon centrifuge tube, and after centrifugation, the cells were rinsed with MEM/FBS and resuspended. An amount of 100 ul of the suspension was transferred to each well of a 96-well plate, which were incubated at 37^0C with 5% CO_2 for 24 h. After that, the culture medium was removed, the cells were washed twice with a plain MEM, and an amount of 100 ul of the test sample was added into the wells, and the plates were placed in a CO_2 incubator at 37^0C for 18 h. Next, the cells were washed with plain MEM, and MTT solution (10 ul) was added to each well and incubated for 2 h. The purple formazan crystals were dissolved by adding DMSO or is opropanol, and the optical density was measured using a plate reader at 570 nm (Trivedi & Badole, 2024).The percentage of cytotoxicity was calculated using the following formula:

$$\text{Cytotoxicity}(\%) = A_{570}(T) / A_{570}(C) \times 100$$

GC-MS Analysis

To characterize the volatile and semi-volatile profile of the bamboo shoot extract, gas chromatography–mass spectrometry was conducted. The analysis utilized a Shimadzu GC-2030 integrated with a GCMS-QP2020 NX system. Compounds were identified by matching their mass spectra against established reference libraries.(Chung, Cheng, Lin, & Chang, Profiling of aroma compounds released from cooking Dendrocalamus latiflorus shoots, 2020, p. 8746)

RESULTS

The bamboo shoot instant soup mix exhibited promising nutritional and functional properties across all evaluated parameters. Key findings include high protein and fiber content, strong antidiabetic and antioxidant activities, and

moderate anti-cholesterol effects. These results highlight the potential of bamboo shoot powder as a functional ingredient for developing health-promoting food products.

Sample Collection

The dried bamboo shoots used for the study were collected from a reliable local source. The collected samples were carefully examined to ensure that they were free from visible impurities, contaminants, or microbial spoilage. The dried bamboo shoots were then cleaned to remove any adhering dust particles or unwanted materials. After cleaning, the dried bamboo shoots were subjected to grinding using a mechanical grinder to obtain a fine powder. The obtained bamboo shoot powder was then Add to avoid contamination after air tight container until further analysis.

Formulation of instant soup mix:

The bamboo shoot soup mix was successfully formulated using bamboo shoot powder along with corn starch, pepper powder, salt, lemongrass powder, and garlic powder as shown in fig 5. The ingredients were weighed accurately and mixed uniformly to obtain a fine powdered soup mix. The addition of lemongrass powder and garlic powder helped in reducing the pungent odour of bamboo shoot powder and improved the aroma and palatability of the soup mix. The soup mix was standardized in the ratio of 1:1, ensuring uniform consistency and flavor. The instant soup formulation was developed using Bamboo shoot powder as the main ingredient. Bamboo shoots are known to be rich in dietary fibre, proteins, vitamins, and various bioactive compounds that contribute to health benefits. The formulation was prepared by incorporating bamboo shoot powder with suitable ingredients to improve the nutritional value, flavor, and overall acceptability of the product and hence it serves as a potential functional food with nutritional and health- promoting benefits.

Phyto chemical Screening:

Aqueous extract of bamboo shoot was prepared using the cold extraction method as shown in Fig 9. Qualitative analysis confirmed the presence of diterpenes, flavonoids, proteins, tannins, carbohydrates, phytosterols, glycosides, and alkaloids, while phenols and saponins were absent as shown in table 3. These phytochemicals underpin the product's bioactivity. It was noted that the presence of flavonoids and tannins, among other secondary metabolites, correlates with the observed antioxidant and hypolipidemic potentials, given their documented roles in scavenging free radicals and modulating lipid metabolism (Soesanto, 2018; Neményi, et al., 2015; Caihong, et al., 2018). These compounds showed positive results indicating that these phytochemicals are present in the bamboo shoot extract. However, alkaloids, phenols, and saponins were not detected in the tested sample as they showed negative results. The presence of flavonoids and tannins suggests potential antioxidant properties, while phytosterols are known for their cholesterol-lowering effects. The detection of proteins and carbohydrates also confirms the nutritional value of bamboo shoots. Preliminary phytochemical screening of the sample revealed the presence of important bioactive compounds such as alkaloids, flavonoids, phenols, tannins, and saponins. These phytochemicals are known to exhibit various biological activities including antioxidant, antimicrobial, and therapeutic properties

Nutritional Composition:

The soup mix provided substantial nutritional value per 100 g (Table 4). It was energy-dense yet low in fat and sugars, with notable mineral content supporting metabolic health. Specifically, the analysis revealed a high fiber content, which is crucial for glycemic control and cardiovascular health, along with significant levels of potassium and magnesium, essential electrolytes for various physiological functions. This comprehensive nutritional profile positions the bamboo shoot-fortified instant soup mix as a viable functional food, offering significant macronutrient and micronutrient contributions (Nurlila, et al., 2024).

BLQ= below limit of quantification

The nutritional composition confirms that bamboo shoot soup mix can be served as a healthy functional food with potential benefits for individuals seeking nutrient-rich and low-sugar dietary options. The nutritional analysis

indicated that the sample contains essential nutrients such as proteins, carbohydrates, and other dietary components that are beneficial for human health. These nutrients play an important role in providing energy, supporting metabolic processes, and improving overall nutritional value. Therefore, the sample may serve as a nutritious functional food ingredient.

Antidiabetic Activity:

The soup mix demonstrated concentration-dependent α-amylase inhibition (Table 5), with up to 84.6% inhibition at 0.6 mL sample. IC50 value was approximately 328µg/mL, indicating potential for glycemic control. This significant inhibitory effect on α-amylase suggests that the bamboo shoot powder-fortified instant soup mix could effectively modulate postprandial glucose levels by delaying carbohydrate digestion (Tiwari & Tiwari, 2025). The nutritional composition of the formulated bamboo shoot soup mix was analyzed to determine its energy value, macronutrients and mineral content. The analysis was carried out using standard methods such as AOAC procedures and FSSAI guidelines. The results obtained were presented in table below: significant inhibitory effect on α-amylase suggests that the bamboo shoot powder-fortified instant soup mix could effectively modulate postprandial glucose levels by delaying carbohydrate digestion (Tiwari & Tiwari, 2025). The anti-diabetic activity was evaluated by measuring α-amylase inhibition using DNSA method. The percentage inhibition was calculated using the standard formula:

% inhibition = (Absorbance of control- Absorbance of test)/Absorbance of control ✕ 100

The control and test absorbance values were recorded and the percentage inhibition was calculated.

The results showed that the inhibitory activity increased with increasing concentration of the sample. This indicates that the sample exhibited concentration- dependent α-amylase inhibitory activity. The highest inhibition of **84.6%** was observed in Sample 3, suggesting strong anti- diabetic potential of the sample. The sample absorbance values were plotted on the maltose standard calibration curve. The sample points were found to lie on the standard curve, indicating comparable reducing sugar release during the reaction. The inhibitory activity of the sample against α-amylase increased with concentration. The IC_{50} value calculated from the inhibition curve was approximately 328µg/ml, indicating moderate enzyme inhibitory potential.

Antioxidant Activity

DPPH assay revealed 78.85% radical scavenging at 20 mg/mL, confirming strong antioxidant capacity attributable to phenolics and flavonoids. This robust antioxidant activity is consistent with prior research highlighting the significant free radical scavenging potential of bamboo shoot phytochemicals (FIP Brisbane 2023: New Medicines, 2023; Tiwari & Tiwari, 2025; Nurlila, et al., 2024, p. 321). The antioxidant activity of the bamboo extract was evaluated using the DPPH assay and the activity was expressed as percentage inhibition (% inhibition) at the tested concentration. The results demonstrate that the bamboo extract is capable of effectively inhibiting DPPH, confirming its antioxidant potential. The high% inhibition reflects significant free radical neutralization, suggesting that the extract can contribute to reducing oxidative stress. These findings indicate that the bamboo extract has antioxidant-rich functional ingredients with the potential to be used as a nutraceutical or functional food formulation

Anti-cholesterol Activity

Cholesterol-binding assay showed dose-dependent reduction, with 12.4% inhibition at 20 mg/mL versus 97.2% for atorvastatin at 10 mg/mL (Table 12). IC50 exceeded tested concentrations, indicating moderate efficacy. Despite this, the presence of various phenolic compounds, including naringin-7-rhamnoglucoside, chlorogenic acid, and caffeic acid, observed in similar bamboo species, suggests a potential mechanistic basis for lipid modulation that warrants further investigation at higher concentrations (Singhal et al., 2013). A standard calibration curve was prepared using different concentrations of cholesterol ranging from 0-12 µg/ml. The absorbance values increased proportionally with the increasing cholesterol concentration, showing a linear relationship between concentration and absorbance. This standard curve was used to determine the cholesterol concentration of the unknown samples. The absorbance values of the test samples at different concentrations (5mg, 10mg, 15mg, and 20mg) were measured as shown in table 10 and the corresponding cholesterol concentrations were calculated using the standard curve.

The results showed that the cholesterol concentration gradually decreased with increasing sample concentration. The highest cholesterol concentration (2.525µg) was observed at 5 mg, while the lowest cholesterol concentration (2.30µg) was observed At20 mg. This decrease in cholesterol concentration indicates that the extract exhibited anti- cholesterol activity. Overall, the results suggest that increasing concentrations of the extract enhanced the cholesterol- reducing effect, demonstrating potential anti- cholesterol activity of the sample. The IC_{50} value of atorvastatin was determined to be approximately 5.4 µg/ml. The bamboo extract did not reach IC_{50} within the tested concentration range(5-20µg/ml), with a maximum inhibition of 12.4%, indicating moderate cholesterol- lowering activity compared to the standard. The results indicated that the sample showed moderate cholesterol- lowering activity.

Shelf-life and Cytotoxicity

Moisture content of the sample was found to be 12.5%, which provides a shelf life of the product for 1-2 months. The cytotoxicity of the extract was found to be 73.12% for a 10 mg/mL sample, proving its bioactive nature with a reasonable limit of cytotoxicity. Thus, it can be concluded that the product has a good window for therapeutic functionality; however, further studies should be carried out to identify the compound responsible for the observed cytotoxic effects and its mechanism of action. The cytotoxic activity of the sample was evaluated using the MTT Assay at different concentrations. The results revealed that the sample exhibited varying cytotoxic effects. The highest cytotoxic activity (73.12%) was observed at 10 mg/ml concentration, suggesting strong cytotoxic potential at this concentration. These findings suggest that the sample exhibits concentration dependent cytotoxicity effects with maximum activity observed at 10 mg/ml.

GC-MS Profile

GC-MS identified 25 compounds, dominated by 4-hydroxybenzaldehyde (36.8% area) and L-lactic acid (28.1%), alongside phenolics like p-cresol and catechol (Table 4). These support observed bioactivities. Specifically, 4-hydroxybenzaldehyde is known for its antioxidant properties, while L-lactic acid contributes to flavor and potential prebiotic effects, collectively enhancing the product's functional profile (Devi, Sarma, Goudar, & Sharma, 2024; Kusalaruk & Prommajak, 2025). Gas Chromatography–Mass Spectrometry (GC–MS) analysis of the plant extract was performed to identify the bioactive compounds present in the sample. The chromatogram revealed 25 different compounds at different retention times (RT) ranging from 5.058 min to 29.837 min. Identification of compounds was carried out by comparing the mass spectra with the NIST library database.

CONCLUSION

The present study successfully formulated a bamboo shoot powder-fortified instant soup mix and demonstrated its significant potential as a functional food for the management of metabolic disorders. The qualitative phytochemical analysis confirmed the presence of biologically active secondary metabolites including flavonoids, tannins, phytosterols, glycosides, alkaloids, and diterpenes, which collectively underpin the observed in vitro bioactivities. Nutritional evaluation revealed a well-rounded macronutrient and micronutrient profile, characterized by high dietary fiber (9.36 g/100 g), appreciable protein content (14.1 g/100 g), low fat, negligible sugars, and rich mineral composition, supporting its application as a health-promoting convenience food. The antidiabetic assessment demonstrated strong, concentration-dependent α-amylase inhibitory activity, reaching 84.6% inhibition at the highest tested concentration with an IC50 of approximately 328 µg/mL. This indicates that regular consumption of the soup mix may help attenuate postprandial glucose spikes by slowing starch digestion, offering a dietary adjunct strategy for glycemic management in pre-diabetic and type 2 diabetic individuals. The DPPH radical scavenging assay revealed robust antioxidant activity of 78.85% at 20 mg/mL, attributable to the rich phenolic and polyphenolic content identified in the GC-MS profile, particularly 4-hydroxybenzaldehyde, catechol, and hydroquinone. This antioxidant capacity is clinically relevant in protecting against oxidative stress-driven cellular damage underlying diabetes and cardiovascular disease.

The cholesterol-binding assay confirmed dose-dependent anti-cholesterol activity, with inhibition increasing progressively up to 12.4% at 20 mg/mL. While this was moderate compared to the pharmaceutical standard atorvastatin, the activity is mechanistically meaningful and consistent with the cholesterol-sequestering role of dietary fiber and phytosterols identified in the formulation. GC-MS analysis identified 25 bioactive compounds spanning phenolic aldehydes, organic acids, aromatic phenols, and heterocyclic compounds, providing a robust chemical basis for the observed biological activities. The shelf life assessment indicated adequate storage stability with a moisture content of 12.5%, supporting a practical shelf life of one to two months under proper conditions. The MTT assay demonstrated bioactive potency at 73.12% cytotoxicity at 10 mg/mL, a concentration substantially exceeding normal dietary intake levels, indicating an acceptable safety margin for functional food use. In conclusion, the bamboo shoot powder-fortified instant soup mix represents a promising, naturally derived, and convenient functional food with multi-target biological activities relevant to the prevention and dietary management of metabolic disorders. The product capitalizes on the established nutritional and medicinal value of bamboo shoots while meeting the contemporary demand for convenient, health-promoting dietary options. Future research should prioritize in vivo animal studies, human clinical trials, sensory optimization, and reformulation to reduce sodium content, with the goal of advancing this product toward commercial application and broader therapeutic validation.

ABSTRACT

Thermal imaging for AI-based material fault identification is a very effective method for precisely detecting flaws in industrial materials. The first step is gathering a dataset of thermal pictures taken with infrared (IR) cameras. These images provide details on the state of the materials, including flaws like fractures and delamination. To increase clarity and accuracy, these photos are pre-processed utilizing methods including edge identification, contrast enhancement using noise reduction. Principal component analysis (PCA) feature selection CLAHE techniques are used to choose the most pertinent thermal characteristics, which lowers computing complexity. In order to capture important thermal patterns that point to material problems, feature extraction is subsequently carried out using deep learning models such as convolutional neural networks and vision transformers. Lastly, materials are classified as either faulty or non-defective using classification techniques such as deep neural networks (DNN)AI-powered system enables real-time, automated fault detection, enhancing predictive maintenance, reducing manual inspections, and improving overall manufacturing efficiency across industries such as aerospace, automotive, and construction.

INTRODUCTION

This study offers a non-invasive technique for diagnosing bearing problems in rotating machinery that is based on thermal images following thermal pictures of rolling-element bearings used to monitor the condition of AI-based materials, a comparison based on classification performance has been carried out using shallow and DL methodologies including ANN and CNN. Finding flaws in machine parts is crucial since any malfunction might result in major damage, the machine and the production system being shut down, and increased maintenance expenses. As a result of this intern, availability and productivity are decreased. Damaged machine parts may increase the likelihood of accidents in the industries [1]. A technique for intelligently identifying lithium-ion battery issues in electric cars is presented in this article. Through the use of support vector machines (SVM), denoising methods, a modified covariance matrix, and optimal parameter selection, the approach accurately determines fault states and degrees. Future fault management techniques and effective battery pack safety assessment are made possible by the suggested method's workable intelligent fault diagnostic solution. Thermal imaging can detect abnormalities like hotspots and thermal gradients, which point to underlying flaws, by recording temperature distributions. Large-scale screening, this non-invasive technique enables real-time monitoring and early fault diagnosis. CNN and other advanced DL models are used in thermal imaging to provide precise and effective defect identification, enhancing the dependability and lifetime [2].

An infrared thermal imager, a detecting device, uses thermal imaging technology to create a temperature field map by receiving different levels of infrared radiation from a sample's surface. The distribution of infrared radiation is described by this temperature field map, which may also be used to assess how the sample's interior and exterior structures differ from one another. This is due to the fact that variations in the assessed object's internal and exterior structures will cause the material to conduct heat differently, which will impact the heat flow [3]. Research is now focused on fault detection techniques, particularly non-intrusive techniques that can also provide the location of problems. Because of the ongoing developments in camera technology and artificial intelligence (AI), vision-based inspection has outperformed other approaches. The latter combination is very reliable, inexpensive, and capable of detecting, classifying, and localizing errors [4].ViT-based DL framework for automated PV module defect diagnosis utilizing infrared thermography images offers improved classification accuracy for a variety of PV fault types by means of sophisticated image preprocessing, data augmentation, and accurate feature extraction. Due to these advancements, the recommended approach for AI-based material fault identification is now more broadly accessible, reasonably priced, and incredibly accurate [5].

- To Design an AI-powered system accurately identifies material defects using thermal imaging dataset.
- To Using preprocessing methods to enhance picture clarity and accuracy, such as noise reduction, Contrast enhancement edge detection, CLAHE techniques
- To Selecting the most pertinent thermal characteristics using PCA lowers computational complexity and enhances model performance.
- To Classify materials using DNN for accurate defect identification, and use CNN, ViT for feature extraction.
- To Create an automated, real-time predictive maintenance system that will decrease human inspections and increase production efficiency in sectors including construction, automotive, and aerospace.

The remainder of the paper is organized into important sections that are explained as follows: Section II lists the current research projects in AI based fault detection in industrial using thermal image that have been completed by different authors. Section III outlines the workflow of the proposed method. The comparison results of proposed model with traditional model for AI based fault detection in industrial using thermal image shown in Section IV. In Section V, together with references, is the conclusion of the suggested work that will be undertaken in a future scope.

Second, the state of research on DL techniques for X-ray picture defect identification is examined. Lastly, we provide a summary of the most prevalent issues in surface defect detection, including restricted sample size, imbalanced sample identification, and real-time processing, along with possible remedies.

Lang et al., (2021) This article examines how AI methods have been used in motor FDD recently. Fault classification and feature extraction are the two primary phases of AI-based FDD. There is discussion of the use of various signal processing techniques in feature extraction. The discussion concludes with a review of the most recent advancements, unmet research needs, and upcoming difficulties in motor fault detection and monitoring. Barnawi et al., (2021) In this study, we propose a method based on IoT UAVs to collect raw data using onboard heat sensors. Utilizing the thermal camera's reported temperature, the probable individuals in the image (of the densely populated metropolis) who could have COVID-19 are identified. An effective hybrid method for a face recognition system is put forth to identify individuals with elevated body temperatures in real-time infrared pictures. Kim et al., (2021) Research into the potential uses of industry 4.0 in related industries has been prompted, in particular, by the rising public interest in this concept, which aims to transform the traditional industrial landscape. In an effort to revolutionize the manufacturing sites, this review attempts to highlight some of the significant advancements achieved using AI in some of the most significant and profitable manufacturing businesses. Gawde et al., (2023)This paper provides a comprehensive evaluation of several problems pertaining to industrial rotating machine multi-fault detection and summarizes the foundational research conducted in the field. The paper also identifies research gaps and major challenges. It provides answers by using recent AI developments to multi-fault detection, providing a solid foundation for further study in this area.

Chen et al., (2021)This article provides an overview of the state of research on machine learning techniques for surface defect recognition, a crucial component of industrial product quality inspection. The application of conventional machine vision techniques in the identification of surface defects in industrial products may be summed up from three perspectives: texture characteristics, colour features, and form characteristics based on the utilization of surface features, unsupervised, and weakly supervised methods. Karabacak et al., (2022)In order to diagnose WG faults under various operating settings, this research presents an intelligent feature selection and classification algorithm. Choosing various loading and speed settings as well as feature sources for experimental condition monitoring investigations of WGs is what makes this work innovative. Fault identification and classification were carried out using vibration, sound, and thermal imaging data that were gathered and examined from the problematic and healthy WGs. Nath et al., (2021)This publication offers researchers and academics a comprehensive overview of rotor defects and is the first of its kind to try to analyse and explain how AI works in RFD. Additionally, this study is distinct in three ways: (i) it highlights the application of AI to fault-specific characteristic features; (ii) it uses fault-wise analysis instead of component-wise analysis with suitable fault classification; and (iii) it provides examples of current research and analysis in line with various stages of an AI-based RFD framework. Gundewar et al., (2021) This article provides a thorough analysis of current developments in the field of induction motor condition monitoring and fault diagnostic research. The primary issues with the induction motor are discussed, including time-domain, frequency-domain, and time-frequency-domain approaches, as well as the use of artificial intelligence algorithms for problem identification.

Deng et al., (2023) Using a Deep Learning method, this research suggests a novel foundation to understand how the controlled drop-test impact energy of conventional CFRP laminates relates to their Barely Visible Impact Damage features. In a parametric analysis, one hundred CFRP laminates with known material specifications and equivalent geometric dimensions were employed. They underwent drop-impact testing with five different degrees of impact energy. Fanwu et al., (2025)In order to overcome significant this paper proposes a novel sparse encoding detection method that uses pre-trained deep neural networks to extract fused multi-scale features, therefore overcoming the challenges associated with automated surface defect identification in manufacturing. Our method addresses the problems of unequal features and inadequate feature representation by constructing sparse dictionaries with low redundancy, requiring just samples free of defects for model training. Rabe et al., (2025)The research team's continuous efforts to provide a functional generalized inline-monitoring solution served as the foundation for this article. FSW issues are identified and categorized by using CNN, which is based on the DenseNet architecture, to analyze recorded process data. To enable classification, CNNs are supplemented with metadata particular to the weld and workpiece. After that, these networks are trained to categorize transient weld data over two sheet thicknesses, three distinct Al alloys, and a broad range of welding settings. Deepak et al., (2024)In order to achieve zero-defect manufacturing, this research suggests a unique method that combines AI-driven heat modeling in complex industrial chains with multi-phase process, product, and system optimization. It integrates real-time sensor data flow with advanced thermal modeling to develop a multistage thermal prediction and management system utilizing machine learning approaches.

PROPOSED METHODOLOGY

The proposed AI-driven thermal imaging system for automated defect categorization consists Thermal images captured using infrared (IR) cameras often contain noise, uneven illumination, and low contrast, which can impact defect detection accuracy. To address these issues, pre-processing techniques are applied to enhance image quality. Edge detection methods, such as the Sobel and Canny algorithms, are used to identify sharp transitions in temperature gradients, helping in the early detection of cracks and delamination. Contrast enhancement techniques, including histogram equalization and adaptive contrast stretching, improve the visibility of defects. Noise reduction filters, such as Gaussian and median filters, are used to eliminate unwanted thermal distortions and improve image clarity. This ensures that only relevant defect patterns remain in the images, making subsequent analysis more effective. After pre-processing, the system extracts meaningful thermal characteristics from the images. Deep learning models, including Convolutional Neural Networks (CNNs) and Vision Transformers (ViTs), are employed to learn and extract critical defect-related features. CNNs analyse spatial relationships within thermal images, capturing local features such as cracks, voids, or delamination. Meanwhile, Vision Transformers process the entire thermal image using self-attention mechanisms, which help in identifying long-range dependencies and complex defect patterns. These models generate feature maps representing unique thermal signatures associated with different material faults. Principal Component Analysis (PCA) is applied to select the most relevant features while reducing computational complexity. PCA transforms the extracted features into a lower-dimensional space, ensuring that only the most significant defect-related thermal characteristics are retained. The final stage involves classifying materials as either defective or non-defective using deep learning-based classification models. A Deep Neural Network (DNN) is trained on the selected features to categorize materials with high precision. The DNN model learns the complex relationships between extracted thermal patterns and corresponding defect categories. This AI-powered classification system enables real-time decision-making, facilitating automated fault detection in industries such as aerospace, automotive, and construction.

Data Collection

Several factors, including the image's backdrop, the objects surface condition, the weather, and the thermocouple, should be taken into account when taking IRT photographs in order to accurately measure an object's temperature using a thermal camera. To train object identification models, a labelling procedure is carried out during. The bounding box coordinates of an item and the kind of object for each image are included in the image label. The deep

learning algorithm is trained using infrared pictures. Following item detection by the algorithm, the approach compares the thermal data to the appropriate coordinates.

Pre-processing (Noise reduction, Contrast enhancement edge detection)

Initially, the samples were reduced in size. Grayscale conversion of RGB pictures was also carried out for model training and processing. To enhance the image, we used the contrast. The term CLAHE refers to limited adaptive histogram equalization. Unlike regular AHE, CLAHE clips the histogram at a predetermined value before calculating the cumulative distribution function, so counteracting noise amplification. The two primary settings that may be adjusted to regulate the quality of photo enhancement are the Clip Limit and the Block Size. The image is then separated into contextual areas that do not overlap, producing M × N tiles. The CL value is then used to compute the contextual region's contrast-limited histogram as follows:

$$N_{avg} = (N_{px} \times N_{py})/N_{gray} \quad (1)$$

Where Ngray is the region's gray level number, Npx and Npy are, respectively, the pixel counts of the region in the X and Y directions, and Navg is the average number of pixels in the context area. Here's how to calculate the actual clip limit:

$$N_{CL} = N_{clip} \times N_{avg} \quad (2)$$

Where, In the interval [0,1], N_{clip} is the normalized clip limit. Pixels that have more pixels than the NCL are trimmed. All of the histogram bins more effectively disperse the portion that surpasses the clip limit. The procedure is repeated if the redistribution results in certain values exceeding the clip limit once more until the excess can be ignored.

Feature Selection (Principal Component Analysis (PCA))

Interpretation challenges arise from the proliferation of big data collecting across all industries. By lowering the dimensionality of datasets without compromising information, PCA can help in this situation. This improves the dataset's interpretability and reaps the rewards of dimensionality reduction. By projecting the features onto new, orthogonal planes, principal component analysis creates additional features. The interpretability of the link between the characteristics is improved by the feature distributions in planes. The following are some important PCA terms that help with understanding it: see: The angle of sight or viewpoint that is used to see (observe) the data points. Dimension: A dataset's columns. The feature is the same as this. Projections are the distances measured perpendicularly between the primary components and the data points. As a result, it is evident that there will never be more main components than there are starting variables. The primary components are always orthogonal, and as the number of PCs rises from PC1 to PCN, their importance falls. Principal component analysis creates feature vectors by applying the following operations to a dataset in the proper order: standardization, covariance matrix calculation, eigenvector, and eigen value computation.

Data points are manipulated by standardization to fit into comparable bounds.

$$Z = (x - \dot{x})/std \quad (3)$$

The covariance matrix computation describes the relationship between any two or more characteristics in a multidimensional dataset. The variance of the feature values and matrix members serve as representations of the covariance.

$$\begin{pmatrix} Var\,(x) & Cov\,(x,y) \\ Cov\,(x,y) & Var(x) \end{pmatrix} \quad (4)$$

Feature Extraction (CNN -ViT)

Natural language processing has been dominated by transformer-based architectures.A CNN is composed of many hidden layers, an input layer, and an output layer. Layers for normalizing, pooling, convolution, and complete connectivity are the usual components of a CNN's hidden layers. For more intricate models, layers can be employed. An illustration of a standard CNN is shown in Figure 2. In several computer vision and deep learning, the CNN design has demonstrated exceptional performance. CNN uses an abstract level of training and prediction, saving the specifics for subsequent portions. Because of its consistent record-breaking efficacy, this CNN model is widely utilized in contemporary DL applications. These CNNs operate on the foundation of linear algebra. The foundation

of representing Weights and data is matrix vectors multiplied. Every layer has an own set of attributes for a collection of images. For example, a CNN's early layers will learn certain fundamental features like borders, bright spots, dark spots, forms, etc. if it receives a face picture as input. Shapes and identifiable things from the image, such eyes, noses, and mouths, will make up the next layer set. The next layer has features that resemble real faces, i.e., objects and forms information might be used by the network to describe a human face. CNN divides the image classification process into smaller components (features) by matching certain regions of the picture instead of the entire image. The features that the CNN gathers for assessment are represented by a 3x3 grid. Filtering is the next step, which involves aligning the feature with the picture patch. After multiplying each pixel by its matching feature pixel one at a time, the total number of pixels in the feature space is divided by the sum of the outcomes. The feature patch is then updated with the feature's final value. A convolution filter is repeatedly used after this process for the remaining feature patches in an attempt to find every match. Chain rule and vector calculus can be used in the CNN learning process. Let y∈If z is a scalar and R H is a vector, z ∈ R then. A vector is defined as follows: if z is a function of y, then the partial derivative of z with respect to y is a vector.

$$(\partial z\ \partial yi) = \left(\frac{\partial z}{\partial yi}\right) \quad (5)$$

The ViT network uses a third-stream model called ViT in addition to this kernel-based texture characteristics that were taken from the CNN-based model. Through the development of associations between both local and far-off pixels, the ViT operates on the basis of the attention mechanism. The input picture is initially split up into tiny pieces in order to carry out the attention mechanism's responsibilities. Similar to a convolution layer with a kernel, this procedure yields a four-dimensional matrix that has three extra dimensions—row, column, and depth and batch indexing. I ∈ $\mathbb{R}H\times W\times C$ is therefore changed to PP ∈ $\mathbb{R}N\times P2\times C$, where H and C stands for the number of channels, and W for the image's width and height. Conversely, the number of patches is N as certained by

$$N = \frac{H\times W}{P^2} \quad (6)$$

Where P is the patch's size table 1 shows that the patch size is 6 × 6 and the image size is 78 × 78. The quantity of patches is determined using the picture and patch size: ($H\times WP2$) =78×78(6)2=169. A 1D embedding vector, $PPLinear_Projection$, with a size of 64, is created by linearly projecting the raw image (I) into a 2D matrix, PP, after patch partitioning.

$$PP = \begin{bmatrix} [I_1][I_2] & \dots [I_3] \\ [I_{14}][I_{15}] & \dots\dots [I_{26}] \\ \dots\dots\dots\dots\dots\dots\dots & \\ [I_{157}][I_{158}] & \dots\dots [I_{169}] \end{bmatrix} (7)$$

$$PP\ Linear\ projection = \begin{bmatrix} [I_1{}^1\ I_1{}^2 \dots . I_1{}^{64}] \\ [I_2{}^1\ I_2{}^2 \dots . I_2{}^{64}] \\ \dots\dots\dots\dots\dots\dots\dots \\ [I_{169}{}^1\ I_{169}{}^2 \dots . I_{169}{}^{64}] \end{bmatrix} (8)$$

Since the transformer's performance is computationally costly, the picture patches are first divided into smaller groups before being applied to bigger image sizes using a positional embedding. Sine and cosine functions of various frequencies are combined in the position embedding, or $EPOS$. If the patch is positioned oddly, use the cosine function; if it is positioned evenly, use the sine function. Where pos and i stand for position and dimension, respectively, the entire positional embedding is kept at different points on this sinusoid. Again, d is the longest possible patch group.

$$E_{POS} = \begin{Bmatrix} \sin\left(\frac{pos}{1000\frac{2i}{d}}\right), i\ is\ even \\ \cos\left(\frac{pos}{1000\frac{2i}{d}}\right), i\ is\ odd \end{Bmatrix} (9)$$

$$EP = concatenate\ (PP_{Linear\ projection}, E_{POS}) \quad (10)$$

After positional embedding and linear projection, the encoded block receives the embedded patch. Each of the eight comparable blocks that make up the encoder has a mixture of six layers, including a normalization layer, a multi-layer perceptron, and A layer of multi-head self-attention. First, the encoder block's input, like EP, is concatenated with the MSA output. The output of MLP first goes via a deep dropout layer and then into a normalization layer. This attention output is concatenated with a skip connection from the input to boost the location effect when the original embedded patch is transferred to the next layer. To determine attention, three embedding matrices are used: key K, query Q, and value V. This weight matrices WQ, WK, and WV are utilized to compute the matrices using the following formulas:

$$Query, Q = EP.W_Q \quad (11)$$

$$Key, K = EP.W_K \quad (12)$$

$$Value, V = EP.W_V \quad (13)$$

Where WQ, WK, and WV are the learnable parameters ∈ℝd model × dk, and E is the token embedding. Equation (14) determines the attention in the MHA layer. the single attention function known as head is carried out repeatedly in parallel using the following equation. where a dot-scaled product named dk keeps the attention value from blowing out.

$$Attention, (Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)\mathrm{V} \quad (14)$$

$$MHA = Attention, (Q, K, V)_{\times 4} \quad (15)$$

Non-linearity is produced in this process by the multi-layer perceptron, which uses Gaussian error linear units to activate succeeding layers after a dense layer. ϕ represents the cumulative distribution of the Gaussian distribution. Lastly, the Transformer feature shape generated by the layer is extracted and flattened using the following formulas.

$$GELU(x) = xP(X \leq x) = x\emptyset\,(x) \quad (16)$$

$$Transformer_{feature\ _shape} = GELU\,(MHA) \quad (17)$$

$$Y_{Transformer} = Flatten(Transformer_{feature\ _shape}) \quad (18)$$

The DNN classifier then receives the Y Transformer. This model's performance on the dataset used for validation was taken into consideration while determining the parameters' initial value, which was predicted by taking into account the dataset's size and complexity.

Classification (Deep Neural Networks)

The classifier for deep neural networks is built. A descendent of the traditional ANN, the DNN is a feed-forward neural network.

$$\mathrm{X} = [\mathrm{x}_1, \mathrm{x}_2, \ldots . \mathrm{x}_\mathrm{D}] \quad (19)$$

Since the deep learning network permits the inclusion of several hidden layers; the concealed layer is the next to appear. The hidden layer uses a bias, bj, and random weights, wi, to map the input layer's input X. Thus, the hidden layer's inputs are expressed as

$$h_j = \sum_i w_i x_i + b_j \quad (20)$$

Where j represents the number of hidden units in the DNN, j = 1, 2, 3, …, k.

The output layer's activation function processes the inputs from the hidden layer to generate the DNN's outputs. For intrusion detection classification, the output layer's nonlinear activation function Soft Max which transforms inputs into a class of probability rð Þ X j was employed. This is the DNN's output, expressed as

$$\sigma(X)_j = \frac{e^{X_j}}{\sum_{k=1}^{k} e^{X_k}} \quad (21)$$

Where X is a vector of inputs to the output layer, j is the number of output units, and j ¼ 1; 2...; k.

Within The network is trained using the inputs to the matching class outputs (normal 1 and abnormal 0) in this DNN configuration. A huge training dataset is used to train the DNN, and each input link's weight is regularly adjusted to minimize training errors. To train the network faster and more efficiently, the DNN's model parameters are changed in figure 4. These tuning parameters, sometimes referred to as hyper parameters, control the optimization and model

selection processes throughout the training of the learning algorithm. Whether the model under fits or over fits during the learning phase is determined by these hyper parameters.

RESULT AND DISCUSSION

The proposed is Deep learning and AI-driven thermal imaging allow for very accurate real-time industrial material failure diagnosis. Deep learning models can automatically classify material flaws like fractures, cavities, or abnormalities by examining thermal patterns. This method decreases mistakes in quality control, increases efficiency, and lowers the cost of human inspection. In production settings, real-time processing guarantees the fast detection of flaws, enabling timely remedial measures. Combining AI and thermal imaging increases the speed and accuracy of flaw identification, which raises the uniformity and dependability of the final output. This automated technology transforms industrial inspection by increasing its speed and dependability. As a result, manufacturers can produce higher-quality products while minimizing waste and reducing downtime. The proposed is shown in table1 represents the distribution of different material faults detected using AI-based thermal imaging in an industrial setting. Among the identified faults, cracks were the most common, accounting for 30% of occurrences (15 cases). Overheating issues followed with 10 cases, making up 20% of the total. Delamination was observed in 8 instances, contributing to 16% of the detected faults. Short circuits were also prevalent, with 12 occurrences, representing 24%. Lastly, 10% of the inspected materials showed no faults, totalling 5 cases. This analysis helps in understanding the dominant issues in industrial materials, allowing for targeted maintenance and quality control.The figure 5represents the distribution of different fault types detected in an industrial setting using thermal imaging. Cracks are the most common fault, occurring in 30% of cases, indicating significant structural concerns. Overheating accounts for 20% of faults, highlighting potential risks of equipment failure. Delamination, which affects material integrity, occurs in 16% of instances. Short circuits, a critical electrical issue, make up 24% of the detected faults. Lastly, 10% of the cases show no faults, confirming the reliability of some materials. This graphical representation helps in understanding fault distribution and prioritizing maintenance efforts for improved industrial safety.

Performance Evaluation

Precision indicates what percentage of identifications is actually correct

$$\text{Precision} = \frac{TP}{TP+FP} \qquad (25)$$

Precision refers to the proportion of correctly identified positive predictions among all predicted positives.

$$Recall = \frac{TP}{TP+TN} \qquad (26)$$

The accuracy and recall metrics' harmonic mean are used to get the F1 score two classifiers' performances are compared using it.

$$\text{FI Score} = \frac{\text{Precision}}{\text{Precision} + \text{Recall}} \qquad (27)$$

The table 2presents the performance metrics for five defect types in an AI-based material fault detection system. Type 1 indicating accurate classification. Defect Type 5 followed closely with 91% precision and 90% F1-score. Defect Type 2 and 4 had similar performance, with F1-scores of 88% and 87%, respectively. Defect Type 3 had the lowest precision (85%) and recall (83%), leading to an F1-score of 84%. Overall, the model demonstrates strong performance in detecting material defects. The figure6 illustrates the performance of an AI-based material fault detection system across five defect types using precision, recall, and F1-score metrics. Defect Type 1 demonstrates the highest precision at 92%, ensuring fewer false positives, with a recall of 90%, indicating strong detection capability. Defect Type 5 closely follows with 91% precision and 89% recall. Defect Types 2 and 4 show balanced performance, achieving F1-scores of 88% and 87%, respectively. Defect Type 3 records the lowest precision (85%) and recall (83%), resulting in an F1-score of 84%. The figure highlights the model's overall reliability in accurately identifying material defects.

CONCLUSION

The AI-driven thermal imaging system successfully automated the categorization of material defects in industrial settings. By utilizing infrared cameras, thermal images were captured to detect flaws such as fractures and delamination. Preprocessing techniques, including edge detection and contrast enhancement with noise reduction, improved image clarity and accuracy. Principal Component Analysis (PCA) was employed to select the most relevant thermal features, reducing computational complexity. Deep learning models, such as Convolutional Neural Networks (CNN) and Vision Transformers, effectively extracted key thermal patterns indicative of material faults. Classification techniques, including Deep Neural Networks (DNN), were used to differentiate between defective and non-defective materials. The system provided real-time fault detection, enhancing predictive maintenance, minimizing manual inspections, and improving overall manufacturing efficiency in industries such as aerospace, automotive, and construction.Future advancements in this system could focus on integrating more advanced deep learning models, such as Transformer-based architectures, to improve accuracy and generalization. Implementing edge AI with optimized hardware could enable real-time, on-device defect detection, reducing latency and enhancing scalability. Expanding the dataset with diverse material types and defect variations would improve model robustness. Additionally, integrating Internet of Things (IoT) technology for seamless data collection and cloud-based analytics could enhance predictive maintenance strategies. Further research could also explore multimodal data fusion, combining thermal imaging with other non-destructive testing methods like ultrasonic or X-ray inspection for comprehensive fault detection.

ABSTRACT

The concept of maintaining health through the harmonious interaction of Doṣha, Duṣhya, Agni, and Srotas is fundamental to Ayurveda. The AṣṭāṅgaSaṅgraha of Vāgbhaṭa presents these principles systematically, while the medieval commentary traditionally associated with the text (most prominently Indu'sŚaśilekhā, the principal surviving commentary) expands the terse original into clinically meaningful explanations. Commentarial traditions have been crucial in preserving and interpreting the text. To critically review the role of Doṣha and Duṣhya in maintaining Śarīra through the interpretative perspective of the PrakāśikāVyākhyā tradition and compare these concepts with other classical Ayurvedic texts. A narrative review based on classical Ayurvedic literature, standard commentaries, and selected contemporary publications in Ayurvedic research. The commentary explains Doṣhas as physiological regulators and Duṣhyas as structural and functional substrates. Their coordinated interaction, mediated by balanced Agni and unobstructed Srotas, maintains physiological equilibrium. Disturbance of this relationship results in Doṣha–Duṣhya Saṃmūrchana, which forms the basis of disease manifestation. The commentary offers an integrated understanding of physiology, pathology, and therapeutics that remains relevant to contemporary Ayurvedic education and clinical practice.

Keywords: Doṣha, Duṣhya, Śarīra, AṣṭāṅgaSaṅgraha, Agni, Ayurveda, Vāgbhaṭa.

INTRODUCTION

Ayurveda defines health as a dynamic state in which Doṣha, Agni, Dhātu, and Mala remain in equilibrium while the mind, senses, and self-function harmoniously. This holistic definition demonstrates that health is not merely the absence of disease but the maintenance of physiological balance through continuous interaction among multiple biological factors.[1]The AṣṭāṅgaSaṅgraha occupies a distinguished position within the Ayurvedic canon because it integrates the teachings of the Caraka and Suśruta traditions into a comprehensive medical treatise covering all eight branches of Ayurveda. Unlike the concise metrical style of the AṣṭāṅgaHṛdaya, it employs both prose and verse, allowing greater elaboration of theoretical and clinical concepts. The surviving medieval commentary by Prakashika Vyakhyahas long been regarded as the principal guide to understanding the AṣṭāṅgaSaṅgraha. Modern reviews of the text note that relatively few commentaries survive, making Indu's work especially important for interpreting Vāgbhaṭa's intent and clinical applications. Among the many physiological principles discussed in the text, the relationship between Doṣha and Duṣhya occupies a central position. The commentary explains that Doṣhas regulate physiological activities, whereas Duṣhyas provide the structural basis upon which those functions operate. Together they maintain the integrity of Śarīra.

Historical Background

The AṣṭāṅgaSaṅgraha, attributed to ĀcāryaVāgbhaṭa, represents one of the most comprehensive compilations of Ayurvedic knowledge. It synthesizes concepts from the Ātreya–Caraka and Dhanvantari–Suśruta traditions while presenting them in a systematic format suitable for physicians and students. Modern scholarship highlights that the AṣṭāṅgaSaṅgraha has comparatively few surviving commentaries, with Prakashika Vyakhya remaining the best-known and most influential. The commentary explains difficult expressions, clarifies terminology, and often correlates Vāgbhaṭa's teachings with earlier authorities, thereby preserving the continuity of classical Ayurvedic knowledge. This interpretative method transforms concise aphorisms into clinically meaningful guidance and contributes significantly to postgraduate Ayurvedic education.

Concept of Doṣha:

The term Doṣha originates from the Sanskrit root duṣ, meaning "to vitiate." However, classical commentators emphasize that this etymology should not lead to the misconception that Doṣhas are inherently harmful. In their balanced state, they sustain life and regulate physiological functions; only when disturbed do they contribute to disease. The classical definition of health remains the foundation of Ayurvedic physiology:

समदोषःसमाग्निश्चसमधातुमलक्रियः।
प्रसन्नात्मेन्द्रियमनाःस्वस्थइत्यभिधीयते॥

"A person is considered healthy when the Doṣhas, Agni, Dhātus, and excretory functions remain in equilibrium and the mind, senses, and self are in a state of well-being."[2] The commentary explains that Doṣhas should be understood primarily as physiological regulators rather than pathological entities. Their balanced state maintains respiration, circulation, digestion, metabolism, tissue nourishment, and structural stability. Disease develops only after quantitative or qualitative disturbance.

Physiological Role of the Three Doṣhas:

Vāta: Vāta governs movement, respiration, circulation, neuromuscular coordination, sensory perception, and elimination. The commentary describes it as the initiating force behind all physiological activities. Without Vāta, neither Pitta nor Kapha can perform their respective functions effectively.

Pitta: Pitta regulates digestion, metabolism, tissue transformation, body temperature, vision, and intellectual functions. The commentary closely associates Pitta with Agni, emphasizing that normal metabolism depends upon their coordinated activity.

Kapha: Kapha provides structural stability, lubrication, nourishment, and resilience. It maintains tissue cohesion and contributes to resistance against disease.

Role of Duṣhya, Agni, and Doṣha–DuṣhyaInteraction in Maintaining Śarīra:

Role of Duṣhya in Maintaining Śarīra:
While Doṣhas regulate physiological functions, Duṣhyas constitute the structural and functional basis upon which these activities are expressed. Indu, in the Śaśilekhā commentary, explains that the body cannot maintain its integrity unless the Dhātus are continuously nourished and protected from pathological alterations. The term Duṣhya refers to those body constituents that are susceptible to vitiation by aggravated Doṣhas but, in their normal state, actively sustain life and bodily functions [1,2] The principal Duṣhyas include the Sapta Dhātus (Rasa, Rakta, Māṃsa, Meda, Asthi, Majjā, and Śukra), Malas, and Srotas. Rather than considering these as static anatomical structures, the commentary emphasizes their dynamic nature. Tissue formation, nourishment, and regeneration are continuous processes dependent upon proper digestion, balanced Agni, and unobstructed Srotas. Thus, Śarīra is maintained through a perpetual cycle of tissue renewal rather than by fixed structural elements. [3]

रसरक्तमांसमेदोऽस्थिमज्जाशुक्राणिधातवः।

"Rasa, Rakta, Māṃsa, Meda, Asthi, Majjā, and Śhukra constitute the seven Dhātus that support the body." [2] According to the Prakashikavyakhya commentary, these tissues should be viewed as interconnected stages of nourishment rather than isolated anatomical entities. Defects occurring at one stage influence the subsequent Dhātus, ultimately compromising the stability of the entire organism.

Agni: The Mediator BetweenDoṣha and Duṣhya
The Prakashikavyakhya repeatedly highlights Agni as the central determinant of physiological equilibrium. Agni is responsible not only for digestion of food but also for the transformation of nutrients into tissue components. Consequently, balanced Agni ensures proper interaction between functional regulators (Doṣhas) and structural substrates (Duṣhyas). [2,4] When Agni remains normal, food is transformed into nutritive essence (Āhāra Rasa), which sequentially nourishes each Dhātu. Conversely, impairment of Agni leads to the formation of Āma, defective tissue metabolism, and susceptibility of Duṣhyas to Doṣha aggravation.

Doṣa–DuṣyaSaṃmūrchana

A distinctive contribution of the prakashikavyakhya is its explanation of Doṣha–DuṣhyaSaṃmūrchana, the process through which disease originates. Aggravated Doṣhas alone are insufficient to produce disease. Likewise, healthy tissues do not become diseased unless exposed to disturbed Doṣhas under favourable pathological conditions. Disease therefore develops only when vitiated Doṣhas interact with susceptible Duṣhyas in the presence of impaired Agni and disturbed Srotas. [1,3] This interpretation provides a multidimensional understanding of pathogenesis. Instead of identifying a single causative factor, the commentary recognizes disease as the consequence of interactions among causative factors (Nidāna), Doṣha imbalance, metabolic impairment, tissue susceptibility, and defective transport mechanisms.

Critical Appraisal

The PrakashikaVyakhya enriches the understanding of the AṣṭāṅgaSaṅgraha by integrating grammar, philosophy, and clinical reasoning. Instead of restricting itself to lexical explanation, it elucidates the physiological significance of Doṣa and Duṣya, thereby facilitating practical application in diagnosis and treatment. A major strength of the commentary is its systems-oriented perspective. The body is viewed as an integrated network in which Doṣa, Agni, Dhātu, Mala, and Srotas continuously interact to maintain health. This holistic framework supports individualized assessment and therapy, reinforcing the Ayurvedic principle that treatment should address the patient as a whole rather than merely the disease. From a contemporary viewpoint, these concepts show conceptual similarities to homeostasis, systems biology, and personalized medicine. Nevertheless, such comparisons should be interpreted cautiously, recognizing that Ayurvedic principles arise from a distinct philosophical and epistemological tradition. They should therefore be regarded as conceptual parallels rather than direct scientific equivalence. [5,8]

CONCLUSION

PrakashikaVyakhya commentary provides a comprehensive interpretation of the relationship between Doṣa and Duṣya in maintaining Śarīra. By emphasizing the central role of Agni, sequential Dhātu nourishment, and the concept of Doṣa–DuṣyaSaṃmūrchana, the commentary presents an integrated model of physiology and pathology. Its holistic perspective continues to influence Ayurvedic education, clinical reasoning, and contemporary research, highlighting the enduring relevance of classical Ayurvedic thought in modern healthcare.

ABSTRACT

Non-alcoholic fatty liver disease (NAFLD) is a common metabolic syndrome which involves overaccumulation of lipids in the liver and may evolve to non-alcoholic steatohepatitis (NASH), fibrosis, and cirrhosis. It causes disease through stop and starts interactions between insulin resistance, increased de novo lipogenesis, influx of free fatty acids, oxidative stress, mitochondrial dysfunction and inflammatory signaling pathways. Imbalance of adipokine and gut-liver axis changes, as well as the dysregulation of major metabolic regulators, including AMPK and PPARs, also contribute to the development of the disease process. Today, NAFLD does not have any particular pharmacological therapy, which is why other treatment options should be developed. Biological active compounds derived in plants have also become of interest because they exhibit multi-target properties with antioxidant, anti-inflammatory and lipidlowering properties. Those phytochemicals regulate major pathways including AMPK, PPAR, Nrf2, and NF-kB, which enhance the hepatic metabolism and decrease the disease severity.This shows the molecular pathogenesis of NAFLD and stresses the prospective of medicinal plants as promising therapeutic agents in prevention and treatment of NAFLD.

Keywords: Non-alcoholic fatty liver disease (NAFLD), Insulin resistance, Oxidative stress, Inflammation, Phytochemicals, Medicinal plants, AMPK signaling, PPAR signaling.

INTRODUCTION

In the absence of an underlying etiology (alcohol or medications), non-alcoholicfatty liver disease (NAFLD) is characterized by the existence of macrovesicular steatosis in 5% of hepatocytes. It discusses a broad range of disorders, including fibrosis and cirrhosis, non-alcoholic steatohepatitis (NASH) and non-alcoholic fatty liver (NAFL). NAFLD is now one of the leading causes of chronic liver disease all over the world (1). An increasing frequency and growing prevalence of obesity, metabolic syndromes, and type 2 diabetes will all require hepatic transplantation since NAFLD will become the cause of cirrhosis more than any others in the next decade. However, the heart disease is the most widespread form of death, and few percent of people have fibrosis and hepatologic complications. Much as obesity is said to be the major risk factors in the progression of NAFLD, it still possible to develop NAFLD even amongst non-obese people and individuals who have none of the ingredients of Metabolic Syndrome (2).

The NAFLD development is attributed to a multi-mechanistic disorder of various normal body functions, including those of metabolism, environment, and genetic influence. The underlying pathophysiological process is the disequilibrium between the fat importation and exportation into and out of the liver, which is regulated through a set of various pathways. NAFLD is found to be of a simple severity like steatosis (presence of additional fat in the liver) to NASH, which is characterized by hepatocellular damage and inflammation. The disease may enter the fibrosis stage and ultimately become NASH-related cirrhosis and/or HCC (3) depending on the presence and variety of the concomitant metabolic risk factors. According to recent data provided by GBD in terms of mortality and disability adjusted years, it is evident that the burden of NAFLD is being encountered throughout the world and that it is growing at an alarming pace (4). The NAFLD has characterized by build-up of triglycerides in the liver cells has not caused by too much alcoholic drinking (>30 g/d in men and >20 g/d in women), use of drugs that are known to cause steatosis and chronic liver diseases. Over the last few years, the pathogenesis of NAFLD has gained knowledge and Many of them have been identified which include genetic predispositions, molecular markers, liver damage and comorbid disorders with NAFLD(5). NAFLD, no particular, pharmacologically, approved drugs are available, which means that lifestyle change (diet, exercising) is the main, though not always the effective method.

To treat, or even prevent, liver fibrosis and fat build up, alternative, natural and holistic methods are being sought, including herbal medicine and acupuncture to target metabolic, oxidative and inflammatory pathways (6). Dietary Supplements: Omega-3 fatty acids, probiotics, and vitamin E (case of non-diabetic NASH) can be viewed as complementary ones (7). Weight reduction of up to 5 percent to 10 percent is capable of enhancing MASLD. Nonetheless, the Mediterranean diet is a medicine against liver disease even in the absence of weight loss. Mediterranean diet is also abundant in fructose, vegetables, lean proteins and fats. It contains high levels of fibre, vitamins, minerals and polyphenols, which are plant substances, which hold antioxidant and anti-inflammatory qualities; the diet contains the following foods (8).

PATHOPHYSIOLOGY OF NAFLD (9):

The major cause of non-alcoholic fatty liver disease occurs as a result of the metabolic risks factors including obesity, insulin resistance, high-fat diets, and genetic susceptibility which facilitate the excessive lipid accumulation in hepatocytes results in hepatic steatosis (10). The continuous deposition of fat causes lipotoxicity, mitochondrial dysfunction, and oxidative stress(11). whereas microbiota changes in the gut increase inflammatory signalling by increasing the endotoxin influx (12). The processes provoke the discharge of pro-inflammatory cytokines that cause chronic inflammation, hepatocellular damage, and fibrogenic pathways. This gradual destruction eventually passes through non-alcoholic steatohepatitis (NASH) which is an inflammation and fibrosis of liver and it eventually leads to cirrhosis and hepatic failure (13).

Insulin Resistance Pathway: Central Mechanism

The hepatic insulin resistance that is defined as the failure to suppress gluconeogenesis despite hyperinsulinemia is one of the pathogenic phenomena in NAFLD. In response to physiological stimuli as a result of the insulin binding insulin receptor, the IRS PI3K Akt signaling pathway is excited, which ultimately results in phosphorylation and nuclear exclusion of the gluconeogenic gene promoter glucose-6-phosphatase (G6Pase) and phosphoenolpyruvate carboxykinase (PEPCK), among others [(14)]. The high hepatic lipid synthesis specifically diacylglycerol-releases (DAG) in NAFLD leads to the activation of protein kinase C epsilon (PKC e) that may leads to loss of the insulin receptor kinase activity, and it also suppresses Akt phosphorylation downstream [(15)]. The defective Akt-signaling does not allow the effective inactivation of FOXO1 that contributes to the sustenance of nuclear localization and persistent expression gluconeogenic enzymes that cause the maintenance of high concentrations of hepatic glucose. Parallel to this is the augmented provision of fatty acids by adipose tissue insulin-resistant that further augments the acetyl-CoA hepatic content that activates pyruvate carboxylase in an allosteric manner and augment the gluconeogenic flux. It has been worth indicating that even in the absence of insulin affecting the production of glucose, the lipogenic cueing by SREBP-1c is maintained to a fairly significant extent, which leads to the accumulation of triglycerides and defines the state of selective hepatic insulin resistance that is reflected in NAFLD. Hepatic steatosis and enhanced gluconeogenesis are one connected by these integrated defects in insulin signaling, as evidence of a milk-to-honey relationship between NAFLD and the pathogenesis of type.

De Novo Lipogenesis (DNL) Pathway

One of the major lipogenic transcription factors that are mainly regulated by insulin signaling is SREBP-1c (Sterol Regulatory Element–Binding Protein-1c). Even though insulin is unable to inhibit gluconeogenesis (selective insulin resistance) the SREBP-1c pathway is insulin responsive. Incessant SREBP-1c stimulation boosts the expression of the lipogenic enzymes. This enhances the synthesis of fatty acids despite the already increased hepatic triglyceride stores. This self-contradictory maintenance of lipogenic signaling adds to the steatosis directly. Carbohydrate Response Element-Binding Protein (ChREBP) is an overload glucose-sensitive transcription factor. During high-carbohydrate diets or the intake of fructose: The activation of ChREBP is over-activated, it works in tandem with SREBP-1c and Enhances hepatic DNL independently of insulin. Therefore, insulin and glucose signals intersect to increase lipid production in NAFLD (16). Stimulation of SREBP-1c and ChREBP: Significant Lipogenic Enzymes ACC (Acetyl-CoA Carboxylase) which is an important enzyme in the synthesis of fatty acids is transcribed. They facilitate the conversion of acetyl-CoA to malonyl- CoA. Malonyl-CoA also blocks CPT-1 (carnitine palmitoyltransferase-1), which, in its turn, suppresses mitochondrial 2-oxidation. This is the slowing pace of fatty acid synthesis. In turn, this causes a reduction of fatty acid oxidation and growth of fatty acids. These two effects trigger lipid accumulation. Fatty Acid Synthase (FAS). It helps in condensing acetyl malonyl Co A with malonyl CoA. In this way palmitate (C16:0) and Palmitate is more highly esterified into Triglycerides. In NAFLD: FAS is significantly upregulated and provokes saturated fatty acid in the blood. SCD1 (Stearoyl-CoA Desaturase-1) It Breaks down saturated fatty acids into monounsaturated fatty acids. It is Necessary in formation of triglycerides and Supplies substrates to the lipid droplets formation. High levels of SCD1 It Stimulates triglyceride production, as well as helps to store lipids in hepatocytes. Triglyceride Accumulation Co-activation of SREBP-1c (insulin-stimulated) and ChREBP (glucose-stimulated) will enhance ACC, FAS, SCD1 which Results in Growth of fatty acid synthesis, Decreased 2-oxidation (through malonyl-CoA inhibition of CPT-1), Enhanced triglyceride esterification into triglycerides and Lipid droplet formation in hepatocytes. The results of this process include hepatic steatosis, which is the typical feature of NAFLD (17).

Free Fatty Acid (FFA) Flux &Lipotoxicity

The surplus FFA could be due to obesity, excessive fatty food intake, or malfunctioning of adipose tissue shown by the lessening of FFA deposition and augmented fatty acid discharges of adipocytes. The term lipotoxicity is used to describe harmful processes in non-adipose tissues, which are caused by the surplus of FFA, including obesity, endoplasmic reticulum stress, inflammation, or insulin resistance. Although people have made numerous attempts to assign the process of toxic free fatty acid actions to a certain metabolic pathway, it demonstrates that lipids interfere with the cellular functions in many ways, which leads to the fact that there are many disturbances simultaneously,

creating the possibility of a branched vicious cycle of self-propagating lipotoxic events. Hence, the fact that lipotoxicity alleviation appears to be incredibly challenging, as silence of a single pathogenic signal cascade does not guarantee that further outruptions will not disrupt the cell activity. Apparently, the most qualitative way is to prevent toxic implications by decreasing excess FFA (18).

Oxidative Stress Pathway

Besides the role of hepatocytes, non-parenchymal cells are also involved in steatosis, inflammation, and fibrosis facilitating the transition to non-alcoholic steatohepatitis (NASH), as well as hepatocellular carcinoma: Kupffer cells (KCs), hepatic stellate cells (HSCs), and liver sinuoid endothelial cells. Overconsumption of lipids alters the redox homeostasis in the liver and increases the mitochondrial 2 oxidation, which results in the generation of reactive oxygen species (ROS) in the mitochondria, endoplasmic reticulum, and peroxisomes. The high level of ROS results in oxidative stress, mitochondrial dysfunction, and lipid peroxidation that damage hepatocytes and cause inflammations. Oxidative stress likewise triggers Kupffer cells utilizing mitochondrial DNA-induced signals and stimulates hepatic stellate cells activation and fibrosis via TGF-b and so forth. Altogether, the ROS-mediated oxidative stress assumes an important role in the pathogenesis and pathophysiology of NAFLD. Consequently, antioxidant treatments such as flavonoids, curcumin, vitamin E, metformin, and coenzyme Q10 have been studied concerning their ability to lessen the effect of oxidative damage and enhance liver pathology in NAFLD models(19). The Nrf2 signal transducer, the Keap1-Nrf2, is an essential cellular defense response to oxidative stress because the activation of Nrf2 triggers the expression of antioxidant and phase II detoxification enzymes that make hepatocytes less sensitive to reactive oxygen species (ROS) and electrophilic damage. This defence action assists in restraining oxidative damage, inflammation and fibrosis in the progression of liver disease. Yet, the clinical effectiveness of Nrf2 agonists in the treatment of NAFLD has not been well-supported with clinical evidence and a large-scale clinical trial is needed to assess its effectiveness and safety. (20).

Mitochondrial Dysfunction

Dysfunction in mitochondria is a serious pathogenic agent of NAFLD. At the initial phases of the disease, the mitochondria respond to the surplus lipid levels by increasing fatty acid 2-oxidation in order to cope with the higher hepatic lipid loads. Nevertheless, a continuous lipid overload ultimately overburdens the mitochondrial capacity leading to ineffective electron transport chain (ETC) operation and over-generation of reactive oxygen species (ROS). This is a mitochondrial dysfunction that causes low efficiency of cells in production of adenosine triphosphate (ATP) despite the availability of sufficient substrates. Moreover, mitochondrial quality control pathways, especially malfunctioning mitophagy, were shaken, and impaired mitochondria that produce large quantities of ROS are accumulated in hepatocytes, which facilitates inflammation and fibrogenesis. Long-term production of ROS also causes oxidative damage to mitochondrial DNA (mtDNA), proteins and lipids which further worsens mitochondrial dysfunction. Besides, lipotoxic intermediates like ceramides and the build-up of lipotoxic intermediates aggravates mitochondrial stress and damages oxidative metabolism, which strengthens hepatocellular injuries and supports the development of NAFLD (21).

PINK1–Parkin pathway

Major role in quality control of mitochondria in mitophagyic destruction of damaged mitochondria. Mitochondrial membrane depolarization, in lipid overloaded hepatocytes in NAFLD, stabilizes PTEN-induced kinase 1 (PINK1) on outer mitochondrial membrane, and suppresses and activate E3 ubiquitin ligase Parkin. Ubiquitinated mitochondrial outer membrane proteins by activated Parkin allow autophagy adaptor proteins to be recruited, including that of p62 and LC3, and thus the damaged mitochondria to be engulfed by autophagosomes and degraded by lysosomes. Disruption of this pathway causes dysfunctional mitochondria to build up, the production of reactive oxygen species (ROS) is elevated, and hepatocellular injury is enhanced, which are factors that lead to the procession of NAFLD (22).

ER Stress Pathway in NAFLD

The problem of endoplasmic reticulum (ER) stress is major key factor that lead to the evolution deterioration of non-alcoholic fatty liver disease (NAFLD). ER has an important part inthe protein folding, lipid synthesis, and calcium homeostasis of hepatocytes. Excess lipid buildup, influx of free fatty acids, oxidative stress, and metabolic overload in NAFLD result in the destabilization of the ER homeostasis in this condition, resulting in the buildup of unfolded or misfolded proteins in the ER lumen. The described condition triggers a protective signaling system referred to as the unfolded protein response (UPR). Three key ER transmembrane sensors mediate the UPR and they include protein kinase RNA-like ER kinase (PERK), inositol-requiring enzyme-1 (IRE1), and activating transcription factor-6 (ATF6) (23).

PERK–eIF2α Pathway

When activated, PERK is autophosphorylated and consequently phosphorylates eukaryotic initiation factor-2 α (eIF2 E). Phosphorylation of eIF2 8 inhibits general protein translation, hence decreasing the movement of new proteins into the ER to relieve the protein-folding strain. Nevertheless, this pathway selectively facilitates the translation of activating transcription factor-4 (ATF4), which governs the amino acid metabolism, antioxidant defense and apoptotic genes. Continuous ATF4 activation leads to the expression of the pro-apoptotic transcriptional factor C/EBP homologous protein (CHOP) that facilitates apoptosis in hepatocytes in the case of chronic ER stress (24).

IRE1–XBP1 Pathway

IRE1 is an endoribonuclease and ER-resident kinase that is activated by the response of ER stress by oligomerization and autophosphorylation. IRE1 activates the unconventional splicing of X-box binding protein-1 (XBP1) mRNA to produce a transcriptionally active form of XBP1, the XBP1s. XBP1s controls expression of ER-associated protein degradation (ERAD), lipid synthesis, and membrane expansion in the ER, thus improving the protein-folding capacity of the ER. Nevertheless, a long-term promotion of IRE1 may also trigger the c-Jun N-terminal signaling, which also leads to inflammation and insulin resistance in the liver in NAFLD.

ATF6 Pathway

Another stress sensor of the ER is the ATF6 which, when activated, moves out of the ER to the Golgi apparatus. Site-1 and site-2 proteins cleave ATF6 in the Golgi releasing an active fragment of a transcription factor. The fragmented ATF6 is then translocated to the nucleus where it activates the transcription of ER chaperone proteins like GRP78 and the ER-associated degradation system. This process promotes the ability of ER to fold and process proteins in conditions of stress. Though they act as adaptive mechanisms to regain ER homeostasis, chronic ER stress leads to the activation of the pro-apoptotic transcription factor C/EBP homologous protein (CHOP), which stimulates the process of hepatocyte apoptosis and may cause inflammation and the progression of NAFLD to non-alcoholic steatohepatitis (25).

Inflammatory Signaling Pathways

Inflammatory reactions are part of the innate immune response to pathogens and can be triggered by different pathogenic molecules such as bacterial and viral antigens, fungal spores, and protozoan amoebas. In humans Inflammatory Signaling Pathways Inflammatory reactions constitute the innate immune response to pathogens and may be induced by various pathogenic molecules, including bacterial and viral antigens, fungal spores and protozoan amoebas.

NF-κB Inflammatory Pathway

In NAFLD, total lipid heads and intestinal endotoxins trigger Toll-like receptor-4 (TLR4) signaling in hepatocytes and Kupffer cells that causes the activation of Nuclear Factor-B(NF-B). NF-B translocation to the nucleus facilitates the expression of pro-inflammatory cytokines such as tumour necrosis factor- α (TNF- α) and interleukin-6 (IL- 6) and interleukin-10 (IL- 10), facilitating the inflammation of the liver and the development of simple steatosis into NASH (26).

c-Jun N-terminal kinase Signaling Pathway

JNK is essential in the development of NAFLD. JNK activates through lipotoxicity, oxidative stress, and inflammatory cytokines and phosphorylates insulin receptor substrate -1 (IRS-1) on serine residues, which inhibits insulin signaling and worsens hepatic insulin resistance and lipid storage [(27)].

NLRP3 Inflammasome Pathway

NLRP3 inflammasome is one of the key mediators of hepatic inflammation in NAFLD. The NLRP3 complex is triggered by lipotoxic stress and mitochondrial dysfunction and that leads to caspase-1 activation. Caspase-1 is activated, releasing pro-interleukin-18 and pro-interleukin-1B to mature cytokines to enhance the effect of inflammatory signaling andcause hepatocellular injury in the liver and also get fibrosis[(28)].

Adipokine Dysregulation

The dysregulation of adipokine is an important pathogenesis of NAFLD. In metabolic syndrome and obesity, has a dysfunction of the adipose tissue that leads to decreased release of the anti-inflammatory adipokine adiponectin and elevated release of the pro-inflammatory adipokines leptin and resistin[(29)]. Adiponectin normally triggers the AMP-activated protein kinase (AMPK) signaling in hepatocytes that promotes the fatty acid burning process and inhibits the lipid build-up in the liver. However, low adiponectin concentration degrades the activation of AMPK, leading to low 2-oxidation and high deposition of triglyceride in the liver. Conversely, high leptin and resistin facilitate inflammatory messages and insulin resistance, which tighten hepatic steatosis and leads to the development of NAFLD [(30)].

AMPK Pathway suppression

AMP-activated protein kinase (AMPK) is a metabolic powerhouse, which governs hepatic lipid metabolism and ensures metabolic homeostasis. In control physiological state, AMPK is activated according to the effect of an elevation in the cellular balance of AMP/ATP and is involved in the restoration of the balance of energy by promoting the activity of catabolic pathways and suppressing the activity of anabolic processes. The activated AMPK in hepatocytes phosphorylates and suppresses acetyl-CoA carboxylase (ACC) leading to the decreased production of malonyl-CoA, one of the major fatty acid synthesis precursors. A low malonyl-CoA concentrations deregulate the inhibition of carnitine palmitoyltransferase-1 (CPT-1) so as to increase fatty acid oxidation before the mitochondrion. Moreover, AMPK inhibits the de novo lipogenesis in hepatocytes by inhibiting transcriptional activities of lipogenic regulators, including sterol regulatory element-binding protein-1c (SREBP-1c) (35). Nevertheless, chronic nutrient overload, insulin resistance and lipotoxicity in NAFLD decrease AMPK activation and disinhibit ACC activity, malonyl-CoA, and decrease fatty acid oxidation. As a result, elevated lipogenesis and reduced lipid oxidation favor the build-up of triglycerides in hepatocytes, which add to hepatic steatosis and NAFLD advancement [(31)].

PPAR Signaling Pathway

Peroxisome proliferator-activated receptors (PPARs) are ligand-activated nuclear transcription factors which control lipid metabolism, energy homeostasis and liver inflammatory responses. Out of the three isoforms PPAR-α and PPAR-g as its pathophysiology in NAFLD. PPAR-alpha ishighly expressed hepatic protein that acts as a major controller of the peroxisomal and mitochondrial processes of fatty acid 2-oxidation. Once activated, PPAR-a heterodimerizes with the retinoid X receptor (RXR) and binds to peroxisome proliferator response elements (PPREs) in the promoter regions of target genes dealing with fatty acid transport and oxidation such as carnitine palmitoyltransferase-1 (CPT-1), acyl-CoA oxidase and medium-chain acyl-CoA dehydrogenase. This transcriptional control increases fatty acid absorption and oxidation, thus stopping lipid build-up in the hepatocytes. In NAFLD, however, a low expression or disturbed function of PPAR- a reduces the hepatic capacity of 2-oxidation, which causes the deposition of triglycerides and free fatty acids in the liver. Conversely, PPAR-g is a gene primarily found in the adipose tissue, and might be aberrantly expressed in hepatocyte during obesity and metabolic stress. PPAR-gamma activation enhances adipogenes, lipid uptake and triglyceride storage gene transcription, fatty acid transport proteins and adipocyte-specific genes. Hepatic PPAR-g could be increased thus supporting lipid deposition and leading to hepatic steatosis and insulin resistance. Disturbance of the PPAR signaling, therefore, destabilizes the

balance between the oxidation and storage of lipids, which is one of the central mechanisms in the hepatic accumulation of fat and the development of NAFLD (32)(33).

Gut-Liver Axis Pathway

The gut-liver axis has a significant role to play in pathogenesis of NAFLD. Intestinal barrier disruption and rising intestinal permeability are caused by changes in the composition of gut microbiota, otherwise known as dysbiosis. This disease promotes the translocation of intestinal luminal bacteria products like lipopolysaccharide (LPS) into the portal circulation. High levels of circulating LPS cause the Toll-like receptor-4 (TLR4) signaling in hepatic Kupffer cells and hepatocytes, which then leads to downstream inflammatory processes like the activation of NF-kB and the generation of pro-inflammatory cytokines, such as TNF- a and IL- 6. Its ensuing inflammatory reaction is a cause of hepatic steatosis, insulin resistance and the evolution of NAFLD to non-alcoholic steatohepatitis (NASH) (34)(35).

Apoptosis Pathways in NAFLD

Hepatocyte apoptosis plays a key role in liver damage and disease pathogenesis in NAFLD. Heptocytes are activated through the programmed cell death pathways by metabolic stress, lipotoxicity, oxidative stress, and mitochondrial malfunction. There are two main mechanisms of Apoptosis in NAFLD the first is the intrinsic (mitochondrial) Apoptosis that is mainly activated by intracellular stresses like lipotoxicity, oxidative stress, mitochondrial dysfunction, and endoplasmic reticulum stress. Various stressors disrupt the balance between the pro-apoptotic and anti-apoptotic Bcl-2 protein family members. The effect of NAFLD on the permeabilization of the mitochondrial outer membrane is triggered by the up-regulation of pro-apoptotic proteins such as BAX and Bak and the down-regulation of anti-apoptotic proteins such as Bcl-2 and Bcl-xL. The release of cytochrome-c into the cytoplasm of the mitochondrion during the intermembrane space is the outcome of this action. The cytochrome-c then combines with procaspase-9 and apoptotic protease activating factor-1 (Apaf-1) to create the apoptosome complex which activates caspase-9. Subsequently, caspase-9 is indirectly activated and this triggers downstream executioner caspases such as caspase-3 and caspase-7, and eventually cause hepatocyte apoptosis and liver damage (36). Extrinsic (Death Receptor) Apoptosis Pathway Other than mitochondrial Apoptosis, death of hepatocytes in NAFLD may also result due to the activation of extrinsic apoptotic pathway, which is activated by hepatocyte death receptors on the hepatocyte membrane. The Fas receptor (CD95)/ Fas ligand (FasL) signaling pathway is one of the most crucial death receptor systems that are affected by NAFLD. Recruitment of the Fas-associated death domain (FADD) adaptor protein and trimerization of receptor FasL binding to the Fas receptor. The complex further that leads to the activation of caspase-8 which triggers a caspase cascade which causes activation of caspase-3 and subsequent apoptosis. Moreover, activated caspase-8 may be able to cleave the Bcl-2 family protein Bid, which connects the extrinsic pathway to the mitochondrial apoptosis pathway and enhances the death of hepatocytes (37).

Fibrosis Mechanism NAFLD to NASH

The liver fibrosis is an important pathological process that occurs in the conversion of non-alcoholic fatty liver disease (NAFLD) to non-alcoholic steatohepatitis (NASH) and advanced liver disease. Constant hepatocellular damage, oxidative pressure, lipotoxia, and the release of proinflammatory cytokines activate hepatic stellate cells (HSCs) that are the key mediators of hepatic fibrogens. In healthy physiological conditions, HSCs are in a resting condition and act as vitamin A storing cells located in the liver. In chronic hepatic injury in NAFLD, however, hepatocyte apoptosis and inflammatory signaling induces the transdifferentiated HSCs into myofibroblast-like cells (38).

The transforming growth factor- β (TGF- B)/SMAD signaling pathway is one of the most significant profibrogenic pathways that are activated by HSC. TGF-B, which is released by hepatocytes damaged, acts on the Kupffer cells and inflammatory cells, binds to the TGF-B receptors on hepatocyte stellate cells, and promotes phosphorylation of intracellular molecules of signaling SMAD2 and SMAD3. These phosphorylated SMAD proteins subsequently form complexes with SMAD4 and translocate to the nucleus, in which they control the expression of fibrogenic genes. This signaling pathway enhances the production and deposition of extra cellular matrix (ECM) components especially collagen type I and type III, these are the major structural proteins that cause liver fibrosis.

Besides heightened synthesis of collagen, activated HSCs also have the expression of alpha-smooth muscle actin (α-SMA) which is a typical differentiation and contraction marker of my fibroblasts. The over-deposition of extracellular matrix proteins and elevated levels of α-SMA over expression interfere with the normal liver architecture and play a role in the formation of fibrosis. Moving on to a progressive form of fibrosis, eventual cirrhosis and hepatocellular carcinoma (HCC) risk in patients with progressive NAFLD develop. (39)

Plant based Therapy in NAFLD

In treatment of non-alcoholic fatty liver disease, plant-based foods and their bioactive compounds have been urged to applyfavorable effects through the following impacts, enhancing the hepatic steatosis, decreasing the oxidative stress and inflammation, and modulating metabolic pathways (40). Natural antioxidants can prevent the appearance and development of NAFLD through various mechanisms, which inhibit the formation of ROS and minimize the destruction of hepatic cells. Bioactive extracts of vegetable origin that exhibit high antioxidant activity have been shown to significantly increase biomarkers of hepatic steatosis, lipid metabolism, and inflammation in NAFLD models (41). Natural antioxidants can prevent the evolution of NAFLD by constraining the build-up of reactive oxygen species and decreasing the hepatic cellular damage (42). Based on experimental studies, NAFLD is enhanced through the use of herbal extracts in inhibiting the inflammation, reducing oxidative stress, increasing lipid metabolism, enhancing insulin sensitivity and apoptosis and enhancing metabolic pathways that play a role in disease progression. Plant extracts can be an effective treatment of non-alcoholic fatty liver disease as bioactive compounds can reduce lipid synthesis and increase fatty-acid metabolism, which is a multifaceted treatment (43),(44).

Medicinal Plants Used in NAFLD (Table 1 – Table 7)

CONCLUSION

Non-alcoholic fatty liver disease (NAFLD) is a complex metabolic state that develops as a result of the complex interplay of insulin resistance, lipid metabolism disorders, oxidative stress, inflammation, and fibrogenic triggering pathways. By facilitating the excessive influx of free fatty acids and prolonged stimulation of de novo lipogenesis mediated by transcription factors such as SREBP-1c and ChREBP, hepatic insulin resistance is at the heart of the matter as it causes triglycerides to build up inside the hepatocytes.Further development of NAFLD is also promoted by mitochondrial dysfunction caused by lipotoxicity and overproduction of reactive oxygen species, which interfere with cellular homeostasis initiating oxidative stress. At the same time, the pathways of ER stress and misfolded protein response due to the causes of hepatocyte apoptosis and metabolic imbalance. NF-KB, JNK, and NLRP3 inflammatory signaling response lead to the augmentation of hepatic inflammation, whereas the deregulation of major metabolic regulators, like AMPK and PPAR, lessens fatty acid oxidation and increases lipid deposition. Moreover, the imbalance in adipokines and gut-liver axis dysregulation enhance insulin resistance and inflammation, which increase disease progression to fibrosis through the action of TGF-B/SMAD in hepatic stellate cell activation.
Plant-based bioactive compounds can be useful in the control of NAFLD, and they mainly affect these mechanisms. Their positive effects can be explained mostly by the regulation of metabolic pathways (AMPK and PPAR activation), inhibition of lipogenesis (SREBP-1c inhibition), stimulation of antioxidant defenses (Nrf2 activation), and the inhibition of inflammatory and fibrogenic signal transduction.

The development of NAFLD is managed by coupled and interconnected molecular pathways and the therapeutic measures to be taken must be aimed at multi-target modulation of these mechanisms. Further insights into these pathways will offer a solid foundation on the creation of specific interventions that could be used to prevent the further evolution of diseases and enhance clinical outcomes.

Table 1.AMPK Activators (Metabolic Master Switch): Activate fatty acid oxidation & reduce lipid synthesis.

Plant	Active constituent	Mechanism of action
Scientific name: *Vitis vinifera* **Family:** Vitaceae **Common name:** Grape (45)	Resveratrol, Proanthocyanidins, Anthocyanins.	✓StimulatesAMPK signalingwhichinhibits SREBP-1c & ACC (lipogenesis) ✓Inhibits the liver de novo lipogenesis. ✓Inhibits TLR4 due to inflammation. ✓ Inhibits NLRP3 inflammasome ✓ Anti-fibrotic through TGF-β inhibition
Scientific name: *Allium sativum* L. **Family:**Amaryllidaceae **Common name:** Garlic(46)	Allicin, Ajoene, Diallyl disulfide, S-allylcysteine.	✓Anti-inflammatory effect and antioxidant effect. ✓Regulates lipid metabolism. ✓Enhances insulin resensitization.
Scientific name: *Cinnamomum verum J. Presl* **Family:** Lauraceae **Common name:** Ceylon cinnamon (47)	Cinnamaldehyd, Eugenol, Procyanidins.	✓ Enhances insulin signaling. ✓Inhibits liver lipogenesis. ✓ Anti-inflammatory effectand antioxidant effect.

Scientific name: *Coptis chinensis Franch.* **Family:** Ranunculaceae **Common name:** Chinese goldthread / Huang Lian (48)	Berberine (major bioactive alkaloid), Coptisine, Palmatine, Epiberberine, Jatrorrhizine	1. AMPK activation: increase oxidation of fatty-acid, lower lipogenesis 2. Insulin sensitivity: ↑ insulin signaling, high glucose metabolism 3. Anti-inflammatory: ↓ TNF-α and IL-6 4. Gut modulation: increases the microbiota and reduces endotoxemia of the metabolism.

Table 2 . PPAR-α activators (β-Oxidation Enhancers): Increase fatty acid breakdown.

Scientific name:*Camellia sinensis* (L.) Kuntze **Family:**Theaceae **Common name:** Green tea (49)	Epigallocatechin gallate, Epigallocatechin, Epicatechin gallate, Epicatechin, Catechin and tannic acid.	1. Tea polyphenols increase antioxidant enzymes and inhibitor of oxidation. 2. EGCG regulates GSK-3β and blocks injury signaling pathways. 3. Inhibits MMP-1 and ERK/MEK/Src stimulated by TNF-a. 4. Activates cardioprotective and PPARg - cytoprotective effects.
Scientific name *Myrica rubra Siebold &Zucc.* **Family:** Myricaceae **Common name** Chinese bayberry / Yumberry. (50)	Myricetin, Anthocyanins, Polyphenols.	1. Strong antioxidant flavonoid compounds suppress the fat build up in the liver. 2. Increases the fatty-acid oxidation. 3. Inhibits proinflammatory processes
Scientific name:*Coffea arabica* **Family**: Rubiaceae **Common Name:** Coffee (51)	Caffeine, Chlorogenic acids, Diterpenes (cafestol, kahweol), Polyphenols.	1.↑ Defense of liver redox-antioxidant (↑ GSH, SOD) 2. ↓ Hepatic fat accumulation 3. ↓ Lipogenesis (↓ SREBP-1c) 4. ↑ β-oxidation (↑ PPAR-α) 5. ↓ Inflammation (↓ TNF-α, IL-6) 6. ↓ Fibrosis progression (↓ TGF-β signaling) 7. Enhances the response to insulin.
Scientific name *Phyllanthus emblica* L. **Family:** Phyllanthaceae **Common name** Amla / Indian gooseberry (52)	Ascorbic acid, Gallic acid, Ellagic acid, Emblicanin A & B, Flavonoids.	1. High antioxidant activity decreases hepatic oxidative stress. 2. Enhanced Lipid metabolism and insulin disability. 3. Inhibits proinflammatory cytokines of steatohepatitis.

Table 3. SREBP-1c Inhibitors (Lipogenesis Suppressors): Reduce triglyceride synthesis.

Scientific name: *Zingiber officinale* **Family:**Zingiberaceae **Common Name:** Ginger, Ginger root (53)	Gingerols (6-gingerol, 8-gingerol), Shogaols (6-shogaol), Zingiberene, Phenolic acids.	1. ↓ Hepatic inflammation (↓ NF-κB, ↓ TNF-α, ↓ IL-1β) 2. ↓ Lipogenesis (↓ SREBP-1c, ↓ ACC) 3. ↑ β-oxidation (↑ PPAR-α, ↑ CPT1) 4. ↓ Oxidative stress (↓ MDA, ↑ SOD) 5. ↑ Insulin sensitivity 6. ↓ Fibrosis (↓ TGF-β signaling)

Scientific name: *Portulaca oleracea* **Family:**Portulacaceae **Common name:** Purslane (54)	Omega-3 fatty acids Flavonoids Alkaloids	1. High in omega-3 - decreases the synthesis of triglycerides. 2. Decreases TNF-α and CRP 3. Increases the insulin sensitivity 4. Inhibits oxidative stress 5. Suppresses lipidogenicactivities
Scientific name: *Olea europaea* **Family:** Oleaceae **Common name:** Olive (58)	Oleuropein, Hydroxytyrosol, Oleic acid.	✓Oleuropein prevents lipid concentration in liver cells. ✓Enhances PPAR-a expression ✓Suppresses SREBP-1c ✓Cellular oxidative stress is suppressed through Nrf2. ✓Enhances the bowel flora balance. ✓Reduces the levels of hepatic fibrosis.
Scientific Name *Nelumbo nucifera Gaertn.* **Family** Nelumbonaceae **Common Names** Sacred lotus, Indian lotus, Kamal, Lotus root (59)	Polyphenols (gallic acid, catechin), Flavonoids (isoquercitrin, quercetin derivatives), Alkaloids, Tannins.	✓Inhibits lipidogenicity and lipogenic genes. ✓serum adiponectin (prevention of NAFLD) ✓Decreases cytokines of inflammation like TNF-a. ✓Enhances accumulation of triglycerides in the liver. ✓Agent of antioxidant hepatic protection.

Table 5. NF-κB Inhibitors (Anti-Inflammatory): Suppress pro-inflammatory cytokines (TNF-α, IL-6).

Scientific name: *Rhus coriaria* **Family:**Anacardiaceae **Common name:** Sumac (60)	Gallic acid Anthocyanins Tannins	1. possesses polyphenolic antioxidant. 2. Reduces hepatic ROS 3. Improves lipid metabolism 4. Anti-inflammatory action 5. Modulates gut microbiota
Scientific name:*Phyllanthus niruri*L. **Family**: Phyllanthaceae **Common names:** Stonebreaker, Chanca piedra. (61)	Major compounds identified include ellagic acid and phyllanthin, along with phenolic and flavonoid components.	1. Enhances liver systemic insulin resistance and signalling. 2. Lessens steatosis and fibrosis genes through gene down-regulation which relieves inflammation and fat build-up. 3. Shows antiangiogenic action, which aids in controlling the growth of adipose tissues and secretion of adipocytokines. 4. Inhibits pancreatic lipase, cholesterol micellization, and α -glucosidase, which adds to the enhancement of lipid metabolism.
Scientific name:*Glycyrrhiza glabra* L. **Family:** Fabaceae **Common name:**Licorice / Liquorice	Glycyrrhizin (glycyrrhizic acid) - pharmacological compound. Glycyrrhetinic acid,	1. Anti-inflammatory: Blocks NLRP3 inflammasome, steatosis, inflammation, and fibrosis of the liver. 2. Bile Acid & Metabolic Regulation: Recover receptors in the liver and decreases the bile acid immune in the serum.

(62)	Liquiritin, Liquiritigenin, Flavonoids and saponins.	3. Changing the Microbiota of the gut: Reduces hepatic triglycerides and changes gut microbial population.

Table 6 Gut–Liver Axis Modulators: Improve microbiota & reduce endotoxin load.

Scientific name: *Cichorium intybus* **Family:** Asteraceae **Common name:** Chicory (63)	Inulin, Chicoric acid, Polyphenols	1. Insulin enhances the microflora. 2. Reduces the hepatic fat accumulation. 3. Inhibits the effect of cytokines. 4. Enhances the metabolism of glucose.
Scientific name: *Lyciumbarbarum* **Family:** Solanaceae **Common name:** Goji berry (64)	Lyciumbarbarum polysaccharides, Carotenoids, Flavonoids	1.Activates AMPK 2. Reduces oxidative stress 3. Anti-fibrotic throughTGF-β inhibition. 4. Enhances resistance of insulin. 5. Improves the activity of mitochondria.
Scientific name: *Portulaca oleracea* **Family:**Portulacaceae **Common name:** Purslane (65)	Omega-3 fatty acids Flavonoids Alkaloids	1. High in omega-3 - suppresses the production of triglycerides. 2. Decreases TNF-a and CRP 3. Enhances the sensitivity to insulin. 4. Inhibits oxidative stress 5. Downregulatory of lipogenic enzymes.
Scientific name *Allium sativum* L. **Family** Amaryllidaceae **Common name** Garlic (66)	Allicin, Ajoene, Diallyl disulfide, S-allylcysteine.	✓Anti-inflammatory and antioxidant effects. ✓Regulates lipid metabolism. ✓Enhances the insulin resistance.

Table 7. Insulin Signaling Improvers (PI3K/Akt Pathway)

Scientific name: *Berberis vulgaris* L. **Family**: Berberidaceae **Common name**: Barberry / European barberry (67)	Berberine (primarybioactive alkaloid) Berbamine, Palmatine, Oxyacanthine, Phenolic compounds.	1.Metabolic regulation Berberine enhances lipid metabolism, insulin resistance, and liver functional indexes of fatty liver disease. 2. Antioxidant regulator Nrf2 which is down-regulated in the fatty liver was recovered following the berberine treatment.
Scientific name: *Panax ginseng* C.A. Meyer **Family:**Araliaceae **Common name:** Asian ginseng, Korean ginseng (68)	Ginsenosides (Rb1, Rg1, Rg3, Rd, Re, etc.) triterpene saponins, Polysaccharides, Peptides, Polyacetylenes, Flavonoids, Essential oils.	1. Improves insulin signaling 2. Activates AMPK & PPAR-α produces hepatic fat 3. Inhibits NF-κBthat reduces inflammation 4. Stimulates Nrf2 → ↓ oxidative stress.

Scientific name: *Glycine max* **Family:** Fabaceae **Common name:** Soybean (69)	Isoflavones (genistein, daidzein), Soy protein, Phospholipids.	1.Isoflavones activate PPAR-γ 2. Minimize lipogenesis genes in the liver. 3. Enhance insulin receptor substrate signalling. 4. Increase adiponectin 5. Anti-oxidative effect through glutathione increase.

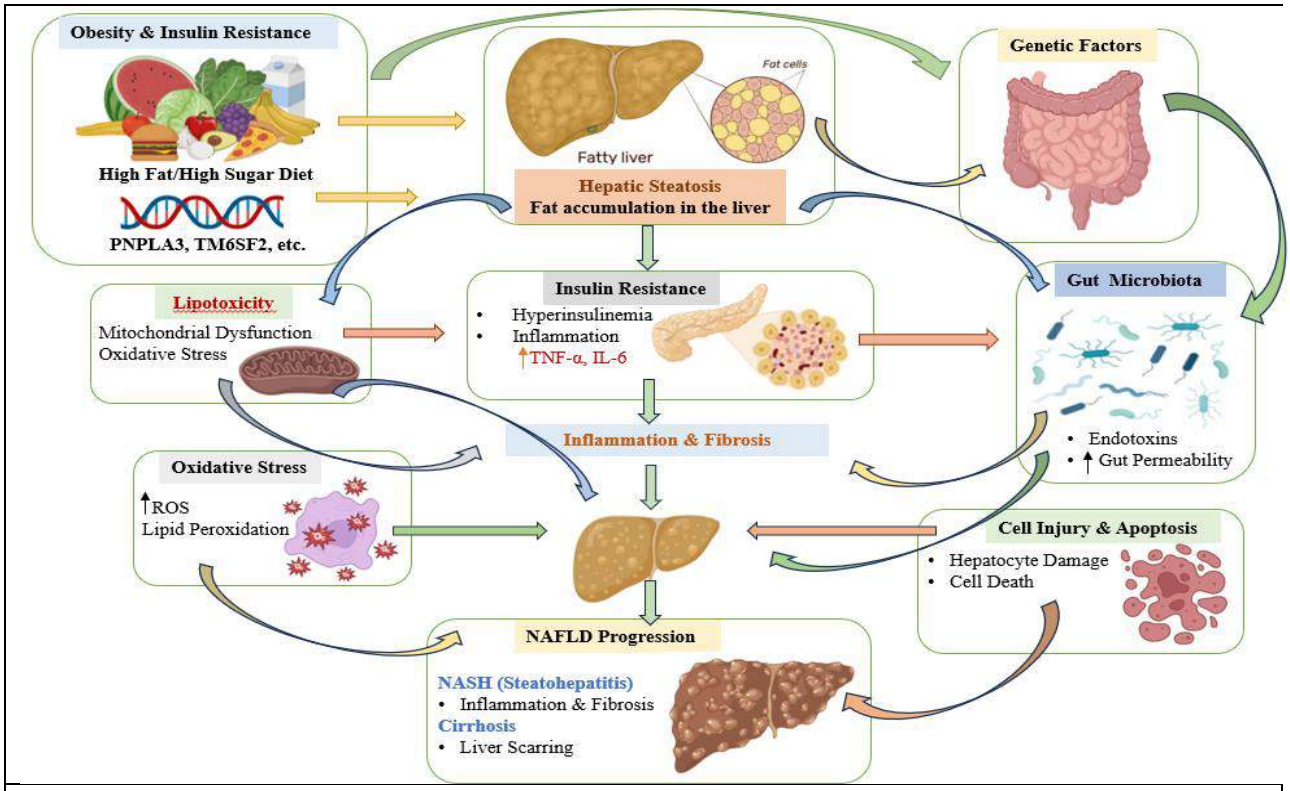

Fig 1: Schematic of the pathophysiological development of non-alcoholic fatty liver disease from hepatic steatosis to fibrosis and cirrhosis.

ABSTRACT

This paper presents an approximate analytical solution to a Susceptible–Infected (SI) epidemic model with a heterogeneous transmission rate using a New Approach to the Homotopy Perturbation Method (HPM). The proposed approach provides a clear description of the temporal evolution of susceptible and infected populations and their interactions within the population. The analytical results are validated through comparison with numerical simulations, showing good agreement between the two approaches. The findings demonstrate the effectiveness of the proposed method in analyzing infectious disease dynamics and provide valuable insights into the influence of model parameters on the evolution of susceptible and infected populations.

Keywords: Susceptible–Infected (SI) model; Heterogeneous transmission rate; New Approach to the Homotopy Perturbation Method; Approximate analytical solution; Numerical simulation.

INTRODUCTION

The study of infectious disease dynamics through mathematical modelling has gained considerable importance in recent years. Mathematical models provide valuable insights into the transmission and progression of infectious diseases within populations and can support the development of effective prevention and control strategies. Among the various compartmental models used in epidemiology, the Susceptible–Infected (SI) model is one of the

fundamental frameworks for describing disease transmission. The foundations of mathematical epidemic modelling were established by W. O. Kermack and A. G. McKendrick, whose pioneering work laid the groundwork for modern compartmental approaches. In the classical SI model, the population is divided into two compartments according to disease status: susceptible and infected individuals. Interactions between these two groups lead to a system of coupled nonlinear ordinary differential equations that describes the evolution of the disease over time. The dynamics of an SI system are influenced by several important epidemiological parameters, including the transmission rate, recovery rate, and natural birth and death rates. Changes in these parameters can substantially affect the rate of disease transmission and its long-term behaviour within a population. However, because the governing equations are nonlinear, obtaining exact analytical solutions is often challenging. Consequently, several analytical and semi-analytical techniques have been developed to obtain approximate solutions to nonlinear differential equations arising in epidemic modelling.

Among these techniques, the Homotopy Perturbation Method (HPM), introduced by Ji-Huan He, has emerged as an effective approach for solving a wide range of nonlinear problems [2–8]. The method combines the principles of homotopy theory with classical perturbation techniques to construct approximate analytical solutions without requiring the presence of a small perturbation parameter. Owing to its relative simplicity, computational efficiency, and rapid convergence, HPM has been successfully applied to nonlinear problems in various fields, including Biology, Physics, and Engineering. Several other analytical and homotopy-based techniques have also been developed for addressing nonlinear systems. These include the Homotopy Analysis Method (HAM) [9], the Adomian Decomposition Method (ADM) [10], Akbari–Ganji's Method [11], and the New Homotopy Perturbation Method (NHPM) [12–27]. Such methods provide alternative approaches for obtaining approximate solutions to nonlinear models. In particular, NHPM offers an efficient framework for constructing approximate solutions by reducing nonlinear problems to a sequence of more manageable equations. This makes it particularly useful for studying complex biological and epidemiological systems. In the present work, a nonlinear SI epidemic model incorporating natural birth and death rates is considered. The resulting system of coupled nonlinear differential equations is investigated using the Homotopy Perturbation Method to derive approximate analytical expressions for the susceptible and infected populations. The accuracy of the analytical solutions is evaluated through comparison with numerical simulations carried out using MATLAB. The good agreement between the analytical and numerical results demonstrates the effectiveness of the proposed approach in describing the dynamics of the SI epidemic model and underscores its potential for analysing nonlinear epidemiological systems.

Mathematical Formulation of the Problem

The model under consideration [1] is given by,

$$\frac{dI}{dt} = \beta SI - (\gamma + \mu)I \quad (1)$$

$$\frac{dS}{dt} = -\beta SI - \mu S + \mu \quad (2)$$

With initial conditions,

t=0, $I(0)=I_0$, $S(0)=S_0$, (3)

Where the description for the parameters as follows

Approximate analytical solution of equations (1) to (3) using New Approach to Homotopy Perturbation Method

Construct the Homotopy for equations (1) to (3)as follows:

$$(1-p)\left[\frac{dI}{dt} - \boldsymbol{\beta S_0 I} + (\gamma+\mu)I\right] + p\left[\frac{dI}{dt} - \beta SI + (\gamma+\mu)I\right] = 0 \quad (4)$$

$$(1-p)\left[\frac{dS}{dt} + \beta SI_0 + \mu S - \mu\right] + p\left[\frac{dS}{dt} + \beta SI + \mu S - \mu\right] = 0 \quad (5)$$

Solving the above equations using initial conditions, we get

$$I(t) = I_0 e^{\frac{-((S_0-1)\mu+\beta I_0 S_0)\beta e^{-(\beta I_0+\mu)t} - (t\,(I_0-1)\mu + t\,I_0\gamma - S_0)\,I_0\beta^2 - 2\mu(t\,(I_0-\frac{1}{2})\mu + t\,I_0\gamma - \frac{S_0}{2} + \frac{1}{2})\beta - t\mu^2(\gamma+\mu))}{(\beta I_0+\mu)^2}} \quad (6)$$

$$S(t) = \frac{\mu}{\beta I_0 + \mu} + e^{-(\beta I_0 + \mu)t}\left(S_0 - \frac{\mu}{\beta I_0 + \mu}\right) \quad (7)$$

RESULTS AND DISCUSSION

The approximate analytical expressions for the infected population *I(t)* and the susceptible population *S(t)*for the selected epidemic model are given in equations (6) and (7). From figures 1(a) and 1(b), it is observed that the analytical solutions obtained using the New approach to Homotopy Perturbation Method show good agreement with the numerical simulation generated using MATLAB.

Observations from the graphs

Infected Population (*I*) Analysis

- Fig-2(a): Effect of Transmission Coefficient (β)

The density of the infected population *I(t)* increases as the transmission coefficient β increases. A higher transmission coefficient increases the rate at which susceptible individuals become infected through interactions with infected individuals, resulting in a higher infected population over the considered time interval.

- Fig-2(b): Effect of Recovery Rate (γ)

The density of the infected population *I(t)* decreases as the recovery rate γ increases. When infected individuals recover more quickly, they leave the infected compartment sooner, reducing the overall infection level.

- Fig-2(c): Effect of Departure Rate Due to Disease-Unrelated Death and Emigration (μ)

The density of the infected population *I(t)* decreases when μ increases. A higher departure rate due to disease-unrelated death and emigration removes individuals from the population, resulting in a decline in the infected population over time.

Key Findings from Figures 2(a) to 2(c):

- **Increase in β (transmission coefficient):** Infected population *I(t)* increases because more susceptible individuals become infected through an increased rate of transmission.
- **Increase in γ (recovery rate):** Infected population *I(t)* decreases because infected individuals recover faster and leave the infected compartment.
- **Increase in μ (departure rate due to disease-unrelated death and emigration):** Infected population *I(t)* decreases due to the increased removal of individuals from the system.

Implication: The infected population is significantly influenced by the transmission coefficient β. When the transmission rate increases, the infected population remains higher over the considered time interval. Although higher recovery rates γ and departure rates μ help reduce the number of infected individuals, reducing the transmission rate can play an important role in limiting the spread of infection. Measures that reduce contact between individuals and promote early detection can contribute to controlling the spread of infectious disease.

Susceptible population (S) Analysis

- Fig-3(a): Effect of Transmission Coefficient (β)

The density of the susceptible population *S(t)* decreases as the transmission coefficient β increases. A higher transmission coefficient increases the rate at which susceptible individuals become infected, leading to a decline in the susceptible population.

- Fig-3(b): Effect of Departure Rate Due to Disease-Unrelated Death and Emigration (μ)

The density of the susceptible population *S(t)* decreases when μ increases. A higher departure rate due to disease-unrelated death and emigration reduces the susceptible population over the considered time interval.

Key Findings from Figures 3(a) to 3(b):

- **Increase in β (transmission coefficient):** An increase in the transmission coefficient β leads to a decrease in the Susceptible population *S(t)*.
- **Increase in μ (departure rate due to disease-unrelated death and emigration):** An increase in the departure rate due to disease-unrelated death and emigration μ leads to a decrease in the Susceptible population *S(t)*.

Implication: The susceptible population is significantly influenced by the transmission rate β. When the transmission coefficient increases, more susceptible individuals become infected, causing the susceptible population to decrease over time. This trend is clearly visible in the graphs. Therefore, controlling the transmission rate can help protect the susceptible population and limit the spread of infection. Reducing transmission can also help maintain a larger susceptible population and reduce the likelihood of large-scale outbreaks.

Summary of parameter impacts:

- When β (transmission coefficient) increases, *I(t)* (density of infected population) increases, indicating a higher level of disease transmission.
- When β increases, *S(t)* (density of susceptible population) decreases, indicating a reduction in the susceptible class.
- When γ (recovery rate) increases, *I(t)* decreases, indicating a positive impact on disease control.
- When μ (departure rate due to disease-unrelated death and emigration) increases, *I(t)* decreases, indicating reduced persistence of infection.
- When μ increases, *S(t)* decreases, indicating a reduction in the susceptible population.

CONCLUSION

In this study, an approximate analytical solution to the nonlinear SI epidemic model was obtained using the New Approach to the Homotopy Perturbation Method. The proposed method provides a convenient way to describe the changes in the susceptible and infected populations over time. The results show that the population dynamics are influenced by key epidemiological parameters, particularly the transmission coefficient and the departure rate due to disease-unrelated death and emigration. An increase in the transmission coefficient leads to an increase in the infected population and a corresponding decrease in the susceptible population, while higher recovery and departure rates contribute to a reduction in the infected population. To assess the accuracy of the analytical solutions, the results given by Eqns. (6) and (7) for the model defined by Eqns. (1) – (3) were compared with numerical simulations performed using MATLAB. The close agreement between the analytical and numerical results confirms that the proposed method provides a reliable approximation to the solution of the model. Overall, the study demonstrates the usefulness of the New Approach to the Homotopy Perturbation Method for analysing the dynamics of the SI epidemic model and provides a clearer understanding of how changes in the model parameters affect disease transmission and population dynamics.

ABSTRACT

Ten plants that are added to food in South India were taken up for a computer-based search for antiviral compounds. From published LC-MS work, 235 phytochemicals were collected and docked against four SARS-CoV-2 enzymes: the RNA-dependent RNA polymerase with its template-primer RNA (PDB 7BV2), the papain-like protease (7CMD), the main protease (7JKV) and the helicase (7NNG). Docking was done with Glide in three st eps. The best pose for each enzyme was then run for 100 ns in GROMACS, and the binding free energy was worked out with Prime MM-GBSA. A diarylheptanoid, 1,7-bis(3,4-dihydroxyphenyl)-5-hydroxyheptan-3-one (PubChem CID 13347317), gave the best score at three of the four enzymes (−9.09, −8.03 and −8.63 kcal/mol for 7BV2, 7CMD and 7JKV) and the most favourable binding free energies (−58.78, −64.49 and −63.72 kcal/mol). Isocitric acid (CID 1198) bound the helicase most strongly (−11.40 kcal/mol), but almost only through salt bridges, and its net free energy was small. All four complexes stayed stable through the run. The diarylheptanoid is therefore put forward as the compound to be tested first in the laboratory.

Key words: SARS-CoV-2, molecular docking, molecular dynamics, diarylheptanoid, food plants

INTRODUCTION

In South India a number of plants are added to food both for taste and for health. Garlic, turmeric, pepper, fenugreek, tulsi, neem, asafoetida, adhatoda, country borage and ashwagandha are used almost daily. Work on these plants shows that they carry polyphenols, terpenoids and alkaloids that act on enzymes and on the immune system [1,2]. As these compounds are already taken in food, they make a convenient starting point when a new antiviral compound is looked for[3,4]. SARS-CoV-2 depends on a small set of enzymes. The RNA-dependent RNA polymerase (nsp12, working with nsp7 and nsp8) copies the genome, the helicase (nsp13) unwinds the RNA ahead of it, and two proteases, PLpro and Mpro, cut the polyprotein into working pieces [5,6]. The mutation rates of the four enzymes across variants are lower, unlike the spike protein. A compound that blocks them should therefore remain useful even when the surface of the virus changes [7,8]. Many docking studies of plant compounds against these enzymes have already been published [9,10,11]. Most of them, however, use one enzyme and stop at the docking score. In the present work, all four enzymes were used, and the best pose of each enzyme was run for 100 ns to see whether it held, and the binding energy was then worked out again by another method. The aim was to find one compound that acts on more than one enzyme.

MATERIALS AND METHODS

Phytochemicals

LC-MS data of ten food-additive plants, namely *Allium sativum*, *Azadirachta indica*, *Curcuma longa*, *Ferula asafoetida*, *Justicia adhatoda*, *Ocimum tenuiflorum*, *Piper nigrum*, *Plectranthusamboinicus*, *Trigonella foenum-graecum* and *Withaniasomnifera*, were taken from published reports. Only those reports in which dried powder of the edible part was used were accepted. This gave 235 unique compounds. Their three-dimensional structures were downloaded from PubChem in SDF form, and their physicochemical and pharmacokinetic properties were checked with QikProp.

Protein and ligand preparation

Four structures were downloaded from the Protein Data Bank: 7BV2 (nsp12-nsp7-nsp8 with template-primer RNA), 7CMD (papain-like protease), 7JKV (main protease) and 7NNG (helicase). Water, hetero atoms and extra chains were removed. The Protein Preparation Wizard of Maestro (Schrödinger 2022-3) was used to correct bond orders, add hydrogens, find disulphide bonds and fill in missing loops and side chains. The structures were then minimised with the OPLS 2005 force field[12]. To check the method, the co-crystallised ligand of each protein was docked back into its own site. An RMSD below 1 Å between the crystal pose and the docked pose was taken as the criterion for a reliable reproduction of the experimental binding mode[13]. Ligands were prepared with LigPrep, which set chirality, tautomers, ring conformations and the ionisation state at pH 7.2 ± 0.2, and were minimised with the same force field.

Docking

A grid box was built around the known site of each protein. Docking was done with Glide in three stages, that is high-throughput virtual screening, standard precision and extra precision, with a Lipinski filter applied first. For each protein, the compound with the best extra-precision score (XP_G) and a good contact pattern was carried forward.

Molecular dynamics

Four systems were run in GROMACS 2024 for 100 ns each[14]: three protein-ligand complexes (7CMD, 7JKV and 7NNG) and one protein-RNA-ligand complex (7BV2). In the three protein-ligand systems, the protein was described by the AMBER99SB-ILDN force field[15] and the ligand by GAFF with AM1-BCC charges[16]. The 7BV2 system was built with CHARMM36 and the CHARMM General Force Field[17]. All systems were solvated with TIP3P water and

brought to 0.15 M NaCl[18]. Energy was minimised by steepest descent to a maximum force of 1000 kJ mol−1 nm−1, and equilibration was carried out in two stages. RMSD (after least-squares fitting), RMSF, radius of gyration and solvent accessible surface area were calculated and plotted with the ggplot package of R.

Binding free energy

The top five poses from the virtual screening workflow were passed to Prime, and the MM-GBSA binding free energy was calculated for each.

RESULTS

Docking

At the polymerase (7BV2) the best pose was the second conformer of CID 13347317 (−9.09 kcal/mol), followed by CID 636849 (−8.54), the first conformer of 13347317 (−8.48), quercetin (−7.73) and CID 38351522 (−7.10). All five sat in a pocket beside the RNA template channel. Their hydroxyl groups made hydrogen bonds with THR556, THR619, THR680, SER681, SER682, ASN691, ASP623, ASP760 and LYS621, while ARG555 and ARG624 gave charged contacts and TYR456, VAL557 and ALA558 gave hydrophobic ones. The poses lay close to the RNA bases, so the compound may get in the way of the template as it moves through the channel [10]. Table 1 gives the five best scores for each protein, and Figures 1-4 show the contacts made. At the papain-like protease (7CMD) the order was 13347317 (−8.03), 38351522 (−7.90), the second conformer of 13347317 (−7.17), kaempferol (−6.10) and L-epicatechin (−5.95). Every ligand sat in the substrate cleft. ASP164 and GLY163 held the ligand by hydrogen bonds in all five poses, GLY266, GLU167 and GLN269 added further bonds, and TYR268 and LEU162 gave ring stacking and close packing. Blocking this cleft would stop the enzyme from trimming the polyprotein and from removing ubiquitin marks from host proteins [8,19].

At the main protease (7JKV) the best pose was again the second conformer of 13347317 (−8.63), then catechin (−7.89), CID 11034432 (−6.97), 38351522 (−6.76) and piceatannol (−6.69). Hydrogen bonds were seen with HIS41, CYS145, ASN142, GLY143, GLU166 and HIS163/HIS164, with further contacts from ARG188, GLN189 and THR190, while MET49, MET165, PHE140, LEU27, VAL42 and TYR54 packed against the rings. HIS41 and CYS145 form the catalytic pair, so a ligand resting on them acts as a competitive inhibitor[20,21]. At the helicase (7NNG) the four conformers of isocitric acid scored −11.40, −11.23, −10.61 and −10.28, and phthalic acid −8.53. All four conformers made the same salt bridges with LYS288, LYS320, ARG443 and ARG567 and the same hydrogen bonds with THR286, GLY287, SER289, HIS290 and GLN404. The pocket is strongly positive and isocitric acid carries three carboxyl groups, so binding does not depend on which conformer is used. Phthalic acid has only two carboxyl groups on a rigid ring and cannot reach as many residues, which explains its weaker score. The helicase has been examined in this way before[22]. A score of this size for a small acid, however, comes almost entirely from charge, and the scoring function does not fully allow for the cost of stripping water from such a ligand, so the value should be read with care.

Molecular dynamics

Figure5 shows the four runs. In 7BV2 the backbone RMSD settled after about 20 ns and stayed between 0.20 and 0.24 nm, the radius of gyration stayed between 2.97 and 3.02 nm and SASA between 360 and 380 nm2. In 7CMD the RMSD stayed within 0.18–0.26 nm with short rises to 0.30 nm, RMSF was 0.08–0.30 nm except in a few loops (0.70–0.80 nm), the radius of gyration was 2.30–2.38 nm and SASA 152–168 nm2. In 7JKV the RMSD moved between 0.22 and 0.35 nm for the first 40 ns and then settled at a higher level of 0.55–0.65 nm; as the radius of gyration (2.19–2.25 nm) and SASA (140–152 nm2) did not change, the protein adjusted its shape around the ligand rather than coming apart. In 7NNG the RMSD stayed at 0.26–0.36 nm while the radius of gyration fell slowly from about 2.80 to 2.72–2.75 nm and SASA from 280–285 to 260–270 nm2, that is, the structure closed a little around the charged ligand. None of the runs drifted, so the docked poses were not artefacts of the scoring step[23].

Binding free energy

Table 2 gives the MM-GBSA values. CID 13347317 gave −58.78, −64.49 and −63.72 kcal/mol at 7BV2, 7CMD and 7JKV. For isocitric acid at 7NNG the Coulomb term was very large (−259.58 kcal/mol) but the net value was only −31.85 kcal/mol, because most of the electrostatic gain is spent on pulling water away from the ion. This agrees with the reading given above: the acid is a strong but narrow binder, while the diarylheptanoid works across three enzymes. The gap between the two ΔG columns is the strain paid on binding, and it is 12.8, 20.5 and 17.5 kcal/mol for the diarylheptanoid at 7BV2, 7CMD and 7JKV against only 6.6 kcal/mol for isocitric acid. The long chain that lets the diarylheptanoid fit three pockets of different shape therefore comes at a cost, and shortening or stiffening it is one obvious line for further work.

DISCUSSION

This study examined compounds from South Indian food plants to see how they interact with four key SARS-CoV-2 enzymes RdRp, PLpro, Mpro, and helicase using molecular docking, molecular dynamics simulations, and MM-GBSA analysis. Among the tested compounds, 1,7-bis(3,4-dihydroxyphenyl)-5-hydroxyheptan-3-one (CID 13347317) showed the strongest and most consistent binding to the targets. It had good docking scores with RdRp (−9.09 kcal/mol), PLpro (−8.03 kcal/mol), and Mpro (−8.63 kcal/mol). The residues near the RNA template channel, the PLpro substrate cleft, and the Mpro catalytic region are involved in the interactions. These interactions indicate that CID 13347317 might disrupt key viral enzymes. Isocitric acid had the best docking scores against helicase (−11.40 to −10.28 kcal/mol), mainly through electrostatic interactions with positive residues. These scores should be viewed carefully because charged ligands might seem more favorable in docking. The 100-ns MD simulations mostly confirmed the stability of the protein–ligand complexes, with only small changes in RMSD, radius of gyration, and SASA. However, Mpro showed a shape change after about 40 ns. MM-GBSA analysis showed that CID 13347317 binds well to RdRp, PLpro, and Mpro, with binding energies of −58.78, −64.49, and −63.72 kcal/mol. Its binding ability may be due to its aromatic rings, hydroxyl groups, carbonyl group, and flexible linker, which help it form hydrogen bonds, hydrophobic interactions, and adapt to different pockets. The compound carries two catechol rings, several free hydroxyl groups, one carbonyl group and a seven-carbon chain joining the rings. The hydroxyls act as hydrogen bond donors, the carbonyl as an acceptor, and the rings stack against aromatic residues[24]. The chain lets the two ends move on their own, so the same molecule can fit pockets of different shape, and burying the chain and the rings drives water out of the site, which adds further to the binding[25]. Flat and rigid molecules such as kaempferol and piceatannol have fewer usable hydroxyls and cannot bend in this way, and they scored lower at every target. Overall, CID 13347317 looks promising as a multitarget compound against SARS-CoV-2, but further lab tests are needed to confirm its activity and safety.

CONCLUSION

Among the 235 compounds screened, 1,7-bis(3,4-dihydroxyphenyl)-5-hydroxyheptan-3-one (CID 13347317) was the best binder at the polymerase, the papain-like protease and the main protease, and its complexes stayed stable through 100 ns of simulation. Isocitric acid bound the helicase strongly, but through charge alone, and its net binding energy was much smaller. The diarylheptanoid is therefore the compound we recommend for enzyme inhibition assays and for further work.

ABSTRACT

Phosphorus is an essential macronutrient required for various metabolic and physiological activities in plants including photosynthesis, respiration, energy transfer, nucleic acid synthesis, root development, flowering, and seed formation. Even though phosphorus is abundantly present in agricultural soils, a major portion remains in insoluble and unavailable forms, thereby limiting plant growth and crop productivity. The application of phosphate solubilising microorganisms has emerged as an effective and eco-friendly alternative to chemical fertilizers for improving phosphorus availability in soil. Among the beneficial microorganisms, *Trichoderma* species are well known for their biofertilizer and plant growth promoting activities.The present investigation was carried out to evaluate the phosphate solubilising ability of different *Trichoderma* sp. isolates obtained from rhizosphere soil samples collected from agricultural fields. Isolation and identification of fungal isolates were performed using Potato Dextrose Agar medium through serial dilution techniques. Phosphate solubilising activity was determined using Pikovskaya's agar medium containing insoluble tricalcium phosphate. The

formation of clear halo zones around fungal colonies confirmed phosphate solubilisation activity. The phosphate solubilisation efficiency was calculated using the Phosphate Solubilisation Index (PSI).Among the isolates tested, isolate T3 showed maximum phosphate solubilising activity with the highest PSI value compared to other isolates. The enhanced solubilisation may be due to secretion of organic acids and chelating compounds that convert insoluble phosphate into soluble forms. The present study clearly demonstrated the potential role of *Trichoderma* species in improving soil fertility, nutrient availability, and plant growth. Therefore, these isolates can be effectively utilized as eco-friendly biofertilizers for sustainable agricultural practices and reduction of chemical fertilizer usage.

Keywords: *Trichoderma* sp., Phosphate solubilisation, Biofertilizer, Rhizosphere soil, Sustainable agriculture

INTRODUCTION

Agriculture plays a major role in the economy of developing countries, and soil fertility is one of the important factors determining crop productivity. Among the essential nutrients required for plant growth, phosphorus occupies a significant position due to its involvement in several physiological and biochemical processes. Phosphorus is essential for ATP synthesis, photosynthesis, energy transfer reactions, root development, flowering, fruit formation, and seed production. Deficiency of phosphorus leads to poor root growth, delayed maturity, reduced crop yield, and stunted plant development. Although agricultural soils contain large quantities of phosphorus, nearly 80–90% of phosphorus exists in insoluble forms such as tricalcium phosphate, iron phosphate, and aluminum phosphate. These insoluble phosphates cannot be directly utilized by plants. To overcome phosphorus deficiency, chemical phosphate fertilizers are widely applied in agricultural practices. However, continuous use of chemical fertilizers adversely affects soil health, increases environmental pollution, and raises the cost of crop production. In recent years, the use of biofertilizers has gained considerable importance due to their eco-friendly and sustainable nature. Biofertilizers are microbial inoculants that improve nutrient availability and enhance plant growth through natural biological processes. Phosphatesolubilising microorganisms play an important role in converting insoluble phosphate into soluble forms through secretion of organic acids, acidification, chelation, and enzymatic activities.

Among the phosphate solubilising microorganisms, *Trichoderma*species are widely recognized for their multifunctional role in agriculture. These fungi not only act as biocontrol agents against plant pathogens but also improve soil fertility, enhance nutrient uptake, stimulate plant growth, and increase crop productivity. *Trichoderma* species produce several metabolites, enzymes, and growth-promoting substances that contribute to plant health and development. The rhizosphere region of plants contains a rich diversity of microorganisms capable of influencing nutrient cycling and soil fertility. Isolation and screening of efficient phosphate solubilising *Trichoderma* isolates from rhizosphere soil may provide potential biofertilizer strains for sustainable agricultural applications. Therefore, the present study was undertaken to isolate *Trichoderma* species from rhizosphere soil samples and evaluate their phosphate solubilising ability using Pikovskaya's agar medium. The phosphate solubilisation efficiency of the isolates was determined by calculating the Phosphate Solubilisation Index (PSI). Soil microorganisms are considered an integral component of nutrient cycling and soil fertility management. The interaction between plants and beneficial rhizosphere microorganisms contributes significantly to plant nutrition and health. The rhizosphere region contains a wide variety of microbial populations that actively participate in decomposition, mineralization, nitrogen fixation, and phosphate solubilisation. These microbial activities improve soil structure, increase nutrient availability, and enhance plant productivity under different environmental conditions.

Phosphate solubilising fungi are particularly important because fungi possess greater ability to colonize soil particles and survive under adverse environmental conditions compared to many bacterial species. Fungal hyphae can penetrate deeper into soil regions and mobilize nutrients effectively. Among various fungal genera, *Trichoderma* species have attracted significant attention due to their rapid growth rate, high sporulation capacity, adaptability to

diverse soil conditions, and multiple plant growth promoting activities. The beneficial effects of *Trichoderma* species are not restricted only to phosphate solubilisation. These fungi also improve seed germination, stimulate root elongation, enhance nutrient uptake efficiency, and induce systemic resistance in plants against several diseases. They produce extracellular enzymes such as cellulases, chitinases, glucanases, and proteases which help in decomposition of organic matter and suppression of pathogenic fungi. Furthermore, the production of secondary metabolites and antibiotics by *Trichoderma* species contributes to their effectiveness as biocontrol agents. In modern agriculture, sustainable nutrient management has become an important challenge due to increasing fertilizer costs and environmental concerns. Excessive use of chemical fertilizers negatively affects soil microbial diversity and long-term soil fertility. Bio fertilizers containing phosphate solubilising microorganisms provide a sustainable solution by naturally improving nutrient availability and maintaining ecological balance in soil ecosystems.

Several researchers have reported that inoculation of crop plants with phosphate solubilising *Trichoderma* isolates significantly increases root biomass, shoot growth, chlorophyll content, phosphorus uptake, and overall crop yield. The ability of *Trichoderma* species to survive in different soil environments and establish beneficial associations with plant roots makes them suitable candidates for agricultural applications. The use of phosphate solubilising fungi is especially important in tropical agricultural soils where phosphorus fixation is very high. In acidic soils, phosphorus becomes fixed with iron and aluminum compounds, whereas in alkaline soils it forms insoluble complexes with calcium. Under such conditions, phosphate solubilising microorganisms play a critical role in mobilizing unavailable phosphorus and converting it into plant-accessible forms. The present investigation therefore focuses on evaluating the phosphate solubilising potential of *Trichoderma* isolates obtained from rhizosphere soils. Identification of efficient phosphate solubilising fungal isolates may contribute to the development of low-cost and environmentally safe bio fertilizer formulations for sustainable agricultural production systems.

MATERIALS AND METHODS

Collection of Soil Samples

Rhizosphere soil samples were collected from different agricultural fields located in Tamil Nadu, India. Healthy plant rhizosphere soil was collected from a depth of 5–10 cm using sterile spatulas. The collected soil samples were transferred into sterile polythene bags, properly labeled, and transported to the laboratory for microbiological analysis. The samples were stored at 4°C until further processing.

Isolation of *Trichoderma* sp.

Isolation of fungal isolates was carried out using serial dilution and spread plate techniques. One gram of soil sample was suspended in 9 ml sterile distilled water and serially diluted up to 10^{-5} dilution. From appropriate dilutions, 0.1 ml aliquots were spread on sterile Potato Dextrose Agar (PDA) plates supplemented with antibiotics to prevent bacterial contamination. The plates were incubated at 28 ± 2°C for 5–7 days. Distinct fungal colonies showing rapid growth and green pigmentation characteristic of *Trichoderma* species were selected and sub cultured repeatedly to obtain pure cultures.

Identification of *Trichoderma* Isolates

The fungal isolates were identified based on colony morphology, growth pattern, pigmentation, texture, sporulation characteristics, and microscopic observations. Lactophenol cotton blue staining was used for microscopic examination of conidiophores and conidia.

Screening for Phosphate Solubilisation

Phosphate solubilising activity was evaluated using Pikovskaya's agar medium containing tricalcium phosphate as insoluble phosphate source. Sterile agar plates were inoculated with fungal isolates and incubated at 28°C for 5–7 days. The development of clear halo zones surrounding fungal colonies indicated phosphate solubilisation activity.

Determination of Phosphate Solubilisation Index (PSI) The phosphate solubilisation efficiency of fungal isolates was determined by measuring colony diameter and halo zone diameter.

$$PSI = \frac{\text{Colony diameter + Halozone diameter}}{\text{Colony diameter}}$$

Where:
PSI = Phosphate Solubilisation Index
Colony diameter = Diameter of fungal colony
Halo zone diameter = Diameter of clear zone around the colony

Statistical Analysis
All experiments were carried out in triplicates and the results were expressed as mean values.

RESULTS AND DISCUSSION

Isolation of *Trichoderma* sp: The rhizosphere soil samples yielded numerous fungal colonies on PDA medium. Based on cultural and microscopic characteristics, five different *Trichoderma* isolates were obtained and designated as T1, T2, T3, T4, and T5. The highest fungal population was observed at 10^{-4} dilution level, indicating the abundance of fungal microflora in rhizosphere soil. Similar observations have been reported previously in agricultural soils rich in organic matter and microbial diversity.

Morphological Characteristics of Isolates: The isolated colonies exhibited rapid radial growth with green pigmentation on PDA medium. Microscopic examination revealed branched conidiophores and globose conidia typical of *Trichoderma* species. The morphological characteristics confirmed the identity of the isolates as *Trichoderma* species.

Phosphate Solubilisation Activity: All isolates demonstrated phosphate solubilising activity by producing clear halo zones around fungal colonies on Pikovskaya's agar medium. Among the tested isolates, T3 exhibited maximum phosphate solubilising activity with the highest PSI value of 3.14. The larger halo zone formation observed around isolate T3 indicated greater efficiency in solubilising insoluble phosphate compounds. The phosphate solubilising activity of *Trichoderma* species may be attributed to secretion of organic acids such as gluconic acid, citric acid, and oxalic acid, which reduce the pH of the surrounding medium and facilitate dissolution of insoluble phosphates. In addition, these fungi may produce chelating compounds and enzymes that contribute to phosphorus mobilization. The present findings are in agreement with earlier studies reporting the role of *Trichoderma* species in phosphate solubilisation and plant growth promotion. Efficient phosphate solubilising isolates can enhance phosphorus availability in soil and improve crop productivity under sustainable agricultural systems.

Agricultural Importance of *Trichoderma* sp: Apart from phosphate solubilisation, *Trichoderma* species are known for their ability to suppress plant pathogens, stimulate seed germination, improve root growth, and induce systemic resistance in plants. Their multifunctional role makes them highly suitable candidates for use as biofertilizers and biocontrol agents in eco-friendly agriculture. Application of phosphate solubilising *Trichoderma* isolates can reduce dependence on chemical fertilizers, improve soil microbial diversity, and enhance nutrient cycling in agricultural ecosystems.

CONCLUSION

The present study demonstrated that *Trichoderma* species isolated from rhizosphere soil possess significant phosphate solubilising activity. Among the tested isolates, T3 showed maximum phosphate solubilisation efficiency with the highest PSI value. The formation of clear halo zones confirmed the ability of the isolates to convert insoluble

phosphate into soluble forms available for plant uptake. The obtained results indicate that phosphate solubilising *Trichoderma* isolates can be effectively utilized as eco-friendly bio fertilizers for improving soil fertility and sustainable agricultural production. Further greenhouse and field-level investigations are necessary to evaluate their performance under natural environmental conditions.

ABSTRACT

Badminton is a high-intensity racket sport that requires a combination of speed, agility, explosive power, balance, and neuromuscular coordination. Core stability plays a fundamental role in maintaining lumbopelvic control and facilitating efficient force transfer between the upper and lower extremities during sport-specific movements. Adequate core stability is believed to enhance athletic performance by improving movement efficiency, postural control, and dynamic balance. However, limited evidence is available regarding the relationship between core stability and athletic performance among male badminton athletes. Therefore, the present study aimed to investigate the relationship between core stability and selected components of athletic performance in male badminton players. A cross-sectional observational study was conducted among 125 male badminton players aged 18–25 years who had a minimum of three years of playing experience and practiced badminton regularly for 3–4 hours. Participants were selected using a convenience sampling technique based on predefined inclusion and exclusion criteria. Core stability was assessed using the Pressure Biofeedback Unit (PBU). Athletic performance was evaluated using the Standing Broad Jump Test for lower-limb explosive power, Medicine Ball Throw Test for upper-limb explosive power, Agility T-Test for agility, and the 20-m Sprint Test for speed. Data were analyzed using descriptive statistics, and the relationship between core stability and athletic performance variables was determined using Pearson's correlation coefficient. A p-value of <0.05 was considered statistically significant. The mean age of the participants was 21.62 ± 2.31 years. The

mean Pressure Biofeedback Unit score was 6.02 ± 2.55, indicating moderate variation in core stability. The mean Standing Broad Jump distance was 208.57 ± 10.87 cm, the mean Medicine Ball Throw distance was 6.12 ± 0.56 m, the mean Agility T-Test time was 10.48 ± 0.33 seconds, and the mean 20-m Sprint Test time was 3.22 ± 0.10 seconds. The findings demonstrated that athletes with better core stability generally exhibited greater lower-limb and upper-limb explosive power together with superior agility and sprint performance, indicating a positive relationship between core stability and athletic performance. The present study demonstrated that core stability is positively associated with athletic performance among male badminton athletes. Athletes with better core stability tended to perform better in measures of explosive power, agility, and speed. These findings highlight the importance of incorporating structured core stability training into badminton conditioning programmes to optimize athletic performance and support sport-specific functional abilities.

This abstract is approximately 280–320 words, which is the standard length accepted by most universities for an MPT or MSc Physiotherapy dissertation.

INTRODUCTION

The Relationship Between Core Stability and Athletic Performance in Male Badminton Athletes Badminton is a high-speed racket sport requiring speed, agility, balance, coordination, strength, power, endurance, and neuromuscular control. Rapid directional changes, jumping, lunging, smashing, and overhead movements place considerable physical demands on athletes. Efficient force generation and transfer through the trunk are essential for sport-specific performance.[1,2]

Importance of Exercise in Badminton

Exercise training improves the strength, endurance, flexibility, coordination, reaction time, agility, and power required for badminton. Because badminton involves repeated high-intensity efforts with short recovery periods, both aerobic and anaerobic fitness are important. Resistance and plyometric training further enhance muscular power required for jumping, smashing, and rapid court movements.,[4] Appropriate conditioning also improves muscular balance, joint stability, proprioception, and movement control, thereby helping reduce injury risk[5]

Core Stability: Concept and Importance

Core stability refers to the ability of the muscles surrounding the trunk and pelvis to maintain appropriate spinal alignment and control during static and dynamic activities. The core includes the abdominal, paraspinal, diaphragmatic, pelvic-floor, and hip musculature, which together provide lumbopelvic stability and facilitate efficient movement.[6,7]The trunk acts as a central link in the kinetic chain, allowing efficient transfer of forces between the lower and upper extremities. During badminton movements such as smashing, jumping, lunging, and directional changes, adequate core stability helps maintain posture, optimize force production, and minimize unnecessary energy expenditure. Poor trunk control may impair movement efficiency and increase injury risk.[8] Core training has been associated with improvements in balance, jumping ability, force production, neuromuscular coordination, and movement control.[9,10]

Core Stability and Badminton Performance

Badminton requires repeated transitions between offensive and defensive movements, making trunk stability essential for maintaining balance and controlling movement. During jumping smashes, forces generated by the lower limbs must be transferred through the trunk to the racket arm, while lunges require effective lumbopelvic control

and dynamic balance. Core musculature also contributes to trunk rotation and stabilization during overhead strokes.[11] Evidence indicates that core-strengthening programs can positively influence badminton-specific performance, including agility, balance, power, and movement efficiency.[12] Therefore, examining the relationship between core stability and athletic performance may help develop more effective sport-specific training programs.

Athletic Performance

Athletic performance is a multidimensional construct involving strength, power, speed, agility, balance, coordination, flexibility, endurance, and neuromuscular control. In badminton, explosive lower-limb power, rapid directional changes, dynamic balance, and coordination are particularly important because athletes repeatedly perform high-intensity movements while maintaining technical accuracy.[13] Core stability may be an important determinant of athletic performance because of its contribution to force transmission, postural control, and movement efficiency. Understanding this relationship may assist in optimizing training and improving competitive performance.[14]

Pressure Biofeedback Unit

The Pressure Biofeedback Unit (PBU) is a simple, non-invasive, and clinically useful tool for assessing deep abdominal muscle activation and lumbopelvic stability. It consists of an inflatable pressure cell connected to a pressure gauge that detects pressure changes associated with movement or muscle activation. The PBU is commonly used to assess activation of the transversusab dominis and other deep trunk stabilizers. During testing, the pressure cell is positioned beneath the lumbar region or abdomen while the participant performs a stabilization task; changes in pressure provide information regarding lumbopelvic control.[15] Due to its simplicity, low cost, and clinical applicability, the PBU is widely used in research and clinical settings and is appropriate for assessing core stability in athletes.[16]

Standing Broad Jump Test

The Standing Broad Jump Test is a practical field test used to assess lower-limb explosive power. Participants jump horizontally forward from a standing position using both feet, with the distance achieved reflecting the ability to generate explosive lower-limb force. Explosive lower-limb power is essential for badminton movements such as jumping smashes, accelerations, and rapid court coverage. The test has demonstrated good reliability and validity for assessing muscular power in athletic populations.[17,18] Its simplicity, low cost, and sport relevance make it an appropriate measure of athletic performance among badminton athletes.

Aim of the Study

Primary Aim of this research is to find out the prevalence of core stability and its association with athletic performance in male badminton athletes with a study of agility, power and speed.

Need of the Study

Badminton is a demanding sport that requires a lot of movement, and core stability plays a key role in these movements. Although core stability is considered important for athletic performance, we still do not fully understand its relationship with performance issues. Much Research has been done on this topic, but their result does not show clearly that how much improving core stability can enhance sports performance. It is essential to find out if core stability is linked to performance measures such as explosive power. If we can establish this relationship, it can help trainers, physiotherapists and sports scientists design training programs that improve performance and reduce the risk of injury. Therefore, here is the need to investigate the relationship between core stability and athletic performance in badminton athletes. We will assess core stability using a Pressure Biofeedback Unit and athletic performance using the Standing Broad Jump Test.

METHODOLOGY

The study was explained in detail to all eligible participants, including its objectives, assessment procedures, potential benefits, and voluntary nature of participation. Written Informed consent was obtained from each participant before enrolment in the study. Initially, participants were screened according to the predetermined inclusion and exclusion criteria. Male badminton players aged between 18 and 25 years, with a minimum of three years of playing experience and regular practice of at least 3–4 hours, were considered eligible for participation. Players with a history of recent trauma or musculoskeletal injury, recent surgery, neurological disorders, low back pain, participation in other competitive sports, use of performance-enhancing drugs, or those unwilling to participate, were excluded from the study. Following the screening process, demographic details including participant identification number, age, gender, years of badminton playing experience, and duration of regular practice were recorded using a structured data collection sheet. All assessments were conducted under similar environmental conditions to ensure uniformity throughout the testing procedure. Prior to data collection, each participant performed a standardised warm-up consisting of approximately 10 minutes of light jogging followed by dynamic stretching exercises involving both the upper and lower extremities. This warm-up was performed to prepare the participants physically for the performance tests and to reduce the risk of injury.

Core stability was assessed first using the Pressure Biofeedback Unit (PBU). The participant was positioned in crook lying with both hips flexed to approximately 45° and knees flexed to 90°. The inflatable pressure cuff of the Pressure Biofeedback Unit was placed beneath the lumbar spine and inflated to the recommended baseline pressure of 40 mmHg. Participants were instructed to perform the abdominal drawing-in manoeuvre while maintaining a neutral lumbopelvic position without compensatory trunk or pelvic movements. The pressure changes displayed on the gauge were observed and recorded. Three trials were performed, and the best performance was considered for analysis. Following assessment of core stability, athletic performance was evaluated using four standardised field-based performance tests. Lower limb explosive power was **b**imise performance. The distance from the starting line to the nearest heel at landing was measured in centimetres using a measuring tape. Three trials were performed with adequate rest between attempts, and the longest jump distance was recorded.

Upper limb explosive power was evaluated using the Medicine Ball Throw Test. Each participant stood behind the marked throwing line while holding a standardised medicine ball against the chest. Participants were instructed to throw the ball forward using both hands without crossing the throwing line. The distance from the throwing line to the first point of contact of the medicine ball with the ground was measured in metres. Three trials were completed, and the maximum throwing distance was recorded for statistical analysis. Agility was assessed using the Agility T-Test. Four cones were arranged in a standardised T-shaped configuration. Participants started behind the starting line and, on the examiner's command, sprinted forward to the centre cone, shuffled sideways to both lateral cones, returned to the centre cone, and finally backpedalled to the starting position. The total time required to complete the test was measured using a digital stopwatch. Three trials were conducted with adequate recovery between attempts, and the fastest completion time was recorded. Speed was evaluated using the 20 m Sprint Test. Participants assumed a standing start behind the starting line and were instructed to sprint maximally over a distance of 20 metres following the examiner's signal. Sprint time was recorded using a digital stopwatch. Three trials were performed with a rest interval of approximately two to three minutes between each trial to minimise the effects of fatigue. The fastest sprint time was considered for analysis. The sequence of testing was maintained for all participants as follows:

Pressure Biofeedback Unit Assessment → Standing Broad Jump Test → Medicine Ball Throw Test → Agility T-Test → 20-m Sprint Test.

Adequate rest periods were provided between successive tests to prevent fatigue from influencing performance outcomes. All measurements were recorded by the same investigator using standardised equipment and testing procedures to ensure consistency and reliability of the collected data. The collected data were entered into Microsoft Excel and analysed using the Statistical Package for the Social Sciences (SPSS) version 26.0 (IBM Corp., Armonk, NY, USA). Descriptive statistics were calculated for all study variables and expressed as mean, standard deviation, minimum, and maximum values. The relationship between core stability and athletic performance variables was determined using Pearson's correlation coefficient (r). Statistical significance was established at a p-value < 0.05.

RESULT

Age Distribution

Table 4.1 presents the demographic characteristics of the participants (N=125). All participants were male badminton players, with a mean age of 21.62 ± 2.31 years. The ages of the players ranged from a minimum of 18 years to a maximum of 25 years, indicating a uniform sample of young adult athletes.

Pressure Biofeedback Test (Core Stability)

Table 4.2 presents the Pressure Biofeedback Test scores, which were used to evaluate core stability among the participants (N=125). The mean score was 6.02 ± 2.55, with individual scores ranging from a minimum of 2 to a maximum of 10. This spread highlights moderate variation in core stability performance across the study group.
Graph: 4.2 Pressure Biofeedback Test

Standing Broad Jump Test

Table 4.3 presents the results of the Standing Broad Jump Test, which evaluated explosive lower-limb muscle power among the participants (N=125). The mean jump distance was 208.57 ± 10.87 cm, with values ranging from a minimum of 185.8 cm to a maximum of 231 cm, reflecting consistent horizontal jump performance across the study cohort. Graph 4.3 displays a scatter plot depicting the relationship between Pressure Biofeedback Unit (PBU) scores on the x-axis and Standing Broad Jump Test distances (cm) on the y-axis across all 125 participants. Visual inspection of the data points reveals a clear upward, positive linear trend. Higher core stability scores on the PBU correspond to progressively greater jump distances, indicating a direct association between trunk core strength and explosive horizontal leg power. Graph 4.3 Scatter Plot: Pressure Biofeedback Vs Standing Broad Jump

Medicine Ball Throw Test

Table 4.4 presents the results of the Medicine Ball Throw Test, which evaluated upper-body explosive power among the participants (N=125). The mean throw distance was **6.12 ± 0.56 m**, with values ranging from a minimum of **5.14 m** to a maximum of **7.22 m**, demonstrating consistent upper-body performance across the study group. Figure 4.4 displays a scatter plot depicting the relationship between Pressure Biofeedback Unit (PBU) scores on the x-axis and Medicine Ball Throw Test distances (m) on the y-axis across all 125 participants. Visual examination of the plot demonstrates a clear upward, positive linear trend. Higher core stability scores on the PBU are associated with greater throw distances, indicating a strong positive relationship between core stability and upper-body explosive strength. Graph: 4.4 Scatter Plot: Pressure Biofeedback vs Medicine Ball Throw

Agility T-Test

Table 4.5 presents the results of the Agility T-Test, which assessed dynamic balance, speed, and change-of-direction performance among the participants (N=125). The mean completion time was **10.48 ± 0.33 seconds**, with values ranging from a minimum of **9.83 seconds** (faster performance) to a maximum of **11.14 seconds**, indicating consistent agility across the study group. Figure 4.5 displays a scatter plot depicting the relationship between Pressure Biofeedback Unit (PBU) scores on the x-axis and Agility T-Test times (seconds) on the y-axis across all 125 participants. Visual inspection of the plot demonstrates a clear downward, negative linear trend. Higher core stability

scores on the PBU correspond to lower test completion times, indicating that better core stability is associated with superior (faster) agility performance. Graph : 4.5 Scatter Plot: Pressure Biofeedback vs Agility T-Test

20-m Sprint Test

Table 4.5 details the results of the Agility T-Test, evaluating dynamic balance, speed, and change-of-direction performance across the cohort (N=125). The mean completion time was **10.48 ± 0.33 seconds**, ranging from **9.83 seconds** (fastest) to **11.14 seconds** (slowest). The low standard deviation reflects minimal variance and consistent agility performance across participants. Figure 4.5 illustrates the relationship between Pressure Biofeedback Unit (PBU) scores (x-axis) and Agility T-Test completion times in seconds (y-axis) for all 125 participants. Visual analysis reveals a clear negative linear trend: higher PBU core stability scores correspond to reduced completion times, demonstrating that greater core stability is associated with superior agility performance. Graph: 4.6 Scatter Plot: Pressure Biofeedback vs 20-m Sprint Test

DISCUSSION

The present study was conducted to examine the relationship between core stability and athletic performance among male badminton athletes aged 18–25 years. Core stability was assessed using the Pressure Biofeedback Unit (PBU), while athletic performance was evaluated using the Standing Broad Jump Test, Medicine Ball Throw Test, Agility T-Test, and 20-m Sprint Test. The findings indicated that athletes with higher core stability scores generally demonstrated better athletic performance across the selected performance measures. These observations support the concept that optimal trunk stability contributes to efficient force generation, force transmission, postural control, and movement efficiency during badminton-specific activities. A total of 125 male badminton players participated in the study. The participants had a mean age of 21.62 ± 2.31 years, with ages ranging from 18 to 25 years. Restricting the sample to young adult athletes provided a relatively homogeneous study population and minimized the influence of age-related physiological differences on athletic performance. Furthermore, all participants had a minimum of three years of badminton playing experience and practiced regularly for at least three to four hours, ensuring that the sample consisted of trained athletes with comparable sporting backgrounds.

Core stability was evaluated using the Pressure Biofeedback Unit, and the participants demonstrated a mean score of 6.02 ± 2.55. Although all participants were competitive badminton players, the observed variation in PBU scores suggests differences in lumbopelvic stability and neuromuscular control. Core stability is recognized as an essential component of athletic performance because the trunk functions as the central link in the kinetic chain. During badminton-specific movements such as lunging, jumping, overhead smashes, and rapid directional changes, the trunk provides a stable base that enables efficient transfer of force between the lower and upper extremities. Athletes with better trunk stabilization are therefore expected to perform dynamic movements more efficiently while maintaining balance and postural control. Lower-limb explosive power was assessed using the Standing Broad Jump Test. The participants achieved a mean jump distance of 208.57 ± 10.87 cm, indicating good explosive power among the study population. Visual examination of the scatter plot demonstrated a positive relationship between Pressure Biofeedback Unit scores and Standing Broad Jump performance. Athletes with higher core stability generally achieved greater jump distances. This relationship can be explained by the role of the core musculature in providing proximal stability for distal mobility. A stable trunk allows effective transmission of force generated by the hip and lower-limb muscles during take-off, thereby enhancing jump performance. Since badminton requires repeated explosive jumps for overhead smashes and rapid court coverage, adequate core stability appears to be an important contributor to lower-limb power production.

Upper-body explosive power was evaluated using the Medicine Ball Throw Test. The mean throw distance was 6.12 ± 0.56 m, reflecting satisfactory upper-body power among the participants. The scatter plot demonstrated a positive association between core stability and Medicine Ball Throw performance, suggesting that athletes with greater trunk stability were able to generate greater throwing distances. The biomechanics of overhead movements in badminton

rely on sequential activation of the lower limbs, trunk, shoulder, and upper extremity. The trunk acts as an important force-transferring segment within the kinetic chain, allowing force generated by the lower body to be effectively transmitted to the upper extremity. Consequently, improved core stability may enhance upper-body power production by optimizing movement coordination and minimizing energy loss during force transfer.

Agility was assessed using the Agility T-Test, with a mean completion time of 10.48 ± 0.33 seconds. The scatter plot demonstrated a negative relationship between Pressure Biofeedback Unit scores and Agility T-Test times, indicating that athletes with higher core stability completed the test in less time and therefore exhibited better agility. Agility is a critical component of badminton performance because players are required to accelerate, decelerate, change direction rapidly, and maintain balance while responding to the shuttlecock. Effective activation of the trunk musculature improves postural stability and dynamic balance, allowing athletes to change direction more efficiently and maintain control throughout complex movement patterns. These findings suggest that enhanced core stability may contribute to improved agility performance in badminton players. Sprint performance was evaluated using the 20-m Sprint Test, with a mean completion time of 3.22 ± 0.10 seconds. Similar to the Agility T-Test, the scatter plot demonstrated a negative relationship between Pressure Biofeedback Unit scores and sprint time. Athletes with better core stability generally completed the sprint in a shorter time, indicating superior acceleration and speed.

Efficient sprinting requires coordinated activation of the trunk and lower-extremity musculature to stabilize the pelvis and maintain optimal body alignment during acceleration. Adequate core stability reduces unnecessary trunk movement and facilitates efficient force transmission through the lower limbs, thereby improving sprint performance. Although badminton involves repeated short-distance movements rather than continuous sprinting, rapid acceleration over short distances is essential for effective court coverage during match play. Overall, the findings of the present study indicate that better core stability is associated with superior athletic performance among male badminton athletes. Positive relationships were observed between core stability and measures of explosive power, while negative relationships were observed with agility and sprint times, where lower completion times represent better performance. These findings support the concept that core stability forms the foundation for efficient movement by enhancing postural control, force transmission, balance, and neuromuscular coordination. From a clinical perspective, the findings highlight the importance of incorporating structured core stability exercises into badminton conditioning programmes. Exercises targeting the deep abdominal muscles, lumbar stabilizers, pelvic musculature, and trunk extensors may improve functional performance by enhancing movement efficiency and reducing unnecessary energy expenditure during sport-specific activities. Sports physiotherapists, strength and conditioning specialists, and badminton coaches should therefore consider integrating evidence-based core stability training into routine athletic conditioning programmes to optimize performance and support injury prevention.

CONCLUSION

The present study was conducted to investigate the relationship between core stability and athletic performance among male badminton athletes aged 18–25 years. Core stability was assessed using the Pressure Biofeedback Unit (PBU), while athletic performance was evaluated through the Standing Broad Jump Test, Medicine Ball Throw Test, Agility T-Test, and 20-m Sprint Test. The findings of the study indicate that athletes with better core stability generally demonstrated superior athletic performance. A positive relationship was observed between core stability and both lower-limb explosive power, assessed using the Standing Broad Jump Test, and upper-limb explosive power, assessed using the Medicine Ball Throw Test. Furthermore, better core stability was associated with faster performance in the Agility T-Test and the 20-m Sprint Test, suggesting that enhanced trunk stability contributes to improved agility and sprint speed. These findings emphasize the importance of the core musculature in providing lumbopelvic stability, facilitating efficient force transmission through the kinetic chain, maintaining postural control, and improving movement efficiency during badminton-specific activities. Since badminton requires rapid multidirectional movements, explosive power, balance, and repeated acceleration and deceleration, adequate core

stability appears to be an important physical component influencing overall athletic performance. The results of the present study support the incorporation of structured core stability training into regular badminton conditioning programmes. Strengthening the core musculature may enhance lower- and upper-body power, improve agility and speed, optimize movement efficiency, and contribute to overall sports performance. Sports physiotherapists, strength and conditioning specialists, and badminton coaches should therefore consider including evidence-based core stability exercises as an integral component of training programmes for competitive badminton athletes. In conclusion, the present study demonstrates that core stability is positively associated with athletic performance in male badminton athletes. Improving core stability may play a significant role in enhancing multiple performance components required for successful badminton performance, thereby supporting its inclusion as an essential element of sports-specific training and rehabilitation programmes.

ABSTRACT

This study presents a comparative laboratory implementation of proportional–integral speed control for a separately excited direct-current motor using a common Lab VIEW supervisory environment. Three configurations are examined: an Arduino Uno connected to an L293D driver, an NI USB-6008 data-acquisition interface connected to the motor drive, and a first-order plant model implemented in software. The controller is identified as proportional–integral because the displayed derivative time is zero. The motor model is reconstructed from the reported electrical and mechanical parameters and is used to interpret the simulated response. Experimental screenshots from the original study are retained as evidence and reorganized into a traceable comparison of signal flow, command history, and terminal tracking values. For the NI USB-6008 implementation, four recorded command sequences produced terminal absolute errors from 0.22% to 1.84%. These values describe individual terminal readings and are not treated as repeated-trial steady-state statistics. The model-based results show qualitative tracking for step and multilevel commands, while the browser panel demonstrates remote supervisory access rather

than networked closed-loop control. The comparison identifies the strengths and limitations of each platform and defines the additional measurements required for rigorous validation.

Keywords: Arduino Uno; data acquisition; DC motor; Lab VIEW; proportional–integral control; remote supervision.

INTRODUCTION

Direct-current (DC) drives remain useful teaching and prototyping systems because their electrical and mechanical dynamics can be related directly to measured voltage and speed. Proportional–integral–derivative control is widely used in industrial practice, but the controller structure and reported gains must be consistent with the implemented algorithm [1]. In particular, a controller with zero derivative time is a proportional–integral (PI) controller, even when the software function is labelled as a general PID block. The PI structure is attractive for speed regulation because the integral action can remove constant tracking offset, whereas excessive integral action may cause actuator saturation and windup [2]. Classical tuning rules remain useful starting points, although final gains should be verified on the physical plant and under the intended operating conditions [3]. LabVIEW-based motor-control studies have used embedded processors, data-acquisition devices, and graphical interfaces for rapid prototyping and education [4]–[9]. These studies demonstrate that a common graphical environment can support signal acquisition, controller execution, actuator commands, and operator visualization. Platform comparisons, however, are meaningful only when the signal paths, sampling conditions, scaling, load, and evaluation metrics are reported consistently. The source study contained three related implementations and a browser view, but its technical claims, figures, and numerical evidence were not organized as a reproducible comparison. The present paper therefore restructures the available material around two objectives: first, to describe the Arduino, NI USB-6008, and first-order-model configurations under one PI-control formulation; and second, to distinguish the observations supported by the archived screenshots from experiments that still need to be performed. No new experimental values are introduced. The contribution is a technically corrected and auditable account of the available implementation evidence, together with a practical validation plan for future work.

MATERIALS AND METHODS

Control formulation:

Figure 1 summarizes the signal path used by the three configurations. A speed reference is compared with the measured or simulated speed, and the resulting error is processed by the PI controller. The controller output is converted to a motor-drive command in the hardware configurations or applied directly to the plant model in simulation. The displayed controller settings are Kc = 1.000, Ti = 0.010 min, and Td = 0.000. Therefore, the control law is written as

$$e(t) = r(t) - y(t), \qquad u(t) = K_c\left[e(t) + \frac{1}{T_i}\int_0^t e(\tau)\,d\tau\right]. \qquad (1)$$

The indicated integral time corresponds to 0.60 s. Because the source record does not report output limits, anti-windup logic, sample time, or the exact discrete realization, Equation (1) describes the continuous-time intent rather than claiming a fully reproducible digital implementation

Arduino-based implementation:

The Arduino configuration uses an Arduino Uno as the digital interface and an L293D quadruple half-H driver to actuate the motor. The Uno is based on the ATmega328P and provides digital input/output and pulse-width-modulation resources suitable for laboratory interfacing [10]. The L293D contains separate logic and output supplies and is intended for inductive loads such as DC motors [11]. In the recorded LabVIEW program, serial

communication, controller computation, output scaling, and front-panel visualization are combined within the main loop. The hardware interface and LabVIEW program are shown in Figure 2.

NI USB-6008 implementation:

The second hardware configuration uses an NI USB-6008 multifunction data-acquisition device. The manufacturer specifies eight single-ended or four differential analog inputs, two analog outputs, and twelve digital input/output lines [12]. The source diagrams show DAQ Assistant blocks used for input acquisition and output generation, together with the same PI settings. Figure 3 separates the signal path, closed-loop arrangement, and recorded Lab VIEW implementation. The available archive does not state the analog-input mode, range, sampling rate, buffer size, output-update rate, or tacho generator calibration; these quantities are therefore treated as required reporting items rather than inferred values.

Model-based implementation:

For model-based evaluation, the displayed parameters are motor constant K = 0.028, armature resistance Rm = 3.3, and inertia $J = 9.64 \times 10^{-6}$. When armature inductance, viscous friction, load torque, and separate electrical and torque constants are omitted, the reduced electromechanical relations are

$$v_a(t) = R_m i_a(t) + K\omega(t), \qquad J\frac{d\omega(t)}{dt} = K i_a(t). \qquad (2)$$

Eliminating armature current gives the first-order speed-to-voltage transfer function

$$G_m(s) = \frac{\Omega(s)}{V_a(s)} = \frac{K}{JR_m s + K^2}. \qquad (3)$$

Substitution of the displayed values produces the reconstructed plant

$$G_m(s) = \frac{0.028}{3.1812 \times 10^{-5} s + 7.84 \times 10^{-4}}, \quad \tau \approx 0.0406 \text{ s}, \quad G_m(0) \approx 35.7. \qquad (4)$$

The numerical time constant and direct-current gain are calculated properties of the simplified model. They are not experimental motor-identification results. Figure 4 shows the archived Lab VIEW model used as the basis for this reconstruction.

Remote supervisory interface:

The archived browser panel mirrors the operator controls and trend display. It supports the narrower claim of web-based remote supervisory access. The material does not include network delay, packet loss, authentication, encryption, disconnect handling, or a remote closed-loop experiment. Accordingly, it is not characterized as an Internet-of-Things controller or as evidence of networked-control robustness. Networked feedback systems require explicit treatment of communication constraints [13], [14].

Evaluation procedure:

The available evidence was reviewed as a set of archived screenshots. Reference values, command transitions, and terminal displayed values were transcribed only when visible. The absolute percentage terminal error for a nonzero final reference was calculated as

$$E_{\text{terminal}} = \frac{|r_f - y_f|}{|r_f|} \times 100\%. \qquad (5)$$

This quantity is reported as a terminal screenshot error. It should not be interpreted as mean steady-state error, accuracy, or repeatability because the dwell time, raw time series, sensor uncertainty, and number of trials are unavailable. The model plots are interpreted qualitatively for the same reason. Table 1 distinguishes reported settings from values reconstructed in this paper.

RESULTS AND DISCUSSION

NI USB-6008 terminal tracking:

Figure 5 consolidates the four NI USB-6008 response records. The command histories include both upward and downward reference changes and one multilevel sequence. The recorded terminal values remain close to the last displayed references. Table 3 gives the directly transcribed final reference, terminal reading, and error calculated with Equation (5). The smallest recorded error is 0.22% for the 2.45-unit terminal command, while the largest is 1.84% for the 1.70-unit terminal command. The other two records give 0.51% and 0.55%. The numerical proximity is encouraging, but the evidence is insufficient for a claim of industrial accuracy. A single displayed endpoint does not show how long the response remained within a tolerance band, whether the sensor was calibrated, or whether the same result can be repeated. Rise time, settling time, overshoot, integral absolute error, and control effort cannot be recovered reliably from the screenshots. The results should therefore be viewed as a preliminary functional demonstration of closed-loop tracking.

Model-based responses:

The three model records in Figure 6 show responses for a step from 11 to 25 displayed units, a step from 25 to 5 displayed units, and a multilevel sequence from 5 to 15 and then to 8.5 displayed units. The output follows both increasing and decreasing commands without a visible sustained offset in the archived panels. This behavior is consistent with integral action in a stable closed loop, but quantitative dynamic indices cannot be reported because raw simulation vectors and the horizontal time calibration are unavailable. The model is useful for explaining the dominant response and for checking controller logic before hardware connection. It should not be treated as a validated digital twin of the motor. Neglected armature inductance, viscous friction, Coulomb friction, driver voltage drop, dead zone, saturation, sensor filtering, load torque, and parameter variation can materially change a physical response. A defensible comparison should estimate motor parameters from measured voltage, current, and speed data and then report the mismatch between predicted and measured trajectories.

Remote supervision and platform comparison:

Figure 7 confirms that the interface can be viewed through a browser. It does not demonstrate that feedback calculations were executed across the network. Keeping the feedback loop local and using the network for supervisory commands is a reasonable architecture because it separates time-critical control from variable communication delay. Before remote operation is claimed as safe, the implementation should specify user authentication, command authorization, update rate, stale-command handling, watchdog behavior, and the state entered after communication loss. The Arduino configuration offers a compact and low-cost embedded path with direct pulse-width-modulation capability. The USB-6008 configuration provides convenient analog and digital data-acquisition channels and integrates naturally with LabVIEW, but its analog-output and sampling characteristics must be matched to the drive. The software model permits repeatable tests without hardware risk and provides an interpretable baseline. These are functional differences rather than a performance ranking: the available evidence does not use identical calibrated units, timing settings, load profiles, or repeated trials across all three implementations.

Limitations and required validation:

The principal limitation is the absence of raw time-series data and test metadata. A complete follow-up experiment should report the motor nameplate, tachogenerator or encoder calibration, supply voltage, load torque, pulse-width-modulation frequency, controller sample time, DAQ channel configuration, filters, output limits, and anti-windup method. Every operating point should be repeated at least five times. Mean and standard deviation should be reported for rise time, settling time, overshoot, steady-state error, integral absolute error, and control effort.

The Arduino and USB-6008 paths should then be tested against the same reference sequence and load using a common calibrated speed sensor. Load-torque steps and supply-voltage changes would reveal disturbance rejection and robustness. For the remote interface, round-trip latency, command-update jitter, access control, disconnection,

recovery, emergency stop, and fail-safe behavior should be measured. These additions would change the work from a functional implementation report into a comparative experimental study.

CONCLUSION

A common LabVIEW environment was used to organize three PI speed-control configurations for a DC motor: Arduino Uno with an L293D driver, NI USB-6008 data acquisition, and a reconstructed first-order plant model. The zero derivative-time setting establishes that the implemented controller is PI rather than full PID. The motor equations and displayed parameters yield a simplified model with an estimated time constant of 40.6 ms and direct-current gain of 35.7. Four NI USB-6008 screenshots give terminal errors between 0.22% and 1.84%, but these are individual endpoint observations rather than repeated steady-state statistics. The simulated records provide qualitative evidence of command tracking, and the browser image supports remote supervision only. The available material therefore demonstrates feasibility and a coherent implementation workflow, while rigorous platform ranking requires calibrated, repeated, disturbance-based experiments with raw data.

Data Availability

The results reported in this paper are derived from the figures and numerical displays contained in the source manuscript. Raw sampled speed, voltage, current, and control-output records were not available for reanalysis. Authors should deposit the raw data and controller files with the submitted revision when those records become available.

Declaration on Ai-Assisted Preparation

During manuscript preparation, a generative language tool assisted with organization, language editing, reference checking, and journal formatting. It did not generate experimental data, figures, equations, or numerical results. The authors must independently verify the manuscript and references, revise the text in their scholarly voice, and accept responsibility for submission.

ABSTRACT

Micro enterprises constitute an important component of entrepreneurial activity in developing economies. This study reviews and examines the role of micro enterprises in economic development, with specific emphasis on evidence from India. The review integrates studies addressing enterprise growth, employment contribution, income generation, regional development, livelihood creation, economic participation, financial access, women's economic participation, institutional support, and formal-informal structure of micro enterprises. On the other hand, the literature reveals the challenges like limited access to finance, technology, infrastructure, skills and institutional support hindering their developmental role towards economic development. Regional heterogeneity and differences between registered and unregistered enterprises further complicate these challenges and affects the relationship between enterprise prevalence and economic development. The study identifies a major gap in the existing literature is its tendency to examine micro enterprises together with small and medium enterprises, leading to difficulty in identifying the specific contribution of micro enterprises. The review further proposes an integrated analytical perspective in which enterprise participation, entrepreneurial capabilities, available resources, enterprise performance and socioeconomic outcomes collectively determine the developmental contribution of micro enterprises.

Keywords: Micro enterprises, Economic Development, Entrepreneurship, Employment generation, Developmental impact, MSMEs.

INTRODUCTION

Economic development is a multidimensional process that extends beyond the expansion of national income and GDP. It encompasses improvements in use of sophisticated technology, continuous innovation, dominance of the tertiary and secondary sector in income and employment generation, productivity, entrepreneurship, living standard, economic inclusion and the reduction of regional disparities. In a developing country like India, achieving these outcomes requires the participation of enterprises across different sectors. India's economy is characterized by its diverse sector, which comprises, agriculture, industry, services, and trade with enterprises of different sizes contributing to the production, employment, and income generation. The activity of each sector are closely related to the broader functioning of the overall economy. Especially businesses are the primary engines of economic activity. Businesses of all sizes contribute to production, employment, and revenue generation as they convert resources into goods and services that satisfy the wants of people and improve their standard of living through creating jobs for people and communities and generate income for households. Consequently, growth and development of the economy significantly depends on the manufacturing and service sector besides agriculture.

Background of the study

Micro, Small, and Medium Enterprises have a long occupied position in India's Economic growth and development. The Ministry of Micro, Small, and Medium Enterprises (M/o MSMEs) describes Micro, Small, and Medium Enterprises as the major contributor to employment, entrepreneurship, income generation, innovation, trade, exports, and inclusive industrial development. These enterprises also accompany large industries through participating in supply chains and ancillary activities, thereby integrating smaller enterprises with wider processes of production and economic activity. The developmental importance of these enterprises is particularly concentrated on the micro enterprises which forms the majority of the registered enterprises and operate across manufacturing, services and trade. However, their significance should not be interpreted only in terms of their numerical dominance. Micro enterprises takes relatively less capital, operate in local and regional markets, and combine self-employment with limited wage employment unlike the large enterprises which needs huge investment. Their collective effect can therefore be economically significant even when the individual enterprise is small in scale and income generation, they also foster entrepreneurship in grass-root levels providing accessible opportunities for self-employment and improving the livelihood of local communities by operating within local and regional economies to the national level. Government programmes also have recognized micro enterprises as vehicles for employment and entrepreneurship. The developmental significance of micro enterprises acts through a number of interrelated channels.

They can create self-employment and income generation at the individual and household levels. At the local level, they facilitate local production, trade and services, and facilitate the circulation of income. Their collective efforts support employment, entrepreneurship, production, market involvement, and economic inclusion at the larger economic scale. Extensive studies on Indian MSMEs have examined their potential contribution to employment generation while, wide range of international studies indicate that interventions supporting micro and small enterprises can influence self-employment and other economic outcomes although the magnitude and sustainability of these effects vary significantly across different contexts. Nevertheless, the existence of magnificent amount of micro enterprises does not automatically translate into proportionately greater economic development. Micro enterprises frequently operate with inadequate finance, limited managerial capabilities, technology constraints, marketing difficulties, infrastructure problems, regulatory burden, limited market access, low productivity, informality, vulnerability to economic shocks. Hence, their ability to contribute effectively to economic development constrained by structural and operational challenges. The developmental contribution of micro enterprises needs to be considered in relation to their productivity, sustainability, formalisation, access to resources, ability to grow and capacity to generate meaningful economic opportunities rather than in terms of their numbers.

The government has increasingly undertaken various measures to address these issues through interventions relating to credit and finance, technology, infrastructure, digitalization, marketing, skill development, and formalisation.

However, the effectiveness of these measures depends on whether formalisation and institutional support actually reflects in the enterprises capabilities and developmental outcomes. Although a substantial body of research has examined MSMEs, entrepreneurship, employment, finance, and enterprise development, the literature has been often dispersed across different aspects of enterprise performance and development. Furthermore, despite the variations in their size, ownership structure, resource limitations, managerial skills, and growth traits, micro enterprises are often regarded collectively under small and medium-sized enterprises. Therefore it is important to have a systematic understanding of the specific pathways through which micro enterprises contribute to economic development, and the challenges affecting their efficient contribution towards economic development. The study aims to review the various existing literature discussing the various dimensions impacting the role of Micro enterprises in economic development, and also the challenges that limit their ability to contribute in the development.

REVIEW OF LITERATURE

The literature on micro enterprises and their contribution to economic development is relatively limited, while extensive research examines micro, small and medium enterprises (MSMEs) collectively rather than treating micro enterprises as a separate enterprise category. Existing studies have addressed the role of smaller enterprises in employment generation, entrepreneurship, income generation and livelihood development, regional development, financial inclusion, formalisation and economic growth whereas another group of studies focused on the challenges faced by the micro enterprises which constraints their performance and developmental potential. A review of this literature proposes that the contribution of micro enterprises to economic development is multidimensional and cannot be assessed through an individual economic indicator.

Micro enterprises as a significant component of the Indian Economy

The literature commonly recognizes MSMEs as an important component of India's economic structure and connects with employment generation, entrepreneurship, production, exports and broader socio-economic development. Pandey and Chaudhary (2024), examined the relationship between MSME performance and major economic indicators and highlighted that the sector contributes to the employment, GDP, Exports, entrepreneurship, innovation, and government support which ultimately impacts the development of the economy while very few studies have highlighted the importance to give separate attention to Micro enterprises and micro entrepreneurs as they are not simply smaller version of medium sized or large sized enterprises which are managed and operated differently. Taiwo, Awolaja, et.al (2012) examined the impact of SMEs on the economic growth with particular attention to micro enterprises and argues that they are not just small-scale units but structural pillars of economic resilience and inclusive growth in developing economies like Nigeria and India. Similarly, Gherhes et al., (2016) distinguished micro-enterprises from larger SMEs and pointed out that micro enterprises are strongly owner-manager centered and may experience distinctive constraints relating to capability gaps, scaling operations and access to appropriate support. This indicates the need for greater attention to micro enterprises as a separate unit of analysis when examining their contribution to economic development. Thus, the tendency to analyse MSMEs as a homogeneous group creates an major conceptual issue.

Micro Enterprises and Employment generation

Employment generation is one of the major contributions of micro enterprises to the economic development which were discussed widely in literature. In the Indian context, specifically several studies have identified that micro enterprises played a significant role in employment generation and that unregistered enterprises accounted for a substantial proportion of employment. Alamelu and Baskaran (2011) emphasized that MSMEs absorb surplus labour from agriculture sector and provide sustainable employment opportunities in manufacturing and service sector, particularly in rural and semi-urban regions. They expand the labour market and reduce the unemployment pressure by engaging marginalized groups, including women and youth. However, E. M. Mutyenyoka and T. Selby. Madzivhandila (2014) argues that despite their role in absorbing a significant portion of the total labour force, MSMEs often fail to provide sustainable career paths or transition workers into formal economy. Being accounted to

be a major provider of employment should not be equated automatically with employment quality or sustainable enterprise growth. Thus, Cravo and Piza, (2016) suggested that assessing the contribution of micro enterprises to the economic development requires a multidimensional framework that considers the sustainability, productivity, and growth rather than relying on numerical counts .

Micro Enterprises, Entrepreneurship, and Self-employment

Another important dimension identified in the literature is the role of Micro enterprises in facilitating entrepreneurship and self-employment as they requires less capital and organizational resources than larger enterprises. Kalaiselvi, V., and Maithily, K. (2024) insisted that they can provide an entry point to participate in entrepreneurial activity. Saluja, D. (2012), Manna, P., and Mistri, T. (2017) highlighted that micro enterprises act as incubators of innovation and entrepreneurial skills, and also encourage self-employment, reduce dependency on large corporations, and helps in diversification of India's industrial sector. Pandey, P., and Chaudhary, A. K. (2024) stressed that micro enterprises are the entry point for entrepreneurship, fostering innovation in both traditional and modern sectors. They can also act as incubators for small-scale innovation, which can later be scaled up into larger enterprises. Literature specifically on Indian MSMEs connects enterprise development with economic development. IMF (2024) proposed that successful self-employment initiatives often lead to formalisation and subsequent hiring of labour, thereby bridging the gap between individual self-employment and firm expansion. However, the impact is not immediate. E. Mills, (2025) emphasized that the reduction of unemployment through entrepreneurship requires a minimum of five years highlighting the distinction between immediate self-employment outcomes and the long-term goal of firm-led job creation. Therefore, the developmental importance of entrepreneurship should be examined not only through enterprise formation but also through enterprise survival, productivity, and the ability to develop beyond subsistence level activity.

Micro Enterprises and Income and Livelihood creation

Micro enterprises contribute to the circulation of income within local economies by providing income generating opportunities for entrepreneurs and other workers which ultimately forms the essential growth component of the economy. D. Panwar, P. Mamgain, and M.C Sati, (2024), said that this circulation is further reinforced by the positive correlation between enterprise investment, job creation, and overall income levels within the local regions. T. Hassan and B. Ahmad, (2016) affirmed that through self-employment, family employment and local wage employment micro enterprises contributes to the livelihood of local community. Particularly, where wage employment is limited, these enterprises becomes a significant source of livelihood for many households. Similarly, D. Panwar, P. Mamgain, and M.C Sati, (2024), expressed that in countries like Ethiopia and India, micro enterprises are instrumental in poverty reduction, and being a means for individuals to secure employment and improve household financial stability. Additionally, Government of India, (2020) and World Bank, (2000), stated that the contribution of micro enterprises to local economies extends beyond direct employment through the creation of multiplier effects within the surrounding ecosystem by sourcing raw materials from local suppliers and procuring machinery or equipment from large or small suppliers. They stimulates broader economic activity beyond individual businesses, by engaging in community-based distribution. Despite their role as catalysts for economic development, Bairagya et al. (2020) points out that the ability of micro enterprises to circulate income is often constrained by systematic challenges like difficulties in accessing finance, which limits their capacity to scale operations and create more job opportunities for more workers. Besides them, external factors like high operational costs, energy shortages, and intense market competition can hinder the sustainability of these enterprises. A small scale or micro level enterprise can have limited output but still makes a significant contribution for the household and individual income making them economically active. Hence, the developmental contribution of micro enterprises should not be evaluated merely through aggregate indicators such as GDP or exports. The livelihood dimension is especially important when evaluating the economic development.

Micro Enterprises and regional development

Micro enterprises contributes for dispersed economic development by operating in every nooks of a country. In contrast to large enterprises which are mostly concentrated in large cities particularly in industrial and metropolitan

regions, micro enterprises are widely spread across rural to urban areas. Kalaiselvi,V., and Maithily, K. (2024), highlighted that micro enterprises promote balanced regional growth by utilizing local resources. Shal, S. (2015), added that these enterprises, bridge urban-rural divides and foster inclusive growth by industrializing rural and backward areas. Manna and Mistri, (2017) explicitly argues that MSMEs can reduce regional disparities through income and employment generation in rural and semi-urban regions, support their economic independence and contribute to sustainable development. Through creating job opportunities and self-employment, micro enterprises have the capacity to prevent rural-urban migration which causes over population in major cities. They also provide large opportunity for semi-skilled and unskilled laborers. This suggests that development role of Micro enterprises extends beyond national-level economic indicators to include the strengthening of local economic ecosystem. However, Shrivas, R., and Chandak, S. (2025) argues that regional presence does not necessarily indicates equal developmental performance. Variations in infrastructure, access to finance, markets, technology, human capital and institutional support between different locations makes a greater differences in their outcomes, growth and development. Accordingly, the geographical contribution of micro enterprises needs to be considered in relation to the local entrepreneurial ecosystem in which enterprises operate.

Micro enterprises and Women's Economic Participation

Women's participation in economic activity represents another important dimension of economic inclusion. Saluja, D. (2012) asserted that micro enterprises create a flexible entrepreneurial environment for women within local social systems, especially for rural women who balance household and farm responsibilities. They are providing home based opportunities for entrepreneurs involved in handicrafts, agro-processing, livestock management which fit women's daily routines. Kanothi R. N., (2009), and K. H. Anantha, S.P. Wani, and T. K. Sreedevi (2009), mentions that these enterprises provide employment opportunities for diverse demographic groups, including women, youth, and people with disabilities, who may otherwise face barriers to entry in traditional labour markets. Additionally, these enterprises strengthen women's leadership, social recognition, and political participation, contributing to community development and also women empowerment. On the other hand, Prentice, (2017) and Aikaeli, (2021) contended that there exist a significant disparities and barriers for women and youth while, MSMEs are often promoted as vehicles for engaging marginalized populations. Furthermore, enterprises owned by youth are more likely to be more informal compared to those owned by older individuals which negatively impacts their income potential and facing severe constraints regarding access to finance and credit. Li, et al. (2026) insists that women entrepreneurs engaged in entrepreneurship are often facing significant issue in access to finance, disadvantages in institutional credit market and underperform male-owned firms in dimensions such as size, growth and efficiency. Thus, while micro enterprises can create opportunities for women's economic participation, their developmental impact may depend substantially on women's ability to access finance, markets, skills, technology and institutional support. Many reviews and text-mining study of Indian women entrepreneurs identified the need to better understand the research landscape surrounding women operating micro enterprises.

Micro Enterprises and Financial Inclusion

Financial inclusion leads to growth and resilience which means access to affordable financial services for undeserved is critical for poverty reduction and economic growth. The literature suggest that micro enterprises often operate with limited internal sources and also face difficulties in accessing formal institutional finance which may reduce their disruption in their operational performance and improve the growth and productivity of the firm and as whole. Gupta and Singh (2026) distinguished between working capital and fixed asset finance and explained that finance affects firm's ability to undertake productive activities. working capital supports liquidity and day to day operations of the firm while, fixed asset finance is associated with investment in machinery, equipment and productive capacity. The IMF (2024), also insists that financing constraints can negatively affect firm growth and productivity. The IMF identifies multiple dimensions behind financial exclusion such as information asymmetry, mismatches between lenders and borrowers, market fractions and cost of capital. Gupta and Singh (2026) explicitly recommends that improving access to flexible and affordable financing, particularly working capital loans, rather than treating all forms of finance as equally useful at all stages of firms. This insists that the issue is not simply whether credit exists, but also whether it is accessible, affordable, adequate and appropriate to the needs of micro enterprises.

The IMF (2024), report states that a larger portion of MSMEs are relying on informal source where available easily, indicating a substantial credit gap and potentially higher financing costs. The nature of dependence of larger enterprises on informal source of credit and finance itself matters for the major performance issue. Vidyarani and Mallick (2025), also analyse formal, informal and combined sources of credit among Indian MSMEs using NSSO data on unincorporated enterprises which is mostly consists agricultural micro enterprises, confirming that the source of finance significantly influences the enterprise performance. On the other hand, more organised enterprises are more likely to obtain formal credit, suggesting that enterprise level characteristics affect financial access. Mishra and Choudhruy (2025) found that financial inclusion and micro enterprise growth has a strong positive relationship. Bank support strengthened this relationship through improved access, advisory support and digital financial services. Further, it insists that positive relationship between financial inclusion and enterprise growth has greater impact on innovation, employment generation and enterprise expansion. Similarly, Gupta and Singh (2026), found that access to formal working-capital finance positively affected employment growth, capacity utilization and labour productivity. Beck and Hoseini (2014), found that greater bank outreach can reduce informality by lowering barriers to entering the formal economy, particularly micro enterprises for micro and smaller enterprises. This suggests that financial deepening can increase the productivity of formal sector firms. This makes financial inclusion an important link between micro enterprises and economic development. If financial inclusion improves productive investment and enterprises sustainability, it can strengthen the contribution of micro enterprises to employment, income generation, and living standard. Conversely financial exclusion may reinforce small scale and informality limiting their capacity to exploit economies of scale and invest in productivity enhancing technologies.

Formalisation and the developmental role of micro enterprises

Formalisation has become increasingly important for business enterprises, particularly micro enterprises and small scale enterprises which are operating with limited financial resources. Registration mechanisms such as Udyam allows any type of enterprises to access formal financial assistance, institutional support, marketing services and other services. Mehrotra and Giri (2023), argues that predominance of micro enterprises and persistent informality are interconnected structural problems. This causes inability of micro enterprises to access sufficient credit to scale their enterprises. In addition to that, predominance of micro enterprises limits economies of scale, technological upgrading, productivity and employment growth. Posti and Maiti (2025), also finds a positive relationship between firm's size and productivity, which reflects in the growth and performance of those enterprises. Keshava, S.R. (2026) examined the growth, employment potential and financial inclusivity during the Udyam formalisation phase, giving specific attention to women-owned enterprises. This indicates that formalisation has become an increasingly relevant dimension for understanding the current developmental role of micro enterprises.

Challenges hindering the Developmental Contribution of Micro Enterprises

Despite the economic significance of micro enterprises, they are facing several structural and operational constraints. NITI Aayog's (2025) analysis identifies that micro enterprises and small enterprises are facing inadequate finance, infrastructure deficiencies, limited market access, skill shortages, while PIB (Press Information Bureau) (2026) identifies credit, technology, markets, infrastructure bottlenecks and delayed payments as persisting major challenges. The challenges face by micro enterprises can also differ from larger SMEs. Gherhes, Cristiana et al., (2016) identifies micro enterprises are particularly owner-manager-centric organization and face distinctive constraints involving growth orientation, business capabilities, owner-manager capabilities and adequate business related institutional support. Similarly, Mehrotra and Giri (2023) also points out an important paradox that despite the significance number of micro enterprises are far enough to make substantial collective contribution to employment and economic activity, but their individual scale, productivity, sustainability and limited growth potential hinders the economic contribution.

DISCUSSION

The literature reviewed indicates that the contribution of micro enterprises to economic development operates through several interconnected mechanisms and includes multi-dimensional processes. First, micro enterprises provide opportunities for self-employment and employment generation for skilled and semi-skilled labour away from agriculture. Second, they create livelihood opportunities through income generation and employment opportunities for entrepreneurs and workers. Third, they contributes to reduction in regional disparities through dispersed existence of enterprises from local to national level and also helps in regional economic development. Fourth, they broaden participation in entrepreneurship and increased economic activity which provides doorway for innovation and standard utilization of products and services. Fifth, micro enterprises facilitate women and marginalised group to participate in entrepreneurship and economic activities contributing to the economic inclusion. Finally, formalisation can strengthen their relationship with institutional assistance, government programmes and wider markets beyond local, national and international markets.

The literature also indicates that these contributions are conditional. Enterprise size, number of enterprises, and the quantity alone will not determine developmental impact. Quality of the business ecosystem, access to resources, owner-manager capabilites, productivity, and institutional support influence the extent to which micro enterprises can generate developmental economic outcomes. The studies signify that these contributions are not automatic. Finance, technology, skills, infrastructure, market access, institutional support, and formalisation influence the capacity of micro enterprises to produce a sustainable economic outcomes. Existing research found that inadequate internal financial sources, lack of appropriate technology, infrastructure, Skills hinders the contribution and developmental role of micro enterprises to the economic development. Further, Methodologically, many studies examined MSMEs collectively, making it difficult to decide whether findings relating to small and medium sized enterprises can be directly generalised to micro enterprises. Consequently, the literature suggests a shift from examining whether micro enterprises are important to the economy and its development to a more analytical examination of how, under what conditions, and to what extent micro enterprises contribute to economic development. This perspective provides the basis for assessing the research gaps surrounding micro enterprises in India for developing a more in depth and integrated understanding of their developmental role.

CONCLUSION

The reviewed literature insists that micro enterprises occupy a significant position in the economic structure of developing economies and particularly in India. Their contribution extends beyond the creation of business enterprises. They provide avenues for self-employment, employment, income generation, regional development, local economic activity and entrepreneurial participation. In case of women entrepreneurs, micro enterprises enables them to earn and achieve economic independence and empowerment. However, the review also states that prevalence of much number of micro enterprises should not be associated directly with economic development particularly, when the contribution of MSMEs towards GDP are measured collectively. The contribution of micro enterprises can vary differently according to their ability to transform entrepreneurial participation and available resources into productive, sustainable and resilient enterprise activity. Financial inclusion is an important catalyst for enterprise growth, but the literature indicates that finance, skills, technology, market access and institutional support are also important. Likewise, formalisation improves institutional integration and enables easy access to finance, but a formal registration itself cannot be treated as synonymous with productivity or development. The regional variations can also affect the impact and reach of these benefits.

The most significant finding from the study is that micro enterprises play a conditional and multi dimensional role in economic development. Their contribution to economic development can be understood through the interaction of structural context, enabling resources, entrepreneurial capabilities, enterprise, performance and socioeconomic outcomes. However, most of the studies are still fragmented. While some studies specifically focus on individual

factors or outcomes, most of the studies continues to combine micro, small and medium sized businesses. The literature review suggests that future studies should make a clear distinction among the micro, small and medium enterprises. And should also study the ways in which institutional support, technology, finance, capabilities, formalisation, and structural factors that collectively affect the productivity, survival, growth, employment, income and inclusive development.

ABSTRACT

In the realm of homeopathy, understanding the role of emotions, such as anger, is crucial in remedy selection. This pilot study explores the connection between anger and the selection of the homeopathic similimum. Recognizing anger as an emotional indicator can help practitioners personalize treatments, addressing both physical symptoms and emotional well-being. A pilot study of 30 cases with predominant anger symptoms was conducted. Remedies were selected on the basis of similimum by repertorization and miasmatic analysis. Each case presented different complaints and was individualized. The study expands our understanding of anger's impact on homeopathic treatment and highlights the importance of exploring anger in remedy selection. Homeopathy can be leveraged to address anger-related health concerns effectively.

Keywords: Homeopathy, Similimum, anger, personality, clinical anger scale.

INTRODUCTION

Homeopathy, a holistic approach to healing, recognizes that emotions play a significant role in a person's health. Anger, as a powerful and complex emotion, affects both physical and mental health. This study aims to examine how anger influences the selection of homeopathic remedies for patients. Anger can result in destructive physical and psychological changes, affecting relationships and social life. According to the World Health Organization (WHO), homeopathy is among the fastest-growing and second-largest systems of medicine.

Conventional treatments for anger include psychotherapy, counseling, and medications:

- Cognitive Behavioral Therapy (CBT): Helps individuals change negative thought patterns related to anger.
- Anger Management Therapy: Teaches coping and communication skills.
- Medications: Such as SSRIs and mood stabilizers, which may have side effects (nausea, insomnia, weight changes, sexual dysfunction, drowsiness, dizziness)

Homeopathy offers a holistic approach, considering individual symptoms and emotions to restore body-mind balance.

Aim and Objective

The **goal** of the study is to analyze the level of anger in specific situations and observe its role in the selection of similimum.

Design of the Study:

A prospective observational study conducted at Government Homeopathy Medical Hospital, Thirumangalam, Madurai. The study used an anger scale, with vital parameters and symptomatic changes recorded monthly.

MATERIALS AND METHODS

Screening: Cases were screened using the anger thermometer.

Study Steps:

- Detailed Case History and Patient Interviews: Exploring emotional aspects, triggers, and reactions.
- Observations and Analysis of Physical Symptoms: Identifying body language and expressions associated with anger.
- Repertorization: Using homeopathic repertory software and methods for similimum selection.
- Materia Medica Study: Matching symptomatology to homeopathic remedies.
- Clinical Anger Scale: Used to assess and measure anger levels.

DSM Classification: The DSM-5 cross-cutting questionnaire was used in the first session.

Sample Questions:

- I was irritated more than people knew.
- I felt angry.
- I felt like I was ready to explode.
- I was grouchy.
- I felt annoyed.

Scoring Interpretation:

- Less than 5: None to slight
- 5.5–10.5: Mild
- 15.5–20.5: Moderate
- 21.5 and over: Severe

Patients aged 20-30 were included. The study was clinical, prospective, non-randomized, and non-controlled, with before-and-after comparison of 30 participants (with consent). Individualized homeopathic remedies were prescribed based on anger symptoms and health status.

Outcome Assessment:

- Improved: 90% progress in patients who attended all sessions.

- Nonconclusive: Withdrawal from treatment before 12 months.
- Miasmatic Background: Cases with predominant anger showed strong miasmatic background.
- Total resolution in some cases.

RESULTS

- 30 cases were enrolled; 3 dropped out for personal reasons, 2 were excluded for missing sessions.
- 25 patients completed the study.
- Anger levels reduced (CAS scale range: 8 to 4, 3, 2); behavior changes observed.
- No adverse effects reported.
- Male cases: Good results in anger management.
- Female cases: Emotional and physical improvements led to greater harmony.
- Selection of Similimum at each visit reflected changes in personality and problem-solving.

SUMMARY AND CONCLUSION

- Anger plays a prominent role in selecting similimum.
- Classical homeopathic treatment is more efficient in anger management than conventional approaches.

However, multi-centric randomized controlled trials with larger sample sizes are needed for stronger recommendations. This pilot study provides valuable insights into anger's role in homeopathy and supports holistic approaches for emotional balance and well-being.

ABSTRACT

The biosynthesis of prostaglandins, the main mediators of inflammation and pain, depends critically on cyclooxygenase-2 (COX-2). A promising therapeutic approach for the creation of analgesic and anti-inflammatory drugs with fewer gastrointestinal side effects is selective inhibition of COX-2. In order to assess the potential analgesic activity of a number of imidazole-based derivatives, the COX-2 enzyme (PDB ID: 4COX) is investigated using in silico molecular docking. Computational analysis was performed on a parent ligand, 2-([2-(2,4-dinitrophenyl) hydrazinyl]methyl)-1H-benzimidazole, and five logically constructed structural derivatives. The current work focuses on evaluating synthetic benzimidazole and aromatic amine derivatives for possible analgesic activity against the cyclooxygenase-2 (COX-2) enzyme using in silico molecular docking. Analgesic and anti-inflammatory effects are linked to the inhibition of COX-2, an important therapeutic target involved in inflammation and pain pathways. Using computational docking software, a number of structurally altered derivatives with benzimidazole nuclei, nitro-substituted aromatic rings, amino groups, hydrazine linkages, aldehyde groups, and acetamide functionalities were created and put through molecular docking analysis. For the majority of the synthetic compounds, the docking results showed strong ligand-protein interactions. Docking scores were measured in kcal/mol for assessing binding affinity, with a negative (lower) binding energy indicating a stronger and more stable interaction of the ligand to receptor protein. Because stable ligand-protein

complexes were formed, compounds with low binding energy values demonstrated superior inhibitory potential toward the COX-2 enzyme. A number of compounds showed favorable binding affinity toward the COX-2 receptor's active site out of all tested derivatives. Compounds, which had docking scores of −7.757 kcal/mol and −8.285 kcal/mol were found to remain stable in the receptor binding pocket via hydrogen bonding, hydrophobic interactions and electrostatic force. It is implied that the generated derivatives can serve as strong COX-2 inhibitors with possible analgesic properties.

Keyword: Molecular docking, COX-2, analgesic action, PyRx, Swiss ADME, Celecoxib, and benzimidazole.

INTRODUCTION

One of the most common and crippling medical conditions in the world, pain affects millions of people and has a significant negative impact on society and the economy. Among the most frequently prescribed medications for treating fever, inflammation, as well as acute and chronic pain, are analgesics, particularly non-steroidal anti-inflammatory drugs (NSAIDs). Nevertheless, the long-term effectiveness of traditional NSAIDs that inhibit both cyclooxygenase-1 (COX-1) and cyclooxygenase-2 (COX-2) without selectivity is restricted due to their considerable gastrointestinal toxicity, risks to renal health, and cardiovascular issues. Pro-inflammatory prostaglandins, thromboxanes, and prostacyclines are synthesized from arachidonic acid by COX-2, which is an inducible isoform of the cyclooxygenase enzyme predominantly found at sites of inflammation. In contrast to COX-1, a constitutive enzyme with cytoprotective roles in the kidneys and stomach mucosa, COX-2 is upregulated in response to inflammatory stimuli, cytokines and mitogens. Imidazole- and benzimidazole scaffold based compounds have attracted a lot of interest in medicinal chemistry on account of their broad spectrum of biological activities like anti-inflammatory, analgesic, antimicrobial, antifungal, antihypertensive and anticancer properties.Benzimidazole's bicyclic aromatic system makes it a great pharmacophore for drug design that targets enzyme active sites because it can engage in hydrophobic and hydrogen-bonding interactions. The benzimidazole nucleus is present in a number of clinically approved medications, such as omeprazole, albendazole, and mebendazole, highlighting its therapeutic versatility. The early phases of drug discovery have been transformed in recent decades by computer-aided drug design (CADD) and molecular docking, which allow for the quick virtual screening of large compound libraries against therapeutic targets. Molecular docking uses scoring functions to estimate the binding affinity and predict a ligand's preferred binding orientation within a protein active site. This method offers important mechanistic insights into ligand-receptor interactions while drastically cutting down on the time and resources needed for experimental screening. The present study aimed at evaluating the analgesic potential of various new imidazole/benzimidazole derivatives using in silico molecular docking against COX-2 enzyme (PDB ID: 4COX).The parent compound, 2-([2-(2,4-dinitrophenyl)hydrazinyl]methyl)-1H-benzimidazole, was chosen due to its structural characteristics that include both dinitrophenylhydrazine and benzimidazole moieties, both of which are known to have biological activity. Five structurally diverse derivatives were rationally designed and evaluated alongside the standard drug celecoxib for comparative analysis. To evaluate the test compounds' pharmacokinetic characteristics and drug-likeness, ADME profiling was also carried out.

Protein Preparation

The crystal structure of human Cyclooxygenase-2 (COX-2) complexed with its inhibitor SC-558 at 2.10 Å resolution was retrieved from the RCSB Protein Data Bank (PDB ID: 4COX). The protein structure was prepared using Discovery Studio Visualizer. Non-structural solvent molecules, which can interfere with docking, were removed by removing water molecules from the crystal structure. Polar hydrogen atoms and Gasteiger charges were added to the protein.The prepared protein was stored in AutoDock Vina-compatible PDBQT format. Key residues in COX-2's well-characterized active site include ARG120, TYR355, SER530, HIS90, VAL349, LEU352, SER353, TYR385, TRP387, PHE381, LEU384, TYR348, and PHE518. Both NSAIDs and COX-2 selective inhibitors target the binding pocket, which holds the arachidonic acid substrate.

Ligand Preparation

The structures of all test compounds were created with the Chem3D program. The conformers generated were minimized with the MMFF94 (Merck Molecular Force Field 94) force field until the root mean square (RMS) gradient was less than 0.100 kcal/mol. Optimized structures were saved in SDF or MOL2 files as needed by AutoDock Vina and converted into PDBQT format with the help of Open Babel.During the conversion process, Gasteiger partial charges were calculated and allocated. The same preparation techniques were applied to the standard medication celecoxib, which was obtained from PubChem (CID: 2662).

Compounds Under Investigation

The compounds listed below were chosen for molecular docking analysis:

Parent ligand (l0): 2-([2-(2,4-dinitrophenyl) 1H-benzimidazole [hydrazinyl]methyl

This compound has a 2,4-dinitrophenyl moiety attached to a benzimidazole ring via a hydrazinylmethyl linker. The COX-2 active site can interact electrostatically and form a variety of hydrogen bonds with the imidazole nitrogen atoms and electron-withdrawing nitro groups.

Derivative 1 (D1): 2-{2-[(3,4-dinitrobenzyl)(phenyl)amino]ethyl}-N-methylaniline

The inclusion of a secondary amine linker bearing a 3,4-dinitrobenzyl group and a phenyl substituent on an N-methylaniline moiety provides additional hydrophobic contacts and possible pi-pi stacking interactions within the COX-2 active site.

Derivative 2 (D2): N-methyl-benzene-1,2-diamine, N-[2-[(2-acetylphenyl)(2,4-dinitrophenyl)amino]ethyl]

D2 has a 2,4-dinitrophenyl moiety, an N-methylbenzene-1,2-diamine scaffold and an acetylphenyl group, which provides a hydrogen bond acceptor carbonyl that may enhance polar and hydrophobic binding interactions.

Derivative 3 (D3): N^1-[2-[(2-aminophenyl)(2,4-dinitrophenyl)amino]ethyl]-N^2-methylbenzene-1,2-diamine

Along with the conserved 2,4-dinitrophenyl pharmacophore and methylbenzene-1,2-diamine moiety, D3 has an aminophenyl substituent that adds another primary amine group that can form hydrogen bonds with active site residues.

Derivative 4 (D4): N^1-(4-formylphenyl)-N^2-(2,4-dinitrophenyl)-N^2-[2-(methylamino)benzyl]ethane-1,2-diamine

D4 provides a flexible scaffold for ideal placement within the binding cleft by incorporating a 2,4-dinitrophenyl group, a 4-formylphenyl group with an aldehyde hydrogen bond acceptor, and a 2-(methylamino)benzyl moiety tethered via ethane-1,2-diamine.

Derivative 5 (D5): N-[2-[(acetamido(3,4-bis(methylamido)phenyl)amino]ethyl]-N-methylaniline
Compared to nitro-containing analogs, D5 is a structurally unique derivative with acetamido and bis-methylamido groups on the phenyl ring. It offers several hydrogen bonding sites and less electron-withdrawing character, which may have an impact on selectivity and binding profile.

Derivative 6 (D6): 2,4-Dinitro-N-[(1H-benzimidazol-2-yl)methylamino]aniline
This derivative, D6, has a benzimidazole pharmacophore connected by a methylamino bridge to a 2,4-dinitroaniline moiety. The existence of two strongly electron-withdrawing nitro groups enhances the electron deficiency of the aromatic ring and could also facilitate intermolecular interactions with amino acid residues in the active binding pocket. The benzimidazole nucleus may have aromaticity and hydrogen bonding capacity that may enhance biological activity and receptor affinity.The amino linkage influences the docking score and selectivity profile by offering structural flexibility and possibly enabling correct orientation within the COX-2 active site.

Derivative 7 (D7): N-[(1H-benzimidazol-2-yl)methyl]-N-formyl-2,4-dinitroaniline hydrazine
This derivative, D7, has a 2,4-dinitroaniline scaffold connected to the benzimidazole ring system and a formyl-substituted hydrazine functionality. The formyl group may improve ligand–protein interactions inside the receptor cavity by adding more polarity and hydrogen bond acceptor qualities. Through hydrogen bonding, the hydrazine linkage improves conformational adaptability and could lead to better stabilization. Additionally, the strong electron-withdrawing nature of the nitro substituents may have an impact on binding orientation, electronic distribution, and general pharmacological behavior.

Derivative 8 (D8): 4-[(2,4-dinitrophenyl)hydrazinyl]-N-[(1H-benzimidazol-2-yl)methyl]benzaldehydeThis derivative has an extended conjugated aromatic framework with a benzaldehyde moiety connected to a dinitrophenyl hydrazinyl group and a benzimidazole-containing side chain. The aldehyde functionality provides another reactive and polar site that can participate in hydrogen bonding interactions with amino acid residues of the target protein. The dinitro substituents exert a strong electron-withdrawing effect that can affect receptor binding affinity and selectivity. The hydrazinyl bridge can increase molecular flexibility and binding adaptability. Aromatic stacking interactions and biological significance are further enhanced by the benzimidazole nucleus.

Derivative 9 (D9): 2-Amino-N-(2,4-dinitrophenyl)-N-[(1H-benzimidazol-2-yl)methyl]hydrazine D9 is a derivative of this with an aminoacetamide hydrazine group associated with a 2,4-dinitrophenyl group and a benzimidazole nucleus. The amino and amide functionalities provide multiple sites of hydrogen bond donor and acceptor which may improve interactions in the active site of the target receptor. The hydrazine moiety might contribute to the flexibility in conformation and allow the ligand to orient in an ideal way during molecular docking studies. Furthermore, the presence of dinitro groups increases electron-withdrawing properties that may affect receptor binding properties and electronic distribution, thus influencing analgesic activity and selectivity.

Derivative 10 (D10):N-[(1H-benzimidazol-2-yl)methyl]-N'-[2,4-dinitrophenyl]-2-aminoacetamide

Standard Drug: d10 is the standard drug celecoxib [4-[5-(4-methylphenyl)-3-(trifluoromethyl)-1H-pyrazol-1-yl] benzenesulfonamide]. This derivative offers a harmonious blend of aromaticity and hydrogen bonding potential by joining a benzimidazole ring to a 2,4-dinitrophenyl aminoacetamide framework. Increased polarity and several interaction sites that can create strong hydrogen bonds with receptor residues are introduced by the aminoacetamide group. While the nitro groups retain strong electron-withdrawing effects that may affect molecular recognition and binding affinity, the benzimidazole scaffold enhances pharmacological significance and contributes to π–π stacking interactions. When taken as a whole, these structural features might enhance docking behavior and possibly have

analgesic effects. A common reference standard in COX-2 docking studies is celecoxib, an FDA-approved selective COX-2 inhibitor. In the COX-2 active site, it has a diarylpyrazole scaffold with a sulfonamide group that establishes a crucial hydrogen bond with ARG513 and HIS90.

Molecular docking protocol

PyRx software with AutoDock Vina as the docking engine was used to carry out molecular docking. PyRx was used to import the prepared protein and ligand PDBQT files. All ligands were loaded one after the other after the macromolecule (COX-2, PDB: 4COX) was designated as the receptor. In order to ensure sufficient conformational sampling, exhaustiveness was set to 8 (default). Binding free energy (kcal/mol) was used to rank the top nine binding poses for each ligand. For additional examination, the pose with the lowest binding energythe most negative value, which denotes the strongest bindingwas chosen. To guarantee that the results could be compared, every docking run was carried out using the same parameters.

Interaction analysis

For a thorough examination of non-covalent interactions, the docked complexes were imported into Discovery Studio Visualizer. All the van der Waals interactions, hydrogen bonds, hydrophobic contacts, pi-pi stacking, pi-cation interactions and salt bridge interactions were identified and recorded.To determine structure-activity relationships and essential pharmacophoric requirements for COX-2 binding, the interaction fingerprints of all test compounds and the standard medication celecoxib were compared.

Adme analysis

All test compounds were profiled in silico for ADME (Absorption, Distribution, Metabolism and Excretion) using SwissADME (www.swissadme.ch) . For each compound, canonical SMILES strings were generated using Chem3D or found on PubChem and uploaded to the Swiss ADME server. All the molecular weight (MW), logP (lipophilicity), number of hydrogen bond donors (HBD), number of hydrogen bond acceptors (HBA), topological polar surface area (TPSA), number of rotatable bonds and water solubility were evaluated. The drug-likeness was assessed by Lipinski's Rule of Five (MW ≤ 500 Da, logP ≤ 5, HBD ≤ 5, HBA ≤ 10) and Veber's criteria (TPSA ≤ 140 Å, rotatable bonds ≤ 10). GI absorption and bioavailability score were also recorded.

RESULTS

Molecular docking results

Using PyRx (AutoDock Vina), all six test compounds (parent ligand L0 and derivatives D1–D10) were successfully docked into COX-2's active site (PDB ID: 4COX). Table 1 summarizes the binding free energies (kcal/mol) of the optimal docked positions and compares them with celecoxib, a common medication Table 1 Shows the test compounds' molecular docking binding energies against COX-2 (PDB: 4COX). The findings show that the test compounds' affinities varied, indicating possible subjects for additional research. These results could lead to the creation of more potent analgesic treatments that target COX-2.

Adme analysis results

The physicochemical and pharmacokinetic properties of all tested compounds were assessed by SwissADME:
MW: Molecular Weight; HBD: Hydrogen Bond Donors; HBA: Hydrogen Bond Acceptors; TPSA: Topological Polar Surface Area; GI Abs: Gastrointestinal Absorption [2-(4-chlorophenyl)-2-aminoacetamide

DISCUSSION

A molecular docking study was carried out to evaluate the binding affinity of the synthetic benzimidazole and aromatic amine derivatives towards the cyclooxygenase-2 (COX-2) target protein related to analgesic and anti-

inflammatory activity. The docking scores in kcal/mol of the most synthesized derivatives showed favorable ligand–protein interactions suggesting a strong inhibitory potential against COX-2 enzyme. Compound 3, N^1-[2-[(2-aminophenyl)(2,4-dinitrophenyl)amino]ethyl]-N^2-methylbenzene-1,2-diamine, showed the highest binding affinity among all the derivatives with a docking score of −10.04 kcal/mol. Compound 10 N-[(1H-benzimidazol-2-yl)methyl]-N′-(2,4-dinitrophenyl)-2-aminoacetamide Docking score: −10.01 kcal/mol. The high negative binding energies represent stable ligand-protein complex formation and better interaction in the active site of COX-2 receptor. The presence of electron-withdrawing nitro groups, aromatic rings, benzimidazole moiety and amino linkages greatly facilitated hydrogen bonding, π–π stacking, and hydrophobic interactions with amino acid residues of the active pocket of the receptor. Because of their heterocyclic nitrogen atoms, which improved hydrogen bond formation and binding stability, compounds with benzimidazole scaffolds showed better interaction patterns. With a docking score of −9.561 kcal/mol, compound 8[4-[(2,4-dinitrophenyl)hydrazinyl]-N-[(1H-benzimidazol-2-yl)methyl]benzaldehyde] also demonstrated excellent binding affinity, suggesting that the hydrazine and aldehyde functionalities may enhance receptor interactions through additional polar contacts. In the same way, Compound 6 [2,4-Dinitro-N-[(1H-benzimidazol-2-yl)methylamino]aniline] showed a docking score of −9.499 kcal/mol, indicating the role of dinitro substitution and the benzimidazole nucleus in enhancing binding interactions and receptor affinity. The binding energies for compounds 1, 2, and 4 were in the range of -8.918 to -9.08 kcal/mol, which suggests moderate to strong affinity towards the COX-2 enzyme. The aromatic amine and nitro functionalities of these derivatives may stabilize the ligand in the receptor cavity by van der Waals and electrostatic interactions. On the other hand, the compound 7 [N-[(1H-benzimidazol-2-yl)methyl]-N-formyl-2,4-dinitroaniline hydrazine] had a docking score of −7.757 kcal/mol, which could be the result of steric hindrance and poor interaction in the active binding pocket. Overall, the docking results indicate that structural changes involving amino groups, hydrazine linkages, nitro-substituted aromatic systems, and benzimidazole nuclei are important for improving receptor binding affinity and possible analgesic activity.

CONCLUSION

The synthetic benzimidazole and aromatic amine derivatives have a strong binding affinity for the COX-2 target protein, according to the current molecular docking study, suggesting that they may have analgesic and anti-inflammatory properties. A stronger and more stable ligand-protein interaction is indicated by a more negative (lower) binding energy value in molecular docking analysis. As a result, substances with lower binding energies are thought to be superior target receptor inhibitors. With a docking score of −10.04 kcal/mol, Compound 3 [N^1-[2-[(2-aminophenyl)(2,4-dinitrophenyl)amino]ethyl]-N^2-methylbenzene-1,2-diamine] had the best binding affinity of all the synthesized derivatives. Compound 10 [N-[(1H-benzimidazol-2-yl)methyl]-N'-(2,4-dinitrophenyl)-2-aminoacetamide] with docking score -10.01 kcal/mol].Strong ligand binding and stable complex formation within the COX-2 enzyme's active site are indicated by these extremely negative values. According to the docking results, amino groups, nitro substituents, benzimidazole nuclei, and hydrazine linkages all considerably improve receptor interaction through hydrogen bonding, hydrophobic interactions, and electrostatic forces. Compounds with lower binding energies demonstrated better predicted inhibitory activity when compared to derivatives with higher docking scores. According to the study's findings, these artificial derivatives might be useful lead molecules for the creation of novel analgesics. Further investigation into their pharmacokinetic properties will be required to confirm their potential as therapeutic candidates. Additionally, examining the structural features that affect their binding affinities could enhance the efficacy of these substances. To confirm their biological efficacy and therapeutic potential, additional experimental validation through ADMET studies, molecular dynamics simulations, and in vitro pharmacological evaluation is required.

ABSTRACT

Corporate social responsibility (CSR) in India has evolved from philanthropy-driven activity to a legislatively mandated, strategically integrated, and increasingly technology-enabled practice. This review synthesises Indian CSR scholarship alongside international empirical research on digital transformation, artificial intelligence, Industry 4.0, and ESG-related sustainability. Rather than presenting CSR 4.0 as an established theoretical stage, the review conceptualises it as an emerging technology-enabled orientation integrating digital CSR, ESG digitalisation, advanced analytics, and technology-supported stakeholder engagement. The study compares corporate and banking-sector CSR in India across strategic orientation, priority areas, stakeholder focus, delivery mechanisms, sustainability integration, and reporting practices. It also examines the principal technological enablers, structural drivers, and implementation challenges associated with technology-enabled CSR. An integrated conceptual framework is proposed linking institutional pressures, sectoral characteristics, digital enablers, CSR processes, and stakeholder outcomes. The review identifies important future research directions, including CSR 4.0 maturity, artificial intelligence-enabled CSR, blockchain-based transparency, ESG linkages, and public–private banking differences. Overall, the study provides an integrated perspective on the changing nature of CSR in India and its transition toward more measurable, transparent, and technology-supported value creation.

Keywords: corporate social responsibility, digital transformation, CSR 4.0, ESG, banking sector, India, Industry 4.0

INTRODUCTION

Background of Corporate Social Responsibility

Corporate social responsibility (CSR) has come out of the realm of discretion to become a significant part of organizational strategy. In the early times, the focus was on giving charity, philanthropy, and voluntary donations for the welfare of society (Gautam & Singh, 2010). With time, CSR evolved and started to be incorporated into the business goals and objectives, reputation and stakeholder relationships, and long-term value creation (Sekhon & Kathuria, 2020). Lately, the CSR agenda has additionally grown to incorporate sustainability, environmental, social and governance (ESG), and digital transformation (Malik & Kashiramka, 2024). The empirical evidence suggests that digital transformation can impact CSR practices, corporate social performance, ESG outcomes, and practices that are oriented toward stakeholders (Song et al., 2025; Sun et al., 2024). All these developments serve as a foundation on which to explore a new paradigm of CSR that is dependent on technology.

CSR in the Indian Context

India offers a unique institutionalized environment since Section 135 of the Companies Act, 2013, legally requires companies to spend on CSR in the name of the company if they qualify to do so. Eligible companies are expected to spend at least two per cent of the average of the net profits of the last three years (Dharmapala & Khanna, 2018; Arora, 2023). This law made CSR a formal compliant nature with reporting and disclosure requirements instead of being a voluntary action based on reputation (Gupta & Chakradhar, 2022; Ahamed & Tripathi, 2023). Hence, several studies have focused on CSR spending, the impact of CSR on companies, CSR disclosure, and corporate reaction to the CSR requirement (Bihari & Shajahan, 2023; Kulkarni & Aggarwal, 2024).

Rationale and Review Gap

Although India has seen a lot of research on CSR, the literature is scattered amongst CSR mandatory compliance, financial performance, sectoral CSR practices, sustainability reporting, and ESG disclosure. Meanwhile, the research on CSR that focuses on technology has been almost entirely along distinct international lines. An extensive synthesis to link these areas in the Indian institutional context is still not available. Limited integration of CSR, ESG, Sustainability and Digital transformation from an analytical perspective in existing literature. The present review fills these lacunae by bringing together the Indian CSR literature, along with the relevant literature on digital transformation and technology-enabled CSR from the international literature. It thus builds a comparative insight into practices of the corporate sector and banking sector and also helps in developing a conceptual understanding of the new trend CSR 4.0 in India.

Aim and Objectives of the Review

The aim of this review is to examine the evolution of corporate social responsibility toward a technology-enabled stage of practice and to compare corporate and banking sector CSR initiatives in India within this evolving landscape.

- To examine the evolution of CSR toward a technology-enabled and digitally supported orientation
- To compare corporate and banking-sector CSR in India across priorities, stakeholder focus, and delivery practices
- To identify key technological enablers, drivers, and challenges and propose an integrated framework for future CSR 4.0 research

Conceptual and Theoretical Foundations of CSR 4.0

Evolution and Emergence of CSR 4.0

The development of CSR is better thought of as an incremental widening of scope as opposed to stages. In the earlier days, CSR was considered as one of the charitable giving, philanthropy, and community welfare (Gautam & Singh,

2010). With time, however, CSR activities became instrumental to CSR strategy by focusing on social and business goals, reputation management, employee engagement, and stakeholder relations (Sekhon & Kathuria, 2020; Singh et al., 2021). This was further extended to sustainability-oriented CSR that added environmental responsibility, climate concerns, and alignment with the Sustainable Development Goals (Sharma & Choubey, 2022). Online stakeholder engagement, online communication, and reporting with the help of technology were added to CSR later. CSR 4.0 is a more technology-driven approach in which AI and big data analysis, IoT, blockchain, cloud systems, and digital platforms are used in CSR planning, implementation, monitoring, and evaluation (Jiang et al., 2023; Li et al., 2021). As opposed to traditional digital CSR, which is mainly for communication and reporting purposes, CSR 4.0 is data-driven decision-making, continuous monitoring, transparency, stakeholder involvement, and measurable social and environmental impact. But CSR 4.0 is not an accepted step in the evolution of CSR as a theory, but rather an emerging integrative attitude.

Key Characteristics and Theoretical Perspectives

Technology is used in CSR governance and impact management. Digital tools can aid in the planning and execution of a programme (Meng et al., 2022), and data analytics can help to identify areas of social need, allocate resources, and assess the effectiveness of programmes (Xu et al., 2023). Digital platforms can also enhance the involvement and transparency of stakeholders, and real-time monitoring can enhance the evaluation of CSR and sustainability results (Sun et al., 2024). Carroll's CSR pyramid continues to hold true in differentiating the responsibilities of economic, legal, ethical, and philanthropic aspects, especially in the compulsory CSR environment in India. The triple bottom line approach of CSR links it with the creation of economic, social and environmental values.

CSR, ESG, and Sustainable Development

There is a close connection between the concepts of CSR, ESG, and sustainable development, although they are conceptually different. While CSR is the social and environmental commitment of organisations, ESG is a more structured approach that offers environmental, social, and governance (ESG) indicators for investors and regulators to measure sustainability performance and risk (Veeravel et al., 2024). The SDGs provide a more general framework for CSR and ESG activity and sustainable development, through which the activities can be considered. However, these spaces are now beginning to merge, with a growing number of studies in India that focus on CSR spending, ESG reporting, sustainability metrics, and the results of a firm (Goud, 2026; Mishra et al., 2024). This convergence helps to establish CSR 4.0 as a concept of CSR, ESG digitalisation, and sustainable development, instead of being an independent entity. These are the major CSR orientations that are summarised in a cumulative and overlapping manner in Table 1, as the CSR orientations are not mutually exclusive.

Evolution of CSR and the Emergence of a Technology-Enabled Stage

Source: Authors' synthesis based on Gautam and Singh (2010), Sekhon and Kathuria (2020), Singh et al. (2021), Sharma and Choubey (2022), Meng et al. (2022), Jiang et al. (2023), Li et al. (2021), Narula et al. (2021), Sun et al. (2024), and Yang and Han (2023).

CSR Landscape and Major Initiatives in India

Regulatory and Institutional Framework

Understanding the regulatory structure of CSR in India, one will understand that the Companies Act, 2013, (Act) provides for the formation of a CSR committee, the draft of a CSR policy, and a requirement to spend not less than two per cent of the average net profits during the previous three financial years on the activities enumerated in Schedule VII of the Act (Arora, 2023). . Empirical evidence on compliance shows that although there is now increased awareness and disclosure of CSR requirements by the listed companies, a significant percentage of companies has been found to lack consistency in adhering to the expenditure criteria of CSR, also representing a persistent gap in the level of implementation despite clarity in the legislation (Arora, 2023; Bihari & Shajahan, 2023).

CSR Alignment with ESG and SDGs

With the pressure from securities market regulators as well as the demand from investors for sustainability-related disclosures, Indian organisations have been increasingly working towards integrating their CSR programmes as part of their ESG goals and the SDGs (Jha & Rangarajan, 2020). Empirical findings show a positive correlation between ESG disclosure quality and a range of measures of firm performance; however, the nature and strength of the relationship is quite diverse across industry and governance environment (Malik & Kashiramka, 2024; Paridhi & Ritika, 2025). Environmental and social reporting has also been linked with firm financial performance in the Indian context, suggesting that the quality of non-financial disclosure may carry economic implications (Sehgal et al., 2022).

Comparative Analysis of Corporate and Banking Sector CSR

The CSR of the corporate and banking sectors in India is governed by the same statutory guidelines, but there are several considerations that make there a difference between the operations of the two sectors: the business models, the stakeholder structure, the regulators' expectations, and the capacity of the companies. Banks have stronger ties with their customers, financial inclusion, and regulatory requirements, while non-financial corporations are more likely to be impacted by environmental effects, supply chains, employees, investors, and local communities. Thus, institutional and stakeholder views provide insights into the varying priorities and implementation of CSR in different industries (Nair & Bhattacharyya, 2019; Kulkarni & Aggarwal, 2024).

Technological Drivers, and Challenges of CSR 4.0

Major Drivers

Regulatory, institutional, strategic, and stakeholder pressures are important factors that influence the adoption of CSR enabled with technology. Mandatory disclosure under Section 135 to collect and report CSR data is fostering more systematic CSR data collection and reporting (Arora, 2023). Investors' and regulators' expectations of companies in terms of ESG also encourage companies to increase the credibility, comparability, and transparency of CSR and sustainability information (Singh et al., 2021). There is a growing expectation from stakeholders of organisations to show social and environmental impact rather than just spend on CSR. Meanwhile, the pressure of corporate image and the overall digital transformation effort of the organization makes it easy to embrace the technology-supported CSR system (Meng et al., 2022). Together, these drivers are helping to drive a paradigm shift from reactive and compliance reporting to more integrated, data-driven, and outcome-oriented CSR reporting.

Major Challenges

In India, there are several key challenges to technology-enabled CSR. The rural-urban digital divide makes it difficult to access and receive digitally delivered education, healthcare and financial-inclusion programmes. Implementing technologies can also be costly, potentially restricting the use of advanced technologies in smaller firms and by implementation partners. Where CSR programmes include financial or personal data, data privacy and cyber security are very significant. The difficulty is that there are no standardised measures of CSR impact, making it hard to compare the impact of different CSR strategies across different organisations and sectors (Kumar et al., 2023). The issue of greenwashing and assurances in sustainability disclosures is also topical, especially when reporting pressure is not necessarily indicative of the actual outcomes (Kumar et al., 2023). Also, some NGOs and other implementation partners may have limited technology, which can decrease scalability. With the increasing adoption of AI also come ethical considerations such as algorithmic bias, transparency, and responsible data usage. The challenges show that CSR 4.0 is not just about technology investment; it is also about better governance, more digital capabilities, and more credible impact measuring systems. The main technological enablers, institutional drivers, and the challenges for the implementation of CSR
India are summarised in Figure 2.

Integrated Interpretation of the Findings

The findings indicate that CSR in India is increasingly shaped by the interaction of regulatory pressures, organisational characteristics, stakeholder expectations, sectoral priorities, and digital transformation. The mandatory CSR requirements have established a common institutional platform, and firms have varied interpretations and operationalization of these requirements based on their sectoral context, resources, and governance structure (Nair & Bhattacharyya, 2019). In this context, technology-based CSR is a new perspective that could help enhance the targeting, execution, monitoring, reporting, and impact assessment of CSR programmes. While there is some empirical evidence about the effect of digital transformation on CSR and ESG-related performance in India, international evidence indicates that digital transformation can positively influence CSR and ESG-related performance (Sun et al., 2024; Yang & Han, 2023). The conceptual framework proposed therefore places regulatory and stakeholder pressures (exogenous), organisational and sectoral characteristics (contextual) and digital technologies (enabling) as factors. All these elements have an influence on CSR processes and can help to achieve better levels of transparency, stakeholder involvement and inclusion, environmental impact and sustainable value creation. But these relationships are still conceptual and need to be validated in corporate and banking environment in India.

Theoretical Implications

The results confirm stakeholder theory in that CSR priorities vary according to the salience of customers, employees, communities, investors, and regulators. Institutional theory is also very relevant in India, where CSR is prescribed by law, which gives rise to a strong coercive pressure, and the extent to which organisations respond to this pressure remains sectoral. The evidence also indicates that digital transformation can be considered a potential extension of the theories of CSR, considering the capability of technology as an important mechanism for the engagement of stakeholders, transparency, and performance.

Managerial and Governance Implications

Technology can help managers to better target, monitor, transparently communicate, and evidence-evaluate their CSR efforts. But data security, digital ability, digital responsibility, and digital equity are important factors for effective implementation. Compliance with the CSR requirements is still non-significant, suggesting the need to have more robust monitoring and implementation. The varying quality of sustainability reporting practices across Indian banks also suggests a need for more consistent and standardized disclosures and impact measurement (Rajawat & Mahajan, 2024). So it's time for organisations to transition from the expenditure approach to compliance to an approach that measures results. CSR committees can help reinforce this transition by incorporating digital monitoring, feedback from stakeholders, and impact measures in the sectors into programme governance and making sure digitalisation does not leave out groups that are under-served.

Future Research Directions

Future study should be focused on the construction and validation of CSR 4.0 maturity measures of Indian corporations and banks. Special emphasis should be placed on targeted, monitored, and evaluated CSRs based on evidence of the relationship between CSR and AI-related innovation (Li et al., 2021). The research should also focus on introducing transparency and digital impact measurement, stakeholder trust, and the effectiveness of technology-enabled inclusion programmes using blockchain. Given the evidence on the relationship between CSR and customer outcomes, there is a need to focus on trust and behavioural outcomes in the context of banking (Hurrah et al., 2024). Future studies are needed to assess the sustainable financial and environmental, social, and governance (ESG) impacts of technology-based CSR. The study of CSR 4.0, ESG performance needs to be studied directly in the Indian context (Goud, 2026). Last but not least, research needs to focus on the rural digital divide to make sure that CSR based on technology means inclusive social value creation and not unequal.

CONCLUSION

The present article has explored the latter development of corporate social responsibility in India from the philanthropy and voluntary engagement with the community to the present context of legislatively mandated, strategically integrated and progressively technology-focused corporate social responsibility. The review does not consider CSR 4.0 as a theoretical classification of CSR, but rather as an emerging descriptive orientation of CSR, which is a result of the intermingling of digital CSR, digital transformation, Industry 4.0 enabled sustainability, Artificial Intelligence (AI) enabled CSR, and ESG (Environmental, Social and Governance) digitalisation. The comparative analysis showed that CSR in the corporate and banking sectors in India has similarities and dissimilarities similarities in terms of the areas of CSR activity, namely education, health and rural development; and dissimilarities in terms of the approach, stakeholders and emphasis on the sectors of activity. CSR in the banking industry is more related to financial inclusion, financial literacy, and digital access, while non-financial companies are showing a higher focus on environmental sustainability. In both industries, there is a lot of potential for CSR targeting, transparency, monitoring, and measuring impacts with the help of artificial intelligence, big data analytics, digital platforms, and other emerging technologies. Technological limitations, data privacy issues, and the digital divide as well as a lack of standardised impact measures still hinder implementation. In general, there is a continuous move from CSR compliance based on expenditures to more transparent, measurable and stakeholder-centred value creation. Future study should investigate the aforementioned constructs through empirical studies in the context of India, CSR 4.0 maturity, ESG linkages, and stakeholder outcomes, along with sectoral differences. In order to convert technological progress into tangible meaningful and sustainable CSR outcomes, greater regulatory uniformity, technological capability and strong impact measurement is needed in India's corporate and banking sectors.

Table 1: Major Evolutionary Orientations of Corporate Social Responsibility and Their Defining Characteristics

Stage	Approximate Orientation	Defining Characteristics	Representative Focus
Traditional CSR	Philanthropic	Voluntary donations, ad hoc community welfare, limited measurement	Charity, disaster relief, local giving
Strategic CSR	Business-integrated	Alignment with business objectives, reputation management, stakeholder engagement	Employee engagement, brand building
Sustainability-oriented CSR	Environmental and social	Climate action, resource efficiency, SDG alignment	Environmental programmes, sustainability reporting
Digital CSR	Technology-supported	Online stakeholder engagement, digital communication and reporting	Digital platforms, e-reporting
Technology-enabled CSR (emerging "CSR 4.0" orientation)	Data-driven and integrated	AI, big data, IoT, blockchain, cloud platforms; real-time monitoring; measurable impact	AI-enabled targeting, digital transparency tools

Note: The technology-enabled stage is presented as an emerging, descriptive orientation synthesising converging empirical literatures rather than as a formally established sequential theory.

ABSTRACT

Rapid AI adoption is transforming employee roles and psychological experiences within knowledge-intensive workplaces. Although such innovations increase productivity, automation, and efficiency of decision making, they create several psychological issues for workers, such as job insecurity, technophobia, skills obsolescence, and altered relations between people. In view of these issues, Emotional Intelligence (EI) becomes a vital skill that sets people apart from intelligent machines. The paper advances a conceptual model that positions emotional intelligence as a dynamic outcome of AI-enabled workplace experiences rather than merely an antecedent of organizational performance. Relying on the theoretical framework of the Job Demands–Resources Theory, Conservation of Resources Theory, Trait Emotional Intelligence Theory, and Social Exchange Theory, the research offers a conceptual framework regarding the relationship between AI-induced job anxiety, AI literacy, self-efficacy, organizational resources, and emotional intelligence. Specifically, the article states that emotional intelligence operates as a valuable psychological resource for adaptive performance and job satisfaction of employees as well as for preventing negative outcomes resulting from workplace changes in the era of artificial intelligence.

Keywords: Emotional intelligence, Artificial intelligence anxiety, AI literacy, Adaptive performance, Job satisfaction, Organizational support, IT employees, Bangalore.

INTRODUCTION

AI technology is one of the latest technological innovations of the twentieth-first century. More organizations are implementing various applications of artificial intelligence such as machine learning, generative AI, predictive analytics tools, robotic process automation, intelligent customer support solutions, and coding environments that use AI. Artificial intelligence technology has brought changes in work structures, skill sets, and employee expectations in the IT sector. Bangalore, which is also called Silicon Valley of India, is one of the leading AI implementation centers in Asia. The city has many technology corporations, software companies, startups, research labs, and innovation hubs that use AI technologies in their businesses. Therefore, IT workers in Bangalore are early adopters and users of AI workplaces. Although there are many advantages to using artificial intelligence technology, various issues and concerns arise with regard to its psychological and sociological impact. Workers are more worried about issues such as job security, relevancy of roles, employability in the future, and changes in workplace expectations. At the same time, organizations are expecting workers to learn new skills and be collaborative, creative, and effective at interpersonal level.

At this juncture, the significance of emotional intelligence takes an unprecedented turn. Emotional intelligence is the ability to perceive, comprehend, control, and harness emotions effectively within personal and professional spheres. Unlike most technical competencies that can be automated by AI technologies, emotional intelligence is a uniquely human competence that cannot be mimicked by machine technologies.

It is not about whether emotional intelligence enhances workplace performance anymore; rather, the real question is how the very workplace facilitated by AI technology impacts the emotional intelligence of workers. This is especially significant in the case of Bangalore, where the fast-paced technological revolution has given rise to distinct organizational and psychological conditions in the IT worker segment. This article aims to analyse the factors affecting the emotional intelligence of IT workers in Bangalore in the age of AI and to establish a framework for understanding the association between the AI-driven workplace environment and workers' emotional competencies.

RESEARCH METHODOLOGY

Research Design

This current study will employ quantitative research methodology in order to study the determinants of Emotional Intelligence of Information Technology employees working in Bangalore city. This study will be an explanatory study since it will seek to determine the relationship between AI-related variables at the workplace and emotional competencies of employees. The population for this study consists of professionals working in software firms, multinational companies, IT service companies, and AI-related technology firms operating in Bangalore. The respondents in the study include software engineers, system analysts, project managers, AI specialists, data analysts, and technology professionals who use AI-based work environment systems. Primary data can be gathered by means of a structured questionnaire that includes scales developed to measure variables such as Emotional Intelligence, AI-related Job Anxiety, AI Literacy, Self-Efficacy, and Organizational Support. For instance, Emotional Intelligence can be measured using the Wong and Law Emotional Intelligence Scale (WLEIS), AI-related Job Anxiety using existing workplace technology anxiety scales, AI Literacy using AI competency scales, Self-Efficacy using General Self-Efficacy Scale, and Organizational Support using Survey of Perceived Organizational Support (SPOS).

Responses may be recorded on a five-point Likert scale ranging from Strongly Disagree (1) to Strongly Agree (5). The collected data may be analysed using descriptive statistics, reliability analysis (Cronbach's Alpha), Pearson correlation, multiple regression analysis, and moderation analysis. Statistical analysis may be performed using SPSS (Version 29) and SmartPLS/AMOS for structural relationship testing.

REVIEW OF LITERATURE

It is evident that the link between EI and organisational consequences has been widely studied within the domains of organisational psychology and management sciences. Previous literature on the topic represents the construct of EI from different theoretical approaches such as the ability approach, the mixed approach, and the trait approach, all of which represent a diverse understanding of EI but agree upon its major dimensions being emotional awareness, emotional regulation, empathy, and interpersonal skills. Regardless of theoretical approaches, however, emotional intelligence has been found to be linked to many organisational variables such as leadership success, organisational commitment, conflict resolution, personal resilience, job satisfaction, and general workplace performance. Therefore, previous research has established EI as an antecedent to positive organisational and individual consequences rather than a consequence.

The introduction of AI in organisational settings has, nevertheless, modified the framework in which emotional intelligence is assessed. Modern studies suggest that AI not only automates the processes but transforms the nature of jobs, workflows, and the psychological state of workers. While AI improves effectiveness by automating cognitive processes, it emphasises even more strongly the importance of uniquely human characteristics such as empathy, emotional regulation, ethics, communication, and teamwork, which are not subject to automation. This has caused a change in understanding the significance of emotional intelligence in technologically advanced workplaces. Moreover, recent scientific studies have found that AI workplaces present opportunities and psychological risks for workers. The introduction of intelligent systems is often accompanied by issues related to fears of job loss, technological uncertainty, monitoring by algorithms, constant changes in skills, and new performance demands. These factors are contributing to AI workplace job anxiety, which has been shown in many studies to cause higher stress levels, lower psychological well-being, and reduced adaptability. Applying Conservation of Resources Theory, scholars suggest that perceived threat to professional identity and career sustainability leads to resource depletion and affects the emotional regulation and interpersonal skills of employees.

However, in contrast, previous research highlights two essential personal resources for successful adaptation to work environments characterised by the presence of AI – AI literacy and technological self-efficacy. Workers who have high AI literacy are more inclined to see technological change as an opportunity for career development rather than a threat for their jobs. Moreover, self-efficacy builds workers' ability to learn and cope with problems and organisational changes. In line with the JD–R model, such competencies can be treated as personal resources that help cope with job strain, develop resilience, and form adaptive emotions in the face of technological change. Apart from personal characteristics, organisational factors have been shown to be equally important predictors of the ability of workers to adapt to work environments enabled by AI technology. According to Social Exchange Theory, organisational factors like clear communication, management commitment, learning opportunities, psychological safety, and the well-being of employees decrease resistance to change and build trust and organisational commitment.

Nevertheless, there are still several gaps that require further exploration within the field of research. Firstly, despite the growing number of studies, most of them view emotional intelligence as a dependent variable, which is used to predict some organisational consequences, whereas the focus on the process of formation of emotional intelligence within an AI-driven environment receives significantly less attention. Secondly, while some studies address individual factors, such as AI anxiety, AI literacy, self-efficacy and organisational support, none of them considers the simultaneous impact of all these factors on the development of emotional intelligence in one conceptual model. Finally, the empirical evidence, dedicated to IT professionals in Bangalore – a unique case of India, where the usage of AI within organisations is most advanced is still rather scarce. The current research paper aims at closing these gaps and developing a theoretical framework that would explain the impact of AI-driven workplace experiences on the development of emotional intelligence among IT professionals.

Objectives of the Study

This research attempts to investigate the effect of AI-enabled work environments on the development of emotional intelligence among IT professionals in Bangalore.

Objectives of the research include:

i. To study the effects of AI-induced job stress on the emotional intelligence of IT professionals.
ii. To analyse the effect of AI literacy on employees' emotional intelligence.
iii. To investigate the connection between self-efficacy and emotional intelligence.
iv. To investigate the effect of organisational support on employees' emotional intelligence.
v. To investigate the effect of emotional intelligence on employees' adaptive performance and job satisfaction.
vi. To develop a conceptual framework for the determinants of emotional intelligence in AI enabled work environments.

Hypothesis

From the theoretical framework and literature review, the following hypotheses can be formulated:
H1: Job Anxiety related to AI is significantly negatively associated with the emotional intelligence of IT employees.
H2: AI literacy has a significant positive association with emotional intelligence.
H3: Self-Efficacy positively affects emotional intelligence.
H4: Perceived organizational support positively impacts emotional intelligence.
H5: Organizational support reduces the negative relationship between job anxiety and emotional intelligence.
H6: Emotional intelligence positively affects adaptive performance.
H7: Emotional intelligence positively impacts job satisfaction.

ARTIFICIAL INTELLIGENCE AND THE TRANSFORMATION OF WORK

The emergence of Artificial Intelligence (AI) is among the most disruptive technological advancements witnessed in the Fourth Industrial Revolution era. Unlike previous instances where technology was used mainly to automate physical activities, modern AI can perform cognitive functions such as data analysis, predictive modelling, decision-making, and many other activities that involve the use of the brain. As a result, AI does not only affect the process of undertaking activities but also changes the nature of work itself. The IT industry has been among the first adopters of AI technology. Nowadays, companies use different AI-based software like coding assistants, automated testing, intelligent project management, predictive analytics, and generative AI to increase efficiency. This enables employees to finish tasks quickly and concentrate on other important things. It has been established that AI adoption by organizations leads to increased innovation and problem-solving capacity in competitive business environments.

Nevertheless, the positive aspects of AI bring considerable challenges for the workforce. First, the implementation of intelligent technologies has transformed the nature of job positions and created blurring boundaries of occupations along with higher demands for ongoing education. People are expected to acquire new skills constantly as technological changes happen with an unprecedented rapidity. This tendency poses many questions concerning potential job displacement, obsolescence of skills, performance pressures, and uncertain future perspectives for employment. In addition to technological and economic implications, the influence of AI on the work process includes psychological and social dimensions. Recent research dedicated to technology-supported workplaces reveals the phenomenon of workers' fear of complex technologies which are seen as a threat to existing skills and professional identity. Algorithmic performance tracking, decision-making, and automation might deprive employees of autonomy and control in their work process and create stress at workplace.

AI has simultaneously elevated the importance of uniquely human abilities. With the automation of more and more analytical and information-related activities, it becomes more and more vital for businesses to focus on such skills that are hard to implement in machines, such as empathy, self-regulation of emotions, social communication, ethical reasoning, creative thinking, and problem-solving. They allow people to interact efficiently with intelligent software

and other people who are their colleagues, customers, and stakeholders. It can be argued that this change in the nature of work has prompted researchers to conclude that the future workforce will consist not of either humans or machines, but rather of complementary entities. Such workplaces demand more than mere technical skills; employees need to have psychological assets that would help them adjust to technological disturbances and uncertainties and cope with them. Thus, emotional intelligence becomes strategically important in such an environment as a resource allowing people to adapt to technological changes in a constructive way.

In light of the fast adoption of AI in Bangalore's technology industry, these issues take on an even more prominent role. With the increasing incorporation of AI in day-to-day activities by companies, the importance of analysing the psychological reaction of workers to changes taking place cannot be underestimated. It is for that reason that the investigation of the connection between work conditions supported by AI and emotional intelligence is of paramount importance.

UNDERSTANDING EMOTIONAL INTELLIGENCE

The construct of Emotional Intelligence (EI) is arguably one of the most significant concepts in organizational psychology as evidenced by its proven impact on employee behavior, interpersonal relations at the workplace, leadership and ultimately job performance. Unlike conventional definitions of intelligence that concentrate on reasoning, memory and problem solving abilities among others, EI places emphasis on the individual's ability to perceive, understand, regulate and use emotions in order to function effectively both at a personal and professional level. The contemporary view of emotional intelligence was formulated by Mayer and Salovey, who defined it as an ability to perceive emotions accurately, to access and generate emotions to facilitate thought processes, understand emotion meanings and regulate emotions for intellectual and emotional development. According to the Ability Model of EI by Mayer and Salovey, EI represents a type of intelligence similar to cognitive intelligence in that it is comprised of certain emotional processing skills, which can be assessed through performance tests. On the other hand, the definition of Trait Emotional Intelligence according to Petrides involves the notion of a set of emotional self-perceptions in the personality structure of the person.

From among the various models created over time, the one suggested by Wong and Law has enjoyed much popularity within organizational studies owing to its applicability in work situations. The framework contains four basic dimensions of emotional intelligence namely self-emotion appraisal, other's emotion appraisal, use of emotion and emotion regulation. The first dimension involves one's ability to comprehend and express their own emotions. Other's emotion appraisal involves the ability to recognize and interpret the emotions of other people such as colleagues, superiors and clients. Using emotion involves the ability to control emotions for performance, motivation and decision-making purposes, whereas the fourth dimension involves emotion regulation whereby individuals are able to control their emotions when faced with difficult situations.

Emotional intelligence is important in organizational settings because of its impact on numerous outcomes related to employees. Employees who score highly in terms of emotional intelligence are usually much better at handling workplace pressure, conflict resolution and adaptability as well as forming good working relationships. Such people usually have the capacity to withstand uncertainties and deal with emotionally challenging situations. Emotional intelligence has been found to be positively correlated with job satisfaction, organizational commitment, leadership effectiveness and team effectiveness. Within knowledge-intensive fields such as information technology, emotional intelligence gains particular relevance. Specialists within this industry often find themselves working in highly dynamic conditions with strict timeframes, sophisticated problem-solving challenges, collaboration across different disciplines, as well as frequent changes in technologies. In addition to this, increased use of virtual teams, telecommuting options, and international projects adds to the growing importance of having effective emotional and interpersonal skills. Apart from technical expertise, specialists in this industry are required to be good communicators, capable of managing stakeholders' expectations, collaborating internationally, as well as adapting to changing realities of the working environment.

Artificial Intelligence being more and more integrated into organizational processes has brought a novel perspective on emotional intelligence research. While AI becomes increasingly competent in carrying out analytical and routine cognitive activities, uniquely human traits of empathy, emotional intuition, moral reasoning, as well as interpersonal skills become highly valued. In spite of the unmatched ability of machines to analyse information quickly and efficiently, they lack the ability to comprehend human emotions, establish trusting relationships, or manage complex social dynamics. Thus, emotional intelligence becomes an integral part of complementing technological intelligence.

Although widely accepted for its relevance, it is important to note that emotional intelligence cannot be viewed as a fixed feature of an individual. The modern organizational context constantly creates and impacts on the employees' emotional experience and abilities. Variables, such as organizational stress, technological uncertainty, learning, organizational culture and managerial support, have the potential to impact on the growth and expression of emotional intelligence. These considerations become especially true for AI-enabled organizations, in which workers face new challenges that can enhance or hinder their emotional abilities.Hence, the current study adopts the idea that emotional intelligence is a dynamic psychological capability, which is affected by the employees' perceptions of workplace situations related to artificial intelligence. In contrast to most research on EI as a predictor of organizational outcomes, the current study treats it as an outcome variable impacted by the factors of AI anxiety, AI literacy, and organizational support. Such an approach makes an important contribution to the growing body of literature on human side of artificial intelligence.

Factors Influencing Emotional Intelligence among IT Employees in Bangalore

The rise of AI technologies in workplaces and their growing impact on the working process has led to considerable interest in studying the way employees adapt to technologically modified work environment. While emotional intelligence has previously been researched as an indicator of the company's success, recent trends indicate that it might be affected by the working environment that arises with the adoption of AI technologies. Employees in AI-oriented firms experience new learning opportunities and innovations along with fears of being unable to protect themselves from the changes and losing jobs because of new technologies. As a result, emotional intelligence may become not only an individual trait but also a dynamic ability that results from the interaction between employees and working systems.

AI-Associated Job Anxiety and Emotional Intelligence

One of the most common psychological issues in connection with the introduction of AI technology is job anxiety. AI-associated anxiety involves the feeling of uncertainty, fear, and apprehension caused by the introduction of intelligent technologies to the workplace. The reasons for such anxieties might include job displacement, automation, performance requirements, and difficulties in adapting to new technologies. Conservation of Resources (COR) theory offers a framework to understand the connection between job anxiety caused by AI and emotional intelligence. COR suggests that people tend to conserve and accumulate certain important resources including competence, status, job security, and occupational identity. Threats of losing these resources might result in anxiety and emotional distress. Emotional distress can lead to a lack of emotional awareness, lower levels of empathy, and inability to regulate emotions effectively. Workers who are worried about being replaced with artificial intelligence may have difficulties maintaining necessary emotional balance.

Researches in the field of technological changes show that uncertainty and threats have negative impact on psychological and organizational adjustment. In the environment based on artificial intelligence, such factors may negatively affect workers' emotional intelligence by preventing them from processing emotions in an appropriate way. Thus, job anxiety caused by AI is likely to have a negative effect on emotional intelligence.

AI Literacy, Self-Efficacy and Emotional Intelligence

Unlike anxiety, AI literacy and self-efficacy may be considered positive psychological resources which contribute to successful adaptation to changes brought about by technology. The notion of AI literacy involves an employee's knowledge about AI principles and applications, its possibilities and limitations. Meanwhile, self-efficacy, based on

the social cognitive theory proposed by Bandura, is the belief in one's ability to perform tasks and overcome difficulties successfully. Individuals with high AI literacy are expected to be well-prepared to perceive technological initiatives taken in organizations and appraise their consequences reasonably. Instead of considering AI merely as a challenge, they will appreciate opportunities to improve their skills, increase productivity and advance in their careers. Likewise, employees with high self-efficacy will have enough confidence to deal with new technologies.

According to the Job Demands–Resources (JD-R) model, personal resources can be very helpful for employees when they have to cope with difficult conditions at work. AI literacy and self-efficacy serve as resources which decrease uncertainty and make individuals feel greater control over changes in work. Those who feel competent working with AI technologies tend to demonstrate emotional stability, resilience and flexibility. This way, such factors become positive determinants of the development of emotional intelligence.

Organizational Support as a Protective Mechanism

Besides individual differences, organizational environment has been found to significantly influence employees' reactions to technological change. Organizational support entails the perceptions of employees regarding how much value an organization places in their performance and welfare especially during times of change. In the case of AI implementation, organizational support may encompass training programs, clear communication, career development, technical and psychological support.

According to Social Exchange Theory, employees' attitudes and behaviors will be enhanced when they feel that the organization gives high levels of support to them. A supportive organizational environment will address fears related to the introduction of AI systems, as well as build up their capacity to cope with the situation. Moreover, a supportive organizational environment may help employees cope with the stress of AI anxiety by offering them resources that lower uncertainty. In summary, organizations which develop their employees in the case of AI implementations may generate higher levels of emotional competencies among their employees. This means that organizational support will help minimize the negative relationship between AI-related anxiety and emotional intelligence.

Emotional Intelligence, Adaptive Performance and Job Satisfaction

The concept of emotional intelligence can be viewed as one of the most crucial factors that help employees cope with change within the organization. For those companies that operate in a technologically demanding industry, it becomes extremely important for the employees to know how to deal with the uncertainties, how to control stress, and how to establish effective communication with others. Adaptive performance represents one of the main outcomes that can be achieved through emotional intelligence. It is important to note that adaptive performance means the individual's ability to adjust his behavior to changing requirements within the job. As we have seen in the previous section, the use of AI will require employees to learn new technologies, interact with intelligent systems, and adapt to new organizational structures. Employees with high emotional intelligence are generally better at coping with such challenges. Job satisfaction is another significant outcome of emotional intelligence. It can be said that employees with high emotional intelligence are able to cope with workplace stressors, to develop productive relationships, and to be positive about their jobs. Their ability to regulate emotions will ensure their well-being and job satisfaction.

Emotional Intelligence as a Mediating Resource

The existing literature reveals that emotional intelligence acts as a strategic psychological tool which links employee experiences and outcomes at work. Employees' AI-related concerns, AI literacy level, self-efficacy and organizational support affect employees' perception of changes brought about by technology. These factors affect emotional intelligence of employees, which further influences their adaptive behavior and job satisfaction. Emotional intelligence may therefore be seen as a mediator which connects employees' positive and negative experiences of AI to their behavioral and attitudinal outcomes. Those employees who manage to preserve emotional intelligence in spite of changes in technology will adapt easily, will be job satisfied and help organizations to succeed. This

approach makes emotional intelligence a core aspect of employees' adaptation in the Age of Artificial Intelligence and serves as a basis for the suggested theoretical framework in the current study.

Discussion And Implications: Emotional Intelligence As A Strategic Human Capability In The Ai Era

Rapid adoption of artificial intelligence by organizations has brought about a revolution in the assessment of employees' competencies and skills. Over the years, competitiveness in the Information Technology industry has been linked to technical skills, domain knowledge, and the ability to solve problems. However, with increasing adoption of AI systems, organizations have come to realize the increasing significance of human-centric skills that cannot be easily automated. Among these skills, emotional intelligence is among the most significant factors that determine employees' productivity and sustainability within organizations.

Review of literature on this topic indicates that emotional intelligence is positioned uniquely within the context of AI-enabled organizations. On the one hand, emotional intelligence can be seen as a psychological strength that enables employees to handle uncertainties created by the presence of advanced technologies. On the other hand, emotional intelligence seems to be affected by employees' interactions with advanced technologies. This implies that emotional intelligence should not be viewed from the perspective of individualistic approach that focuses only on individual's personal attributes. One of the key insights obtained through a review of the literature is the ambivalent effect of the introduction of AI on the emotional experience of employees. Even though AI allows reducing routine activities, increasing the level of productivity and providing assistance in decision-making, it raises many fears related to job security, skill relevance and professional identity. An employee who considers AI as a threat might face a higher level of anxiety and uncertainty which can affect his/her ability to regulate emotions and communicate with others in time. Such outcomes are especially important in competitive environments within which constant improvement is expected from people.

On the contrary, the literature review proves that employees who have a high level of AI literacy and self-efficacy are more likely to consider AI as an assisting technology. Being knowledgeable and confident enough to use this technology helps them to minimize uncertainty and develop feelings of control and encourages them to adapt proactively. Thus, it becomes evident that the relationship between AI and emotional intelligence cannot be considered as purely negative. The direction of such a relation mainly depends on the way in which employees perceive technological transformation.

Insights can be gained from the Bangalore context as well. Being the capital of India's technology industry, Bangalore is a unique case of AI being adopted at a rapid pace by both multinational companies, start-ups, and IT service providers. Workers who find themselves working in such an environment have to adapt to continuous innovations, international competition, and changing skills requirements. Therefore, Bangalore is a perfect place to study the effect that technological development can have on the emotional competencies of workers. Moreover, experiences of IT workers in Bangalore can prove useful for other countries which are building up their digital economy and face AI adoption as well. Organizations as facilitators of the process of adaptation is another major implication of the research. All the literature proves the fact that employees adapt more successfully to technological changes if there is organizational support, communication, and training in place. Organizational support acts as a protective function for employees and helps minimize their fears associated with uncertainty. It also increases employees' confidence and makes them ready for change.

This study further refutes the belief that technology proficiency is enough for individuals to thrive in the future work environment. Although the importance of technical skills cannot be understated, the increasing influence of AI makes emotions and inter-personal skills equallyimportant. The activities related to empathy, conflict resolution, leadership, moral decision-making, teamwork, and inter-personal skills are still very much dependent on the emotional intelligence of humans. Since corporations are increasingly automating cognitive tasks, emotional skills can become important differentiators and sources of competitive advantage. From an organizational point of view, this research suggests including the concept of emotional intelligence in HRM practices. Employee development programs in IT

sector tend to focus mostly on certifications and digital skills while giving little emphasis to emotions and psychology. In order to thrive in the future, companies need to embrace a more balanced approach combining technological intelligence with emotional resilience and adaptability. Recruitment process, leadership training, employee wellbeing programs, performance management system should all include emotional intelligence as an important competency.

Implications on a larger scale are no less significant as well. The topics of discussion about AI among the general public are primarily oriented towards issues of automation, efficiency, and labour market disruption. Although those are valid topics, little attention is paid to the emotional side of technological evolution. It is necessary for policymakers, educators, and managers to acknowledge that preparation for a technologically evolving world entails not just technical skills but emotional competencies too. Educational curricula and programs should be designed so that people could develop their emotional skills along with acquiring digital competencies, thus, being able to adjust to new realities of the workplace environment better.

In the end, the rise of AI technology does not lessen the significance of human capabilities but changes the way we see their importance. With machines becoming more efficient in conducting cognitive tasks, emotional understanding, establishing relationships, handling uncertainty and being empathic becomes even more valuable. Emotional intelligence becomes one of the key assets of humans in the era of Artificial Intelligence.

Analysis and Interpretation

From the literature considered within the current study, it becomes clear that the impact of Artificial Intelligence on emotional intelligence should be assessed not through a purely technological prism. Instead of creating an equal effect in every aspect of employees' work, Artificial Intelligence gives rise to a complex work environment where technology, psychology and organization interact and contribute to shaping up the emotional skills of employees. In all considered studies, emotional intelligence does not become an inherent property of individuals but rather appears as a dynamic ability influenced by the employees' perception of technological changes, organizational resources and adaptive self-efficacy.

It can be noticed that one of the prominent features observed within the reviewed literature is the coexistence of mechanisms of resource depletion and enhancement. Artificial Intelligence-induced job anxiety turns into a psychological demand depleting cognitive and emotional resources of employees due to the growing uncertainty about the security, identity and employment prospects in the future. On the other hand, AI literacy, self-efficacy and organisational support turn out to be personal and organisational resources replenishing the feeling of competence and predictability of employees. The synthesis presented above also indicates a shift in concepts in emotional intelligence research. Prior research in organisations mostly viewed emotional intelligence as a factor affecting leader effectiveness, organisational commitment, and employee performance. Contemporary research increasingly points towards the influence of organisations, disruption due to technology, and learning environments on emotional intelligence. The current study advances this line of research further by conceiving of emotional intelligence as an output of AI-based work experience.

The analysis shows that there is a connection between the levels on which the identified factors influence the process. Job insecurity due to the application of AI technologies is mainly caused by external technological factors, while AI literacy and self-efficacy can be considered as the factors reflecting individual adaptability resulting from the learning process. The organisational support factor operates at the institutional level by affecting the interpretation of technological change made by employees. The relationship between the three levels suggests that emotional intelligence should not be considered merely as a psychological phenomenon of the individual, but as a result of the interaction between technological systems, organisations and individuals.

One of the significant contributions of the current model is that of its theoretical integration. While previous research often uses one single theory to describe employees' adaptation to technology, this model integrates different theories

to explain different aspects of AI-powered workplaces. The conservation of resources theory helps understand psychological vulnerability; job demands-resources model helps understand adaptability; social exchange theory helps understand organizational influence; and emotional intelligence theory helps understand behavior. Using all four together provides a more integrated explanation compared to one used by each individual theory separately.

There is no agreement in the literature that accepts deterministic views on AI. Instead of delivering uniformly good or bad results, the use of AI creates conflicting psychological experiences. It presents to employees both possibilities of development and worries about their replacement by technology. As a result, emotional intelligence becomes the tool with which employees deal with conflicting experiences. Organisations able to enhance enablers and mitigate threats will succeed in cooperation with AI.

FINDINGS AND SUGGESTIONS

Findings

Review of literature and the suggested research framework suggest that emotional intelligence will be an increasingly important strategic competence in organizations that use AI. Job anxiety due to AI use will negatively affect employees' ability to regulate their emotions and function socially, while AI literacy and self-efficacy will positively impact on their emotional resilience and flexibility. Support from the organization also serves as a protective factor that reduces uncertainty resulting from technological change. As a result, emotionally intelligent employees are likely to perform better and enjoy better working relationships and job satisfaction.

CONCLUSION AND FUTURE DIRECTIONS

The advent of AI has significantly changed the current workplace by bringing about numerous possibilities. However, alongside such changes, there arise new challenges related to job security, complex technology, obsolescent skills, and shifting workplace requirements for workers. As a result, the issue of what human capabilities are necessary for successful adaptation to a dynamically changing technological environment becomes increasingly important from the point of view of scientific and business research.

In this article, I explored the topic of emotional intelligence as one of the most important psychological capabilities in relation to the current AI-driven workplaces, in particular the case of IT employees working in Bangalore. Based on the relevant scientific sources and theories, I showed how the concept of emotional intelligence should not be regarded only as an organizational prediction tool but also as a capability which depends on the experience of technological change among employees. The paper shows that AI-related job anxiety reduces emotional capabilities because of increased uncertainty and emotional stress, while AI literacy and self-efficacy increase them because of higher confidence and adaptability. Organizational support was also found to be an important contextual condition for positive employee adjustment to technological change. Further, the topic has been discussed in light of the increasing importance of emotional intelligence in the era of Artificial Intelligence. With the advent of AI, automation of cognitive and analytical tasks has taken place, making uniquely human abilities, such as empathy, emotional regulation, communication skills, ethics and problem solving, more valuable. In this situation, emotional intelligence can be seen as much more than just a personality trait; rather, it is an organizational resource that makes for employee well-being and performance.

As far as the relevance of Bangalore to our topic is concerned, we need to mention that the presence of many technology firms, adoption of AI technologies, and a diverse population make Bangalore an interesting subject for studying employees' perception of changes brought by artificial intelligence to the workplace. Our research may add to the knowledge about how workers in emerging digital economies perceive AI.® As technology development proceeds at an ever-increasing rate, the importance of our topic will only continue to grow.

However, despite the value of findings made possible by the current study, there are still a number of areas left untouched by researchers. First of all, further studies could be conducted in order to test the relationship between the suggested factors and emotional intelligence. Secondly, the longitudinal approach would be useful for studying the way in which emotional intelligence changes in time with the increase in workers' experience with artificial intelligence. Also, future research could examine differences among demographic groups, among levels of organizational hierarchy, and in technology-based industries to identify what factors affect worker adjustment differently. Comparisons across different countries and cultures could shed light on the importance of social and institutional factors that affect emotions in response to technological changes.

Moreover, further research should be focused on new trends like generative AI, human-AI teamwork, algorithmic management, and virtual workplace. All of these trends will change the way of interactions at the workplace in the future and will give rise to both challenges and opportunities related to emotional intelligence. Maintaining emotional balance and healthy interpersonal relations at the highly automated workplaces is one of the main directions for future research. In summary, the future of work will not revolve around the clash between the intelligence of humans and artificial intelligence. Instead, it will depend on how well people and organizations combine their technological abilities and unique human qualities. Among these human qualities, emotional intelligence plays a key role. While artificial intelligence will keep transforming work, those organizations that will focus both on technology and emotional intelligence of humans will have more chances to succeed. Emotional intelligence can prove itself to be one of the most important skills in the future intelligent world.

Table 1. Major Constructs Used in the Proposed Framework

Construct	Operational Definition	Measurement Scale	Expected Direction
AI Job Anxiety	Fear arising from AI adoption	Technology Anxiety Scale	Negative
AI Literacy	Knowledge and understanding of AI	AI Literacy Scale	Positive
Self-efficacy	Confidence in handling AI	General Self-efficacy Scale	Positive
Organizational Support	Perceived organizational assistance	SPOS	Positive
Emotional Intelligence	Ability to perceive and regulate emotions	WLEIS	Dependent Variable
Adaptive Performance	Ability to adjust to workplace change	Adaptive Performance Scale	Positive Outcome
Job Satisfaction	Overall work satisfaction	Job Satisfaction Scale	Positive Outcome

Table 2. AI Adoption–Emotional Intelligence Matrix (NEW)

Stage of AI Adoption	Workplace Change	Dominant Psychological Response	EI Competency Becoming Critical
AI-assisted tasks	Productivity enhancement	Curiosity	Self-awareness

ABSTRACT

Cross-lingual representations learned by multilingual transformer models often exhibit substantial geometric drift, where embeddings corresponding to the same semantic class diverge across languages. Such instability limits the robustness of multilingual classification systems even when predictive accuracy remains high. We introduce a simple class-conditional regularization strategy that explicitly constrains geometric embedding structure across languages at training time. The approach combines centroid alignment, which reduces cross-lingual intra-class variance, with a supervised contrastive term that preserves inter-class separation. Our lightweight approach is architecture-independent and introduces no additional parameters or inference time overhead. Experiments on multilingual emotion classification across English, Hindi, and Gujarati show that our proposed regularization substantially reduces cross-lingual representation drift and improves the alignment-separation structure compared to baseline multilingual models. This suggests that class-level geometry stabilization suffices to enhance cross-lingual consistency without modifying model architectures or requiring parallel data.

Keywords: Cross-lingual, Class-conditional regularization, Experiments on multilingual emotion classification across English, Hindi, and Gujarati

INTRODUCTION

Multilingual transformer models have become the dominant approach for cross-lingual text classification, as they enable a single shared encoder to transfer knowledge across languages with varying resource availability. Models such as mBERT and XLM-R learn partially aligned semantic spaces during large-scale multilingual pretraining, allowing them to generalise to new languages without explicit parallel supervision [1,2]. As a result, they are widely used for multilingual classification tasks, including sentiment and emotion analysis. Despite their strong predictive performance, recent studies have shown that the internal representations learned by multilingual models can be unstable across languages. In particular, embeddings corresponding to the same semantic class may occupy different regions of the representation space depending on the input language [3,4]. This phenomenon, commonly referred to as cross-lingual representation drift, is often exacerbated during task-specific fine-tuning, where supervision from a dominant language can distort the shared geometry and degrade cross-lingual generalisation [5,6] . Such instability is especially problematic for classification tasks in low-resource settings, where models rely heavily on cross-lingual transfer. While accuracy may remain competitive, inconsistent embedding geometry undermines robustness and interpretability, and can lead to unpredictable behaviour when models are deployed across languages.

In this work, we address cross-lingual representation drift from a class-level perspective. We introduce a training-time Class-Conditional Geometry Regularization (CCGR) strategy that explicitly stabilises the geometry of class-specific embeddings across languages, without relying on sentence-level alignment or parallel data. The proposed approach operates directly in embedding space, requires no parallel supervision, and introduces no additional parameters or inference-time cost. We evaluate the method on multilingual emotion classification across English, Hindi, and Gujarati. Although baseline multilingual models already achieve strong classification accuracy, our analysis reveals substantial cross-lingual drift in their internal representations. The proposed regularization significantly improves representation stability and alignment across languages, highlighting the importance of controlling embedding geometry during fine-tuning beyond optimising predictive performance alone. While centroid alignment and contrastive objectives have been studied independently, their joint use as a class-conditional regularization mechanism to explicitly stabilise cross-lingual embedding geometry during supervised fine-tuning has not been previously explored. Contributions: We

- Identify and quantify class-level cross-lingual representation drift that persists in multilingual models despite strong classification accuracy.
- Propose a lightweight class-conditional regularization strategy that aligns class-specific embeddings across languages during fine-tuning, without modifying model architectures or introducing inference-time overhead.
- Empirically demonstrate that stabilizing class-level embedding geometry is sufficient to substantially reduce cross-lingual drift and improve alignment–separation structure in multilingual emotion classification.

Related Work

Multilingual Representation Learning

Multilingual transformer encoders such as mBERT and XLM-R demonstrate emergent cross-lingual alignment despite being trained without explicit parallel supervision [1,2] . However, subsequent analyses show that this alignment is uneven and sensitive to both language distance and downstream fine-tuning [5,6] . These findings suggest that shared pretraining alone is insufficient to preserve stable multilingual geometry during supervised learning.

Cross-Lingual Representation Drift

Several diagnostic studies have investigated how multilingual representations degenerate after fine-tuning. Lauscher et al. describe representational degeneration, where semantically equivalent inputs drift apart across languages [3] . Nickerson et al. further show that drift can occur at both sentence and label levels in classification settings [4] . Related work has also observed language bias and dominance effects, where representations collapse toward high-

resource languages [7]. These studies focus primarily on characterising drift rather than proposing corrective training objectives.

Alignment Using Parallel or Pseudo-Parallel Data

Many alignment approaches rely on sentence-level supervision. Contrastive and ranking-based objectives applied to parallel corpora have been shown to improve cross-lingual consistency [8,9] . Other works employ knowledge distillation or teacher–student frameworks to transfer alignment from a high-resource language to multilingual models[10] . While effective, such methods depend on high-quality parallel data or large auxiliary corpora, which are often unavailable for low-resource or domain-specific tasks.

Label-Aware and Class-Level Alignment

An alternative direction explores alignment using label information rather than sentence pairs. Some methods constrain output distributions across languages [11] , while others leverage prototype-based representations in few-shot learning settings[12] . Supervised contrastive learning has been shown to effectively structure representation geometry using label information [13] . Our results support prior observations that representation geometry plays a critical role in model robustness beyond predictive accuracy [14] . While related to prototype-based and label aware methods, our approach differs in both objective and usage. Prototypical networks construct class representatives episodically for few shot inference, whereas our centroids are used exclusively as a training time regularization signal and are discarded at inference. Moreover, we align class geometry across languages rather than learning task-specific prototypes. This distinction allows our method to stabilize multilingual representation structure without modifying the classifier or inference pipeline. In contrast to prior approaches that rely on sentence-level alignment, parallel data, or output-level constraints, the proposed method directly regularises class-level embedding geometry across languages using only label supervision.

Positioning and Novelty

Although our approach is related to prior work on prototype-based learning and supervised contrastive objectives, it differs fundamentally in both purpose and usage. Prototypical networks construct class representatives episodically and replace the classifier during inference, typically in few-shot learning settings. In contrast, the class centroids in our method are computed only during training, act solely as a regularization signal, and are completely discarded at inference time. The proposed method does not modify the classifier, does not perform nearest-prototype inference, and does not assume episodic or few-shot training. Similarly, while supervised contrastive learning promotes class separation, it does not explicitly constrain cross-lingual class geometry. Our contribution lies in showing that explicitly regularizing class-conditional embedding geometry across languages during supervised fine-tuning is sufficient to substantially reduce cross-lingual representation drift, even when predictive accuracy is already high. To the best of our knowledge, this class-level geometry stabilization perspective has not been previously explored in multilingual classification.

METHOD

This section describes the proposed class-conditional regularization strategy for reducing cross-lingual representation drift in multilingual transformer models. The method operates as an auxiliary training objective and does not modify the model architecture or inference procedure. An overview of the proposed training-time regularization framework is illustrated in Figure 1and algorithm is stated in Algorithm 1.

Problem Setting

Let $D= \{(x_i, y_i, l_i)\}$ denote a multilingual dataset, where x_i is a text sample, $y_i \in \{1,\ldots C\}$ is its class label, and l_i denotes the language. A shared multilingual encoder produces a sentence-level embedding $h_i \in R^d$ for each input. Although such encoders often achieve strong classification performance, embeddings corresponding to the same class may

exhibit significant geometric divergence across languages. The goal is to reduce this cross-lingual drift while preserving class discrimination.

Sentence Representation

We use a multilingual transformer encoder based on XLM-R and extract the [CLS] token as the sentence-level representation. All embeddings are l_2-normalized prior to centroid computation and similarity measurement. This normalization places embeddings on the unit hypersphere, stabilizes centroid estimation, and ensures that cosine similarity reflects angular distance rather than vector magnitude.

Class-Conditional Centroids

For each class C and language l, a language-specific centroid is computed as

$\mu_{c,l} = \frac{1}{N_{c,l}} \sum_{i \in D_{c,l}} hi (1)$

where Dc,l denotes the set of samples belonging to class c in language l . A cross-lingual class centroid is then defined as the mean of all language-specific centroids:

$\mu_c^* = \frac{1}{|L|} \sum_{l \in L} \mu_{c,l}$ (2)

where L is the set of languages.

Algorithm 1: Training with Class-Conditional Regularization

1. For each multilingual mini-batch $\mathcal{B}$ do
2. Compute normalized CLS embeddings $\{\boldsymbol{h}_i\}$ using encoder M.
3. Compute cross-entropy loss $\mathcal{L}_{\text{CE}}$.
4. For each class c and language l in $\mathcal{B}$ do
5. compute class centroid $\boldsymbol{\mu}_{c,l}$
6. end for
7. Compute cross-lingual centroids $\boldsymbol{\mu}_c^*$.
8. Compute centroid alignment loss $\mathcal{L}_{\text{centroid}}$.
9. Construct positive and negative cross-lingual pairs.
10. Compute contrastive loss $\mathcal{L}_{\text{contrast}}$
11. total loss $\mathcal{L}_{\text{total}} \leftarrow \mathcal{L}_{\text{CE}} + \lambda_1 \mathcal{L}_{\text{centroid}} + \lambda_2 \mathcal{L}_{\text{contrast}}$
12. Update model parameters via backpropagation.
13. end loop.

Centroid Alignment Loss

To encourage cross-lingual consistency within each class, we minimize the distance between each language-specific centroid and the corresponding cross-lingual centroid:

$$L_{centroid} = \sum_{c=1}^{C} \sum_{l \in L} \left\| \mu_{c,l} - \mu^*{}_c \right\| (3)$$

This loss explicitly reduces intra-class geometric variance across languages without collapsing representations.

Contrastive Separation Loss

While centroid alignment promotes cross-lingual consistency, class discrimination is preserved using a supervised contrastive objective. Positive pairs consist of embeddings from the same class across different languages, while negative pairs correspond to different classes. We employ a cosine-margin contrastive loss:

$$L_{contrast} = \sum_{(i,j) \in P} \left(1 - \cos(h_i, h_j)\right) + \sum_{(i,j) \in N} max\left(0, \cos(h_i, h_j) - m\right)) (4)$$

where P and N denote positive and negative pairs, respectively, and m is a fixed margin.

Training Objective:

The final training objective combines standard cross-entropy loss with the two auxiliary regularization terms:

$$L_{total} = L_{CE} + \lambda_1 L_{centroid} + \lambda_2 L_{contrast} \quad (5)$$

The weights λ_1 and λ_2 control the strength of centroid alignment and contrastive separation, respectively. All auxiliary components are used only during training and introduce no additional inference-time cost.

RESULTS AND ANALYSIS

This section evaluates the proposed class-conditional regularization in terms of cross-lingual representation stability. Rather than focusing on marginal accuracy gains, the analysis examines how consistently the same semantic class is represented across languages in the learned embedding space, since baseline multilingual models already achieve strong predictive performance. All results are reported on held-out test sets for English, Hindi, and Gujarati. We evaluate representation stability using two complementary geometry-based metrics. Cross-lingual drift measures the average intra-class variance of embeddings across languages, capturing how consistently a semantic class is represented irrespective of input language. The alignment–separation metric (ASM) jointly reflects compactness within classes and separation between different classes, making it sensitive to geometric degeneration that is not reflected by classification accuracy alone.

Effect of Regularization Components

The contribution of individual regularization components is analysed through the ablation study reported in Table 1. The baseline multilingual model exhibits substantial cross-lingual drift, indicating that embeddings associated with the same class diverge across languages despite strong predictive performance. Introducing a supervised contrastive term alone leads to only marginal reductions in drift and does not improve the overall alignment–separation structure. In contrast, centroid-based regularization results in a pronounced decrease in drift and a large increase in the alignment–separation metric. This observation indicates that explicitly enforcing class-level alignment across languages is the primary mechanism responsible for stabilizing representations. The full class-conditional regularization, which combines centroid alignment with contrastive separation, achieves the lowest drift and the highest alignment–separation score among all configurations. While centroid alignment encourages consistency within classes across languages, the contrastive term helps maintain separation between different classes, leading to a more structured and stable embedding space.

Sensitivity to Regularization Strength

The sensitivity of the proposed method to the centroid regularization weight λ_1 is examined in Table 2. Drift decreases consistently as λ_1 increases, with the strongest regularization yielding the lowest drift. No instability or performance degradation is observed at higher values of λ_1, indicating that the method is not overly sensitive to precise hyperparameter tuning. The monotonic trend suggests that stronger class-level alignment leads to more language-invariant representations, supporting the interpretation that the proposed regularization enforces a meaningful structural constraint rather than a fragile parameter-dependent effect.

Cross-Dataset Generalisation

To assess whether the proposed regularization generalises beyond the primary emotion classification setting, we additionally evaluate the method on a multilingual movie review sentiment dataset spanning English, Hindi, and Gujarati. This dataset differs substantially from the main benchmark in domain, writing style, and input length, and exhibits natural imbalance across languages. Despite achieving reasonable classification performance, the baseline multilingual model exhibits severe cross-lingual representation drift on this dataset, indicating that sentiment representations remain highly language-dependent. In contrast, the proposed class-conditional regularization substantially reduces drift and yields more stable class-level embeddings across languages. Table 3 reports drift and alignment stability metrics for both models. The proposed method reduces drift by more than 96% relative to the base line while simultaneously increasing the alignment stability metric by overa factor of three. These results

demonstrate that the regularization consistently stabilises cross-lingual embedding geometry even under pronounced domain shift, without modifying the underlying model architecture or trainingprocedure.

DISCUSSION

Across all experiments, improvements in representation stability are achieved without modifying the underlying model architecture or introducing additional inference-time costs. The results demonstrate that stabilising class-level geometry is sufficient to reduce cross-lingual drift, even when baseline multilingual models already achieve strong predictive accuracy. These findings emphasise the importance of analysing internal representation structure in multilingual systems, beyond standard classification metrics.

Limitations

The current evaluation is limited to a small number of languages and emotion categories. While our experiments focus on emotion classification, the proposed regularization is task-agnostic and can be applied to other multilingual classification settings, which we leave for future work. Extending the evaluation to additional typologically diverse languages remains an important direction for future work, although the current results already demonstrate consistent behaviour across two distinct datasets and domains.

CONCLUSION

This paper addressed the problem of cross-lingual representation drift in multilingual classification models and showed that high predictive accuracy does not necessarily imply stable embedding geometry across languages. We introduced a simple class-conditional regularization strategy that aligns class-specific representations across languages while preserving inter-class separation during training. The method operates directly in embedding space, requires no parallel data, and introduces no additional inference-time cost. Experimental results demonstrate that explicitly controlling class-level geometry leads to more stable and consistent multilingual representations. These findings highlight the importance of representation-level regularization for improving cross-lingual robustness in multilingual models.

ABSTRACT

The present study is aimed to find out the scanning electron microscopic and the ultrastructure of changes in the pair of two testis, two seminal vesicle, two vas deference of the adult male insects *Odontopus varicornis*. Treated with the study on median lethal dose of phytopesticide *Azadirachta indica* was determined to be approximately 0.05 ppm for 48 hours. The testis, vas deferens, and seminal vesicle were studied morphologically using scanning electron microscopy (SEM). In the present study, detailed surface observations of these reproductive organs were examined. The testis were flattened leaf-like structures with white connective tissues and layers of a peritoneal connective sheath that resembled crystals. The testicular follicles were distinguished by their secretory activity and had several pinocytotic pits. Myoepithelial cells and folded or ruffled connective tissues coated the testicular tubes. The vas deferens had a thick outer tubular shape with myoepithelial cells and folded cuticle. Numerous pinocytotic pits and secretory granules in the epithelial layer demonstrated the membrane's ability to increase secretory activity. The insect's seminal vesicle demonstrates its tubular shape with ruffled muscles on the outside. There were more secretory materials in the lumen. Smooth longitudinal and circular muscle covers the seminal vesicle on the outside. Future research on reproductive behavior,

evolutionary relationships, reproductive physiology, and the effects of toxicants in Hemiptera will benefit greatly from the basic information this study provides on the male reproductive system in *Odontopus varicornis.*

Keywords: *Odontopus varicornis*, *Azadirachta indica*, Testis, Seminal vesicle, Vas deference, SEM study.

INTRODUCTION

From the perspective of the insect species propagation, reproduction is a crucial physiological activity that, naturally leads to the high biotic potential of insects, which makes them a successful group of animals. Scanning electron microscopy (SEM) was employed to observe and characterize the surface morphology of the tissues. One technical tool that has proven to be helpful in surface modification research is the scanning electron microscope. In many morphological research, scanning electron microscopy is a crucial tool because it reveals surface structure (Song, Y *et al*., 2013; Liu, C. 2008). The male reproductive system of *Codophila varia* was investigated using both light microscopy and scanning electron microscopy to characterize its structural features (Özyurt, N., and Candan, S. 2014). Improved understanding of toxicity, illness, and medication delivery mechanisms at the ultrastructural level in different biological models (Grover, A *et al*., 2022). Upon using electron microscopy to study the larvae, we discovered 106 conidia adhered to the larva's rear folds (Duan, Y *et al*., 2017). Using SEM, we observe various nanoscale and microscale organization of in-situ chitin in the wing, head, eye, leg, and dorsal and ventral thoracic regions of the periodical cicada Magicicada septendecim, as well as in other insects and arthropods, following the removal of a cuticle's proteinaceous and mineral matrix (Chandran, R *et al*., 2016). Scanning electron microscopy, on the other hand, presents the objects in grayscale but permits the examination of minute details of structure due to its excellent resolution and the potential for higher magnifications. We describe the method we employ to prepare arthropods kept as museum specimens for digitalization and eventual visitor presentation (Adamski, Z *et al*., 2025).

The cells appeared to be non-ciliated. One common characteristic of the ductus deferens epithelium was globular apical protrusions. Additionally, the ductus deferens lumen revealed a large number of spermatozoa (Mohd, K *et al*., 2018). With the exception of using a concentrated electron beam rather than light to "image" the object and learn more about its composition and structure, electron microscopes operate exactly like their optical counterparts. The seminal vesicles play the primary role of secretory activity in creating seminal fluid, which is required for the transport of the sperm, according to these findings, which represent the first attempt to examine the ultrastructure of the male reproductive organs in Panorpidae. The epididymis assumes the original role of storing sperm (Xie, S. and Hua, B., 2010). We demonstrated many kinds of biological samples using a scanning electron microscope. In the last ten years, a SEM Tabletop model has completely changed how scanning electron microscopes are use (Ghosh, N *et al*., 2011). Based on their traits in comparable species, the potential roles of different sensilla are examined. This study offers a crucial starting point for additional investigation into Xylotrechus grayii sensory processes and regulatory strategies (Chen, J.M *et al*., 2014).

These discoveries enhance our knowledge of the antennae's anatomy in these two species, making it easier for us to differentiate between them (Wei, C *et al*., 2015). Investigating the spermatogenic and spermiogenic stages of adult male testes by ultrastructural analysis may provide important insights into how heavy metal contamination affects insects at the ultracellular level (Shonouda, M. and Osman, W. 2018). The auxiliary glands' tubular structure and tracheoles covering their outside are visible in the SEM pictures (Özyurt, N., Candan, S. *et al*., 2015). Scanning electron microscopy was used to examine the gross and fine morphology of microstructures, such as sensilla, microsculpture, and pores. With a basal scape, a pedicel, a funicle made up of five antennomeres, and a club made up of three lamellae, O. eremita's antenna displayed the characteristic lamellicorn morphology of scarab beetles (Zauli, A *et al*., 2016). Testicular follicles with a clear spermatogenesis gradient stretching from the periphery to the center have been identified by scanning electron microscopy (SEM) investigations. Growth, maturation, and

differentiation areas make up this gradient. The placement of the cells inside the follicle, nuclear morphology (size, shape, and chromatin density), and cytoplasmic features are all taken into consideration when making this classification (Arslan, H. *et al*., 2026). We describe and analyze the morphological characteristics of the first, second, and third instar larvae and the puparium of *R. belforti* based on observations obtained using scanning electron microscopy (da-Silva-Xavier, A. and de Carvalho Queiroz, M.M., 2016).

We report the first scanning electron microscopy investigations of adult male and female *H. ligurriens* antenna sensilla. These investigations may aid in differentiating the species from other calliphorid flies and are essential for advancing our knowledge of insect morphology from a forensic entomological perspective (Hore, G *et al*., 2017). The scientific world has recently paid more attention to drastic decreases in insect populations, or "Ecological Armageddon," which are often thought to be the result of large-scale issues such habitat fragmentation, pesticide use, land-use changes, and climate change (Grubisic, M *et al*., 2018). To fully understand how a SEM instrument operates, it is crucial to comprehend the principles of operation of both characteristics. SEM is known for being simple to use. With that information, one may carry out the imaging and analysis with great case (Mohammed, A. and Abdullah, A., 2018). Food webs in seemingly unrelated places are connected by organisms that migrate across ecosystem boundaries. Aquatic insects change from aquatic larvae to terrestrial adults as part of their life cycle, connecting the dynamics of terrestrial insectivores with freshwater ecological processes (Kraus, J.M., 2019). However, the objectivity and authenticity of the observation location may be compromised while preparing insect samples for scanning electron microscopy (Chen, X.F and Hu,M,Y, 2001).

Insect SEM sample preparation typically involves cleaning, tissue fixation, dehydration, metathesis, drying, and sputter coating (Zhou, W *et al*., 2006). The mechanism of action of the local isolates was investigated using SEM tests in comparison to commercial and reference strains (Sharma T *et al*., 2017). This insect's potential utility as an indicator species is crucial. We can use it to measure pollution in the air, water, and soil, which will help us regulate pollution and stop habitat loss in the future (Parikh, G *et al*., 2021). Tween 20 fixative made it easier for the wood boring beetle's body wall to be penetrated than it would have been without it. As a result, the body's tissues and organs were better fixed, allowing for clear scanning electron microscopy studies of insect sensilla ultrastructures (Zhang, Y.R *et al*., 2020). This is particularly true for investigations on plant-insect interactions, where DSEM could expedite routine imaging of plant and insect sections (Watts, S *et al*., 2022). Light and scanning electron microscopy were used to examine the architecture and histology of the male reproductive system of *I. speciosus* (Özyurt Koçakoğlu, N *et al*., 2023). Compared to a light microscope, an electron microscope can view considerably smaller objects at the sub cellular, molecular, and atomic levels due to its higher magnifications and stronger resolving ability. The microscope's best resolution is achieved when the lighting sources have the lowest wavelength (Kannan., M 2018).
We conducted in-situ field testing to see if such contaminants could reduce pollinator foraging and, thus, the pollination ecosystem function that those insects serve (Ryalls, J.M and Langford, B., 2022). Irradiation cysts occasionally showed a lack of axonemes, failure to reabsorb the cytoplasm, incomplete sperm cell divisions that produced several copies of the same organelle within the same cell, and general disarray of sperm arrangement (Paoli, F., *et al*., 2024). We have proven that it is viable to enhance preservation of specimens using a scanning electron microscopy approach. Additionally, this method of seeing genitalia allows for improved visibility, description, and comprehension of the morphological features of fly genitalia when combined with confocal laser scanning microscopy (Silva, I.G *et al*., 2025). This study provides a detailed morphological analysis of the stridulatory files in two closely related mole crickets and explains interspecific and sexual variation in file organization in Gryllotalpidae (Hu, H., Li, *et al.,* 2026). With particular reference to the male reproductive process in the test insect, *Odontoupus varicornis*, the current investigation was carried out to scanning electron microscopic changes in the testis, seminal vesicle, and vas deference while exposed to *Azadirachta indica*.

MATERIALS AND METHODS

Insect rearing

Collect the Government arts college campus botanical gardens adult male insects of *Odontopus varicornis* were taken to the zoology laboratory and grown in six plastic tubs, gathered from the having a dimension 30x22x28 cm, at a laboratory temperature of 28° ± 1°C and relative humidity of 80 ± 5%. *Odontopus varicornis* feeds mainly on the seeds of Malvaceae (mallow) plants. In the present study, the insects were fed daily with soaked cotton seeds (Bombax ceiba) as well as seeds of their host plants, (*Sterculia foetida*) and *Gossypium* sp. The insects showed good growth and survival on these food sources. The insect cages were cleaned every alternate day by removing excreta and other waste materials to maintain proper hygiene.

Tissue Preparation for Scanning Electron Microscope (SEM)

The mortality was recorded for *Odontopus varicornis* 48 hours of exposure injecting the *Azadirachta indica* of various concentrations. The calculated LD_{50} value was *Azadirachta indica* 48h. Male insects the testis, seminal vesicle, vas deference of control and treated insect were prepared for this, the dissected samples were fixed in 2.5% glutaraldehyde in 0.1 m phosphate buffer, pH 7.4) at +4°C for 24 h. then the samples were washed in 0.1 m phosphate buffer and dehydrated in removal of water. After drying, the tissues were mounted on metal stubs using conductive tape, coated with thin layer of conductive materials model (JEOL-JFC 1600) and they were examined with SEM (JEOL-JSM-IT 200) the photographs were taken at various magnifications.

RESULTS

Reproductive system of *Odontopus Varicornis*

The male insect pair of testis, a pair of vas deference, and a pair of seminal vesicles make up the male reproductive system of *Odontopus varicornis*. The vas deference connects the paired testis to the seminal vesicle. Each testis lobe enclosed by an outer sheath and has a smooth surface. The vas deference, which is long tubular and white is attached to each testis lobe by a narrow canal. Once completely formed, the sperm use the vas deference to move from the testis to the seminal vesicle. It was externally covered with the fat body. There were claspers, used to hold the female during mating and the penis. The testis of the control insect was tubular in shape and coated in many membranes and cells. Beneath this, it was found to have folded cuticle covering it. The many follicles that make up each testis are clustered together and covered in sperm. Each follicular cyst has several secretory vesicles as well as an outer layer of muscle. (Fig. 1 and 2). The apical cells of the treated insect's testis follicle showed a variety of changes, such as pycnotic epithelial cells and the disintegration, vacuole, and disarray of the special cells' secretory granules. (Fig. 3 and 4). The control insects' vas deferens had a thick outer tubular wall with a layer of ruffled membrane and a folded cuticle. Each tubule was made up of columnar epithelial cells with several secretory vesicles and granules, as well as a membrane that resembled a microvillus. They are referred to as pores. (Figs. 5 and 6). The tubules had a shrunken appearance, a thick, rope-like plasma membrane lining them, and an outside layer of broken circular muscle surrounding them. Showing that the secretory tubules are disrupted (Figs. 7 and 8). The seminal vesicles of the control insect displayed a tubular shape enclosed by a layer of longitional muscle. The tubules were externally covered by a thick, folded cuticle. Many tiny secretory vesicles and secretory globules were present in the epithelial cells. (Figs. 9 and 10). A significant degree of secretory activity was indicated by the cells' many pinocytotic pits and microvilli. High pinocytotic pits were visible in the rope-like basement membrane, and breakdown of the secretory globules and vesicles. (Figs. 11 and 12).

DISCUSSION

These ultrastructural alterations most likely represent diapause-related adaptive strategies. This work offers new insights into the reproductive development of O. fuscidentalis through the integration of multi-scale imaging. It also serves as a useful reference for future comparative research on the evolution of sperm and reproductive adaptations in insects with complex life cycles (Yasanga, Thippawan, 2026). Photographs taken using a light microscope, SEM, or TEM show the lumen of the auxiliary gland tubules, which have a considerable capacity and are filled with secretion (Polat, I., and Amutkan Mutlu, D. 2020). Similarities with other mosquito species were revealed by the ultrastructure and sperm structure characterisation. Lastly, our research yielded useful data that could aid in comparative biology and reproduction studies (da Silva, H.B *et al.,* 2025). The SEM architecture of seminal vesicle consists of outer rope like structure of connective tissues with many myoepithelial cells. Many pinocytotic vesicles made up the epithelial cell, and certain materials were both secreted and absorbed by the secretory granules (Vivekananthan, T. and Sethuraman, S., 2015). Compared to chemical pesticides, their low toxicity to people is advantageous, particularly in India where pesticide misuse is prevalent. Further research should focus on optimizing dosage for field applications, treating vast areas in various agro-ecological zones, and considering socioeconomic factors (Dutta, P *et al.,* 2018).
The reactions of C. aeruginosa to the volatile semiochemicals generated by their host plants, as well as the behaviors displayed during host and habitat selection, were also covered (Zhang, L *et al.,* 2013). The adaptive diversity of the morphology of the male reproductive system is reflected in this range in testis dimensions (Özyurt Koçakoğlu, N., Arslan, H., Candan, S. 2026). For more taxonomic, phylogenetic, and reproductive biology research in curculionids, the types of acrosomal and flagellar structures as well as chromatin condensation patterns are crucial characteristics (Dos Reis *et al.,* 2007). SEM examination appeared to be suitable for differential diagnosis between FA and actual bloodstains on hard surfaces, however the results may be equivocal on tested fabrics (Pelletti, G *et al.,* 2022). During the maturation of the male accessory glands in *T. brasiliensis* and *T. melanica*, secretory granules of varying sizes, shapes, and electron densities were observed (Freitas, S.P.C *et al.,* 2010). The majority of features showed little indication of a phylogenetic link with any other clade of nematocerous Diptera, indicating the need for thorough morphological analyses of numerous families' immatures (Wihlm, M.W *et al.,* 2012).

As a result of this research, it has been demonstrated that P. ataturki's male reproductive system components are highly similar to those of other species in the Tettigoniidae family (Mutlu DA, 2021). A pair of oval-shaped testis connected to a seminal vesicle by vasa deferentia make up the male L. longipalpis reproductive system. It comes after an ejaculatory duct with an ejaculatory pump, which is a big, muscular bulb connected to the trachea (Spiegel, C.N *et al.,* 2013). Instead of momentarily retaining spermatozoa, the seminal vesicles are mostly used for secretion. Instead, the highly coiled distal section of the vas deferens, known as the epididymis, is where the sperm are momentarily housed (Lyu, Q.H *et al.,* 2018). This study used scanning electron microscopy (SEM) to characterize and examine the morphological traits of all larval instars and puparia of *L.cuprina* (Mendonça, P.M *et al.,* 2014). Although the male *P. parallelus's* testis structure is very similar to that of other Orthoptera species' male reproductive systems, there are some broad morphological distinctions between them despite their cytological similarities (Polat, I., and Amutkan Mutlu, D 2019). It provides the basis for reconstructing character evolution at the phenotypic level and developing complex evolutionary scenarios (Wipfler, B *et al.,* 2016). The ejaculatory bulb, two vasa efferentia, two seminal vesicles, two tubular vasa deferentia, two accessory glands (mesadenia), a single muscular ejaculatory duct that opens via the aedeagus, and two testis-where various stages of spermatogenesis are visible make up the male reproductive system (Elelimy, H.A.S., *et al.,* 2017). Additionally, the results of this study could be applied to phylogenetic relationships: the observations of these structures could serve as a source of information about their phylogenetic traits and as a source of fundamental knowledge that could aid in the future understanding of some of their functions and sexual behaviors (Sontigun, N *et al.,* 2018).

Each testis has a seminal vesicle in the middle. The seminal vesicle is where the majority of mature sperm are kept. A seminal vesicle that resembles a stalk connects each testis to the vas deferens. *Vasa deferentia* fuse with the ejaculatory duct at the distal portion. The aedeagus is connected to it. The findings will advance knowledge of Curculionidae

reproductive cell biology (Ö. Koçakoğlu, N., *et al.,* 2019). Clear transmission electron microscopy observations of insect sensilla ultrastructures were obtained as a result of the body's tissues and organs being more fixed. In order to improve the accuracy of target sensilla location, the next stage of this preparation involved locating the insect sensilla in the sample embedded in the resin block using fluorescence microscopy. This increased the precision of the slicing (Zhang, Y.R., *et al.,* 2020). The testis, vas deferens, and accessory glands make up the male B. turkiyae's reproductive system. Examining the oval and yellow testis cross-sections revealed that they were packed with follicles. These follicles contain cysts that exhibit sperm growth stages. The germarium, growth zone, maturation zone, and transformation zone are situated, respectively, from the follicles' distal ends to their proximal ends (Polat, İ., Mutlu, D.A. and Suludere, Z., 2023). Ultimately, the axoneme exhibits microtubular doublet array disorder, the central complex vanishes, and eventually the auxiliary microtubules as well (Paoli, F *et al.,* 2014).

Preventing the response could impede activation and fertilization, which would lower female fitness and alter population dynamics (Krueger, S *et al.,* 2022). This page aims to provide biological control against *G. campestris*, describe its male reproductive system, and provide characteristics that could be helpful for future research on the taxonomy and phylogeny of other Orthoptera species (Bayram, G.G. and Candan, S., 2021). We hypothesize that the absence of a long common ejaculatory duct is compensated for structurally. This illustrates how dependable C. pallens auxiliary glands are during spermiation (Liu, X *et al.,* 2023). The results were contrasted with the male reproductive organs of a few other Coleoptera species. The species of the Coleoptera order differ in a few traits, such as the quantity and form of testicular follicles and accessory glands (Amutkan Mutlu, D *et al.,* 2025). Furthermore, identifying possible morphological characteristics will serve as a useful foundation for further research on this topic (Özyurt Koçakoğlu, N *et al.,* 2026). Which are similar to the results of other workers name *Odontopus varicornis* (Mohan., T. 2013) and (Lousia., M. 2010). *Sphaerodema rusticum* (Rajathi., V 2004) and (Shoba., 2011) and (N.G.Tamilselvi., 2013). *Aulacophora fovelcollis, Aulacopho ranigripennis* (Vivekananthan., T *et al.,* 2015). *Codophila varia* (Nurcan Ozyurt *et al.* 2014). *Bittacidae* (Qi-Hui Lyu *et al.,* 2018). *Isotomus speciosus* (Nurcan Ozyurt kocakoglu *et al.,* 2023). *Oxythyrea funesta* (Özyurt Koçakoğlu, N *et al.,* 2026). The male reproductive system of *Odontopus varicornis* was also compared structurally with those of several other hemipteran species.

CONCLUSION

Scanning electron microscopy (SEM) is used in toxicology to investigate the ultra-structural harm that medications, poisons, or environmental contaminants cause to tissues and cells. It gives high-resolution photographs of surface topography, allowing toxicology to observe morphological alterations, cellular necrosis, and membrane deterioration. The current study offers basic details on how the phytopesticide *azadiratin indica* damages the male reproductive system by affecting a pair of testis, seminal vesicles, and vas deference detective works in the ultra structure of *Odontopus varicornis* a scanning electron microscope. Future research on the toxicity of insect reproduction will benefit greatly from these discoveries.

ABSTRACT

In Ayurveda, Dhatu Sarata (tissue excellence) and Sara Pariksha serve as fundamental diagnostic and therapeutic tools to evaluate an individual's intrinsic biological strength (Bala), immune resilience, and functional tissue quality beyond mere physical appearance. To summarize the diagnostic, prognostic, and therapeutic applications of DhatuSarata across five core clinical domains based on classical concepts and contemporary literature. A descriptive synthesis was conducted utilizing classical Ayurvedic literature, commentary frameworks, and contemporary clinical studies focusing on Sara Pariksha and its applications in health assessment, disease management, and preventive care. The clinical utility of DhatuSarata is categorized into five key domains: Assessment of Patient Strength (Bala): Evaluates biological endurance and immune capacity independent of physical body size. Individuals with Rakta Sara possess moderate strength (Anatibala), whereas those with Mamsa, Majja, and Shukra Sara are inherently strong (Balavan).Holistic Evaluation Beyond Disease: Assesses mental resilience (Sattva Sara), behavioral tendencies (Aloulya), and qualitative attributes across all seven Dhatus and the mind (Satva).Prognosis and Progression (Sadhyasadhyata): Tracks the depth of pathogen-tissue interaction (Dosha-DushyaSammurchana). Superficially located pathoses (Rasa Dhatu) resolve quickly, whereas deeper involvement (Asthi, Majja, and ShukraDhatus) yields chronic (Yapya) or incurable (Asadhya) prognoses. Treatment Selection and Dose Calibration: Directs therapeutic intensity based on intervention tolerance (Sahishnutva). Rakta and Meda Sara individuals require gentle care (Sukumaropachara), whereas Asthi Sara individuals exhibit high physical resilience (Kleshasaha) and endure intense cleansings (Shodhana).Preventive Healthcare and Early Detection: Identifies suboptimal tissue states (HeenaSarata) prior to disease manifestation, facilitating targeted rejuvenative therapies (Rasayana),

personalized diets, and lifestyle modifications to prevent disease progression. DhatuSarata provides an essential personalized framework in Ayurveda, bridging holistic clinical diagnosis, treatment calibration, prognostic assessment, and targeted preventive healthcare.

Keywords: Ayurveda, DhatuSarata (tissue excellence) and Sara Pariksha, Sukumaropachara, Kleshasaha

INTRODUCTION

Amongst the various traditional system medicines, Ayurveda is an emerging branch for preventive as well as curative aspect of treatment. Ayurveda means the science of *Ayu*i.e Life. The fundamental basis of the human body as described in *AshtangHrudaya* is " *DoshaDhatu mala moolam hi shariram*" [1]which is - the *Tridoshas* which maintains the physiological functions , *SaptaDhatu* – which maintains and supports the body structure and *Trimalas* – whichare the metabolic waste products. The *Tridoshas* – *Vata, Pitta* and*Kapha* are said to be the *Stambha* – pillar of the body. The equilibrium state of the *Doshas, Agni, Dhatu , Mala* along with pleasure of mind results in Health. The important entity which is described as *Dhatu* which means *DharnatDhatavah* –That which supports and maintains the body structure. They are 7 in number *Rasa, Rakta, Mamsa ,Meda , Asthi , Maja and Shukra[2].Sarata*which means of highestpotentiality or to excel. The *DhatuSarata* is one among the *Dashavidhapariksha* / tenfold examination described in Ayurveda texts. [3]The formation of the *Dhatus* is not an individualized entity but of a sequential order . The *Aahar* which gets digested with the help of *Jatharagni* gets converted into the *Rasa Dhatu* and from *Rasa Dhatu* subsequent *Dhatus* are formed. This process is carried out by the individual *Agni* of that *Dhatu* known as *Dhatvagni* like *Rasa Dhatvagni, RaktaDhatvagni, MamsaDhatvagni* and so on. The quality of *Dhatus* depend on the *Jatharagni* and the *Dhatvagni*. Impairment in any of these results into the *Dosha-Dhatu* vitiation. [4]So, the*Aahar*having *Sngidha, Guru, SheetaGunaDhatuVardhakand opposite* are*DhatuKshaya Kara. [5]*There are various features for the assessment of *DhatuSarata*. Far from being a simple measure of physical appearance, *DhatuSarata* serves as a vital clinical approach evaluating tissue integrity, physiological performance, immunity, and overall disease susceptibility. Within *AyurvedicNidanaPaddhati*, this assessment bridges structural physical examination with accurate diagnosis, prognostic evaluation, customized treatment strategies, and long-term preventative care.

Aim

To assess the importance of the *DhatuSarata* in *AyurvedicNidanPaddhati* (Ayurveda Diagnostic Method)

Objectives

- To describe the available information regarding the *DhatuSarata* in *Charak Samhita , Sushruta Samhita*
- To clinically correlate the effect of the Symptoms described in the *Dhatu Sara Lakshana*
- To evaluate the effect of *DhatuSarata* assessment in Diagnostic approach

DISCUSSION

The *Dhatusarata* is said to be the excellence of *Dhatu* formed. This aspect in assessment of the probable dushti that can be occurred in the *Dhatus*. The Diagnostic and Clinical Relevance of DhatuSarata in NidanaPaddhatiInAyurvedic diagnosis (NidanaPaddhati), DhatuSarata (the assessment of tissue quality and functional excellence) serves as a vital component of the DashavidhaPariksha (tenfold clinical examination). Rather than evaluating structural mass alone, Sara Pariksha offers a nuanced understanding of an individual's constitutional strength, therapeutic tolerance, and disease trajectory. [8]The diagnostic and therapeutic applications of *DhatuSarata* can be summarized through five core clinical domains:

Assessment of Patient Strength (*Bala*)

DhatuSarata enables the physician to measure intrinsic vitality beyond mere physical stature. As illustrated by classical commentators, a slender frame does not necessarily imply weakness. Persons with *Rakta Sara* are categorized as *Anatibala* (moderate strength), whereas individuals possessing *Mamsa*, *Majja*, and *Shukra*Sara are inherently *Balavan* (endowed with high endurance and physical capacity). *Sara Pariksha* is explicitly mentioned for the assessment of *BalaPramana* (quantum of strength) of the patient. *Bala* means biological strength or power of resistance against diseases, correlating with the immunity of the individual. [9]

Comprehensive Understanding Beyond the Disease

Sara Pariksha evaluates holistic physical, psychological, and behavioral characteristics. For instance, Sattva Sara denotes superior mental endurance, courage, and psychological resilience. Certain social and behavioral markers described in classical literature—such as *Aloulya* (non-greediness) and *Vitta* (wealth/societal standing)—warrant modern objective validation to establish their contemporary clinical relevance. *Dhatusarata* examination gives an idea about the qualitative state of seven *dhatus* and *satva*(mind), serving as a subjective type of examination for quantification of bala (strength)[10]

Determination of Disease Progression and Prognosis (Sadhyasadhyata)

The depth of tissue involvement directly influences disease severity. As morbidity advances sequentially through deeper tissues (*UttarottarDhatu*), the prognosis shifts toward Yapya (manageable but chronic) or *Asadhya* (incurable). Assessing *Sarata* helps determine whether the underlying tissue matrix is strong enough to resist deep pathogenetic lodging (*Dushya-DoshaSammurchana*). The deeper the dhatu involved, the harder the disease is to treat; this is why a Rasa-dhatu level disease like simple fever resolves quickly, while an *Asthi-dhatu* disease like osteoarthritis requires prolonged, intensive therapy. Diseases involving *Asthi*, *Majja*, and *Shukradhatus* have very bad prognosis and are often incurable**. [11]**

Selection and Calibrating Intensity of Treatment

Tissue excellence dictates a patient's capacity to tolerate therapeutic interventions (Aushadha and ShodhanaSahishnutva)[12] Rakta Sara: Associated with AkleshaSahishnutva (low tolerance for physical discomfort or harsh therapies); this gives inability to face difficulties and intolerance of heat.Meda Sara: Requires Sukumaropachara (gentle management), as these individuals cannot endure strenuous labor or harsh cleansing regimens; they are delicate and cannot tolerate severe treatment. *Asthi Sara*: Characterized as *Kleshasaha*(highly resilient, enthusiastic, and capable of enduring strenuous activity and intense therapies); they are enthusiast with great endurance, strong and have stable-firm body.On the basis of *Bala*, the physician decides the type of medicine and its dose to be given in *Samshodhana or SamshamanaChikitsa*. [13]

Preventive Healthcare and Early Detection

By recognizing suboptimal tissue excellence (*Asara or HeenaSarata*) prior to clear clinical manifestation, *DhatuSarata* provides an opportunity for targeted preventive care. Early identification of vulnerable *Dhatus* allows for personalized dietary regimens, lifestyle modifications, and specific *Rasayana* (rejuvenative) therapies before irreversible *DushitaDhatu*changes occur. *Rasayana* therapy in Ayurveda serves as a key to preventing disease progression by strengthening the *dhatus* before they become vitiated.[14]

CONCLUSION

Dhatu Sara *Parikshan*can open a door for the improved diagnostic methods along with offering an option to predict and prevent the future occurrence of the disease.

Possibilities/Limitations and Challenges for the assessment of *DhatuSarata*

In the midst of the multiple laboratory tests and various radiological tests available, it is highly needed that the Ayurveda diagnostic methods needs to be read thoroughly , modified as per the todays' era and used in common practice. In spite of the great importance of *Sarata* described in classics, its practical assessment is still a point of discussion.

Table 1: Dhatu Sara Lakshana

Dhatu	Charak Samhita [6]	Sushrut Samhita [7]
Tvak Sara	unctuous (*Snigdha*), smooth (*Shlakshna*), soft (*Mridu*), charming (*Prasanna*), delicate (*Sukumara*), lustrous (*Saprabha*) and the hair on the skin are unctuous (*Snigdha*), smooth (*Shlakshna*), soft (*Mridu*), pleasant (*Prasanna*), delicate (*Sukumara*), minute (*Sukshma*), sparse (*Alpa*), deep rooted (*Gambheera*). Person with *UttamTvak/Rasa Sara* is endowed with happiness (*Sukh*a), good fortune (*Soubhagya*), sovereignty (*Aishwarya*), enjoyment (*Upabhoga*), intelligence (*Buddhi*), knowledge (*Vidya*), health (*Aarogya*), pleasure (P*raharsha*) and longevity of life (*Aayushyatwa*)	One, whose skin (*Tvak)* and hairs (*Roma*) are good looking (*Suprasanna*) and soft (*Mrudu*),

Rakta Sara	Ears (*Karna*), eyes (*Netra*), face (*Mukha*), tongue (*Jihva*), nose (*Nasa*), lips (*Oshtha*), palms (*Panitala*), soles of the foot (*Paadatala*), nails (*Nakha*), fore head (*Lalata*), penis (*Medhra*) are unctuous (*Snigdha*), red (*Raktavarna*), beautiful (*Shrimad*) and dazzling (*Bhrajishnu*). This *RaktaSaratva* gives happiness (*Sukha*), arrogance (*Uddhatam*), good grasping power (*Medha*), self-respect (*Manasvitvam*), delicacy (*Soukumaryam*), less strength (*Anatibalam*), inability to face difficulties (A*kleshsahishnutvam*) and intolerance of heat (*Ushnasahishnutvam*)	unctuous (*Snigdha*) and coppery nails (*TamraNakha*), eyes (*Nayana*), palate (*Talu*), tongue (*Jivha*), lips (*Oshtha*), palms and soles (*Panipadatala*).
Mamsa Sara	Temples (*Shankha*), forehead (*Lalaat*), atlanto-occipital joint (*Krukatika*), eyes (*Akshi*), zygomatic bone region (*Ganda*), jaw (*Hanu*), neck (*Griva*), shoulder (*Skandha*), abdomen *(Udara*), axilla (*Kaksha*), chest (*Vaksha),* joints of limbs are stable (*Sthirapani-pada sandhi*), heavy (*Guru*), good looking (*Shubha*) and well-covered with muscles (*Mamsopachita*). This *MamsaSarata* gives forgiveness (*Kshama*), patience (*Dhruti*), non-greediness (Aloulya), wealth (Vita), knowledge (*Vidya*), happiness (*Sukha*), kindness (*Aarjava*), strength (*Bala*), health (*Aarogya*) and long life (*Deerghayu*)	*Mamsa Sara* person is known to possess few depressions (hollows) in the body(*AchhidraGatra*) , have well-covered (concealed) bones and joints and musculature(*Gudhaasthi Sandhi, Mamsaupachita*)
Meda Sara	Complexion (*Varna*), voice (*Swara*), eyes (*Netra*), hairs (*Kasha*), small hairs (*Loma*), nails (*Nakha*), teeth (*Danta*), lips (*Oshtha*), urine (*Mutra*), faces (*Purisha*) are excessively unctuous (*Snigdha*). This *Medasarata* gives wealth (*Vita*), sovereignty (*Aishvarya*), happiness (*Sukha*), enjoyment (*Upabhog*), charity (*Pradaan*), kindness (*Aarjava*), delicacy and they cannot tolerate severe treatment (*Sukumaropacharata*)	*Medasara* person is known to pass unctuous (*Snigdha*) urine (*Mutra*) and sweat (*Sweda*), has a mellow voice (*SnigdhaSwara*), a bulky body (*BrihatSharira*) and are incapable of doing physical labor (*AayasaAsahishnu*).
Asthi Sara	Heels (*Parshni*), ankles (*Gulpha*), knees (*Janu*), forearm (*Aratni*), collarbones (*Jatru*), chin (*Chibuk*), digits (*Parva*), bones (*Asthi*), nails (*Nakha*), teeth (*Danta*) are robust or big (*Sthula*). This *Asthisarata* gives enthusiasm (*Mahotsaha*), activeness (*Kriyavanta*), endurance (*Kleshasaha*), well-built body (*Sara-sharir*), strong stable body (*Sthira-sharira*) and long life (*Aayushmanta*).	big head and shoulders (*Mahashiraskandha*) , big teeth (*Brihatdanta*), big jaws (*BrihatHanu*), bones and nails (*Brihatasthi* and *Brihatnakha*
Majja Sara	Soft body (*Mrudvanga*), strong (Balavanta), unctuous complexion (*Snigdhavarna*), melodious voice (*Snigdhasvara*), prominent joints (*Sthula sandhi*), long joints (*Dirgha sandhi*), rounded joints (*Vrutta sandhi*). This *Majjasarata* gives long life (*Dirghayusha*), strength (*Balavanta),* well learning (Shrutabhaj), richness (*Vittabhaja*), special knowledge of science (*Vidhnyanbhaj*), progeny (*Apatyabhaj*) and respect (*Sammanbhaj*)	*Majjasara* person is known to be not lean and thin (*Akrusha),* but to be powerful (*UttamBala*) to possess mellow (*Snigdha)* and sonorous (*Gambhira*) voice (*Swara*) and is endowed with good fortune (*Soubhagyopapanna*) and has big eyes (*Mahanetra*).
Shukra Sara	Gentleness (*Soumya*), gentle look (*Soumyaprekshina*), milky white sclera (*Kshirpurnanetra*), good sexual capacity (*Praharshabahula*), unctuous (*Snigdha*), round (*Vritta*), firm (*Sara*), even (*Sama*) and compact (*Samhat*) teeth (*Danta*) and their teeth resemble like Arabian jasmine (*Shikhardanta*), have pleasant and unctuous complexion and voice (*Prasannasnigdhavarnaswara*), these people are lustrous	*Shukrasar*a person is known to possess unctuous (*Snigdha*), compact (*Samhat*) and white *(Shweta*) bones (*Asthi*), teeth (*Danta*) and nails (*Nakha*) and has excessive sexual desire and children (*Bahulakamapraja*).[

	(*Bhrajishnu*) and have prominence of gluteus region (*Mahasphik*). This *Shukrasarata* gives liking by women (*Stripriyatva*), they enjoy intercourse (*Striupabhogitva*) and have strength (*Balawanta*), happiness (*Sukhabhaj*), sovereignty (*Aishwaryabhaj*), health (*Aarogyabhaj*), wealth (*Vittabhaj*), respect (*Sammanbhaj*) and good progeny (*Apatyabhaj*)	
Sattva Sara	excellent memory, devotion, gratitude, intelligence, purity, enthusiasm, skill, courage, freedom from excessive despondency, organized conduct and the capacity to engage in virtuous activities.

ABSTRACT

Diabetic peripheral neuropathy (DPN) is a prevalent and incapacitating consequence of diabetes mellitus that is characterised by increasing peripheral nerve loss, sensory impairment, and persistent neuropathic pain. The primary goal of current treatments is to alleviate pain symptoms; they do not address the biological processes that underlie the development of the disease. In DPN, oxidative stress, neuro inflammation, microglial activation, matrix metalloproteinase-9 (MMP-9) production, and nuclear factor kappa B (NF-κB) signalling are all crucially regulated by the mitogen-activated protein kinase (MAPK) pathway. A unique chance for medication repurposing is presented by avutometinib, a first-in-class RAF–MEK clamp inhibitor licensed for MAPK-driven cancers. This review shows the mechanistic rationale for avutometinib in DPN by focusing on the RAF–MEK–ERK pathway to decrease neuro inflammation, oxidative stress, neuronal damage, and neuropathic pain. Avutometinib, which targets the RAF-MEK-ERK pathway to reduce neuro inflammation, oxidative stress, neuronal damage, and

neuropathic pain, is discussed in mechanistic detail in this article. To validate its effectiveness as a disease-modifying treatment for diabetic peripheral neuropathy, more preclinical and clinical studies are required.

Keywords: Diabetic Peripheral Neuropathy(DPN), Avutometinib, Drug Repurposing, MAPK Signalling, RAF-MEK-ERK, NF-Kb, Neuro inflammation, Oxidative Stress, Neuropathic Pain.

INTRODUCTION

Diabetic peripheral neuropathy (DPN) is one of the most common and debilitating complications of diabetes mellitus (DM) that occurs in approximately 50% of all diabetes patients throughout their life.[1] Progressive damage to the peripheral nerves causes symptoms that include pain, tingling, numbness and loss of sensation, often in the lower limbs. DPN is a complex and heterogeneous condition, involving metabolic and vascular abnormalities that are caused by chronic hyperglycaemia, which all lead to a reduction in quality of life and significant complications such as lower limb amputation, foot ulcer and foot infection.[2] Increased levels of reactive oxygen species (ROS), advanced glycation end products (AGEs) and deranged critical signalling pathways like the mitogen-activated protein kinase (MAPK) cascade are responsible for the chronic hyperglycaemia. These processes stimulate activation of nuclear factor kappa B (NF-κB) which causes damage to neurones, activation of microglial cells and the release of pro-inflammatory cytokines (such as tumour necrosis factor (TNF) alpha and interleukin (IL) 1 beta). [3] In addition, oxidative stress and matrix metalloproteinase (MMP-9) upregulation, that leads to blood-nerve barrier damage, hasten the onset of neuropathy. Although diabetes management has improved, diabetic peripheral neuropathy (DPN) remains a significant clinical and socioeconomic challenge in the world, particularly in the context of an increasing incidence of diabetes. [1,4]

Limitations of Current Therapeutic Strategies

The current therapeutic strategies each have their own limitations. Current treatment approaches of DPN are mainly targeted at symptomatic relief, without attempting to treat the underlying cause of the disease. Typical medications used are antidepressants like duloxetine, tricyclic antidepressants, like amitriptyline, and anticonvulsants like pregabalin. While these medications can be effective for some patients, the medications are ineffective for others and many patients receive inadequate doses of these medications for chronic pain. [1,5] In addition, such therapies may have significant side effects, making their prolonged use challenging and potentially addictive. The current treatments are not directed towards critical pathogenic mechanisms like oxidative stress, neuro inflammation or the blockade of signaling pathways - they cannot stop or reverse neuronal degeneration. Thus, new therapeutic approaches targeting the underlying mechanisms of DPN, which include MAPK and NF-κB, are necessary. An investigation of signal transduction pathways could be used to treat only the symptoms of the illness. [6,7]

Pathophysiology of Diabetic Neuropathy

Hyperglycaemia is the most common etiology of diabetic peripheral neuropathy (DPN) (Figure 1). Excessive production of Reactive Oxygen Species (ROS) and the accumulation of Advanced Glycation End-products (AGEs) are two signals that activate a major branch of the mitogen-activated protein kinase (MAPK) pathway that is the RAF-MEK-ERK signalling cascade. These are both encouraged by extended high blood glucose levels. Constant activation of this pathway leads to a number of pathological events that lead to peripheral nerve damage and neuropathic pain.[1] The activation of the RAF-MEK-ERK pathway triggers the activation of nuclear factor kappa B (NF-κB), especially p65. This results in higher levels of transcription of pro-inflammatory cytokines like tumour necrosis factor α (TNF-α) and interleukin-1 beta (IL-1β). These inflammatory mediators promote peripheral and central sensitisation, increase neuro inflammation and increase neuronal excitability.[2] The activation of the MAPK also leads to an up regulation of matrix metalloproteinase-9 (MMP-9) that digests extracellular matrix components and disrupts the blood-nerve barrier. If the blood-nerve barrier is damaged, inflammatory cells can gain easier access

into peripheral nerves which leads to damage to the neurons and promotes progression of neuropathy. [8,9] In the central nervous system, the activation of the MAPK pathway is also involved in microglial activation. Activated microglia release inflammatory cytokines, chemokines, nitric oxide and reactive oxygen species, which contribute to central sensitisation – an important mechanism involved in chronic neuropathic pain. [8,9]

Avutometinib: Chemical and Pharmacological Background

A new RAk-100 pathway inhibitor, called avutometinib (VS-6766), is in development. Unlike other MEK inhibitors, avutometinib is a unique RAF-MEK clamp inhibitor that inhibits both MEK phosphorylation through the RAF kinases and MEK kinase activity. Both strategies are effective in the continual inhibition of the mitogen-activated protein kinase (MAPK) signalling pathway, a key pathway in cell proliferation, inflammation, survival and stress response. [10,11] The MAPK pathway, which involves extracellular signal-regulated kinase (ERK), MEK, and RAF, is often derailed in many clinical situations such as cancer and inflammatory diseases. Abnormal activation of this signalling pathway leads to the increased generation of inflammatory mediators, cytokines and matrix degrading enzymes, all of which contribute towards tissue damage with subsequent disease progression. Compared to conventional MEK inhibitors, avutometinib leads to the sustained inhibition of downstream ERK signalling, avoiding the re-activation of compensatory pathways which is frequently seen with conventional MEK inhibitors. Frequently seen with traditional MEK inhibitors. [12,13]

Mechanism of Action

figure 2: Avutometinib, a first-in-class RAF-MEK clamp inhibitor, blocks this detrimental cascade by blocking the RAF-MEK-ERK signalling pathway. Avutometinib is expected to have a beneficial effect on the integrity of the neurons, reduce the activation of microglia, inhibit the expression of MMP-9, and decrease the activation of NF-κB and subsequent production of pro-inflammatory cytokines, all of which are expected to be beneficial in relieving diabetic neuropathic pain. The recognised importance of MAPK signalling in disease pathogenesis offers a compelling mechanistic justification for exploring Avutometinib as a novel disease-modifying treatment candidate, even though this therapeutic hypothesis needs to be confirmed in experimental models of diabetic neuropathy.

Clinical Applications In Cancer

Avutometinib was originally developed against cancers resulting from the over-activation of the MAPK pathway. In tumours that express mutations in KRAS, BRAF and other components of the MAPK. The drug has demonstrated a potent anticancer activity in signalling network. The combination therapy was well tolerated and led to effective and durable disease control in clinical trials, particularly when applied to recurrent low grade serous ovarian cancer with a KRAS mutation. Avutometinib is currently being evaluated in other solid tumour types, such as melanoma, colorectal, pancreatic and non-small-cell lung cancer. Long-term inhibition of MAPK signalling is a mechanism that can overcome resistance mechanisms that often limit the effectiveness of traditional targeted drugs, as demonstrated by clinical research, and can be addressed with avutometinib. Avutometinib has a therapeutic efficacy well demonstrated in oncology, as well as its pharmacokinetic profile and safety. These results provide a good framework to explore its potential application in the field of non-oncological diseases associated with pathological MAPK mediated signalling. Avutometinib is a potential agent for investigation in diabetic peripheral neuropathy due to the established role of the activation of RAF–MEK–ERK in neuroinflammation, oxidative stress, and neuropathic pain. [10,14]

Mechanistic Link Between Avutometinib and Diabetic Peripheral Neuropathy

Diabetic peripheral neuropathy (DPN) is a multifactorial neurodegenerative complication of diabetes characterized by chronic pain, sensory impairment and progressive nerve degeneration. The recent evidence suggests that activation of mitogen-activated protein kinase (MAPK) signalling pathway is a key player in the initiation and progression of diabetic neuropathy. Hyperglycaemia-induced oxidative stress activates a series of downstream mediators that are regulated by the RAF–MEK–ERK pathway and are associated with neuroinflammation, neuronal damage and pain sensitisation. Thus, MAPK signalling is a promising therapeutic target for DPN.

Mapk–Nf-Kb Axis In Diabetic Neuropathy

Among the downstream effectors of MAPK signalling, there is a prominent one called nuclear factor kappa B (NF-κB) that plays a major regulatory role in neuroinflammation. Excessive glucose levels in diabetes causes an increase in the production of reactive oxygen species (ROS), which activates the RAF–MEK–ERK pathway. Transcription is upregulated by activated ERK, which, when it increases the phosphorylation and nuclear translocation of the p65 subunit of NF-κB, leads to an increase in the transcription of pro-inflammatory cytokines such as tumour necrosis factor-alpha (TNF-α), interleukin-1 beta (IL-1β), and interleukin-6 (IL-6). The MAPK–NF-κB signalling axis, which is continually activated during chronic inflammation, results in chronic inflammation in the spinal cord and peripheral nerves.[16]Avutometinib may reduce RAF–MEK–ERK signalling in an efficient manner, and inhibit NF-κB activation and inflammatory responses related to diabetic neuropathy.

Mapk-Mediated Regulation of Mmp-9

Neuroinflammatory processes and extracellular matrix remodelling are related to the proteolytic enzyme matrix metalloproteinase-9 (MMP-9). Diabetic neuropathy has been associated with elevated levels of MMP-9, which has been shown to be associated with nerve degeneration, infiltration of inflammatory cells, and disruption of the blood–nerve barrier. The activation of the MAPK pathway stimulates the expression of the transcriptional factors like AP-1 and NF-κB, leading to upregulation of MMP-9. Indirectly increased MMP-9 activity facilitates neuroinflammation and neuronal damage by breaking down the extracellular matrix proteins that surround peripheral nerves. Furthermore, MMP-9 has been associated with the degradation of sensory nerve fibres and demyelination, which are involved in worsening neuropathic pain.[17] Avutometinib may decrease neuropathic symptoms by inhibiting the expression of MMP-9 and by preventing the loss of structural integrity of peripheral neurones through the inhibition of MAPK signalling.

Mapk Signalling and Microglial Activation

Microglia are specialised immune cells of the central nervous system that play a big role in the development of neuropathic pain. Hyperglycaemia generated inflammatory signals activate microglia in the spinal cord, which subsequently releases inflammatory cytokines, chemokines, nitric oxide, and reactive oxygen species. These mediators facilitate the central Sensitisation and enhance the transmission of pain. The MAPK pathway is an important modulator of microglial activity. When ERK signalling is activated, inflammatory mediators are produced which exacerbate neuronal injury and an increase in microglial proliferation. Experimental studies show that inhibition of MAPK signalling significantly reduces microglial activity and reduces pain-related behaviours.[16,17] Thus, the inhibition of RAF–MEK–ERK pathway by avutometinib may reduce microglial activation and neuroinflammation associated with diabetic neuropathy.

Mapk Signalling and Oxidative Stress

One of the main pathogenic mechanisms in diabetic neuropathy is oxidative stress. Chronic hyperglycaemia results in cellular damage due to increased production of reactive oxygen species in mitochondria and the promotion of advanced glycation end products (AGEs) production. Excessive ROS activates the MAPK signalling pathway that leads to Inflammatory reactions and neuronal death. Remarkably, oxidative stress and MAPK activation are linked bidirectionally. Although MAPK signalling is triggered by oxidative stress, active MAPK increases the production of ROS via inflammatory and mitochondrial pathways. Chronic pain and gradual nerve degeneration are caused by this vicious cycle. Thus, inhibition of the RAF-MEK-ERK pathway can break this vicious cycle and reduce oxidative damage. Continuous inhibition of MAPK signalling by avutometinib may help to avoid oxidative damage of neurons and preserve nerve function.[16,17]

Proposed Therapeutic Role of Avutometinib in Diabetic Peripheral Neuropathy

The importance of MAPK signalling in oxidative stress, NF-κB activation, production of MMP-9, and microglial activation provides a strong case for the investigation of the possibility of using avutometinib to treat diabetic peripheral neuropathy. Avutometinib has the potential to be more effective than currently used drugs that only treat

symptoms, since it attacks multiple pathogenic processes. Although there is no direct experimental evidence of this, the clear involvement of MAPK signalling in diabetic neuropathy suggests that avutometinib might be a disease-modifying drug that can help to reduce neuropathic pain, prevent neuronal damage, and decrease neuroinflammation.

Pain Reduction

In DPN, the activation of inflammatory signalling pathways sensitises spinal neurones and peripheral nociceptors, leading to enhanced inflammatory responses.In DPN, inflammatory signalling pathways are chronically activated, sensitising peripheral nociceptors and spinal neurones, resulting in enhanced inflammatory responses. Hyperglycaemia activates the RAF-MEK-ERK pathway leading to an increase in production of pro-inflammatory cytokines such as TNF-α, IL-1β and IL-6 which require NF-κB activity and to an increase in peripheral and central sensitisation. In addition, activation of MAPK leads to activation of microglial cells in the spinal cord area, leading to the prolonged secretion of inflammatory mediators that sustain Chronic pain.[16,17] Inhibition of the RAF–MEK–ERK' pathway may help to block NF-κB activation and reduce the level of pro-inflammatory cytokines in the body when treating with Avutometinib. Furthermore, the abnormal processing of pain can be diminished by reducing central sensitisation and microglial activation. Therefore, the effects of mechanical allodynia, thermal hyperalgesia and spontaneous neuropathic pain associated with diabetic neuropathy could be reduced by avutometinib.

Neuroprotection

Diabetic peripheral neuropathy is a progressive deterioration of the neurons. A variety of processes including oxidative stress, mitochondrial dysfunction, prolonged inflammation and breakdown of the extracellular matrix lead to axonal degeneration and Schwann cell injury. By boosting inflammatory signalling and elevating matrix metalloproteinase-9 (MMP-9) Production, activation of the MAPK pathway worsens neuronal death. Avutometinib has the potential to protect peripheral nerves in a number of ways by inhibiting the RAF–MEK–ERK pathway. Sustaining structural integrity of the blood-nerve barrier and preventing demyelination may be achieved by inhibiting the generation of inflammatory cytokines, downregulating MMP-9 and reducing oxidative stress.[16,17] In addition, reduced inflammatory signalling can help to maintain axonal function, protect neurons and stop the disease process. These combined activities indicate that avutometinib may have a role as a neuroprotective drug as well as for the relief of symptoms related to pain.

Potential Restoration Of Glymphatic Function

Recent studies suggest that glymphatic dysfunction may be a component of diabetic neuropathy pathophysiology through its ability to hinder the clearance of metabolic waste products and inflammatory mediators from neuron tissue. Chronic neuroinflammation distributes water channel (Aquaporin-4s) on the end-feet of astrocytes in a non-polarised manner, reducing the efficiency of glymphatic transport, leading to accumulation of neurotoxic chemicals. The indirect effects of Avutometinib on the lymphatics remain unknown, but inhibition of the MAPK pathway may indirectly preserve the function of the lymphatics via reduction of oxidative stress and neuroinflammation. Inflammatory cytokines and microglial activation inhibition may restore astrocyte homeostasis and polarity of AQP4, which may clear the interstitial fluid and decrease the accumulation of inflammatory mediators. Restoring lymphatic function may help restore neuronal preservation and decrease neuropathic pain.[18,19]

Future Perspectives

Need For Preclinical Animal Studies

Although the RAF–MEK–ERK signalling pathway has been shown to be involved in diabetic peripheral neuropathy (DPN), the therapeutic potential of avutometinib has not yet been investigated in experimental models of diabetic peripheral neuropathy (DPN). Therefore, comprehensive pre-clinical studies are required to evaluate its safety, efficacy and mechanisms of action. Well-established animal models of DPN, such as streptozotocin (STZ)-induced diabetic rats or streptozotocin–nicotinamide (STZ–NA) diabetic models, should be used in future research since they closely mimic the metabolic and neuropathic characteristics seen in individuals with type 2 diabetes mellitus.

Behavioural tests including mechanical allodynia, motor function tests, thermal hyperalgesia and cold allodynia should be performed to determine Avutometinib's analgesic efficacy.

Apart from the behavioural evaluation, oxidative stress biomarkers (malondialdehyde, superoxide dismutase, catalase, glutathione, and glutathione peroxidase), inflammatory mediators (TNF-α, IL-1β, IL-6), activation of NF-κB (p65), expression of MMP-9 and proteins in the MAPK pathway (RAF, MEK, ERK) should be studied. The histopathological evaluation of sciatic nerve tissue and the immunohistochemical examination of microglial markers and aquaporin 4 (AQP4) will further elucidate the neuroprotective and anti-inflammatory effects of Avutometinib. Thses investigations would offer crucial proof as to whether blocking the RAF–MEK–ERK pathway would reduce neuroinflammation, maintain peripheral nerve architecture, and enhance functional results in diabetic neuropathy.[20]

Clinical Translation

Cautiously planned clinical trials are needed following promising preclinical results to assess the translational potential of Avutometinib in diabetic peripheral neuropathy patients. Early phase clinical trials should first investigate safety, tolerability, pharmacokinetics, and optimal dose in diabetes patients to assess therapeutic efficacy. Future RCTs should investigate whether Avutometinib is effective for pain, sensory function, nerve conduction velocity, and quality of life in comparison with existing treatments for neuropathic pain. Markers such as those associated with oxidative stress, inflammatory cytokines, MAPK signalling, and neuronal damage could be useful indicators of treatment response and/or disease change. One of the major benefits of therapeutic repurposing is the existing clinical and pharmacological safety data that is available, which can allow for the faster research process and reduce the cost and time for clinical translation. For chronic neurological diseases, however, a thorough long-term safety and effectiveness study, as well as one to determine appropriate dosing regimens for Avutometinib, will be required before its use. Overall, the clear mechanistic connection between MAPK signalling and diabetic neuropathy suggests that Avutometinib could be a promising disease-modifying drug for this condition. Further preclinical and clinical studies should be performed to determine whether blocking the RAF-MEK-ERK pathway can offer sustained neuroprotection, decrease neuroinflammation and enhance clinical results in diabetic peripheral neuropathy patients.[21]

CONCLUSION

The current treatment of DPN is a serious diabetes complication, and primarily reduces the symptoms rather than halting the disease. The evidence of the role of RAF-MEK-ERK (MAPK) signalling pathway in the modulation of neuroinflammation, oxidative stress, neuronal damage and microglial activation is growing. Avutometinib is a promising therapeutic candidate for repurposing as a first-in-class RAF-MEK clamp inhibitor owing to its ability to inhibit MAPK signalling and pathological events downstream. There are compelling science-led reasons to investigate this further, although there are no trials that have focused specifically on Avutometinib in DPN. It remains to be seen whether MAPK inhibition offers more than just alleviation of the symptoms of pain, and further preclinical and clinical research is required to confirm its therapeutic potential. Considering the advantages of this drug, it is a valuable option worth further investigation, and could be a novel and innovative drug repurposing approach for treating diabetic neuropathic pain.

ABSTRACT

Parkinson syndrome is a chronic, progressive neurodegenerative disorder characterized by the loss of dopaminergic neurons in the substantia nigra, leading to classical motor symptoms such as bradykinesia, rigidity, resting tremor, and postural instability, along with a wide range of non-motor manifestations including mood disturbances, sleep disorders, autonomic dysfunction, and cognitive impairment. This review synthesizes current evidence on the epidemiology, pathophysiology, clinical features, diagnostic criteria, and management of Parkinson syndrome, highlighting how advancing age, male sex, environmental toxins, and specific genetic mutations contribute to rising global prevalence and disease burden. At the molecular level, the disorder is driven by interconnected mechanisms such as dopaminergic neuron degeneration, alpha-synuclein aggregation with Lewy body formation, mitochondrial dysfunction, oxidative stress, impaired protein clearance, neuro inflammation, and disrupted mitophagy, which together accelerate neuronal loss and clinical progression. Clinically, early recognition of premotor and non-motor symptoms, alongside structured diagnostic criteria, improves diagnostic accuracy and enables timely initiation of dopaminergic therapies, adjunct pharmacologic agents, and, in selected cases, deep brain stimulation to optimize motor control and quality of life. Despite symptomatic benefits of current treatments, there is still no cure, underscoring the need for continued research into disease-modifying strategies targeting mitochondrial health, protein handling, and neuro inflammatory pathways, as well as comprehensive, multidisciplinary care models to address the long-term functional and psychosocial impact of Parkinson syndrome.

Keywords: Pathophysiology bradykinesia, dopaminergic therapies,

INTRODUCTION

Parkinson's disease (PD), commonly referred to as Parkinson's syndrome, is a degenerative neurological condition that impairs movement. Tremors, stiffness, sluggish movements, and balance issues are some of its symptoms. The loss of dopamine-producing cells in the substantia nigra, a region of the brain, is the origin of these symptoms [1]. One chemical messenger that aids in regulating coordination and movement is dopamine. Parkinson's syndrome primarily affects older persons and usually manifests after the age of 60; however, it can occasionally manifest earlier. Although the precise aetiology of Parkinson's disease is uncertain, environmental and genetic factors are thought to be involved [2]. The chance of contracting the condition may be raised by exposure to chemicals, head trauma, and specific genetic variations [3]. Parkinson's disease progresses gradually, and each person has symptoms to varying degrees. In addition to movement symptoms, non-motor symptoms such as sadness, sleep difficulties, and cognitive abnormalities can also be experienced by patients with Parkinson's [4]. The quality of life is greatly impacted by symptoms, which necessitate thorough management. Although there isn't a cure for Parkinson's syndrome at this time, therapies like medicine, physical therapy, and occasionally surgery can help control symptoms and enhance day-to- day functioning [5]. The most effective treatment for motor symptoms remains levodopa, a medication that increases dopamine levels in the brain [6]. Research is ongoing to understand the illness process better and investigate potential treatments. For individuals with Parkinson's disease, enhancing outcomes and quality of life requires early diagnosis and customized treatment strategies [7]. In conclusion, millions of people worldwide have Parkinson's condition, a complicated, progressive illness. Addressing the issues raised by this illness requires greater patient support, research, and awareness [8–10].

Epidemiology of Parkinson's Syndrome

After Alzheimer's disease, Parkinson's disease (PD), also referred to as Parkinson's syndrome, is the second most prevalent neurological illness. Millions of individuals worldwide are impacted by it, and older persons are particularly susceptible. The majority of Parkinson's disease diagnoses occur beyond the age of 60, and the risk of the disease rises dramatically with age [11]. Parkinson's disease is becoming more prevalent worldwide. The number of persons with Parkinson's disease has more than doubled in the last few decades. The illness affects more than 10 million people worldwide, according to the latest research [12]. Longer life expectancies, ageing populations, and improved detection techniques are the primary causes of this trend. Experts estimate that the number of cases will double again by 2040, particularly in nations with ageing populations [13]. Men are slightly more likely than women to have Parkinson's disease. Research indicates that men are around 1.5 times more likely than women to develop Parkinson's disease (PD), while the exact causes of this disparity are yet unknown [14]. Each country has a different prevalence of Parkinson's disease (the total number of cases that currently exist). About 1 in 100 adults over 60 is impacted in high- income countries. From 5 to 35 instances per 100,000 people annually, the incidence (new cases per year) similarly rises with age [15]. Due to under diagnosis or limited access to healthcare, the actual numbers in lower-income areas may be higher than those reported. The risk of Parkinson's disease is influenced by several environmental and lifestyle factors in addition to age and gender. Long-term exposure to industrial chemicals, pesticides, or herbicides, for instance, has been associated with an increased risk [16]. However, some behaviours, such as smoking and drinking coffee, have been linked to a lower risk of Parkinson's disease (PD), probably because of biological effects on dopamine levels [17]. Additionally, genetics is involved. About 10–15% of Parkinson's cases are related to family history or specific genetic mutations, such as those in the LRRK2, PINK1, or SNCA genes, even though the majority are sporadic (not inherited) [18]. Many people with Parkinson's spend years or even decades living with the condition because it advances slowly. This indicates that the cost of healthcare is rising, including for long-term care and rehabilitation as well as for treatment. Particularly in ageing countries, the illness has a significant effect on patients, families, and healthcare systems. There is a great need for increased awareness, early detection, and more reasonably priced treatment choices due to the rising prevalence of Parkinson's disease, particularly in middle- and low-income nations [19].

Pathophysiology of Parkinson's Syndrome

The primary cause of Parkinson's disease (PD), a degenerative neurological condition that impairs mobility, is the death of dopamine-producing neurons in the substantia nigra, a region of the brain. The disorder is caused by several interrelated biochemical alterations in the brain, many of which are currently being studied.

Dopamine Neuron Degeneration

Degeneration of dopaminergic neurons in the substantia nigra pars compacta is the primary characteristic of Parkinson's disease. Dopamine, a neurotransmitter necessary for motor coordination, is produced by these neurons. The hallmark motor symptoms of Parkinson's disease (PD), such as tremors, stiffness, and slowness of movement, are brought on by the disruption of dopamine transmission between brain areas, including the striatum. [20] Alpha-

Synuclein Accumulation and Lewy Bodies

The aberrant accumulation of a protein known as alpha-synuclein is another significant characteristic. This protein misfolds and aggregates to create Lewy bodies inside neurons in Parkinson's disease. These inclusions are poisonous and disrupt regular cellular processes, including mitochondrial activity, protein recycling, and synaptic transmission. [21]

Mitochondrial Dysfunction

The cell's energy manufacturers, the mitochondria, are greatly impacted in Parkinson's disease. Energy deficiencies and an increase in reactive oxygen species (ROS) are caused by a decrease in mitochondrial activity, particularly complex I of the respiratory chain. This leads to cell damage and neuronal death. [22]

Oxidative Stress

When dangerous chemicals like ROS overpower the body's defences, oxidative stress Results. Excessive ROS harms crucial components in dopamine-producing neurons, including proteins, lipids, and DNA, in Parkinson's disease. Oxidative stress accelerates the death of these neurons, which are already at risk. [23]

Impaired Protein Clearance

Misfolded proteins are often eliminated by cells using mechanisms like the autophagy- lysosome pathway and the ubiquitin-proteasome system. These systems become less effective in Parkinson's disease. Toxic proteins, such as misfolded alpha-synuclein, accumulate and harm neurons as a result. [24]

Genetic Mutations

Some people have mutations in genes like PINK1, Parkin, LRRK2, and SNCA, which can raise their risk of developing Parkinson's disease, even though the majority of PD cases are not hereditary. These genes play a role in neuron protection, protein clearance, and mitochondrial health. Mutations can increase a neuron's sensitivity to stress or result in early- onset Parkinson's disease. [25]

Impaired Mitophagy

The process of removing damaged mitochondria is called mitophagy. This mechanism is disturbed in PD, particularly when there are mutations in the PINK1 and Parkin genes. Defective mitochondria accumulate as a result of poor mitophagy, further harming neurons. [26]

Neuro inflammation

Neuroinflammation results from the overactivity of microglia, which are immune cells in the brain, in Parkinson's disease. Although these cells often aid in brain protection, when they are chronically activated, inflammatory chemicals are released that may damage neurons. [27]

Mitochondrial DNA Damage

The DNA found in mitochondria, or mt DNA, is frequently damaged or erased in Parkinson's disease. This makes neurons more vulnerable and reduces their ability to produce energy. Neuron death increases as a result of cells' inability to produce enough energy or adequately repair their mitochondria. [28]

Clinical Presentation of Parkinson's Syndrome The motor symptoms of Parkinson's disease

Up to 80% of dopaminergic cells in the nigro-striatal pathway are thought to be destroyed before the hallmark motor symptoms of Parkinson's disease manifest [29]. The initial motor signs are typically used to diagnose the condition. The UK PDs' established criteria serve as the basis for the diagnosis—the brain bank. The diagnosis requires one more symptom, such as muscle rigidity, resting tremor, or postural instability, together with a slowness of voluntary movement initiation and a progressive decrease in the speed and amplitude of repetitive activities (bradykinesia) [30]. Excluding symptoms that could point to other aetiologies, such as Parkinsonian syndromes, which have their own neuropathological alterations, is step two in the diagnosis process. Step three is to determine at least three criteria that support Parkinson's disease (PD), including unilateral onset of symptoms, persistent asymmetry of clinical symptoms, good response to levodopa treatment, and induction of dyskinesia. Usually, one side of the body has symptoms first, and within a few years, the opposite side will also experience problems.

The axial and limb rigidity, with or without the cogwheel phenomena, the stooped body position, inclination to walk with a shuffling pace and without swinging their arms. Bradykinesia can result in hypomimia, or an expressionless face, and micrographia, or reduced handwriting amplitudes. Approximately 80% suffer from limb tremor, most frequently a resting pill-rolling hand tremor. The propensity of the thumb and index finger to make contact and move in a circular motion is related to pill rolling [31]. Other tremor kinds may also occur, and occasionally the tremor affects the legs [32]. Blocking, hesitation, and gait festination—where steps get smaller and faster—are additional gait abnormalities besides shuffling that can cause falls and loss of balance. Movement freezing occurs in 25% to 60% of patients, typically years after the beginning [33]. Another motor symptom of Parkinson's disease is dystonia. A prolonged muscular contraction that is often accompanied by aberrant postures, motions, or both is referred to as dystonia. Rarely, this could be a PD prediagnostic sign. Unilateral equinovarus foot posture, forearm-hand flexion or upper arm-forearm flexion, writer's cramp, oro- mandibular dystonia, torticollis, or other combinations of these symptoms are common prediagnostic dystonias. Most of the time, PD symptoms start to show up ten years after the dystonia first manifests. Dystonia in young-onset familial Parkinson's disease usually affects the foot, causing inversion of the affected foot or cramping pain [34].

The non-motor symptoms of Parkinson's disease

Patients may have a range of pre-motor symptoms before the onset of motor symptoms and the diagnosis. These could begin as early as ten or more years before the diagnosis [35], and non-motor symptoms could cause the diagnosis to be delayed [36]. According to a study of 109 newly diagnosed patients who had not yet begun treatment, symptoms like constipation, excessive daytime sleepiness, sleep issues, and a lack of emotional involvement and interest (apathy) may have occurred in as many as 60–70% of patients before the diagnosis and were more prevalent than in standard controls. Additional pre-motor symptoms included anhedonia, or the inability to enjoy tasks that one would usually find enjoyable, memory problems, mood swings, excessive perspiration, exhaustion, and discomfort. Constipation and acting out dreams (REM behaviour sleep disorder), frequent nightmares, daytime drowsiness and postprandial fullness were often reported to occur more than 10 years before the onset of motor symptoms [37]. Depression and anxiety may also occur long before the diagnosis is made [38].

Diagnostic Criteria

Bradykinesia, which is described as "slowness of movement and decrement in amplitude or speed," is necessary for the clinical diagnosis of Parkinson's disease (PD). This is typically determined by tapping fingers, tapping feet, or pronating and supinating hands. When excluding markers (Table 1) are present, one can clearly rule out Parkinson's disease and identify a potential alternative diagnosis. Additionally, a number of "red flag" characteristics ought to

cause the diagnosis to be reevaluated [4]. A Parkinsonian condition must also be confirmed by the presence of stiffness or rest tremor. Thirty per cent of patients with pathologically established Parkinson's disease did not have tremor at presentation. [39] Patients who have not received treatment should be evaluated by a specialist in movement disorders. Five important topics for conversation at diagnosis include providing contact information for the local PD nurse specialist (PDNS), directing to written or online information about newly diagnosed PD, and informing insurance and vehicle licensing organizations. [40] With an overall diagnostic accuracy of 81% in post-mortem investigations of clinically diagnosed PD, it is necessary to reevaluate the clinical diagnosis on a routine basis. [41]

Treatment of Parkinson's disease

There is currently no cure for Parkinson's disease (PD), and the disease's aetiology is most likely complex. Dopaminergic medications are used to treat symptoms and try to fix the motor abnormalities. The most common and recommended first treatment for patients is levodopa, a prodrug of dopamine. Response is typically good in the beginning. Most patients experience a shorter duration of response to individual doses (wearing-off symptoms), alternate phases with good and poor response to medication (on-off symptoms), involuntary movements of the head, trunk, or limbs (dyskinesias), and other motor complications as the disease progresses and the system's capacity to store dopamine decreases. These variations are controlled with additional dopaminergic drugs. These consist of dopamine receptor agonists, catechol-O-methyltransferase inhibitors, monoamine oxidase type B inhibitors, and amantadine, an NMDA receptor antagonist. [42]

Discussion on Parkinson's Syndrome

Parkinson's disease, sometimes referred to as Parkinson's syndrome, is a progressive, long- term neurological condition marked by the death of dopamine-producing neurons in the brain's substantia nigra. Dopamine, a vital neurotransmitter involved in coordinating fluid and regulated movements, is reduced as a result of this neuronal loss. Parkinson's disease is characterized by bradykinesia (slowness of movement), postural instability, muscle rigidity, and resting tremor. Furthermore, patients frequently suffer from non-motor symptoms that can significantly impair quality of life, such as mood problems, autonomic dysfunction, cognitive loss, and sleep disruptions. Although the precise origin of Parkinson's illness is unknown, a mix of environmental exposures, including chemicals, and genetic predispositions is thought to be responsible. [1] The primary method of diagnosis is clinical examination, which is occasionally aided by neuroimaging techniques such as dopamine transporter scans. Using drugs like levodopa and dopamine agonists to restore dopamine levels or mimic its function, treatment plans concentrate on symptom management. Deep- brain stimulation and other surgical procedures are successful in reducing motor symptoms in patients with severe disease and sequelae. [7] There is presently no proven cure for the condition, despite continuous research into neuroprotective medications to slow its growth.

To create more effective treatment strategies, more research into the disease's complex causes and symptoms is necessary. [2]

CONCLUSION

Since ancient times, people have been aware of Parkinson's syndrome. The same symptoms that we now know are associated with Parkinson's disease, such as stiffness, delayed movement, and shaking hands, were reported by healers as early as ancient times. Over time, medical professionals and scientists discovered that these issues are caused by alterations in the brain, particularly a loss of cells that produce the dopamine neurotransmitter, which aids in controlling movement. Doctors now have a better understanding of Parkinson's disease and may develop treatments that lessen its symptoms, such as deep brain stimulation surgery and medications that mimic or replace dopamine. Still, there isn't a whole remedy. Today's scientists are researching brain cells, genes, and novel preventative medicines in an effort to halt or slow the disease.

Table 1: Current International Parkinson and Movement Disorder Society (MDS) Diagnostic Criteria for Parkinson's disease

Category	Criteria/ Description	Possible Alternative Diagnosis (if present)
Definition of Parkinsonism	Bradykinesia and rest tremor and/or rigidity	—
Supportive Criteria	- Clear and dramatic response to dopaminergic therapy - Levodopa- induced dy skinesia - Limb rest tremor - Olfactory loss - Abnormal MIBGSPECT	—
Exclusion Criteria (PD excluded if present)	- Cerebellar signs - Downward vertical supranuclear gaze palsy or slowd own wards accades - Behavioural variant FTD or progressiveaphasiawithin5years - Lower limb signs only for>3years	MSA,PSP PSP FTD,PSP VP, NPH Drug-induced parkinsonism
	- Treatment withd opamine receptor antagonists - Absence of observable response to high-dose levodopa (>600 mg/day) - Cortical sensory loss, apraxia, or progressive aphasia - Normal dopaminergic functional imaging(e.g., dopamine transporter SPECT)	MSA,PSP,CBD,AD Non-degenerative
Red Flags	- Wheel chair use within 5 years of onset - Absent progression over 5years - Early severedys phonia, dysarthria, or dysphagia - Inspiratorys tridor - Severe autonomic failure within 5 years - Recurrent falls with in 3 years - Disproportion at eantecollis or limb contractureswithin10 years - Absence of any non-motor features after 5 years - Other wise unexplained pyramidal signs - Symmetrical parkinsonism Throughout disease course	MSA,PSP Non-degenerative(e.g.,essential tremor, dystonic tremor, drug-induced) MSA,PSP MSAMSA PSP MSA Non-degenerative MSA, VP Atypicalparkinsonism

ABSTRACT

The rapid accumulation of plastic waste in terrestrial ecosystems has become a critical environmental concern due to its persistence and resistance to natural degradation. This study focuses on the isolation and characterization of plastic-degrading bacteria from soil samples collected from plastic-contaminated sites. Soil samples were subjected to enrichment culture techniques using polyethylene and other common synthetic polymers as the sole carbon source. Distinct bacterial colonies were isolated and screened for their degradation potential through weight loss analysis, clear zone formation on polymer-containing media, and biochemical assays. Morphological, physiological, and molecular characterization, including 16S rRNA gene sequencing, were performed to identify the efficient isolates. The results revealed several bacterial strains exhibiting significant plastic degradation capability, suggesting their potential application in bioremediation strategies. Enzymatic activity assays indicated the involvement of extracellular enzymes such as laccases, proteases, and esterases in polymer breakdown. This study highlights the diversity of soil microorganisms capable of degrading plastics and emphasizes their promising role in sustainable management of plastic waste through eco-friendly biological approaches.

Keywords: Plastic degradation, Soil bacteria, Bioremediation, Polyethylene, 16S rRNA sequencing, enzymatic activity, Microbial characterization

INTRODUCTION

Plastic pollution has emerged as a major environmental concern due to the extensive use of synthetic polymers such as polyethylene (PE), polypropylene (PP), polystyrene (PS), and polyethylene terephthalate (PET). These materials

are widely utilized in packaging, textiles, construction, automotive components, and consumer products because of their durability, lightweight nature, and cost-effectiveness. However, the same properties that make plastics commercially valuable—particularly their resistance to physical, chemical, and biological degradation—also contributes to their persistence in the environment (Geyer et al., 2017). It is estimated that billions of tons of plastic waste have been produced globally, with a significant proportion accumulating in landfills and natural ecosystems (Geyer et al., 2017). Most conventional plastics are derived from petrochemical sources and possess long polymer chains that are highly stable and resistant to microbial attack. Polyethylene (PE) and polypropylene (PP), for instance, have simple hydrocarbon backbones that lack functional groups accessible to enzymatic breakdown, making them particularly recalcitrant in natural environments (Shah et al., 2008). Similarly, polystyrene (PS) contains aromatic rings that increase structural rigidity and resistance to degradation, while polyethylene terephthalate (PET) has ester linkages that are more susceptible to hydrolysis but still degrade very slowly under natural conditions (Webb et al., 2013).

The accumulation of plastic waste in terrestrial and aquatic ecosystems has led to severe ecological consequences. In marine environments, plastic debris can fragment into microplastics due to exposure to ultraviolet radiation, mechanical abrasion, and oxidative processes. These microplastics can be ingested by marine organisms, entering the food chain and potentially affecting human health (Andrady, 2011). Terrestrial ecosystems are also affected, as plastic waste alters soil structure, reduces water infiltration, and interferes with plant growth (Rillig, 2012). Furthermore, plastics can adsorb toxic pollutants such as heavy metals and persistent organic pollutants, facilitating their transport through ecosystems (Andrady, 2011). Conventional disposal methods such as land filling and incineration pose additional environmental and health risks. Land filling occupies large areas of land and may result in the leaching of harmful additives, including plasticizers and stabilizers, into soil and groundwater (Hopewell et al., 2009). Incineration, although capable of reducing the volume of plastic waste, can release toxic gases such as dioxins and furans if not properly managed (Hopewell et al., 2009). Recycling offers some relief; however, it is often limited by economic constraints, contamination issues, and the degradation of plastic quality after repeated processing (Geyer et al., 2017). Therefore, sustainable and eco-friendly alternatives for plastic waste management are urgently needed.

In recent years, biological degradation using microorganisms has gained considerable attention as a promising and environmentally friendly strategy. Certain bacteria and fungi have demonstrated the ability to colonize plastic surfaces and produce extracellular enzymes capable of breaking down polymer chains into smaller molecules (Shah et al., 2008). Biodegradation involves several stages, including bio deterioration, bio fragmentation, assimilation, and mineralization. During this process, microorganisms utilize degraded plastic fragments as carbon and energy sources, ultimately converting them into carbon dioxide, water, and biomass under aerobic conditions (Webb et al., 2013). Several microbial species have been identified as potential plastic degraders. For instance, species of Pseudomonas, Bacillus, and Rhodococcus have shown the ability to degrade polyethylene and polystyrene under laboratory conditions (Shah et al., 2008). The discovery of Ideonella sakaiensis, capable of degrading PET through the production of PETase and MHETase enzymes, represents a significant breakthrough in the field of plastic biodegradation (Yoshida et al., 2016). These findings highlight the potential of microbial biotechnology in addressing plastic pollution. Soil from landfill and trenching grounds is considered a rich source of plastic-degrading microorganisms due to prolonged exposure to plastic waste and diverse environmental stress conditions. Microorganisms in such habitats undergo adaptation and selection pressures that enhance their metabolic capabilities to utilize recalcitrant substrates, including synthetic polymers (Shah et al., 2008). The continuous accumulation of plastic waste in these environments creates ecological niches that favour the growth of plastic-colonizing microbial communities.

The trenching ground located at Devguradia, Indore, receives municipal solid waste from surrounding urban areas and provides favourable conditions for microbial adaptation and evolution. The presence of mixed waste, fluctuating temperatures, moisture, and nutrient availability may stimulate microbial diversity and metabolic versatility. Such environments are likely to harbor bacteria with enhanced degradative potential due to long-term exposure to plastic substrates. Studies have shown that landfill sites often contain microbial consortia capable of degrading various

polymers more efficiently than single isolates, indicating the importance of synergistic interactions among microorganisms (Webb et al., 2013). Exploring landfill soils for plastic-degrading bacteria not only contributes to our understanding of microbial ecology but also offers practical applications in waste management. Isolating and characterizing indigenous microbial strains from sites like the Devguradia trenching ground may provide valuable candidates for bioremediation strategies. These strains could potentially be used in composting systems, bio augmentation approaches, or enzyme-based degradation technologies to accelerate plastic breakdown under controlled conditions.

In conclusion, plastic pollution represents a critical environmental challenge driven by the widespread use and persistence of synthetic polymers. Conventional disposal methods are inadequate and often harmful, necessitating sustainable alternatives. Microbial degradation offers a promising solution, particularly through the exploration of landfill and trenching ground soils as reservoirs of plastic-degrading microorganisms. Continued research in this field may pave the way for innovative biotechnological interventions to mitigate the growing plastic waste crisis. The characterization of isolated bacteria is a crucial step in identifying potential plastic-degrading microorganisms. Preliminary identification typically involves morphological, microscopic, and biochemical analyses. These conventional microbiological techniques provide essential information about the taxonomic position and metabolic capabilities of bacterial isolates (Cappuccino & Sherman, 2014).

Colony Morphology

Colony morphology is examined by observing bacterial growth on nutrient agar or selective media. Characteristics such as colony shape (circular, irregular, filamentous), size (small, medium, large), color (white, cream, yellow, pigmented), elevation (flat, raised, convex), margin (entire, undulate, lobate), and texture (smooth, rough, mucoid) are recorded. These features provide preliminary clues regarding bacterial genera. For example, species of Bacillus often form large, irregular, dry colonies, whereas Pseudomonas species may produce smooth colonies with characteristic pigmentation (Cappuccino & Sherman, 2014). Morphological characterization is particularly important when screening environmental isolates from landfill soils, as such habitats contain diverse microbial populations adapted to harsh conditions. Observing colony variation helps in selecting morphologically distinct isolates for further testing.

Gram Staining and Cell Shape

Gram staining is a differential staining technique that categorizes bacteria into Gram-positive (purple) and Gram-negative (pink/red) groups based on differences in cell wall structure. Gram-positive bacteria possess a thick peptidoglycan layer that retains crystal violet stain, whereas Gram-negative bacteria have a thinner peptidoglycan layer and an outer membrane, causing them to take up the counterstain safranin (Beveridge, 2001). Microscopic examination also reveals cell shape (cocci, bacilli, spirilla) and arrangement (chains, clusters, pairs). Many plastic-degrading bacteria reported in previous studies belong to Gram-positive genera such as Bacillus and Gram-negative genera such as Pseudomonas (Shah et al., 2008). Determining Gram reaction and morphology narrows down identification and guides subsequent biochemical testing.

Biochemical Characterization

Biochemical tests are performed to assess the metabolic and enzymatic capabilities of bacterial isolates. These tests are essential for confirming genus-level identification and understanding the degradative potential of isolates

Catalase Test: The catalase test detects the presence of the enzyme catalase, which breaks down hydrogen peroxide into water and oxygen, producing visible bubbles. Most aerobic and facultative anaerobic bacteria, including Bacillus and Pseudomonas, are catalase-positive (Cappuccino & Sherman, 2014).

Oxidase Test: The oxidase test identifies bacteria that produce cytochrome c oxidase. A positive reaction results in a color change (dark purple/blue). This test is particularly useful in identifying Pseudomonas species, which are oxidase-positive (Shah et al., 2008).

Starch Hydrolysis Test: In this test, bacteria are cultured on starch agar plates. After incubation, iodine is added. A clear zone around the colony indicates starch hydrolysis due to amylase production. Many Bacillus species exhibit positive starch hydrolysis, reflecting their ability to produce extracellular enzymes that may also contribute to polymer degradation (Cappuccino & Sherman, 2014).

Carbohydrate Fermentation Tests:

These tests determine the ability of bacteria to ferment specific sugars (e.g., glucose, lactose, and sucrose), producing acid and/or gas. Changes in pH indicators within the medium reveal fermentation patterns. Such metabolic profiling assists in differentiating closely related genera.

Relevance to Plastic-Degrading Bacteria

Morphological and biochemical characterization provides foundational knowledge before proceeding to molecular identification techniques such as 16S rRNA gene sequencing. Environmental isolates capable of degrading plastics often demonstrate enzymatic activities such as esterase, lipase, or oxygenase production, which contribute to polymer breakdown (Shah et al., 2008). By combining colony morphology, Gram reaction, and biochemical profiles, researchers can tentatively identify bacterial genera involved in plastic degradation. These conventional methods remain essential, especially in preliminary screening of isolates from landfill and trenching ground soils such as Devguradia, Indore, where diverse microbial communities are exposed to plastic waste over extended periods.

Molecular Characterization

Advanced identification of bacterial isolates is carried out using 16S rRNA gene sequencing, which allows for precise taxonomic classification at the genus and species levels. This molecular approach is more accurate than morphological or biochemical methods alone, especially for closely related or environmentally adapted strains. By comparing 16S rRNA sequences with reference databases such as NCBI GenBank, researchers can confirm the identity of plastic-degrading bacteria and study their phylogenetic relationships (Clarridge, 2004). Molecular characterization also helps in understanding the plastic-degrading potential of isolates. Certain clades of bacteria are known to harbor enzymes like PETase, lipase, and esterase that facilitate the breakdown of synthetic polymers (Yoshida et al., 2016). Sequencing data can therefore guide the selection of strains for further biodegradation studies and biotechnological applications. Additionally, evolutionary analyses using 16S rRNA sequences provide insights into how environmental pressures, such as prolonged exposure to plastic waste in landfill soils, drive adaptation and diversification among microbial communities (Shah et al., 2008).

Environmental Significance

The discovery of plastic-degrading bacteria in the Devguradia trenching ground underscores the remarkable ability of microorganisms to adapt to environments heavily impacted by human activity. Prolonged exposure to plastic waste has created selective pressures that favor microbes capable of utilizing synthetic polymers as a carbon source, demonstrating nature's intrinsic capacity for self-remediation. Harnessing these naturally adapted bacteria for bioremediation offers several environmental benefits. Their application can significantly reduce plastic accumulation in terrestrial and aquatic ecosystems, mitigating the long-term ecological hazards associated with persistent synthetic polymers. Additionally, microbial degradation provides a sustainable waste management strategy, reducing reliance on conventional methods such as land filling, incineration, and chemical treatments that often pose environmental and health risks. Moreover, integrating microbial bioremediation into waste management practices supports circular economy principles by converting plastic waste into benign or useful by-products through biological processes. This approach not only conserves resources but also aligns with global efforts toward environmental conservation, pollution reduction, and the development of eco-friendly technologies. By studying and applying plastic-degrading bacteria from polluted sites like Devguradia, researchers can develop scalable solutions that contribute to both ecosystem restoration and sustainable urban waste management.

CONCLUSION

The trenching ground at Devguradia, Indore represents a promising ecological niche for isolating plastic-degrading bacteria. Isolation and characterization of such microorganisms provide valuable insights into biological plastic degradation mechanisms, including enzymatic pathways and microbial metabolic strategies. These studies contribute to understanding how environmental exposure drives microbial adaptation and the evolution of polymer-degrading capabilities. Further research focusing on enzyme optimization, microbial consortium development, and field-scale applications can enhance the efficiency and reliability of microbial plastic waste management. Integrating these biotechnological approaches with existing waste management systems has the potential to reduce environmental pollution, promote sustainable practices, and support circular economy initiatives by transforming plastic waste into environmentally benign products.

ABSTRACT

Spiders are highly significant arthropods that play a crucial role in the ecosystem. In this study, the orb-weaver spider species *Mangora baii* Mi & Li, 2021 has been recorded in India for the first time; the specimen was collected from the Gariaband district of Chhattisgarh. Previously, this species, which is native to China, had been recorded there only once. It represents the first species of this genus to be documented in India. Key identifying characteristics include an oval-shaped abdomen featuring broad transverse black lines, a black cephalothorax, a long fourth pair of legs, and a wide longitudinal line on the ventral side of the abdomen.

Keywords: Orb Weaver, Chhattisgarh, Gariaband, India, Mangora baii, Spiders

INTRODUCTION

Orb-weaver spiders belong to the family Araneidae and are characterized by their behavior of weaving orb-shaped webs [1,3,11]. They are specific creatures within the order Araneae (spiders) [14]. They possess a large, rounded

abdomen and are nocturnal in nature [7,10,11]. Globally, there are 3,181 species representing 200 genera [14]; in India, 234 species belonging to 111 genera are found [11]. *Mangora* O. Pickard-Cambridge, 1889 is a specific genus of orb-weaver spiders belonging to the family Araneidae; 190 species have been recorded worldwide, with occurrences in Southeast Asia, South and North America [2,4,14]. *Mangora baii* Mi & Li, 2021 is a distinctive Chinese species within this genus that is found exclusively in China [4].

The first specimens of this species were recorded from Yunnan, China where both male and female specimens were collected [4]. No species of this genus had been recorded in India until now [11]. Chhattisgarh is the first state where this species has been recorded. Some studies conducted in the state have recorded certain orb-weaver spiders [5,6]. 15 species were recorded from the Deobhog region [7] and 17 from the Chhura region of Gariaband district in Chhattisgarh state [8]. Three species *Cyrtophora moluccensis*, *Arachnuraangura* and *Gea subarmata* were recorded for the first time as new state records from this same Gariaband region [5,6,9]. A specimen of *Poltys illepidus* has recently been recorded from Kawardha [13]. Chhattisgarh is a unique state in terms of its flora and fauna, hosting a wide variety of wildlife. Documenting this particular spider species at the national level is a small step towards better exploring spider diversity across India and facilitating the future recording of this species in other states.

MATERIAL AND METHODS

Mangora baii Mi & Li, 2021 was collected using the hand-picking method during a field survey in the forest region of the Gariaband district, Chhattisgarh (20°34'12"N 82°06'10"E, Elevation 403.26 m) (Fig. a). Only a single adult female specimen was obtained during the survey and was preserved in 70% ethanol; live photographs were taken using a Canon EOS 200D II DSLR camera. The specimen was deposited in the Zoology laboratory of Government D.B. Girls' P.G. College, Raipur (vial no. DBZ497), where its morphological examination was conducted. Morphological and genital structures were examined with the aid of a stereozoom microscope. Identification was achieved by matching the specimen's characteristics with published data. All secondary data were sourced from the World Spider Catalogue (2026).

RESULT

This article provides a comprehensive account of a species of orb-weaver spider, detailing its new distribution as well as its morphological and genital characteristics; the full description is provided below.

Taxonomy

Family: Araneidae Clerck, 1757

Genus: Mangora O. Pickard-Cambridge, 1889

Mangora baii Mi & Li, 2021

(Fig. b-g)

Specimen Examination

Gariaband, Chhattisgarh, India, 1♀; Collected from Gariaband forest region, Chhattisgarh, India; 20°34'12"N 82°06'10"E, Elevation 403.26 m; 29 March 2026; 11: 49 AM (+05:30 GMT), vial no. DBZ497; The specimen was collected by Jashavant Nayak; deposited and Examined in the Zoology lab of Govt. D. B. Girl's P. G. College Raipur, Chhattisgarh, India.

Morphological Description

The cephalothorax is small, black, round, and dorsoventrally flattened (Fig. b-c). The sternum is oval-shaped, and the eyes are situated in the anterior terminal region of the carapace. The ventral carapace is pale black in color. The degenerated pedipalps are long, distinct, and project vertically (Fig. e). The chelicerae are black, rectangular, and project vertically, positioned close to each other. The abdomen is large and oval-shaped (Fig. c). The dorsal region

features two transverse black patches and one longitudinal black patch; the longitudinal patch (or line) is attached to the cephalothorax (Fig. d-g). Two white, wing-shaped, and irregular patches are located on the lateral sides of the abdomen (Fig. e-f). All the legs are transparent, with yellow-brown rings present at the joints. Their leg formula is 1423. leg I is the longest leg, coxa small in length and wide, trochanter wide and short, femur long, cylindrical, transparent and hairy, patella medium in length and cylindrical, tibia long and hairy, metatarsus long cylindrical, tarsus long, cylindrical, hairy, with a claw at the end (Fig. g). Leg II and Leg III are similar to Leg I, but leg IV differs slightly; it features dark black bands on the patella and tibia, while the other segments are just like those of Leg I.

Epigyne: The epigynum is wide and bell-shaped; the scape is located in the posterior region and is distally wide; the copulatory ducts are long, slender, and slightly curved; the copulatory openings are narrow and rounded; and the Spermatheca are slightly rounded and attached to each other (Fig. h-i).

Diagnosis

The species has specific characteristics like, the abdomen has two transverse patches and one longitudinal patch, the scape is distally widened and the conductor is long, membranous, and basally trifurcated (Mi and Li, 2021).

Global Distribution: China, present record in India.

DISCUSSION

In 2021, Mi and Li collected and identified numerous specimens of *Mangora baii* Mi & Li, 2021 comprising both males and females from Xishuangbanna, Yunnan, China. This species is native to China and had previously been recorded only there. This article reports a new distributional record for the species, marking its first recorded occurrence in India. In the present study, the specimen was collected from the forest region of the Gariaband district in Chhattisgarh. This is the first species of this genus to be recorded in India; however, only a female specimen was documented in this instance. The two scientists described the significant morphological characteristics of this species and laid the foundation for a new species. The morphological characteristics of the recorded specimen match well with the female specimens of the same species; therefore, it belongs to that very species. The most common shared characteristics include a dark black cephalothorax, a single longitudinal band, and two transverse bands. Additionally, the structure of the epigyne is quite similar; thus, based on the aforementioned characteristics, it can be concluded that both specimens belong to the same species. This is a rare orb-weaver spider found in India, restricted solely to the state of Chhattisgarh. The present study documents a new record of the spider, indicating its occurrence in the state of Chhattisgarh and in India; this provides us with unique insights into spider diversity in the region.

CONCLUSIONS

A study has recorded the presence of the Chinese orb-weaver spider species *Mangora baii* Mi & Li, 2021 in the Gariaband district of Chhattisgarh. Previously recorded only in China, India is the second country where this species has now been documented. This study reveals a new distribution range for the species in India and adds another species to the country's spider fauna.

ACKNOWLEDGMENTS

Many thanks to all the authors who made significant contributions to conducting this study. We also extend our sincere gratitude to the Principal of Government D.B. Girls' Post Graduate College, Raipur, for providing the facilities for specimen examination and other laboratory resources at the college.

ABSTRACT

Tellurium Nanoparticles using *Conus betulinus* was synthesized by Eco-friendly method. UV- Visible spectroscopy analysis confirmed the formation of Nanoparticles. Fourier Transform Infrared Spectroscopy indicates the presence of reducing agents. Atomic Force Microscopy analysis showed the nanoparticles formed are of agglomerated rocky shape. The Scanning electron microscopy images also confirmed the presence of the flaky nanostructures. The inhibitory activity of nanoparticles was studied and an excellent inhibition activity was observed against the fungus confirms the antibiotic property. DPPH Scavenging and Hydrogen peroxide scavenging results shows excellent property towards anti-aging Applications

Keywords: Tellurium nanoparticle, *Conus betulinus , anti bacterial activity, antioxidant activity, ecofriendly synthesis*

INTRODUCTION

Significant effect is observed for the nanoparticles due to its small size. The small size of the nanoparticles makes it to use in the various fields. Tellurium Nanoparticle contributes wide range of medicinal applications. Nanoparticles

play an important role in medicine especially in antibacterial and anticancer activity [1-4].In order to reduce the hazardous nature of chemicals, green method of synthesis of nanoparticles is widely accepted [5]. Alloying improves its properties towards the applications of optical and electronic devices, solar cells and rechargeable batteries and in medicinal field, agricultural field [6-13].Eco-friendly method of synthesis [14] is currently used in the research than the physico-chemical methods due to its cost effective and reduced toxic evolution. For the current investigation, *Conus betulinus* a species of sea snail is used to synthesize Tellurium Nanoparticles. The element Tellurium was chosen for this study since the elements in sixth group was reported less. Due to its excellent properties, various researchers have taken Te into account [15-22].

MATERIALS AND METHODS

Tellurium nanoparticles (TeNPs) were synthesized using a green synthesis approach with *Conus betulinus* extract as the reducing and stabilizing agent. 0.01 M tellurium chloride solution was prepared in double-distilled water and mixed with the *Conus betulinus* extract at different volume ratios of 9:1, 8:2, 7:3, 6:4, and 5:5 (tellurium chloride solution). The reaction mixtures were stirred continuously at 800 rpm using a magnetic stirrer under dark conditions to prevent photo-induced degradation. Among the different ratios investigated, the 5:5 ratio exhibited the highest yield of tellurium nanoparticles and was therefore selected for bulk-scale synthesis. A visible color change from the initial reaction mixture to a milky white suspension was observed within 1 h, indicating the formation of TeNPs. Following synthesis, the nanoparticle suspension was centrifuged at 15,000 rpm for 15 min to separate the nanoparticles. The resulting pellet was washed three to four times with deionized water to remove unreacted precursors and residual impurities. The purified nanoparticles were subsequently lyophilized to obtain a dry powder. The lyophilized tellurium nanoparticles were stored in a cool, dry, and dark environment until further physicochemical characterization and biological evaluation.

Antibacterial Activity

The antibacterial activity of the synthesized tellurium nanoparticles (TeNPs) was evaluated against *P. acnes* and *S. oralis* using the agar well diffusion method. Nutrient agar plates inoculated with 24 h bacterial cultures were prepared, and wells were loaded with TeNPs at concentrations of 500, 250, 100, and 50 μg/mL. After incubation at 37°C for 24 h, the zones of inhibition were measured. Gentamicin served as the positive control. All experiments were performed in triplicate, and data were analyzed using GraphPad Prism 6.0 (USA).

Antifungal Activity

The antifungal activity of TeNPs was assessed against *Cryptococcus neoformans* and *Aspergillus fumigatus* using the agar well diffusion method. Potato dextrose agar plates seeded with 72 h fungal cultures were treated with TeNPs (500, 250, 100, and 50 μg/mL) and incubated at 28°C for 72 h. The antifungal activity was determined by measuring the inhibition zones. Amphotericin B was used as the positive control, and the results were analyzed using GraphPad Prism 6.0 (USA) [23,24].

Anti-inflammatory Activity

The anti-inflammatory activity of TeNPs was determined using the bovine serum albumin (BSA) protein denaturation assay. TeNPs (10–500 μg/mL) were mixed with 1% BSA, incubated at room temperature for 10 min, and heated at 51°C for 20 min. After cooling, absorbance was measured at 660 nm. Acetylsalicylic acid was used as the standard, and the percentage inhibition of protein denaturation was calculated. All experiments were performed in triplicate.

Antioxidant Activity

The antioxidant activity of TeNPs was evaluated by DPPH and hydrogen peroxide scavenging assays. For the DPPH assay, TeNPs (10–500 μg/mL) were mixed with 0.1 mM DPPH solution, incubated in the dark for 30 min, and absorbance was recorded at 517 nm. Ascorbic acid served as the reference standard [25,26]. For the hydrogen

peroxide scavenging assay, TeNPs (10–500 μg/mL) were mixed with 43 mM hydrogen peroxide solution and incubated for 10 min. The absorbance was measured at 230 nm against a phosphate buffer blank. Ascorbic acid was used as the positive control, and the free radical scavenging activity was calculated.

RESULTS AND DISCUSSION

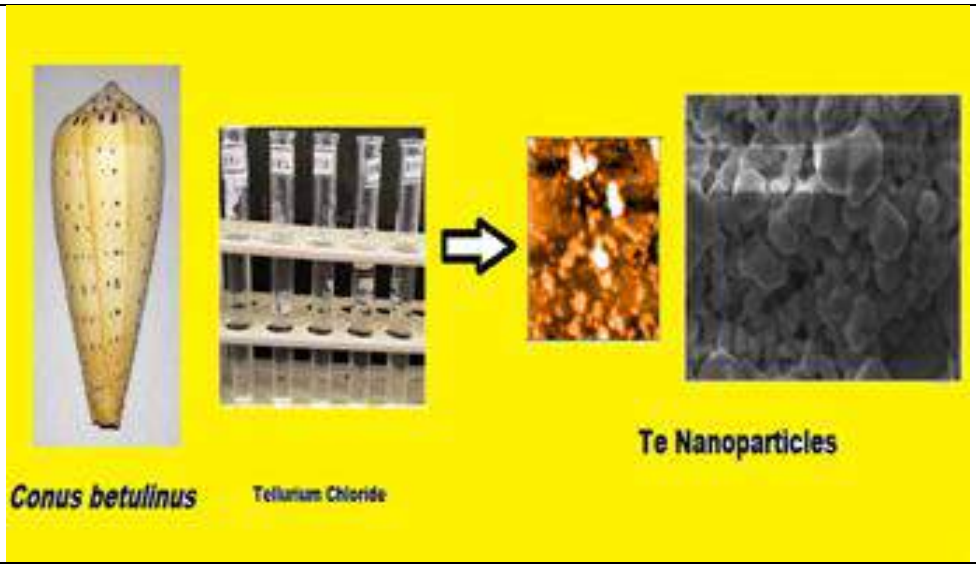
UV-Visble Spectroscopy

The optical absorbance properties of the synthesized Tellurium Nanoparticles were investigated using extract of *Conus betulinus* in the wavelength range 200-1100 nm at ambient temperature. Figure 1 indicates the UV –Visible diffuse reflectance spectra of Tellurium Nanoparticles using extract of *conus betulinus* . There is a strong absorption peak around 300nm which confirms the presence of Te nanoparticles. FTIR analysis of Tellurium nanoparticles shows a strong absorption peak around 3324cm^{-1} which shows the presence of N-H stretching frequencies, 1638 cm^{-1} due to CO stretching frequency and peak around 700cm^{-1} to 1100 cm^{1}due to C-O stretching frequency in Figure 2. IR Spectra shows the presence of biogenic reducing agents.

Atomic Force Microscopy

An Atomic Force Microscopy topographical image of Te nanoparticles is shown in Figure 3 which shows the agglomerated rock like structure. The average length of the rock structure is in 21.7 nm. It may be due to the Metal bindings. SEM characterization of Tellurium Nanoparticles showed a homogeneous image around 200nm in Figure 4. XRD was carried out to determine the purity and the particle size of the synthesized nanoparticles. From the Figure 5, the particle was calculated. The size of the particle was found to be 54.28nm. The antibacterial activity of the Tellurium nanoparticles against *Streptococcus oralis* and *Propioni bacterium acnes* were determined using agar well diffusion method. The result shows a good inhibiting effect at higher concentration in Figure 6 and 7.From the graph, it was clear that the inhibiting level increases as the concentration increases. Inhibitory concentration at 50 percentage was found to be 55.22 μg/ml. Dose dependent increase in the antibacterial activity was observed. At higher concentration (500 μg/ml), 92% excellent inhibition activity was observed Antifungal activity of Tellurium Nanoparticles were determined against *Cryptococcus neoformans and Aspergillus fumigates.* The Zone of inhibition shows excellent results at higher concentration in Figure 8 and 9. The inhibitory effect of Tellurium nano particles was studied against *Cryptococcus neoformans* and *Aspergillus fumigates* at various concentrations using Potato dextrose agar medium proved a good inhibition activity. The results showed that at500 μg/ml, a high inhibitory activity was observed. Pathogens growth can be inhibited. Hence it can be used as excellent antifungal agent. The percentage inhibition of synthesized nanoparticles was calculated for DPPH radical scavenging activity of Tellurium nanoparticle using standard ascorbic acid solution. At 517nm, a good inhibition effect was observed around the 67.32% for 500 μg/ml. Figure 10 exhibits the photographs of DPPH radical scavenging activity of Tellurium nanoparticles and figure 11 is the absorbance data of Te nanoparticle at 517nm.The plot of concentration versus percentage of inhibition exhibits a good percentage of inhibition in triplicates is shown in figure 12.This shows that the free radicals exist in our body will get scavenge using this Te nanoparticles. Hence it finds its application in anti-aging property. At higher concentration, excellent inhibition property is observed. The inhibitory concentration at50% is found to be 97.55 μg/ml. Inhibitory concentration for Hydrogen peroxide scavenging activity at 230nm at 50 percentage was found to be 55.22 μg/ml is represented in figure 13. Dose dependent increase in the antibacterial activity was observed. At higher concentration (500 μg/ml), 92% excellent inhibition activity was observed. Figure 14 shows Concentration versus Percentage of inhibition of Te nanoparticle.

CONCLUSION



Various methods such as physical, chemical and Biological methods are available to synthesis Nanoparticles. Green synthesis of Nanoparticles is an important method to synthesis, Since it is highly efficient for the Fabrication of

Nanoparticles at Nanoscale without affecting our Environment. By Eco-Friendly Method, using *Conus betulinus* Te Nanoparticles can be synthesized. This method of Biogenically synthesized Te Nanoparticles is characterized using UV-visible Spectra, IR Spectra. Also, the surface morphology of the Nanoparticles is confirmed by SEM and AFM techniques. The extract of *Conus betulinus* is successfully employed for the preparation of Te Nanoparticles. The nanoparticles synthesized shows good absorbance around 300 nm. The presence of Bio-active agents in the extract was confirmed from FTIR studies. The results of Atomic Absorption spectra showed the formation of Nanoparticles. Also, SEM images confirm the Flaky Nanoparticles. Anti-Bacterial and Anti-Fungal applications showed excellent percentage of inhibition at higher concentration. The scavenging effect of DPPH and Hydrogen Peroxide showed that the synthesized Nanoparticles can be employed for Anti-Aging application.

ABSTRACT

This article diagnoses a queueing model involving two parallel servers that are prone to failure, examined using fuzzy parameters. Customers arrive following a Poisson processes. Each customer requires two obligatory services, one from each of the parallel servers, ie. server 1 and server 2. Service is performed in parallel, and after collecting the service from one server, the customer transitions to the other. Completion of both services is need before departure. The two servers are subject to breakdowns but are restored after repair, incorporating reliability aspects into the model. Let us take the processes of Stochastic $\{((S(\tau),N(\tau)): \tau \geq 0\}$ and derived the Probability vectors using Matrix Geometric Method and conducts a detailed review of performance benchmarks for Markovian Lining up model of two parallel servers with Unreliable server under trisectional fuzzy ordering approach. Performance metrics are calculated using specific parameter values, with the findings presented through numerical tables and graphical illustrations.

Keywords: Two Parallel Servers, Unreliable Server, Trisectional Fuzzy Ranking, Matrix Geometric Method.

AMS Subject classification: 90B22, 60K25 and 60K30.

INTRODUCTION

A two parallel servers system in queuing theory refers to a service model where two servers operate at the same time and independently, handling customers or jobs from a single, shared queue. Each incoming customer waits in line until one of the servers becomes available, and then is directed to that server for service. This setup increases the system's capacity and reduces customer waiting times compared to a single-server system, making it more efficient in handling moderate to high traffic. A common example of this, can be found in a bank where two tellers serve clients from a unified line - the next available teller assists the next person in the queue. Another example is a hospital emergency room, where two doctors attend patients as they arrive, reducing delays in treatment. This dual-server model is widely used in real-world systems to enhance service efficiency, manage customer flow, and improve user satisfaction. In a queuing system with Server Breakdown, one or more servers may fail or break down randomly during operation. This model introduces additional layers of complexity, incorporating concepts of system reliability and repair dynamics (often modeled using exponential times as well). Consider a customer support centre with two call agents (server). If the one agent experiences a technical issue such as lose of internet connectivity (breaks down), that the server is temporarily out of service. After the repair time, the agents might recover (get reconnected) after a few minutes and resume service. In real-world systems like data centers, telecommunication networks, or healthcare facilities, both these models can be used together. For instance, a system may have two parallel servers (like two X-ray machines).However, each machine could occasionally fail and need maintenance. Once repaired, they rejoin the service process, maintaining overall system efficiency.

Ranking method. Performance analysis of biserial servers connected with a Main Server by Fuzzy Ordering approaches have studied by Syamala et.al [24]. Syamala et.al [25] have found a 3D based CT scan Retrial queueing model by Fuzzy Ordering approach. Vandana Saini et.al [26] have studied an analysis of a Feedback Bi-tandem Queueing Network in Fuzzy Environment.

Model Description

Consider a Markovian queuing model of two parallel servers with unreliable environment. Consumers come at the system in proportion to a complete random processes with probability λ and are served by two parallel servers namely server 1 and server 2. Customer served on the basis of FCFS. Each customer requires two compulsory services from server 1 and server 2 are exponentially distributed with probability μ_1 and $\mu_2$respectively. The services are performed in parallel and a customer receives the two services from different servers, rather than sequentially on the same one. The arriving customer either enters into the server 1 or server 2 to get a service. After completing the first service from server 1, then the customer enters into server 2 with a probability λ_{12}. Similarly, after completing their first service from server 2, then the customer enters into server 1 with a probability λ_{21}. The customer departs the system only after completing both services. The server may tend to unforeseen disruption with probability u and after it is to be restored and goes to routine service with probability v.

Let$(S(\tau), N(\tau)): \tau \geq 0\}$ be a Processess of Stochastic, where $N(\tau)$ is the Current customer load in the system and

$$S(\tau) = \begin{cases} 0, When\ Server\ exists\ idle \\ 1, When\ Server\ 1\ exixts\ busy \\ 2, When\ Server\ 2\ exixts\ busy \\ 3, When\ Server\ is\ on\ breakdown \end{cases}$$

The Quasi –Birth and Death (QBD) procedure together with outcome space as follow:

$\varphi = \{(0,0) \cup (i,j); i = 1,2,3, j \geq 1\}$

A procedure utilize QBD and an infinitesimal creator matrix Z is

$$Z = \begin{pmatrix} L & M & 0 & 0 & 0 & 0 & \dots \\ N & Q & P & 0 & 0 & 0 & \dots \\ 0 & F & Q & P & 0 & 0 & \dots \\ 0 & 0 & F & Q & P & 0 & \dots \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \end{pmatrix}$$

Where,

$$L = (-3\lambda); \qquad M = (\lambda \quad \lambda \quad \lambda); \qquad N = \begin{pmatrix} \mu_a \\ \mu_b \\ 0 \end{pmatrix}$$

$$Q = \begin{pmatrix} -(\mu_a + \lambda_{ab} + u + \lambda) & \lambda_{ab} & u \\ \lambda_{ba} & (\mu_b + \lambda_{ba} + u + \lambda) & u \\ v & v & -(2v + \lambda) \end{pmatrix};$$

$$P = \begin{pmatrix} \lambda & 0 & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & \lambda \end{pmatrix}; \qquad F = \begin{pmatrix} \mu_a & 0 & 0 \\ 0 & \mu_b & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

The fixed row stochastic matrix is $\sigma Z = 0,$ Where $\sigma = (\sigma_0, \sigma_1, \sigma_2, \sigma_3, \dots \dots \dots)$

From (1),

$$(\sigma_0, \sigma_1, \sigma_2, \sigma_3, \dots \dots \dots) \begin{pmatrix} L & M & 0 & 0 & 0 & 0 & \dots \\ N & Q & P & 0 & 0 & 0 & \dots \\ 0 & F & Q & P & 0 & 0 & \dots \\ 0 & 0 & F & Q & P & 0 & \dots \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \end{pmatrix} = 0$$

$\sigma_0 L + \sigma_1 N = 0$ ------ (2)

$\sigma_0 M + \sigma_1 Q + \sigma_2 F = 0$ ----- (3)

$\sigma_1 P + \sigma_2 Q + \sigma_3 F = 0$ ------ (4)

$\sigma_2 P + \sigma_3 Q + \sigma_4 F = 0$ ------ (5)

$\vdots$

$\vdots$

$\sigma_i P + \sigma_{i+1} Q + \sigma_{i+2} F = 0$ ------- (6)

The Proportional measure is obtained

$\sigma_i = \sigma_1 X^{i-1}; i \geq 2$ -------- (7)

By equation (3), we acquire

$X_{n+1} = -Q^{-1}(P + X_n^2 F)$ -------- (8)

The regularizing state is

$\sigma_0 e + \sigma_1 (I - X)^{-1} e = 1$ -------- (9)

e is the column vector with all the entries equivalent to one.

The fixed condition of a QBD of this category is furnished by

$\sigma Pe < \sigma Fe$

σ Partitioned ($\sigma_0, \sigma_1, \sigma_2$) is probability distribution of two producer array is acquired from

S = P + Q + F,

$$S = \begin{pmatrix} -(\lambda_{ab} + u) & \lambda_{ab} & u \\ \lambda_{ba} & -(\lambda_{ba} + u) & u \\ v & v & -2v \end{pmatrix}$$

And σ could be exhibit to be halted in order that $\sigma S = 0 \; as \; well \; as \; \sigma e = 1$.

Thus, the fixed state of a QBD of this class is $(\sigma_0 + \sigma_1 + \sigma_2)\lambda < \sigma_0 \mu_a + \sigma_1 \mu_b$

Key Performance Indicators:

The successive performance metrics have been acquired for the disparity in the Entry rate and service tariff.

$\sigma(E) = Probability \; of \; the \; system \; is \; idle = \sigma_0$

$\sigma(S1)$ = Probability of the server 1 is busy = $\sum_{k=1}^{\infty} k \, \sigma_{0k}$

$\sigma(S2)$ = Probability of the server 2 is busy = $\sum_{k=1}^{\infty} k \, \sigma_{1k}$

$\sigma(BD)$ = Probability of the server is on breakdown = $\sum_{k=1}^{\infty} k \, \sigma_{2k}$

$\sigma(N)$ = Probability of the mean number of customer present in the system

$= \sigma(E) + \sigma(S1) + \sigma(S2) + \sigma(BD)$

Trisectional Fuzzy Trapezoidal Ranking – Algorithm

Definition: Trapezoidal fuzzy Number:

A Trapezoidal Fuzzy Number $\widetilde{A}(x)$ is represented by $\widetilde{A}(p\ q\ r\ s)$ with the membership function

$$\mu_{\widetilde{A}}(x) = \begin{cases} \frac{x-p}{q-p}, p \leq x \leq q \\ 1, \quad q \leq x \leq r \\ \frac{x-s}{r-s}, \quad r \leq x \leq s \\ 0, \quad \text{otherwise} \end{cases}$$

Let us take an Segment data (M,N). The tripartite of this Segment is taken as

$d = \frac{H-G}{3}$, then the mandatory trapezoidal fuzzy numeral is $[G, G+d, G+2d, H]$.

Contemplate a normal trapezoidal fuzzy numeral $\widetilde{A} = [p\ q\ r\ s]$ depicted in Fig. 2. Prolong the Connecting lines R(p,0) and T(q,1) as RTQ and the Connecting lines S(s,0) and U(r,1) as

SUQ. The overlap of prolonged lines RT and SU is Q. The Positional point for overlap point Q is (x, y), where

$$x = \frac{pr - qs}{r - s - q + p},$$

$$y = \frac{x-q}{q-p}$$

The suggested ranking method is grounded on the idea of the in-center Fig. 3 of a triangle QRS and is formally defined as follows.

$R(\widetilde{A}) = \frac{ax + bp + cs}{a+b+c}$

where $a = s - p$, $b = \sqrt{y^2 + (s-x)^2}$, $c = \sqrt{y^2 + (x-p)^2}$

Numerical Computation:

The Statistical outcomes are attained by modifying quantities of the remaining inputs and modifying the parameter value λ from 0.49 via 0.52.

Case (i): Contemplate the arrival rate $\tilde{\lambda}$ = [0.34 0.44 0.54 0.64], the service rates $\widetilde{\mu_a}$ =[1 1.1 1.3 1.4] and $\widetilde{\mu_b}$ = [1.3 1.4 1.6 1.7]; $\widetilde{\lambda_{ab}}$ = [0.3 0.4 0.6 0.7]; $\widetilde{\lambda_{ba}}$ = [0.5 0.6 0.8 0.9]; $\tilde{u}$ = [0.1 0.2 0.4 0.5]; $\tilde{v}$ =[0.2 0.3 0.5 0.6].
Now the mapping function of the trapezoidal fuzzy numeral [0.34 0.44 0.54 0.64] is

$$\mu_{\tilde{\lambda}}(x)=\begin{cases}\frac{(x-0.34)}{(0.44-0.34)}, & 0.34\le x\le 0.44\\ 1, & 0.44\le x\le 0.54\\ \frac{(x-0.64)}{(0.64-0.54)}, & 0.54\le x\le 0.64\\ 0, & otherwise\end{cases}$$

$R(\tilde{A}) = \frac{ax+bp+cs}{a+b+c}$, $R(\tilde{\lambda}) = \frac{0.3(0.49)+1.50748(0.34)+1.50748(0.64)}{0.3+1.50748+1.50748}$ =0.48999≈ 0.49.

Comparably we can get going for whole other trapezoidal fuzzy rates in this similar path.
Then we put in the Trisectional Fuzzy grading Method to the trapezoidal fuzzy numerals.

$R(\tilde{\lambda}) = 0.49$, $R(\widetilde{\mu_a}) = 1.2$, $R(\widetilde{\mu_b}) = 1.5$, $R(\widetilde{\lambda_{ab}}) = 0.5$, $R(\widetilde{\lambda_{ba}}) = 0.7$, $R(\tilde{u}) = 0.3$,
$R(\tilde{v}) = 0.4$. and $X = \begin{pmatrix}0.29246 & 0.09268 & 0.08957\\ 0.11625 & 0.23365 & 0.08138\\ 0.20439 & 0.16313 & 0.46531\end{pmatrix}$,

The likelihood point σ_0 and σ_1 is concocted utilizing the X matrix in equation (1) and (7). These rates are swapped in regularizing state $\sigma_0 e+\sigma_1 (I-X)^{-1} e$ to acquire σ_0= (0.18794) and σ_1= (0.11523, 0.09200, 0.11958). The residual points σ_i's is all disposed in **Table 1** after being created utilizing the correlation $\sigma_i=\sigma_1 X^{i-1}$, $i\ge 2$. In general, the likelihood is 0.99993≅1.

Case (ii): Contemplate the arrival rate $\tilde{\lambda}$ = [0.3 0.4 0.6 0.7] the service rates $\widetilde{\mu_a}$ =[1 1.1 1.3 1.4] and $\widetilde{\mu_b}$ = [1.3 1.4 1.6 1.7] ; $\widetilde{\lambda_{ab}}$ = [0.3 0.4 0.6 0.7]; $\widetilde{\lambda_{ba}}$ = [0.5 0.6 0.8 0.9]; $\tilde{u}$ = [0.1 0.2 0.4 0.5]; $\tilde{v}$ =[0.2 0.3 0.5 0.6].
Now the mapping function of the trapezoidal fuzzy numeral [0.3 0.4 0.6 0.7] is

$$\mu_{\tilde{\lambda}}(x)=\begin{cases}\frac{(x-0.3)}{(0.4-0.3)}, & 0.3\le x\le 0.4\\ 1, & 0.4\le x\le 0.6\\ \frac{(x-0.7)}{(0.6-0.7)}, & 0.6\le x\le 0.7\\ 0, & otherwise\end{cases}$$

The likelihood point σ_0 and σ_1 is concocted utilizing the X matrix in equation (1) and (7). These rates are swapped in regularizing state $\sigma_0 e + \sigma_1 (I - X)^{-1} e$ to acquire σ_0= (0.24837) and σ_1= (0.15585, 0.11376, 0.15633). The residual points σ_i's is all disposed in Table 9 after being created utilizing the correlation $\sigma_i = \sigma_1 X^{i-1}$, $i \geq 2$. In general, the likelihood is 0.99944≅1. In Table 10, the performance measures of σ (E), σ (S1), σ (S2), σ (BD), σ (N) are calculated by varying the Service rates $\widetilde{\mu_a}$ and $\widetilde{\mu_b}$ and fixed the other values. It tabulates us that, when the Service rates raised, the probability of the system idle raised. Also if the Service rates raised, then the probabilities of σ (S1), σ (S2), σ (BD), and σ (N) are decreased. From, Figures 5(i)-(v), if the service rates μ_a and μ_b raises, then the probability that the system is idle σ (E) raises. On the other hand, the probability that server 1 is busy σ (S1), server 2 is busy σ (S2) and the server is breakdown σ (BD) and the mean number of customers present in the system σ (N) all decreases.

CONCLUSION

This study look into a Markovian queuing model involving two parallel servers exposed to random breakdowns, after each breakdown the servers undergo repairs before resuming service and service interruptions get solved. This model is figured out by using the Matrix Geometric Method. Also, we applied Trapezoidal Fuzzy Ranking technique and convert the crisp values to fuzzy numbers. We assorted entry rate and mean service rate and give rise to likelihood vectors and performance measures. We visually mean to demonstrate system dynamics. The pictogram representation discloses that as the entry rate raises, then likelihood that the system is idle decreases. On the other hand, the likelihoods that server 1 is busy, server 2 is busy and the server is breakdown and the norm of current customer count in the system all raises. Further more if the mean service rates raises, then likelihood that the system is idle raises. On the other hand, the likelihoods that server 1 is busy, server 2 is busy and the server is breakdown and the norm of current customer count in the system all are decreasing.

ABSTRACT

In this article, the new concept mean absolute difference of cubic and square labeling was presented. The Graph for which every edge label is the mean absolute difference of the difference of the cubes of the vertices and the difference of the squares of the vertices. It is also observed that the weights of the edges are found to be distinct. Here few graphs are characterized for Mean absolute difference of cubic and square labeling such as cycle, windmill, mirror, flag and butterfly.

Keywords: Labeling, Cubic Labeling, Square Labeling, Graceful Labeling

INTRODUCTION

The field of Mathematics plays a very important role in Science and Engineering. Especially, graph theory plays a major role in Mathematics. Graph theory started its journey from the problem of Konigsberg bridge. Field of graph theory plays a vital role in various fields. Graph theoretical concepts are widely used to study and to model various applications in different areas. They include study of molecules, construction of bonds in chemistry and the study of atoms. Numerous algorithms are used to solve problems, that are modeled in the form of graphs. Graph theory is used to calculate the shortest distance and to find minimum spanning tree. One of the most important areas in graph theory is graph labeling. Graph labeling is an assignment of integers to its vertices or edges which are subjected to certain conditions. Graph labeling is being used in many applications like coding, X-ray crystallography, circuit design, communication network and data base management. All Graphs in this article are taken as finite and undirected. The symbols $V(\hat{G})$ and are denoted as vertex set and edge set of a graph $\hat{G}$. The total number of vertex in the graph is $E(\hat{G})$ called the order of $\hat{G}$ denoted by p and the total number of edges in the graph is called the size of $\hat{G}$ denoted by q is called (p, q) graph.

REVIEW OF LITERATURE

Most graph labeling methods trace their origin to that of one introduced by Rosa [6] in 1967, Rosa [6] called a function f a β-valuation of a graph G with q edges if f is an injection from the vertices of G to the set {0,1,2, …, q} such that when each edge uv is assigned the label $|f(u)-f(v)|$ the resulting edge labels are distinct. Golomb[4] subsequently called such labeling as graceful and this is now the popular term. Rosa [6] introduced β-valuations as well as the number of other labeling as tools for decomposing the complete graph into isomorphic subgraphs. In particular, β-valuations originated as a means of attacking the conjecture of Ringel that K_{2n+1} can be decomposed into 2n+1 subgraphs, that are all isomorphic to a given tree with n edges. Rosa has identified essentially three reasons why a graph fails to be graceful.

- G has "too many vertices" and "not enough edges"
- G " has too many edges"
- G "has the wrong parity"

Rosa [6] defined an α-valuation as a graceful labeling with the additional property that there exist an integer k so that, for each edge *uv* either $f(u) \le k \le f(v)$. Graphs with α-labelings are useful in the development of the theory, of graph decompositions. Graph labeling is regularly updated by Gallian [3] and it is published by Electronic Journal of Combinatorics. Some basic concepts are taken from Frank Harary[5]. The square sum labeling is defined by Ajitha, Arumugam and Germina[1] and the concept of square difference labeling was introduced by Shiama [7,8]. Shalini, Paul Dhayabaran[9] introduced the concept of an absolute differences of cubic and square difference labeling. Shalini, Gowri, Paul Dhayabaran [10,11] studied various graphs for an absolute differences of cubic and square difference labeling. Shalini, Sri Harini, Paul Dhayabaran [12,13] introduced the concept of sum of an absolute differences of cubic and square difference labeling and also proved various graphs. Shalini, Subha, Paul Dhayabaran [14] investigated an absolute difference labeling for disconnected graphs

Basic Definitions

Definition 3.1

A linear graph (or simply a graph) $\hat{G}$ = (V, Ɛ) consists of set of objects $V = \{v_1, v_2, v_3, \ldots\ldots\ldots, v_n\}$ called vertices and another set $Ɛ = \{e_1, e_2, e_3, \ldots\ldots\ldots, e_k\}$, whose elements are called edges, such that each edge e_k is identified with an unordered pair (v_i, v_j) of vertices.

Definition 3.2

A graph $\hat{G}$ is said to be connected if there is atleast one path between every pair of vertices in $\hat{G}$, otherwise the graph is dis-connected.

Definition 3.3

Let $\hat{G}$ be a graph. Let $\hat{G}'$ be a copy of G. The mirror graph M($\hat{G}$) of $\hat{G}$ is defined as the disjoint union of $\hat{G}$ and $\hat{G}'$ with additional edges joining each vertex of $\hat{G}$ to its corresponding vertex in $\hat{G}'$.

Definition 3.4

The flag Fl_n is obtained by joining one vertex of C_n to an extra vertex called the root.

Definition 3.5

$C_n : C_n @ W_k$ denote two cycles of order n sharing a common vertex with k pendant edges attached at the common vertex.

Main Results

Definition 4.1

A graph $\hat{G}$ is said to be mean absolute differences of cubic and square labeling if there exist a bijection

λ :V(Ĝ)→*{1,2,3,…..p}* such that the induced function λ^* : Ɛ(Ĝ) → distinct numbers is given by

$$\lambda^*(uv) = \frac{|[\lambda(u)]^3 - [\lambda(v)]^3| + |[\lambda(u)]^2 - [\lambda(v)]^2|}{2}$$

Definition 4.2

A graph Ĝ is said to be mean absolute differences of cubic and square graph if it admits mean absolute differences of cubic and square labeling.

Theorem 4.1

The cycle C_n is a mean absolute differences of cubic and square graphs for $n \geq 3$.

Proof:

Let Ĝ be a graph of cycle C_n. Let $\{v_1, v_2, v_3, ..., v_n\}$ be the vertices of C_n and $\{e_1, e_2, e_3, ..., e_n\}$ be the edges of C_n which are denoted as in the Fig 4.1. The cycle C_n consists of n vertices and n edges. The vertices of C_n are labelled as given below.

Define λ : V(Ĝ)→ $\{1, 2, 3, ..., n\}$ by

$$\lambda(v_i) = i; 1 \leq i \leq n$$

Then the induced edge labels are:

$$\lambda(e_i) = \frac{3i^2 + 5i + 2}{2}; 1 \leq i \leq n-1$$

$$\lambda(e_n) = \frac{n^3 + n^2 - 2}{2}$$

The edges of the cycle graph receive distinct numbers.

Hence, the cycle C_n $(n \geq 3)$ is a mean absolute difference of cubic and square graphs.

Theorem 4.2

The wind mill WM_n is a mean absolute difference of cubic and square graphs for $n \geq 3$.

Proof:

Let Ĝ be a graph of wind mill WM_n. Let $\{v_0, v_1, v_2, ..., v_n, v_1', v_2', v_3', ..., v_n'\}$ be the vertices of WM_n and $\{e_1, e_2, e_3, ...e_n, e_{n+1}, e_{n+2}, ...e_{2n}, e_1', e_2', e_3', ...e_n'\}$ be the edges of WM_n which are denoted as in the Fig 4.4

The wind mill WM_n consists of $2n + 1$ vertices and $3n$ edges.

The vertices of WM_n are labelled as given below.

Define λ : V(Ĝ)→ $\{1, 2, 3, ..., 2n+1\}$ by

$$\lambda(v_0) = 1$$

$$\lambda(v_i) = 2i; 1 \leq i \leq n$$

$$\lambda(v_i') = 2i + 1; 1 \leq i \leq n$$

Then the induced edge labels are:

$$\lambda(e_i) = \frac{i^3 + 4i^2 + 5i}{2}; 1 \leq i \leq 2n$$

$$\lambda(e_i') = 6i^2 + 5i + 1; 1 \leq i \leq n$$

The edges of the wind mill graph receive distinct numbers.

Hence, the wind mill WM_n $(n \geq 3)$ is a mean absolute difference of cubic and square graphs.

Theorem 4.3

The mirror $M(P_n)$ is a mean absolute differences of cubic and square graphs for n ≥ 2.

Proof:

Let $\hat{G}$ be a graph of mirror $M(P_n)$

Let $\{v_1, v_2, \ldots\ldots, v_n, v_1', v_2', v_3', \ldots\ldots, v_n'\}$

be the vertices of $M(P_n)$ and $\{e_1, e_2, e_3, \ldots\ldots, e_{n-1}, e_1', e_2', e_3', \ldots\ldots e_{n-1}', a_1, a_2, a_3, \ldots\ldots a_n\}$ be the edges of $M(P_n)$ which are denoted as in the Fig 4.7.

The mirror $M(P_n)$ consists of $2n$ vertices and $3n - 2$ edges.

The vertices of $M(P_n)$ are labelled as given below.

Define $\lambda : V(\hat{G}) \rightarrow \{1, 2, 3, \ldots\ldots, 2n\}$ by

$\lambda(v_i) = i; 1 \le i \le n$

$\lambda(v_i') = n + i; 1 \le i \le n$

Then the induced edge labels are:

$$\lambda(e_i) = \frac{3i^2 + 5i + 2}{2}; 1 \le i \le n-1$$

$$\lambda(e_i') = \frac{3i^2 + 5i + 3n^2 + 5n + 6ni + 2}{2}; 1 \le i \le n-1$$

$$\lambda(a_i) = \frac{n^3 + 3n^2 i + 3ni^2 + n^2 + 10i}{2}; 1 \le i \le n$$

The edges of the mirror graph receive distinct numbers.

Hence, the mirror $M(P_n)$ $(n \ge 2)$ is a mean absolute difference of cubic and square graphs.

Theorem 4.4

The flag Fl_n is a mean absolute differences of cubic and square graphs for $n \ge 3$.

Proof :

Let $\hat{G}$ be a graph of flag Fl_n.. Let $\{v_1, v_2, v_3, \ldots\ldots, v_n, v_{n+1}\}$ be the vertices of Fl_n and $\{e_1, e_2, e_3, \ldots\ldots, e_n, e_{n+1}\}$ be the edges of Fl_n which are denoted as in the Fig. 4.10.

The flag Fl_n consists of $n + 1$ vertices and $n + 1$ edges.

The vertices of Fl_n are labelled as given below.

Define $\lambda : V(\hat{G}) \rightarrow \{1, 2, 3, \ldots\ldots, n+1\}$ by

$\lambda(v_i) = i; 1 \le i \le n$

$\lambda(v_{n+1}) = n + 1$

Then the induced edge labels are:

$$\lambda(e_i) = \frac{3i^2 + 5i + 2}{2}; 1 \le i \le n-1$$

$$\lambda(e_n) = \frac{n^3 + n^2 - 2}{2}$$

$$\lambda(e_{n+1}) = \frac{n(n^2 + 4n + 5)}{2}$$

The edges of the flag graph receive distinct numbers.

Hence, the flag $Fl_n (n \ge 3)$ is a mean absolute difference of cubic and square graphs for $n \ge 3$

Theorem 4.5

The butterfly $C_n : C_n @ U_K$ is a mean absolute difference of cubic and square graphs for $n \ge 3$

Proof :

Let $\hat{G}$ be a graph of butterfly $C_n : C_n @ U_K$.

Let $\{v_1, v_2, v_3, ..., v_{2n-1}, u_1, u_2, u_3, ..., u_k\}$

be the vertices of $C_n : C_n @ U_K$ and $\{e_1, e_2, e_3, ..., e_{2n}, e_1', e_2', e_3', ...e_k'\}$ be the edges of $C_n : C_n @ U_K$ which are denoted as in the Fig. 4.13

The butterfly $C_n : C_n @ U_K$ consists of $2n - 1 + k$ vertices and $2n + k$ edges.

The vertices of $C_n : C_n @ U_K$ are labelled as given below.

Define $\lambda : V(\hat{G}) \rightarrow \{1, 2, 3, ..., 2n - 1 + k\}$ by

$\lambda(v_i) = i; 1 \le i \le 2n-1$

$\lambda(u_i) = 2n-1+i; 1 \le i \le k$

Then the induced edge labels are:

$$\lambda(e_1) = \frac{n^3 + n^2 - 2}{2}$$

$$\lambda(e_i) = \frac{i(3i-1)}{2}; 2 \le i \le 2n-1$$

$$\lambda(e_{2n}) = \frac{(2n-1)^3 - n^3 + (2n-1)^2 - n^2}{2}$$

$$\lambda(e_i') = \frac{(2n-1+i)^3 - n^3 + (2n-1+i)^2 - n^2}{2}; 1 \le i \le k$$

The edges of the butterfly graph receive distinct numbers.

Hence, the butterfly $C_n : C_n @ U_K$ $(n \ge 3, k \ge 2)$ is a mean absolute difference of cubic and square graphs.

RESULT AND DISCUSSION

Shalini and Paul Dhayabaran introduced the concept of an absolute difference of cubic and square labeling and also investigated some families of graphs which admits an absolute difference of cubic and square labeling. In this article I introduced the new concept mean absolute difference of cubic and square labeling and proved some families of graphs comes under mean absolute difference of cubic and square labeling.

CONCLUSION AND SUGGESTION

In this article, formula has been established for mean absolute difference of cubic and square labeling. It is concluded that certain families of graphs such as cycle, wind mill, mirror, flag and butterfly is a mean absolute difference of cubic and square labeling. Graph labeling applied in various fields such as Cryptography, X-Ray, Computer Networks, Database, Route Problem and Coding Theory.

ABSTRACT

The present study aimed to document the cicada fauna in the Nongkhyllem Wildlife Sanctuary of Meghalaya, India. For this, a trail survey was conducted from 2018 to 2024, using acoustic behaviour to locate them, followed by visual identification. A total of 37 species belonging to 30 genera under two subfamilies, Cicadinae and Cicadettinae of the family Cicadidae were recorded. Among these, 12 cicadas were the new records for the state of Meghalaya, and *Tosena fasciata fasciata* is not only new to Meghalaya but also a new record for the Indian subcontinent. The majority of the cicada species were found to be annual, whereas only one species i.e. *Chremistica ribhoi* is periodical, and a greater number of them appeared during summer, followed by spring and then autumn and the least during winter. However, the protection of pristine and undisturbed forests habitat must be ensured for a successful conservation measure for cicada fauna in Meghalaya state of India.

Keywords: Cicadas, Nongkhyllem Wildlife Sanctuary, New distribution records and Range extension

INTRODUCTION

Cicadas are insects that belong to the order Hemiptera, which feed on plant sap with their pointed mouthparts called a rostrum. The order Hemiptera is subdivided into two suborders, Auchenorrhyncha and Sternorrhyncha. The

suborder Auchenorrhyncha contains four infra-orders, viz. Fulgoromorpha (plantshoppers), Cicadaomorpha (Cicadas, leafhoppers, spittlebugs), Coleorrhyncha (moss bugs) and Heteroptera (the true bug) [1,2]. The infraorder Cicadomorpha contains 3 superfamilies, of which the superfamily Cicadoidea contains the cicadas. The superfamily Cicadoidea is again divided into two families - Cicadidae and Tettigarctidae. The majority of the cicadas fall within the Cicadidae, while only two existing species (*Tettigarcta crinita* and *Tettigarcta tomentosa*) along with some fossil species that comes under Tettigarctidae[3]. The family cicadidae presently consists of two existing subfamilies viz., Cicadinae and Cicadettinae.

Cicadas are the most well-known among sound producing insects, by their loud tymbalisation in the form of unique calls, which is the main characteristic of these species. This acoustic capability in cicadas is confined only to the males. They are distributed most abundantly in the tropical regions, and exhibit a diverse range in size, shape and colouring [4]. Based on their life cycle, cicadas of the world can be categorised into three types, i.e., annual, proto-periodical and periodical cicada. The annual cicadas are those cicadas that emerge every year (e.g. *Macrosemia umbrata, Tosena melanoptera, Dundubia mannifera,* etc.), and the majority of the Indian cicadas fall under this category, while proto-periodical cicadas are those that, though they emerge every year, come out in some years in a greater number (e.g. *Okanagana rimosa* and *Platypedia* sp.). However, there is no proto-periodical cicada in India. On the other hand, the periodical cicadas are those cicada species that emerge together after a long period of time (*Magicicada septemdecim*, and *Chremistica ribhoi*). These periodical cicada species remain underground during nymphal development for several years and emerge in mass scale after it completes its life cycle [5-7]. Many periodical cicadas have their life cycle ranging from 2 to 17 years, depending on the species. Interestingly, 98% of the cicadas around the world are of the annual cicadas, and very few of the 3000 cicadas in the world are periodical in nature [8,9].

Cicadas play a major role in maintaining the forest ecosystem. Most often they serve as the prey base for a number of mammalian, avian, reptilian and amphibian species and forms the part of the food chain and food web, regulating predator populations through the phenomenon called the predator satiation [10]. On the other hand, the nymphal stage of the cicada, while residing on the underground for a couple of years, makes a tunnel in the soil that enhances soil aeration, water infiltration in the soil and nutrient transformations by consuming xylem sap of the plant roots [5]. By doing this, there is an exchange of nutrients between belowground and aboveground, resulting in enhancement of the productivity of the soil and the entire ecosystem, and supporting the biodiversity. Hence, they are also called the bioindicator of the ecosystem that delights the health of the entire ecosystem. Therefore, site-species studies of the distribution pattern of cicada species are important not only to understand the health of the ecosystem but also it helps in drawing a holistic approach in the conservation planning for policymakers. Unfortunately, like other insect fauna, studies of the cicada were undocumented for a few decades. There were a few studies on the distribution of cicada in Meghalaya state [7,11-13]which mostly covered the taxonomy aspect of species. None of the studies covered cicada fauna in the Nongkhyllem Wildlife Sanctuary of Meghalaya. On the other hand, only one species of periodical cicada was described by Hajong and Yaakob [7], and still many more species might have been undiscovered from the state. Considering the ecological importance of cicada, the present study was initiated to evaluate species composition, status and habitat preferences of cicadas in Nongkhyllem Wildlife Sanctuary of Meghalaya, India.

Study Area

Nongkhyllem Wildlife Sanctuary (Figure 1) is located in Ri-Bhoi District of Meghalaya, which falls within the Indo-Burma biodiversity hotspots. The area has a tropical monsoon climate; the summers are hot and wet, while the winters are cool and dry. The sanctuary lies under geographical coordinates 25.9236°N and 91.8821°E and the altitude ranges between 200 m and 950 m above sea level; the average annual rainfall is about 250 cm. The major part of the habitat is tropical moist deciduous forest with patches of tropical semi-evergreen forest, especially in the river valleys and streams. Since this forest is rich in terms of flora and fauna diversity, which are ecologically significant. Many researchers explored its diversity and richness, in which they reported various species of both plants and animals. The sanctuary has been estimated to have about 50 species of mammals, including the Asiatic elephant, wild boars, deer, Bengal tiger, clouded leopard, etc. over 25 species of reptiles including Gecko, King cobra, monocled cobra etc.

and according to a bird surveys conducted in this sanctuary records over 400 species of birds, including various endangered species like the Rufous Necked Hornbill (*Aceros nipalensis*).

METHODOLOGY

Survey and data collection

Surveys were conducted throughout the different sites of the Sanctuary during the years 2018 to 2024. For survey of cicada fauna, we generally follow forest trails and the male cicada cicadas by their calls. We also attempt to locate the female individuals within the vicinity of the calling males. To record the GPS coordinates, a Garmin (eTrex) receiver was used. The survey and sampling were carried out monthly in order to investigate its seasonal phenology in every month of the years. Most of the collections of the specimens were done during several field excursions by RT and SRH, which are presently housed in the Entomology laboratory, Department of Zoology, NEHU, Shillong, Meghalaya (India).

Identification

Most of the cicada species were identified in the field itself visually through photography. Whereas, the unidentified species were collected using hand picking, sweeping net, flight interception traps and light trap. The unidentified collected specimens were brought to the lab for identification and for further studies.

For cicada morphology, we consulted the original descriptions of Indian cicadas by Distant [11]. We also followed Moulds [14] for the latest morphological terminology. For taxonomy and nomenclature, Sanborn [15] was followed. For the latest taxonomy of cicada classification and nomenclature, Marshall *et al.*[16] and Hill *et al.*[17] were also followed. The following websites were also consulted-http://www.indiancicadas.org; http://www.cicadamania.com.

RESULTS

Abundance of cicada species

The survey carried out between 2018 and 2024 in Nongkhyllem Wildlife Sanctuary found 37 species of cicada (Figure 2a&b) belonging to 30 genera, ten tribes, under two subfamilies. The taxonomy details of the cicada species of Nongkhyllem Wildlife Sanctuary are summarised in Table 1. Of the total 37 species of cicada, 32 species were belonged to the sub-family Cidadinae while 5 Cicadittinae (Figure 3). This clearly indicates that the sub-family Cidadinae was dominant at the study site. The sub-family Cidadinae consisted of eight types (Cryptotympanini, Dundubiini, Gaeanini, Leptosaltrini, Tosenini, Ayuthiini, Platypleurini and Psithyristriini) while the sub-family Cicadittinae had two types (Cicadatrini and Cicadettini). Among all these type categories, the highest number of species was represented by Dundubiini with 9 species, followed by Leptosaltrini with 7 species, Gaeanini with 6 species, Cryptotympanini with 4 species, Cicadettini with 3 species, while Cicadatrini, Psithyristriini and Tosenini represented 3 species each, the remaining types, namely Ayuthiini, Platypleurini and Tosenini represented by two species each. This indicates that the Dundubiini was the most dominant among the type categories (Figure 4).

The subfamily Cicadinae consisted of 26 genera with 32 species as compared to Cicadettini with 2 genera with 5 species (Figure 5). The genus Meimuna consisted of the highest number of species, followed by *Cryptotympana, Dundubia, Mogannia, Pomponia* and *Tosena,* each with two species and the remaining 24 genera represented with one species each

Cycle of emergence

Out of the 37 species identified, only one species i.e. *Chremistica ribhoi* is a periodical cicada, while the remaining cicada species are annual cicadas. This *Chremistica ribhoi* species seems to be the only periodical cicada in the Indian subcontinent and is endemic to Ri-Bhoi district of Meghalaya, where it is locally known as 'Niangtaser'. They complete their life cycle in four years times, and hence, they occur once in every four years in large numbers where bamboos are predominates. As their last emergence was in the year 2022, the next emergence will be in the year 2026.

As the mass emergence of this cicada species coincides with the FIFA World Cup tournament, local football fans have coined a popular name of this cicada as the 'World Cup insect' and locally is also known as 'Niangworldcup'. However, the remaining 36 cicada species (*Mogannia obliqua, Mogannia effecta, Balinta octonotata, Collogaeana festiva, Euterpnosia madhava, Graptotettix guttatus, Guduba maculata, Platypleura nobilis, Pomponia linearis, Purana metallica, Pomponia ramifera, Khimbya diminuta, Tosena melanoptera, Salvazana mirabilis, Macrosemia umbrata, Dundubia mannifera* etc.) appear in every year but in different months or seasons in the annual season cycle (Table 1). The species *Platypleura nobilis* was the first cicada to appear during the annual cycle; it emerges in January, while *Dundubia intermerata* is the last cicada to appear at the end of every year and persists till December. The present study has also revealed that a greater number of cicadas appeared during summer, followed by spring and then autumn and the least during winter (Fig. 6).

Size variation

The present study also found a variation in the size of the different species of cicada in the Nongkhyllem Wildlife Sanctuary of Meghalaya, India. Among them, *Tosena melanoptera* was found to be the largest cicada, whereas *Gudaba maculata* was the smallest cicada observed during the study period in Nongkhyllem Wildlife Sanctuary.

Range extension

Interestingly, as many as 12 species of cicada, which were documented in Nongkhyllem Wildlife Sanctuary, is the new distribution record from Meghalaya (Table 1). These include – *Mogannia obliqua, Mogannia effecta, Khimbya diminuta, Meimuna silhetana, Balinta octonotata, Collogaeana festiva, Euterpnosia madhava, Guduba maculata, Pomponia linearis, Pomponia ramifera, Purana metallica, Graptotettix guttatus*. In addition to these, the distribution record of *Tosena fasciata fasciata* is not only new to Meghalaya state but also new to the Indian subcontinent.

DISCUSSION

The present study reported 37 cicada species belonging to 2 sub-families, 10 tribes and 24 genera, indicating the richness of the habitat. The presence of 37 cicada species as compared to 189 in India [18] (Price *et al.*, 2016) further indicates richness in Nongkhyllem Wildlife Sanctuary of Meghalaya. This finding not only signifies the faunal diversity of Meghalaya but also highlights the conservation importance of the northeastern Himalayan region, which is part of the Indo-Burma Biodiversity Hotspot [18]. There is a possibility of having a greater number of cicada species in this protected area, as more acoustic behaviour could be detected that needs to be analysed for future identification of the species. Therefore, it an increase trends of new distribution records and new species were added to the Indian cicada from Meghalaya [19]. The distribution and abundance of cicada species seem to be depended on the micro-climatic conditions that not only facilitate their habitat but also provides suitable food resources. Seasonal rainfall along with specific host plant influences their distribution as well their abundance [20]. Some species, such as *Pomponia ramifera, Pomponia linearis, Platypleura nobilis, Cryptympana corva, Macrosemia umbrata, Meimuna tripurasura, Tosena melanoptera, Dundubia mannifera, Dundubia intermerata* appear to be uniformly and abundantly distributed in the sanctuary. On the other hand, a few other species such as *Gudaba maculata, Rustia dentivitta, Huechys sanguinea, Vittagaena dives,* and *Tanna sp.* can be considered as rare species because of their elusiveness and were hardly encountered and spotted during the study period. This variation in distribution patterns of cicadas in Nongkhyllem Wildlife Sanctuary may be attributed to differences in the ecological and vegetation structure associated with the altitudinal variation in different regions and their habitats.

The presence of more representative cicada species belonging to sub-family Cicadinae as compared to Cicadettinae further supports the fact that the tropical forest harbours large-bodied cicada species [21]. Similar phenomenon also reported in other tropical forests throughout Southeast Asia, where the northeast is part of it [18,22]. The presence of more representatives of the tribe Dundubiini may be because of the vegetation structure and mature evergreen forest patches within the protected area. The presence of a greater number of annual emerging cicada species in the study area may be because of suitable climatic conditions, along with the availability of forest resources that initiated

overlapping generations [23]. This signifies localised adaptability to specific climatic conditions along with forest phenology. On the other hand, the present study also reported the distribution range extension of 12 cicada species for the first time in Meghalaya state, further not only indicates for molecular taxonomic study, which will be instrumental in developing evidence-based conservation and management of cicada and other regionally important species of northeast India.

CONCLUSION

The Nongkhyllem wildlife sanctuary harbours a lavish diversity of cicada species due to the presence of a wide variety of host plants that provide them with an ideal breeding habitat. There is still the possibility of discovering more cicada species in Nongkhyllem and other parts of Meghalaya with further field work, both temporal and spatial; some may be brought to light in the future. Furthermore, as cicadas occupies abundantly in pristine and undisturbed forests, their conservation must depend on protecting intact forest habitats in the near future. Further, Nongkhyllem Wildlife Sanctuary may be developed as an immense potential site for eco-tourism by targeting cicadas as the flagship species for nature lovers.

ACKNOWLEDGEMENT

All the authors duly acknowledge the Meghalaya Forest Department for granting the research permit for research work on cicada in Meghalaya. Special thank goes to the Chief Conservator of Forests & CWW, Govt of Meghalaya, for the permission and logistic support during field research. We also acknowledge Mr. J. Rani and Mr. N. Syngkli, both caretakers ofLailad beat house and the caretakers of Umtasor beat house for assisting us during our field study. We also thank Prof. H. J. Syiemlieh for helping us, especially in the field.

ABSTRACT

The Economy of Uttarakhand is paradoxical in the sense that tourism is a significant contributor to the economic growth but a large proportion of population still depends on agriculture for the subsistence livelihoods. The agriculture in hilly region is constrained by fragmented land holdings, rainfed farming systems, low productivity and climatic vulnerability. These restrictions have increased out-migration and in this context Homestay-based agritourism has become a new and feasible way of rural diversification. This study reports operational models, socio-economic contributions, comparative analysis and challenges faced by two home stays offering the agritourism namely, BSR Farm and Jack Pahadi Homestay operating in Pauri Garhwal district of Uttarakhand. A case study method was used and information was collected through field observation and interviews with owners and other stakeholders. The results show that agritourism complement farm income, generates employment opportunities, strengthen community linkages and stimulateen dogenous development. BSR Farm follows a dairy-integrated agritourism model and Jack Pahadi Homestay is based on a diversified model of organic farming and adventure tourism. Both Homestays are utilizing local resources to preserve local art, craft and culture, and use digital platforms to attract visitors and improve economic sustainability. Both agritourism enterprises, while successful, face constraints such as infrastructure constraints and water

scarcity. The study suggests policy implications for strengthening homestay-based agritourism in mountain regions for ensuring sustainable development anduplift the rural economy.

INTRODUCTION

The North Indian Himalayan region is predominantly rural with a substantial segment of its population dependent on natural resource-based livelihoods, specifically agriculture, horticulture, livestock and forestry (Government of Uttarakhand, 2017; NITI Aayog, 2021). The livelihood structure of the Himalayan state is predominantly agrarian with subsistence agriculture as the major source of rural livelihoods. Research indicates that agriculture is the main or secondary occupation for the majority of rural households, often for subsistence rather than commercial reasons (Mamgain& Reddy, 2017; Ministry of Agriculture & Farmers Welfare, 2018). The mountainous terrain, fragile ecosystems and limited cultivable land have a significant bearing on the agriculture in the Himalayan states, which leads to difficult and less remunerative farming (Ministry of Agriculture & Farmers Welfare, 2018). In the hilly regions of Uttarakhand, agriculture is primarily characterized by small and fragmented landholdings, rainfed farming systems, and low levels of mechanization (Department of Agriculture Uttarakhand, 2020). Despite ecological richness and cultural heritage, agriculture in Uttarakhand is low in productivity and highly dependent on climatic conditions, which limits its income-generating potential. The difficult topography limits access to irrigation, modern agricultural inputs and market infrastructure leading to low agricultural productivity (Awasthi, 2010; Bansal & Diwakar, 2024). In these regions, farmers primarily cultivate traditional crops such as millets, pulses, paddy, wheat, and horticultural produce as part of mixed farming systems with livestock rearing (Mohanty et al., 2024). Agriculture is largely for household consumption with low marketable surplus, leading to subsistence-based livelihoods (Department of Agriculture Uttarakhand, 2020; Doss, 2013).

Moreover, increasing challenges such as climate variability, declining soil fertility, wildlife depredation, labour shortages due to outmigration and declining economic returns from farming have further intensified the vulnerability of hill agriculture(Awasthi, 2010; Sharma et al., 2021). As a result, many rural households are compelled to diversify their livelihood strategies beyond conventional farming. In this context, promoting sustainable and diversified agricultural approaches, including horticulture, organic farming, value addition, and farm-based tourism, has emerged as an important pathway for enhancing rural livelihoods and improving the economic resilience of farming communities in Uttarakhand (Lal et al., 2021; Sati, 2021).

Out-migration from the hill regions

The economy of Uttarakhand is a paradox in comparison to the employment opportunities available to the people of the state. While sectors like tourism have contributed greatly to the state's Gross Domestic Product (GDP) and a significant portion of economic output, this development has not been mirrored in local employment in proportion, particularly in rural mountain regions (Shah & Malakar, 2026). The economic activities are unevenly distributed and the development of industrial and service sector is mainly concentrated in the plains like Dehradun, Haridwar and Udham Singh Nagar. In contrast, the hill districts are found lagging in industrialization, infrastructure and employment generation (Planning Commission, 2014). So the rural populations of mountain areas are still dependent on low-return agricultural activities and seasonal work and so there is a disconnection between economic development and livelihood opportunities (Ministry of Statistics and Programme Implementation, 2018). One of the most important effects of this imbalance is the mass exodus from the hilly areas (Sati, 2021). Migration has emerged as a distinct socio-economic phenomenon in Uttarakhand particularly among rural youth. The main push factors for migration are lack of employment opportunities, poor infrastructure, and decreasing agricultural viability (Awasthi, 2010; Sharma et al., 2021). A large section of the rural population migrates to urban centres in search of better

employment, education and living conditions (Government of Uttarakhand, 2018). Studies reveal that more than half of the migration out of Uttarakhand is for employment indicating the lack of opportunities of employment in the state (Awasthi, 2010). This trend has led to the emergence of "ghost villages", rural depopulation, and the abandonment of agricultural land. Besides demographic changes, migration also has a deep impact on rural economies, social structures and cultural continuity (Bansal & Diwakar, 2024). This has led to Uttarakhand being called a "money-order economy", where rural households depend largely on remittances sent by migrant family members. Migration provides short-term economic relief, but it undermines the long-term viability of rural communities and local development (Lal et al., 2021).

Deen Dayal Upadhyay Homestay Scheme

To overcome these challenges, the Government of Uttarakhand has initiated various schemes designed to promote rural livelihoods and check migration. Among these, the DeenDayal Upadhyay Homestay Scheme has become an important intervention for tapping the tourism potential of the state for local economic development. The scheme, launched in 2018, seeks to promote homestay tourism by providing financial assistance and subsidies to rural households for developing accommodation facilities. It seeks to generate self-employment opportunities, particularly for rural youth, while also addressing the shortage of tourist accommodation in remote areas (Lakhera et al., 2025). Homestay tourism provides a distinctive model for inclusive and sustainable development through the active participation of local communities in the tourism value chain. Unlike traditional tourism, which is often a boon for outside investors, homestays allow local people to use their existing resources like houses, land and cultural knowledge to make money (Adhikari, 2023). This model does not only diversify household income but also promotes cultural exchange, preservation of traditional practices and community participation. Research has shown that homestay tourism has a great potential to generate self-employment, improve rural incomes and reduce migration(Tew& Barbieri, 2012). Furthermore, homestays promote the development of agritourism and experiential tourism in mountain areas by merging tourism with agriculture and local traditions (Bhatta &Ohe, 2020; Roman &Kawęcki, 2024). In recent years, homestay initiatives in Uttarakhand have shown encouraging results in terms of livelihood diversification and rural development (Adhikari, 2023; Bhatta et al., 2026). These also provide opportunities for young people to carry out entrepreneurial activities in their home villages thus partially reversing migration trends. In addition, homestays indirectly generate employment through linkages with local supply chains such as agriculture, handicrafts, transportation and cultural services. This multiplier effect increases community resilience and bolsters the rural economy (Kretzmann& McKnight, 1993; Roman & Kawęcki, 2024).

Agritourism

The combination of agricultural activities with tourist experiences led to the emergence of agritourism as a sustainable and innovative way to diversify rural areas. It refers to a type of tourism where travelers participate in farm-based activities and experience agricultural lifestyles, rural culture, local food and natural landscapes. Agritourism provides tourists with the chance to participate in activities such as harvesting crops, feeding livestock, farm stays, nature walks, preparing traditional food and attending cultural festivals, while farmers get another income stream besides traditional farming. Agritourism is being increasingly recognized as an important strategy to diversify livelihoods, particularly in rural and mountain areas where agriculture is becoming less profitable due to increasing production costs, climate variability and fragmented landholdings. Agritourism has increasingly gained recognition as an important livelihood diversification strategy, particularly in rural and mountainous regions. Agritourism has been proposed as a tool to improve farm income, preserve cultural heritage, promote sustainable land use and enhance rural economies at a global levelIt enables farmers to use available farm resources, landscapes and indigenous knowledge to generate additional income, while creating jobs for local communities. Agritourism has been promoted worldwide as a means of increasing farm income, preserving cultural heritage, promoting sustainable land use, and strengthening rural economies. It enables farmers to use available farm resources, farm landscapes and indigenous knowledge to generate additional income and at the same time generate employment opportunities for local communities. Agritourism has economic value but also promotes environmental awareness, cultural exchange and the preservation of traditional farming methods and local food systems.

In the Indian context, agritourism has gained momentum in recent years, especially in states with rich agricultural traditions and tourism potential. In hilly regions such as Uttarakhand, agritourism offers considerable opportunities due to the presence of scenic landscapes, biodiversity, traditional farming systems, and cultural diversity. By linking agriculture with tourism, agritourism can help address challenges of declining farm income, rural unemployment, and out-migration. It also contributes to rural entrepreneurship and supports sustainable community-based development, making it a promising strategy for strengthening rural livelihoods in mountain regions.

Objective of the study

The present study is designed to examine the feasibility and effectiveness of homestay-based agritourism as a strategy for income diversification among mountain dwellers. By focusing on in-depth case studies of two agritourism enterprises BSR Farm and Jack Pahadi Homestay in Pauri Garhwal district, the research aims to provide empirical insights into the operational models, economic contributions, and challenges associated with homestay initiatives. The case study approach allows for a detailed understanding of how individual entrepreneurship, government support, and local resource utilization interact to shape the success of homestay ventures. The study specifically seeks to analyze how homestays contribute to income diversification, employment generation, and reduction of migration pressures in rural mountain regions. It also examines the constraints faced by entrepreneurs in sustaining such ventures, including infrastructural limitations, resource constraints, and market access issues. By doing so, the research contributes to the growing body of literature on agritourism and rural development in the Himalayan context and provides policy-relevant insights for scaling up homestay-based livelihood models.

METHODOLOGY

The present study was conducted in the state of Uttarakhand, located in the Indian Himalayan. The state has witnessed increasing out-migration due to limited livelihood opportunities, making it an appropriate setting to examine homestay-based income diversification. An exploratory research design was adopted, employing a qualitative case study approach to gain in-depth insights into the functioning and feasibility of homestay-based agritourism enterprises. BSR Farm and Jack Pahadi Home stay in Pauri Garhwal district were purposively selected for the study. The selection was based on criteria such as operational diversity, integration of agriculture with tourism, accessibility for field investigation, and their representativeness of emerging rural entrepreneurial models in the region. Both cases reflect distinct approaches to homestay-based income diversification, thereby enabling comparative analysis. Primary data were collected through field visits, direct observation, and informal, in-depth interactions with the entrepreneurs and local stakeholders involved in the enterprises. A comparative framework was applied to examine similarities and differences between the two case studies, thereby enhancing the robustness of the findings.

RESULTS AND DISCUSSION

This section presents the findings from the in-depth case studies of BSR Farm and Jack Pahadi Homestay, highlighting their role in promoting income diversification among rural households in Uttarakhand. The analysis focuses on enterprise structure, livelihood contributions, employment generation, and linkages with local communities. It also examines the integration of agriculture with tourism activities as a strategy for enhancing farm income and resilience. A comparative perspective is adopted to identify similarities and differences in operational models, while simultaneously discussing the key constraints and opportunities influencing the sustainability of homestay-based agritourism in mountain regions.

Case 1: BSR Farm

BSR Farm is a perfect hideaway in the mountains in a small village called Kholachauri situated in the Pauri Garhwal district of Uttarakhand. It is about 10 km from Pauri and is situated at an altitude of around 1600 feet above the mean

sea level. Kholachauri is a tranquil place with oak and deodar trees and apple orchards. The village is surrounded by captivating view of the Himalayan range. The Farm was established in 2016, whereas the Homestay was added in 2019 by its owner, Mr. Abhishek Sen. Mr. Sen is 29 years old and is a passionate entrepreneur. He completed his graduation in Civil Engineering in 2015. After that he attended training program under Dairy Entrepreneurship Development Scheme of the National Dairy Research Institution, Karnal. After completing the training program, he applied for loan under NABARD's DEDS Scheme and in 2016 he established his own dairy farm. Later on, he added poultry and fish farming. After working for three years as agri-entrepreneur, he decided to expand his farm by adding accommodation facilities for the tourists. All these facilities are spread over 34 nali ancestral farm land, which belongs to Mr Sen's family.

Mr. Sen operates the farm with the help of hired labor. Due to snowfall in winter season, farming is mostly confined to summer months. Most of the farm produce is utilized in the homestay and for household consumption. A small quality of farm produce is also sold to the visitors. The homestay was established by Mr. Sento provide exposure of farming, mountains and natural beauty to the tourists coming from different places. The ATC has two types of cottages with all the essential facilities for the visitors. The guests are served local cuisine prepared from farm produce. The Centre also has a conference hall which is used for organizing events, parties, and other gatherings. The farm has a "machan" which is used as an observation deck by the visitors and an open air restaurant for day visitors. Open car parking area is also available for guests. Apart from these facilities, the homestay haslaundry services, luggage carrying assistance and indoor games facilities. The homestay offers various activities to the tourists. Extension Training Centre, Pauri brings group of farmers for farm visits and conducts training programs on dairy, fish farming, poultry, etc. at the agritourism centre. Farming and nature enthusiasts are encouraged to do plantation in the farm premises and they are sent regular updates about the trees planted by them. This activity not only promotes green cover but also helps the owner to keep in touch with the guests and increases the likelihood of their future visits. The guests are allowed to pluck fruits and vegetables on their own or with the help of farm workers and use them for preparing food. Fresh farm produce is available for sale and is often brought by tourists when they leave. Walks to nearby villages are arranged to provide learning experience and fun time for tourist groups. Local guides are hired for these trips, who charge according to the time and places covered.

BSR Centre is situated close to the forest and hiking and other activities are arranged for guests in these forests. Jagriti Swayam Sahayata Samuh, a local band, is often invited for giving music and dance performances. Trekking and camping activities are organized by the Centre and are in great demand. The Centre organizes at least one of these activities during their stay. The Centre organizes three day camps for tourists and treks are planned according to the requirement of the guests. Bird watching, bonfire and celebration of local festivals are other interesting activities organized by the ATC to keep the guests engaged and make their stay memorable and fun-filled. The Centre mostly uses digital media for promotional activities. A private company called "Channel Manager" handles all social media accounts of the homestay. They keep in touch with the visitors through Whatsapp and update them about upcoming events, activities and promotional offers. BSR Farm Homestay is registered on most of the online booking sites and receives a number of reservations through these sites. The Farm receives most of its remittances from accommodation facilities, which is supplemented by other agritourism activities and farm products. The homestay has generated direct and indirect employment for local people. Six people are hired on regular basis for managing the homestay and include three cooks, one care taker and two servers. It is open for guests round the year and when the tourist footfall is high, Mr.Sen employs skilled labor for farm activities from the village on daily wage basis.

Local people are also hired to act as tour guides by Mr. Sen and they get paid according to the itinerary. They charge additional amount for activities like trekking, hiking and village visits. Villagers also earn additional income through various activities such as singing, folk dances, traditional group activities and exhibition of traditional art and crafts. Local taxi drivers are hired for taking guests to nearby places and most of the essential goods are procured from local shops by visitors, thus benefitting local businesses and economy. Mr. Sen has received 25 percent subsidy on the loan

taken from NABARD under the Dairy Employment Development Scheme. Under Deen Dayal Upadhyay Homestay Scheme, he has received 33 percent subsidy on the loan amount and 55 Percent subsidy in the loan taken from bank. Though the homestay is being managed well by Mr. Sen, he reported several constraints. Due to water scarcity in the hills,fulfilling water requirement of the farm and homestay is a herculean task. He tried to operate the fish farm for a year but discontinued it due to scarcity of water.The Centre is 10 km away from Pauritown and is located in the mountains. As a result, Mr Sen finds it difficult to procure goods and services for running the homestay. Most of the essential items for running the ATC have to be procured from Dehradun, which turn out to be expensive. BSR Farm Homestay is situated in a very remote location in Pauri Garhwal district, but the thrill of travelling to a difficult place and beautiful view attract a number of visitors to the farm. Though located at a remote place, the ATC is being managed sustainably and is an important source of income for the owner and local community.

Case 2: Jack Pahadi Homestay

Jack Pahadi Homestay is a versatile agritourism centre situated on the northern slopes of beautiful Garhwal Himalayan ranges at a height of 1900 meters above the mean sea level. It is located in Sila Village in Duggada block in Pauri Garhwal district of Uttarakhand. It is at a distance of about 49 km towards south of the district headquarters and around 85 km from the state capital, Dehradun. Jack Pahadi Homestayis surrounded by deodar forests and is close to number of picnic spots and tourist places like Hanumangadi temple, Lansdowne, BhaironGadi temple, LangoorGadi temple, etc. Most of these places are within walking distance of the ATC and can be easily reached while staying at Jack Pahadi Homestay. Some prominent peaks visible from the homestay are Chaukhamba, Kedarnath Dham, Nanda Devi, Kartikswami,Bhairongadi trek, Trishul, Neelkanth, Chandrashilla Peak. The ATC provides great opportunities forvisitors interested in organic farming, village tours, trekking, cycling, jungle camping, wildlife adventure, aero-sports, angling, rock climbing, bird watching, star gazing, photography, meditation, yoga, etc. Mr. Pankaj Jugral is the owner of Jack Pahadi Homestay. He completed B. Tech in 2017 and worked for an adventure tourism company-Skylink Travel Pvt Ltd., Delhi for one year. After gaining some experience in tourism sector, he moved back to his hometown and started Jack Pahadi Homestay in 2018 and runs it with the help of his parents and younger brother.

Mr. Jugral's family owned agriculture land and his grand-parents practiced farming, but his father discontinued it when he joined the Indian Army. Mr. Jugral realized the potential of tourism and farming on his ancestral land and started polyhouse cultivation of exotic crops on a small scale initially. Later, he scaled it up as he started earning a profit. Presently, he cultivates a wide range of fruits (apple, apricot, citrus fruit and banana), vegetables (tomato, garlic, cabbage, brinjal, tomato, radish, potato, capsicum, cucumber, onion and pea) and excotic vegetables (broccoli, cherry tomato and micro greens) Jack Pahadi Homestay was initially established within the home of Mr. Jugral and no additional investment was made. Later, when he started a profit from the venture, he added various components. Currently, the homestay provides the visitors an experience of Uttarakhand's culture and hospitality and serves local organic produce. The homestay has three standard rooms with shared washroom andtents are also available near the farm for camping. Jack Pahadi Homestay offers several activities for visitors. The guests can participate in farming and help the host family. The tourists can also visit nearby villages and explore rural life and interact with the local people. The ATC organizes local festivals in which the villagers and the guests participate actively. The events are planned beforehand and promoted through social media sites. Apart from engaging the visitors, these events also help in the promotion of homestay and boost the local economy as villagers sell their handicrafts and food items to the visitors during these events. Adventure activities organized by the homestay includetrekking, cycling, jungle camping, wildlife adventure, aero-sports, angling and rock climbing.

The homestay also has three tents which are rented to the visitors interested in camping and the host also arranges other activities such as camp fire, star gazing, bird watching, and photography session for visitors. Professional yoga teachers have been hired by the ATC to organize one to three week workshops. These events are promoted and interested participants can register beforehand and participate in these courses. These camps attract a number of participants from nearby homestays and hotels also. Jack Pahadi Homestay has its own online website

(https://jackpahadihomestay.com/) through which tourists can book their accomodation. Mr. Jugral also promotes the venture through Instagram, YouTube and Facebook. The centre earns revenue mainly by providing accommodation facilities to the visitors. It also sells processed and value added food items for revenue generation. Jack Pahadi Homestay has generated employment opportunities to local people in different sectors. MrJugral is expanding his venture and has employed local people for carrying out the construction work. The construction work has been sponsored under MNREGA and 10-15 people have been provided employment. The homestay organizes trekking activities for visitors in collaboration with local trekking companies. Under this arrangement, the homestay earns a commission, while the trekking company gets customers. Mr. Jugral has availed benefits under two government schemes. He received an amount of Rs two lakh loan under DeenDayal Upadhyay Homestay Scheme from Uttarakhand Tourism Department and subsidy of 33% in return. He has established accommodation facilities from this amount. For construction work at the ATC, the labors were paid under MNREGA scheme. Jack Pahadi Homestay started as an adventure tourism venture and diversified into other activities and services. It is engaged in organic farming and has also established a very innovative setup called eco village for attracting more visitors. During off season, the farm is converted into camping groundand helps the owner to supplement the farm income.

Comparative analysis of BSR Farm and Jack Pahadi Homestay

The highlights two distinct yet complementary models of agritourism-led livelihood diversification in the mountainous context of Uttarakhand. Both enterprises demonstrate how the integration of agriculture with tourism can enhance rural incomes and create sustainable livelihood opportunities, but they differ significantly in their operational strategies and diversification approaches (Figure 1). Perusal of Table 1 explains that BSR Farm follows a relatively structured and resource-based model centered on dairy farming as its core enterprise. Tourism activities are designed to complement farm operations, with an emphasis on experiential learning such as farm visits, fruit picking, and exposure to rural life. The homestay component primarily supports the agricultural base, creating a steady income stream while maintaining a strong linkage with traditional farming practices. In contrast, Jack Pahadi Homestay adopts a more diversified and market-oriented approach by integrating organic farming with adventure and experiential tourism. Its operational model extends beyond agriculture to include activities such as trekking, camping, yoga workshops, and eco-tourism experiences, thereby appealing to a broader segment of tourists. Despite these differences, both case studies share several common features (Table 1). They effectively utilize local natural and cultural resources to design authentic tourist experiences and rely heavily on digital platforms for marketing and outreach. Both enterprises have also contributed to local employment generation, directly through hiring staff and indirectly through linkages with local guides, artisans, and service providers (Table 1). However, the scale and nature of diversification differ notably. BSR Farm exhibits a more agriculture-centric model with limited diversification, whereas Jack Pahadi Homestay reflects a dynamic and adaptive model with multiple revenue streams. These differences underscore the flexibility of agritourism as a livelihood strategy, allowing entrepreneurs to tailor their ventures based on available resources, skills, and market demand.

CONCLUSION

The present study demonstrates that agritourism has considerable potential as a rural diversification strategy in mountain regions. The case studies of BSR Farm and Jack Pahadi Homestay highlight two distinct yet complementary models of agritourism development—one centered on dairy-based farm integration and the other on diversified organic farming and adventure tourism. Both enterprises have successfully leveraged local natural and cultural resources to create unique visitor experiences, thereby enhancing farm income and generating employment opportunities for local communities. Their integration with local supply chains, use of digital marketing platforms, and engagement with government support schemes further strengthen their sustainability. However, the findings also reveal critical challenges, including water scarcity, geographical remoteness, high transportation costs, and infrastructural limitations. These constraints underline the need for improved policy interventions, investment in rural infrastructure, and sustainable resource management practices. In conclusion, agritourism represents a viable

and scalable approach to rural development in the Himalayan context, provided that systemic challenges are addressed through coordinated efforts among policymakers, entrepreneurs, and local communities.

Table 1: Comparative analysis of BSR Farm and Jack Pahadi Homestay

Dimension	BSR Farm	Jack Pahadi Homestay	Comparative Interpretation
Location and Setting	Village:Kholachauri, District:Pauri Garhwal, Uttarakhand	Village:Sila, Block:DuggadaDistrict: Pauri Garhwal, Uttarakhand	Both are located in remote Himalayan villages and capitalize on natural beauty and mountain landscapes for tourism appeal.
Entrepreneurial Background	Civil engineering graduate with training in dairy entrepreneurship	B.Tech graduate with prior experience in adventure tourism	Both ventures are youth-led enterprises initiated by educated entrepreneurs who returned to their native villages.
Genesis of Enterprise	Began as a dairy farm (2016) and diversified into homestay (2019)	Started as an adventure tourism homestay (2018) and diversified into farming	While BSR evolved from agriculture to tourism, Jack Pahadi expanded from tourism into diversified farming.
Agricultural Component	Dairy, poultry, exotic vegetables and farm produce used in homestay	Organic farming with fruits, vegetables, exotic crops under polyhouse	Jack Pahadi demonstrates greater crop diversification, whereas BSR emphasizes integrated farming model.
Tourism and Visitor Activities	Farm visits, fruit plucking, trekking, village walks, bird watching, bonfire and cultural performances	Farming participation, village tours, trekking, cycling, camping, yoga, aero-sports	Both integrate experiential tourism, though Jack Pahadi offers more adventure and wellness-based activities.
Employment generation	Employs local labor, guides, musicians, taxi drivers and artisans	Employment for villagers, trekking companies, yoga instructors, MNREGA workers	Both enterprises generate local employment and foster community participation, though institutional linkages.
Marketing Strategy	Heavy reliance on digital platforms	Self-managed website and social media promotion	Both use digital marketing
Income Sources	Homestay, agritourism activities and sale of organic farm products	Homestay, adventure activities and processed/value-added food products	Both depend mainly on accommodation facilities supplemented by farm-based and tourism-related income diversification.
Government Support	NABARD subsidy under Dairy Entrepreneurship Development Scheme and DeenDayal Upadhyay Homestay Scheme	DeenDayal Upadhyay Homestay Scheme and MNREGA support	Institutional support played a crucial role in both cases.

ABSTRACT

Research on *Cyphostemma setosum*, a rare perennial climber endemic to southern India, is still lacking, especially in the field of in vitro tissue culture, despite the fact that the Vitaceae family contains many species of medicinal significance. Reliable regeneration systems must be established for biotechnological applications, secondary metabolite enhancement, and conservation. Auxins and cytokinins, including α-naphthalene acetic acid (NAA), 2,4-dichlorophenoxyacetic acid (2,4-D), 6 benzylaminopurine (BAP), and kinetin (Kn), were added to Murashige and Skoog (MS) medium in varying concentrations and combinations to grow nodal, internodal, and leaf explants of *C. setosum.* The explants were monitored for callus characteristics, percentage response, and callus initiation time. The significance of interactions between plant growth regulators was assessed through statistical analysis. Depending on the type of explant and the combination of plant growth regulators, callus induction varied considerably. Nodal explants developed callus in 7–8 days on MS medium containing NAA (2.0 μM) + BAP (0.5 μM), with a maximum induction rate of 99.8%. Internodal explants consistently responded when 100% of the friable greenish-white calli were induced using NAA (2.0–2.5 μM) + BAP (0.5 μM) or NAA (2.0 μM) + Kn (0.5 μM). Under NAA (2.0 μM) + BAP (0.5 μM) or NAA (2.0–2.5 μM) + Kn (0.5 μM), leaf explants displayed the fastest and most prolific callusing, reaching 100% induction in 8–10 days. Compact and less proliferative calli were produced by media containing 2,4-D**.** The findings show that rapid and friable callus formation in *C. setosum* is largely dependent on optimized auxin-cytokinin interactions. For this understudied medicinal species, this work establishes the first

standardized and effective callogenesis protocol, laying the groundwork for potential uses in somatic embryogenesis, phytochemical enhancement, genetic transformation, and conservation initiatives.

Keywords: *Cyphostemma setosum,* plant tissue culture, callus induction, explant, plant growth regulators, *in vitro* culture

INTRODUCTION

The 16 genera and 900 species that make up the Vitaceae family are known for their woody climbers with tendrils and fleshy fruits. This family includes the *Vitis, Cissus,* and *Cyphostemma*. These plants' polyphenols, flavonoids, and stilbenes have antibacterial, anti- inflammatory, and anticancer qualities. A perennial climber native to southern India, *Cyphostemma setosum* is used to treat inflammation and digestive issues. Biotechnological research is still scarce despite their therapeutic potential. Callus cultivation is essential for metabolic research and species conservation. *Cissus setosa,* found in arid regions of India, has medicinal applications. The informant consensus factor from the Thoda tribes of Nilgiris, Western Ghats, India, was effective in treating peptic ulcers [1]. Indigenous healers in Tamil Nadu use aerial parts for ulcer treatment [2, 3]. Plant tissue culture involves cultivating cells, tissues, and organs isolated from parent plants on nutrient media [4]. This enables the rapid production of disease-free plants identical to that of parents, facilitates somatic embryogenesis, adventitious bud development, and studies of plant growth and secondary metabolism [5]. Growth regulators are essential for callus formation, and auxin-cytokinin balance is crucial. Specific hormone concentrations depend on endogenous levels, genetics, and tissue type [6]. Plant tissue cultures demonstrate totipotency and cell theory [7]. Researchers have investigated the conditions for organ [8] or tissue [9] cultivation in artificial media [10, 11]. Successful in vitro culture [12, 13] requires proper growth regulators, and their various combinations represent significant advancements in plant tissue culture [14].The ability to regenerate plants has enabled tissue culture applications to study cell differentiation and development using in vitro systems. Key advances include meristem culture for virus-free plants [15] and totipotency in haploid cells for producing is ogenic lines for plant breeding [16, 17].

Conservation of natural resources involves judicious use of Earth's resources through the preservation of genetic, species, and ecological diversity [18, 19], requiring long-term immediate benefits [20]. As the global population approaching eight billion, species extinction rates have increased [21], primarily because of human activities, including development, overexploitation, disturbance, pollution, and non-native species [22, 23]. Plants that contain secondary metabolites are used medicinally [24]. Although synthetic medications such as aspirin have partially replaced natural products, higher plants remain vital sources of secondary metabolites for flavor, fragrance, agrochemical, and medicinal industries [25]. Novel plant-derived compounds warrant prioritization of biodiversity preservation. Plant tissue cultures enable the production of therapeutic compounds [26]. Research has shown that explant type and genotype affect callus formation, with 2,4-D, NAA, BAP, and kinetin acting as regulators following the auxin-cytokinin paradigm [27, 28]. Cissus studies have demonstrated that nodal/leaf explants grown on MS medium with auxin-cytokinin combinations produce calli. *C. quadrangularis* shows effective callus production for phytosterols [29] and robust micropropagation through multiple-shoot induction. Limited callus techniques exist for *cyphostemma* species and *C. setosum* [30, 31]. Optimizing 2,4-D/NAA with BAP/kinetin addresses this gap, given the auxin success in related genera [32]. Despite research on related genera, *Cyphostemma* studies remain limited, with no standardized callus protocol for *C. setosum.* This study aimed to develop callus formation protocols using various explants and PGRs to enable metabolite research and support the conservation of this medicinal species and to assess explant responses for effective in vitro callus induction in *Cyphostemma setosum* (Vitaceae).

MATERIALS AND METHODS

Plant Material Collection: In May 2025, specimens of *Cyphostemma setosum* (Family: Vitaceae) in a mature and healthy state were gathered from natural populations in the Tiruchirappalli district of Tamil Nadu, India, at the geographical coordinates of the peak of the vegetative stage. Latitude: 10.738115°, Longitude: 78.681384°; altitude: approximately 85 m above mean sea level. Red loamy soil, tropical dry deciduous vegetation with sporadic scrub areas, and an average annual rainfall of 800 to 900 mm are the characteristics of the collection site.This species is a perennial climbing vine that grows well in semi-open spaces with moderate sun exposure and lateritic slopes. Using local flora, researchers at the Botanical Survey of India (BSI), Southern Regional Center, Coimbatore, India, confirmed the taxonomic identity of *Cyphostemma setosum* (Roxb.) Alston (Identity No.: BSI/SRC/5/23/2024-25/Tech./372). For future reference, a representative voucher specimen was prepared, pressed, and placed in the Department of Botany's Herbarium at the National College (Autonomous), Tiruchirappalli.

Explant selection: Nodal explants, internode pieces, and juvenile leaf segments were used as the experimental materials for callus induction [33]. To remove any remaining dust or dirt, the explants were thoroughly cleaned for 15 minutes under running tap water and then rinsed with distilled water after being treated with a mild detergent solution. [34].

Surface sterilization: Explant sterilization was performed under aseptic circumstances in a laminar airflow cabinet. Depending on the type of tissue, the prewashed explants were immersed in either 0.1% (w/v) mercuric chloride ($HgCl_2$) or a 2% (v/v) sodium hypochlorite solution for 5–10 minutes after being treated with 70% ethanol for 30–60 seconds. The explants were then rinsed three or four times with sterile double-distilled water to remove any leftover sterilizing agents. **[35].**

Culture medium: Murashige and Skoog (MS, 1962) medium used as the foundational media. It was solidified with 0.8% (w/v) agar and supplemented with 3% (w/v) sucrose [36]. Plant growth regulators (PGRs) include auxins [2,4-dichlorophenoxyacetic acid (2,4-D), α-naphthalene acetic acid (NAA)] and cytokinins [6-benzylaminopurine (BAP), kinetin (Kn)] have been studied in a variety of combinations and concentrations. After adjusting the medium's pH to 5.7 ± 0.1, it was autoclaved for 20 minutes at 121 °C and 15 pressure [37].

Culture conditions: All cultures were maintained at a temperature of 25 ± 2 °C with a photoperiod of 16 h of light and 8 h of darkness [38]. Illumination was provided by cool-white fluorescent lamps, delivering light at an intensity of approximately 40 to 50 μmol m^{-2} s^{-1}. The relative humidity was maintained between 55 and 60 percent [39].

Experimental design and statistical analysis: For each treatment, three independent replicates were employed per experimental condition, with a minimum of ten explants per replicate. The proportion of callus induction was determined by the number of explants that responded [40]. After a culture period of 4–6 weeks, the fresh weight, callus induction frequency, and morphological characteristics were recorded. Using SPSS or GraphPad software, statistical analyses were performed using Duncan's multiple range test (DMRT) and analysis of variance (ANOVA) at a significance level of 5% ($p < 0.05$) [41].

Callus evaluation: Callus formation was evaluated based on percentage response, texture (friable), and coloration (white or creamy yellow) [42]. The fresh weight of the calli was measured after removing excess surface moisture. Morphological observations were documented and photographed using a computerized stereomicroscope [43].

RESULT AND DISSCUSSION

Response of nodal explants to plant growth regulators

Nodal explants of *Cyphostemma setosum* demonstrated a favorable response to in vitro culture, successfully generating calluses under various plant growth regulator (PGR) treatments. Callus initiation was first observed approximately 7–8 days post-culture, with well-established callus masses forming 30 days later. The frequency and morphology of callus formation varied significantly depending on the type and concentration of the applied PGRs (Table 1). Among the auxin treatments, NAA was notably effective in promoting callogenesis, with callus induction increasing with NAA concentrations up to 2.0 mg L^{-1}, followed by a slight decrease at higher concentrations. Nodal explants cultured with 2.0 mg L^{-1} NAA exhibited earlier and more vigorous callus development. Cytokinin treatments, when applied individually, resulted in a comparatively lower callus response. BAP and kinetin at 0.5 mg L^{-1} induced callus formation; however, the resulting calli were generally compact and exhibited limited proliferation compared to those produced under auxin-containing treatments. Conversely, the addition of NAA in combination with BAP significantly enhanced callus induction and proliferation. The most favorable response was observed on MS medium containing NAA (2.0 mg L ^{4}) and BAP (0.5 mg L ^{4}), which produced friable, whitish-green, and rapidly proliferating callus tissues. The combination of NAA and kinetin also supported callus formation, although the response was moderate, and the calli were more compact. The observed variations in callus morphology underscore the significance of PGR type and concentration. Media supplemented with NAA generally promoted friable, pale-green calli, whereas cytokinin-dominated treatments produced compact cream-colored tissues.

Friable callus is particularly desirable for subsequent subculturing and applications involving cell suspension cultures, transformation, and secondary metabolite production. The importance of the auxin–cytokinin balance in regulating callus induction and proliferation has been well documented [20,46]. Thus, the present observations align with the established role of PGR interactions in regulating cellular dedifferentiation and subsequent callus proliferation. The temporal pattern of callus development is shown in Figure 1. During the first week of culture, small proliferating nodular masses appeared primarily at the cut surfaces of explants (Figure 1a). By the second week, these proliferations increased in size and developed into whitish, compact callus tissues (Figure 1b). In the third week, the calli became progressively more friable and developed a pale green to greenish coloration (Figure 1c). After four weeks, well-established, friable, whitish-green callus masses were obtained (Figure 1d). These morphological changes indicate the progressive cellular proliferation and differentiation of explant tissues under optimized PGR conditions. Similar PGR-dependent variations in callus morphology and proliferation have been reported in other plant tissue culture systems [44,47,48]. The present results demonstrate that nodal explants of *C. setosum* respond particularly well to an appropriate auxin–cytokinin combination, with NAA + BAP producing a favorable friable callus phenotype.

Response of internodal explants to plant growth regulators

Internodal explants of C. setosum demonstrated a positive response to in vitro culture under various PGR regimes. Callus initiation typically occurred within 8–10 days, with well-established callus tissue developing after approximately 30 d. The response of internodal explants was contingent upon the concentration and combination of the PGRs employed (Table 2). Among the treatments, the combination of NAA and BAP yielded the most effective results. MS medium supplemented with NAA at 2.0–2.5 mg L^{-1} and BAP at 0.5 mg L^{-1} resulted in the highest callus induction, achieving approximately 100% induction. The calli produced under these conditions were friable, greenish-white, and rapidly proliferating, indicating their suitability for subsequent subculturing. A similarly high callus response was observed with NAA combined with kinetin, particularly at 2.0 mg L^{-1} NAA + 0.5 mg L^{-1} kinetin. However, the callus produced under this treatment was comparatively more compact than that obtained with NAA + BAP. In contrast, cytokinin alone and low concentrations of NAA elicited weak responses in the present study. BAP alone resulted in sparse tissue growth and limited callus development, whereas treatments with lower NAA concentrations delayed callus initiation, generally requiring 25–30 days, and produced compact cream-colored callus masses. The highest callus induction frequency was recorded for MS medium containing NAA (2.0 μM) + BAP (0.5

μM), NAA (2.5 μM) + kinetin (0.5 μM), and NAA (2.0 μM) + kinetin (0.5 μM), with 100.0 ± 0.0% induction, according to the experimental observations. Callus initiation under these treatments occurred within approximately 8–12 days, followed by the development of friable-to-compact green calluses with vigorous proliferation. Conversely, lower NAA concentrations in combination with BAP resulted in significantly lower induction frequencies of approximately 20–30%, along with delayed initiation and weak callus formation. BAP alone produced only 30.0 ± 1.7% callus induction. The progressive development of calluses from internodal explants is depicted in Figure 2. Initial swelling and tissue enlargement were observed at the cut surfaces of the freshly inoculated internodal segments (Figure 2a). Callus initiation was evident after approximately two weeks of culture (Figure 2b), followed by the development of friable callus masses during the third week (Figure 2c). By the fourth week, the calli had developed into more prominent green callus masses (Figure 2d). These results demonstrate that the interaction between auxin and cytokinin is crucial for efficient callus induction in internodal explant. The greater response of internodal tissues compared with nodal tissues may be associated with differences in physiological status, endogenous hormone levels, and morphogenic competence of the explant tissues [45,49]. Similar effects of explant source and PGR combinations on callus induction have been reported for other plant species [10,30,36]. The present results further indicate that internodal tissues can serve as a reliable explant source for establishing proliferative callus cultures in *C. setosum.* The production of friable callus under optimized NAA + BAP conditions is particularly valuable because such callus can be further exploited for subculture, regeneration, and investigations of secondary metabolite production.

Response of leaf explants to plant growth regulators

The *C. setosum* leaf explants demonstrated significant morphogenic potential when subjected to various combinations and concentrations of auxins and cytokinins (Table 3). Callus induction was effectively achieved on MS medium supplemented with NAA, 2,4-D, and BAP, either individually or in combination with kinetin. The response was markedly influenced by the composition and concentration of plant growth regulators (PGRs). Among the assessed treatments, the MS medium containing NAA (2.0 μM), BAP (0.5 μM), and kinetin (0.5 μM) yielded the most favorable outcome, achieving 100% callus induction within approximately 10–12 days. The resulting calli were friable, light green, and exhibited rapid proliferation, indicating their suitability for further subculturing and morphogenetic analysis. A similarly high response was noted with NAA (2.0–2.5 μM) combined with kinetin (0.5 μM), which also resulted in 100% callus induction within approximately 8–12 d. The calli were predominantly greenish-white and friable, with substantial proliferation. Treatment with 2,4-D (5.0 μM) and kinetin (0.5 μM) also achieved a relatively high induction frequency of approximately 90%; however, the resulting callus was comparatively more compact. In contrast, both lower and higher NAA concentrations produced weaker responses in this study.

NAA concentrations of ≤1.0 μM or ≥3.0 μM, particularly when combined with BAP, led to delayed callus initiation of approximately 25–30 days and the formation of compact, cream-colored calli with limited proliferation. Callus development from leaf explants progressed throughout the culture period. Initial swelling and tissue expansion were observed at the cut surfaces within approximately 7–10 days of culture, followed by the emergence of distinct callus masses (Figure 3A–D, callus masses). NAA + BAP treatment produced the most favorable response, achieving 100% callus induction within 8–10 days and generating friable greenish-white calli with strong proliferation. These findings align with previous studies, indicating that the interaction between auxins and cytokinins plays a crucial role in determining callus induction frequency, morphology, and proliferation [20,30,36,44]. The superior response observed under NAA + BAP and NAA + kinetin treatments suggests that an appropriate auxin–cytokinin balance facilitates efficient dedifferentiation and proliferation of leaf tissues. Conversely, the relatively compact callus induced by 2,4-D-containing media may reflect differences in the physiological effects of synthetic auxins on cellular dedifferentiation and proliferation [48]. Similar PGR-dependent responses have been documented in other species, including *Cissus quadrangularis* and *Vitis vinifera* [32,37]. The ability of leaf explants to produce rapidly proliferating friable callus under optimized conditions underscores their potential as an alternative explant source for *C. setosum* tissue-culture.

Comparative response of explants and significance of callus induction

A comparative analysis of the three explant types revealed distinct responses to plant growth regulator (PGR) treatments among nodal, internodal, and leaf tissues. Nodal explants initiated callus formation relatively early, typically within 7–8 days; however, their overall induction response was lower than that of internodal and leaf explants. Internodal explants exhibited a highly consistent response, with treatments involving NAA + BAP and NAA + kinetin achieving up to 100% callus induction rate. Leaf explants also demonstrated a robust morphogenic response, with NAA + BAP + kinetin achieving 100% callus induction within approximately 8–12 d. Consequently, internodal and leaf tissues proved to be more efficient explant sources than nodal tissues under the culture conditions tested in this study. The superior response of internodal and leaf explants may be attributed to their physiological characteristics, endogenous hormone balance, and tissue-specific morphogenic competence [45,49]. These findings underscore the necessity of optimizing both explant type and PGR concentration to establish efficient callus culture. Combinations of auxin and cytokinin were consistently more effective than individual cytokinin treatments, whereas excessive or suboptimal auxin concentrations generally led to delayed initiation and reduced proliferation. The production of friable and rapidly proliferating calli is crucial for downstream biotechnological applications. Friable callus tissues provide suitable material for repeated subcultures, cell suspension cultures, elicitation, and secondary metabolite studies [22,32,35]. Previous research on Vitaceae has also highlighted the potential of callus cultures for the production and investigation of valuable secondary metabolites [32,50]. Therefore, the optimized callus induction system developed in this study provides a valuable foundation for further phytochemical investigations and biotechnological applications of *C. setosum.* Overall, the results indicate that *C. setosum* possesses significant in vitro morphogenic potential, with callus induction strongly dependent on the explant source and PGR combination. Among the treatments tested, NAA in combination with BAP or kinetin consistently promoted rapid and vigorous callus formation, with internodal and leaf explants exhibiting the most favorable overall responses. The establishment of a reproducible callus induction protocol provides a basis for subsequent studies involving plant regeneration, secondary metabolite production, phytochemical profiling, elicitation, and other biotechnological applications of this medicinally important plant species.

CONCLUSION

The present study successfully established efficient protocols for Murashige and Skoog (MS) medium supplemented with different auxin and cytokinin concentrations and combinations was used to induce callus in nodal, internodal, and leaf explants of *Cyphostemma setosum.* Among the treatments evaluated, the combination of NAA with BAP or Kn was found to be the most effective, particularly NAA (2.0 μM) + BAP (0.5 μM) and NAA (2.0 μM) + Kn (0.5 μM), achieving up to 100% callus induction within 8–12 days. The resulting calli were predominantly friable, ranging in color from green to cream, and exhibited varying degrees of proliferation, depending on the explant type and hormonal balance. These results highlight the substantial morphogenic potential of *C. setosum* explants under ideal in vitro conditions and offer a solid basis for future studies on genetic transformation, somatic embryogenesis, and secondary metabolite synthesis. This standardized methodology may contribute to conservation efforts, sustainable utilization, and future biotechnological applications of this rare medicinal plant within the Vitaceae family.

ACKNOWLEDGEMENT

The authors express their sincere gratitude to the Department of Botany, National College (Autonomous), Tiruchirappalli - 620 001, for providing the necessary laboratory facilities and support during the course of this research. The corresponding author, Dilipkumar Yuvaraj, extends heartfelt thanks to his supervisor, Dr. Ramar Karuppiah, for his valuable guidance, encouragement, and critical suggestions throughout the study.

ABSTRACT

Nyctanthes arbor-tristis Linn. is a medicinal plant widely used in traditional healthcare systems because of its diverse pharmacological properties and rich phytochemical composition. The present study investigated the phytochemical constituents, antioxidant activity, antimicrobial efficacy, and bioactive compound profile of the ethanolic leaf extract of N. arbor-tristis. Fresh leaves were extracted by cold maceration using ethanol and subjected to qualitative phytochemical screening, determination of total phenolic content (TPC), total flavonoid content (TFC), thin-layer chromatography (TLC), gas chromatography–mass spectrometry (GC–MS), antioxidant assays (DPPH and FRAP), and antimicrobial evaluation against selected Gram-positive and Gram-negative bacteria. Qualitative phytochemical analysis confirmed the presence of phenolics, flavonoids, alkaloids, tannins, glycosides, steroids, and saponins. The total phenolic and flavonoid contents were estimated as 0.156 mg GAE/g and 3.31 mg QE/g of dry extract, respectively. The ethanolic extract exhibited concentration-dependent antioxidant activity with an IC_{50} value of 27.9 µg/mL, which was comparable to that of the standard antioxidant, ascorbic acid (27.0 µg/mL). The extract also demonstrated promising antibacterial activity against Bacillus subtilis, Pseudomonas fluorescens, Escherichia coli, and Staphylococcus aureus, with the highest activity observed against B. subtilis. GC–MS analysis identified several bioactive compounds, including eugenol, β-caryophyllene, phytol, farnesol, nerolidol, caryophyllene oxide, hexadecanoic acid, and octadecanoic acid, which are known for their antioxidant and antimicrobial properties. These findings support the therapeutic potential of N. arbor-tristis as a promising natural source of bioactive compounds for pharmaceutical and nutraceutical applications.

Keywords: *Nyctanthes arbor-tristis*; phytochemicals; GC–MS; antioxidant activity; antimicrobial activity; medicinal plants

INTRODUCTION

Medicinal plants continue to play a crucial role in healthcare globally due to their rich composition of bioactive secondary metabolites. These compounds contain tannins, alkaloids, flavonoids, terpenoids, steroids, carbohydrates, and iridoid glycosides which are highly effective for their wide range of biological actions, including anti-inflammatory, antioxidant, antibacterial, and other pharmacological effects (Edigaet al., 2005). There has been an increase of interest in plant-based medicines, prompted by the need for medications that are safer, more affordable, readily available and culturally acceptable, alongside the increasing necessity for novel, natural medication alternatives. Nyctanthes arbor-tristis Linn., often known as night jasmine, Parijat, or Harsinghar, is one of several medicinal plants that is very important in traditional medicine systems. This plant is in the Oleaceae family and is well-known for its fragrant blossoms that bloom at night and its many medicinal uses. The name Nyctanthes comes from Greek words that mean "night" and "flower." This is because it blooms at night (Vats et al., 2009; Meshram et al., 2012). N. arbor-tristis is used in traditional medicine to treat a wide range of illnesses, from skin problems and parasite infections to arthritis and fever (Parekh & Soni, 2020; Khushpreet Kaur et al., 2025). N. arbor-tristis is a deciduous shrub or small tree that grows in subtropical and tropical areas. In India, it is found in the outer Himalayan foothills, from Jammu and Kashmir to the Godavari basin, through Nepal, Assam, Bengal, and Tripura (Kritikar& Basu, 1935; as mentioned in Soldier et al., 2024). The plant prefers semi-shaded, quiet areas and usually blooms between July and October (Soldier, Singh, & Singh, 2024). Phytochemical studies of N. arbor-tristis have revealed a diverse array of secondary metabolites. These comprise iridoid glycosides (e.g., arbortristoside A, B, C), flavonoids (kaempferol derivatives), phenolics, terpenoids, steroids, and essential oils (Ashokkumar et al., 2024). Pharmacognostic investigations, encompassing meticulous microscopic analyses of the stem, have delineated tissue organisation, physicochemical properties, and purity indicators, hence facilitating the establishment of quality-control standards (Joshi, Chauhan, Sukanya,&Uniyal,2018).

In vitro and in vivo investigations both strongly support the pharmacological potential of N. arbor-tristis. In recent studies it is observed that the ethanolic extract significantly increased the hemagglutination antibody (HA) titre (humoral response) and foot-pad swelling in the DTH assay. (More, P. R., Tanavade, S. S., Dudhal, N. M., Atole, V. D., & More, S. S. (2023). A bioactive extract was recently confirmed to mitigate inflammation in LPS-stimulated macrophages by blocking the NF-κBsignalling system, hence decreasing the production of pro-inflammatory cytokines (TNF-α, IL-6, IL-1β), reactive oxygen species, and preventing the degradation of IκBα (Sharma et al., 2023). The same study also found that these anti-inflammatory benefits were linked to a number of active substances, such as iridoid glycosides, kaempferol glucosides, and betulinic acid (Sharma et al., 2023). Moreover, N. arbor-tristis extracts exhibit antidiabetic and antibacterial properties; a methanolic leaf extract (ME-NL) demonstrated significant inhibition of mammalian α-glucosidase and inhibited the proliferation of both Gram-positive and Gram-negative bacteria. In silico docking studies corroborate this by revealing stable interactions between flavonoid/glycoside compounds (such as luteolin rhamnosyl-galactoside) and enzyme targets (Govindasamy et al., 2025). The plant's anti-rheumatic efficacy has been confirmed in vivo: hydroethanolic leaf extracts decreased oedema and inflammatory cytokines in a Freund's adjuvant-induced rat arthritis model, corroborating its traditional application in rheumatism (Sharma et al., 2023). There are still gaps in the research, even though a lot of it has been done. For example, there isn't enough data on how phytochemical and pharmacological profiles change in different parts of India. Environmental factors such as soil composition, climate, altitude, and precipitation might alter the manufacture of secondary metabolites. Therefore, it is important to know how these differences in the environment affect the medicinal power of N. arbor-tristis (Khushpreet Kaur et al., 2025). The current work aims to investigate and evaluate the phytochemical composition, antioxidant activity, and other bioactivities present in leaf extracts of Nyctanthes arbor-tristis also this research also seeks to elucidate the plant's therapeutic potential by linking geographical variations with bioactive content and efficacy, thereby informing both traditional practices and futuremedication development.

MATERIAL AND METHODS

Collection of plant materials

Fresh mature leaves were collected from Bhiwadi, Rajasthan in the first week of November2024. The collected plants were identified at the Botany Department, Aligarh Muslim University. Then the collected leaves were separately cleaned with fresh tap water thrice to remove dust and debris over and behind on the leaves. And finally left to dry in the shade for a month then ground to fine powder.Finally crushed fine powder of NAT leaves were proceeded to investigate the study of phytochemicals. Leaves contain Alkaloids, Glycosides, Flavonoids, Steroids, Terpenes and in miscellaneous Ascorbic acid, Amorphous resin, Benzoic acid, Benzoic ester of loganin, carotene, Fructose, Glucose, Hexatriacontane, Mannitol, methyl Salicylate, Tannic Acid. All these important phytoconstituents are being used in Ayurvedic medications and reported for Anthelmintic, Antibacterial, Antifungal, Anti- Inflammatory, Antioxidant, Anti-pyretic, Arthritis, Asthma, Bronchitis, Cholecystagogue constipation, cough Dyspepsia, Flatulence, Heartburn, Hepatoprotective, Immunopotential, Nausea Reptile Venom, Rheumatism, Ringworm & Sciatica etc.

Extraction of Plant Material

The extraction of bioactive constituents from *Nyctanthes arbor-tristis* (NAT) leaves was carried out using a cold maceration technique. Fresh mature leaves (165.0 g) were collected, washed, and shade-dried at room temperature for one month, yielding 45.0 g of dried material. The dried leaves were pulverized using a mechanical grinder to obtain 40.28 g of fine powder, with an observed handling loss of 1–2 g. The approximate yield of dried powdered material from fresh leaves was 24%. A portion of 20.0 g of the air-dried green leaf powder was transferred into a Duran bottle containing 200 mL of ethanol. The mixture was placed on a magnetic stirrer and agitated at 350 rpm for 24 h at ambient temperature (25–30 °C). Following maceration, the mixture was filtered through What man No. 1 filter paper (460 mm × 570 mm), and the plant residue was subsequently washed four times with 20 mL portions of ethanol to ensure exhaustive extraction. The combined filtrate, exhibiting a greenish coloration, was concentrated using a Rotavapor R-300 at 60 °C under reduced pressure (up to 700 mmHg vacuum) to obtain the crude extract. The ethanol-insoluble residue weighed 17.65 g, while the dark green crude extract obtained after solvent removal weighed 2.30 g. The handling loss during the concentration step was 0.05 g. The percentage yield of the ethanol-insoluble residue was calculated to be 88.25%, whereas the crude extract yield was 11.5%. The crude extract was transferred to an airtight container, appropriately labelled, and stored at 4–5 °C until further phytochemical and analytical investigations. Extraction is the method of removing active constituents from a solid or liquid by means of solvent.(Table-1).

Gas Chromatography (GC) and Mass Spectroscopy (GC-MS)

Gas Chromatography (GC) and Gas Chromatography–Mass Spectrometry (GC-MS) analyses were performed to characterize the volatile constituents of the NAT leaf extract. The extract was prepared in AR-grade methanol, and 1 µL of the solution was used for GC-MS injection. Volatile compounds were captured using headspace solid-phase micro-extraction (SPME) with a DVB/CAR/PDMS fiber. The fiber was pre-conditioned in the GC injector port at 270 °C for 4 hours, placed in the sample vial for 20 minutes at room temperature, and subsequently inserted into the injection port for desorption at 260 °C for 10 minutes in splitless mode. Analyses were performed using an Agilent 8890A GC system coupled to a 5975C VL Triple Axis mass detector. Chromatographic separation was achieved on an HP-5MS capillary column (25 m × 0.5 mm, 0.33 µm film thickness) with helium as the carrier gas at a flow rate of 0.6 mL/min. The injector and transfer line temperatures were maintained at 260 °C and 280 °C, respectively. The oven temperature program was set as follows: initial temperature 40 °C (held for 3 min), ramped at 4 °C/min to 160 °C, then increased at 10 °C/min to 280 °C and held for 3 minutes. (Table-1) Mass spectra were recorded in the 33–333 Da range using electron ionization at 70 eV. Compound identification was performed through comparison of acquired mass spectra with the instrument's reference library database. Chemical profiling involved determination of metabolite names, molecular formulas, molecular weights, and structural information for the detected volatile constituents.

Phytochemical Analysis of NAT Crude

NAT leaves extract was analyzed by using conventional protocols for phytochemical screening: -

Determination of Total Phenol Content (TPC): - The total phenolic content (TPC) of NAT leaf crude was determined by Folin Ciocalteu method as described by Singleton and Rossi(Singleton, V.L.; Rossi, J.A..,1965).100µLof the extract is mixed with 500 µL of the FC reagent and 400 µL of Na_2CO_3 at 75% (w/v). After 10 minutes of being stirred and incubated in the dark at room temperature, the absorbance of the solution is measured at 760 nm by using a UV Spectrophotometer. The results are expressed in mg gallic acid equivalent/g of dry extract with reference to the calibration curve of gallic acid.

Determination of Total Flavonoid Content (TFC): - Thetotal flavonoid contents (TFC) of NAT leaf crude was determined as described by (Dehpour A et al.,2009) .500 µL of the extract, 100 µL $AlCl_3$, 100 µL 1M Sodium acetate, and 2.8 mL of distilled water. The mixture is incubated in the dark and at room temperature for 30 minutes of very well stirred. The blank is made by replacing the extract with 95% methanol and the absorbance is measured at 415 nm using UV spectrophotometer.

Qualitative Phytochemicals Screening: Preliminary phytochemical analysis of the NAT leaves extract was carried out using standard qualitative methods to identify the presence of major bioactive constituents (Harborne, 1998; Trease and Evans, 2009).

Carbohydrates (Molisch's Test): A volume of 2 mL of the extract was treated with a few drops of α-naphthol solution, followed by the careful addition of concentrated sulfuric acid along the wall of the test tube. The formation of a violet ring at the interface confirmed the presence of carbohydrates (Harborne, 1998).

Alkaloids (Mayer's Test): The extract (2 mL) was acidified with 1% HCl and heated on a steam bath for 3–4 min, followed by filtration. To 1 mL of the filtrate, Mayer's reagent was added. The appearance of a creamy white precipitate indicated the presence of alkaloids (Trease & Evans, 2009).

Saponins (Foam Test): About 1 mL of the extract was diluted with 8–10 mL of distilled water and shaken vigorously. Persistent foam formation indicated the presence of saponins (Sofowora, 1993).

Tannins (Ferric Chloride Test): To 1 mL of the extract, 2 mL of 5% ferric chloride solution was added. The development of a dark blue coloration confirmed the presence of tannins (Harborne, 1998).

Glycosides (Keller–Killiani Test): The extract (2 mL) was treated with glacial acetic acid containing a trace of ferric chloride, followed by the addition of concentrated sulfuric acid. The formation of a greenish-blue colour indicated the presence of glycosides (Trease & Evans, 2009).

Steroids (Liebermann–Burchard Test): To 2 mL of the extract, acetic anhydride was added, followed by concentrated sulfuric acid. The appearance of a blue coloration confirmed the presence of steroids (Harborne, 1998).

Flavonoids (Shinoda Test): The extract (2 mL) was treated with concentrated HCl and a small amount of magnesium turnings. The development of a pink to red coloration indicated the presence of flavonoids (Sofowora, 1993).

Phenolic Compounds: To 2 mL of the extract, distilled water and ferric chloride solution were added. The formation of a green coloration indicated the presence of phenolic compounds (Harborne, 1998).

Thin Layer Chromatography Profile

The crude extract of NAT leaves was subjected to thin-layer chromatography (TLC) to obtain its preliminary phytochemical profile. The analysis was performed on Merck silica gel 60 F254 aluminium-backed plates. The mobile phase consisted of ethyl acetate: methanol: water in the ratio 7.5:1.5:1.0 (v/v/v), which provided optimal separation of metabolites. The spotted plates were developed in a pre-saturated chamber and subsequently dried in an oven at 80 °C. Visualization of separated components was carried out under UV light using a TLC chamber.

Chromatographic behaviour was evaluated by measuring solvent front migration, solute migration, and corresponding Rf values. The NAT crude extract showed a prominent spot with a solvent run of 8.0 cm, solute run of 6.5 cm, yielding an Rf value of 0.8125, as presented in Table-3.

Biological activities

In VitroAntimicrobial Activity

The extracts of *Nyctanthes arbor-tristis* (NAT) were evaluated for their antibacterial activity against Bacillus subtilis, Staphylococcus aureus, Pseudomonas fluorescens, and Escherichia coli using the serial dilution technique. Approximately 10^9 bacterial cells were inoculated into 10 mL of nutrient broth (Wiegand. Et.Al, 2008). The NAT extracts, including ethanolic (NAT EtOH) and aqueous (NAT aq) extracts (200 µg), were added separately and thoroughly mixed under continuous shaking at 200 rpm, followed by incubation at 37 °C for 48–72 hours. At intervals of 6 hours, 1 mL of the culture was withdrawn, serially diluted up to 10^{-6}, and spread onto nutrient agar plates, which were further incubated at 37 °C for 24 hours. The antibacterial activity was assessed by counting the colony-forming units (CFU) at each dilution. Ampicillin trihydrate was used as a standard reference antibiotic under identical experimental conditions for comparison

DPPH Free Radical Scavenging Assay

The antioxidant potential of the synthesized samples was assessed using two complementary in vitro assays, namely the DPPH free radical scavenging assay as per the methods (Nwidu et al.and Oyaizu).The DPPH (2,2-diphenyl-1-picrylhydrazyl) assay is based on the ability of antioxidants to donate hydrogen or electrons to the stable DPPH radical, resulting in its reduction from a deep violet color to a yellow-colored hydrazine derivative. Briefly, a 0.1 mM DPPH solution was freshly prepared in methanol and protected from light. Different concentrations of the test samples (50–300 µg/mL) were prepared and mixed with an equal volume (1 mL) of DPPH solution. The reaction mixtures were incubated in the dark at room temperature for 30 minutes, after which the absorbance was recorded at 517 nm using a UV–Visible spectrophotometer. A methanol–DPPH mixture without sample served as the control. The percentage scavenging activity was calculated using the following equation:

$$\% \text{ Inhibition} = \frac{A_{\text{control}} - A_{\text{sample}}}{A_{\text{control}}} \times 100$$

A higher percentage inhibition indicated stronger free radical scavenging capacity.

RESULTS AND DISCUSSION

Phytochemical screening: -The phytochemical **analysis** of NAT leaf extract shows in below table as +ve sign & -ve sign for those present or absent: -

Total Phenolic content (TPC) is expressed in terms of Gallic acid equivalents (mg GA eq./g of dry plant extract), whereas total Flavonoids content is expressed in terms of Quercetins equivalents (mg Q eq./ g of dry plant leaves extracts) using the following equation based on the calibration curves(Singleton Et.Al, 1999): -

$Y = 0.007x + 0.186$, Where R^2=0.992.

TPC (mg /g) = C×V/g,

Were,

C = Concentration of gallic acid equivalent from standard curve (µg / mL).

V = Volume of the extract used (mL).

g = Weight of extract and the contents were expressed as gallic acid equivalents (mg GA E / g).

GC-MS Analysis: - The screening and the identification of the volatile compounds of NAT leaves extract were conducted through GC-MS Chromatograph. Using the GC-MS technique more than 35compounds were identified.

***In Vitro* Antimicrobial Activity**

The antimicrobial activity of the test samples was evaluated against B. subtilis, P. fluorescens, E. coli, and S. aureus using the agar well diffusion method (Valgas et al., 2007). The results demonstrated that antimicrobial efficacy followed the order

Subtilis> P. Fluorescens>E. coil > S. aureus

The reference (control) exhibited minimal activity with negligible zones of inhibition, whereas the NAT aqueous extract showed moderate antimicrobial effects. Notably, the NAT alcoholic (ethanolic) extract exhibited the highest antimicrobial activity, producing the largest zones of inhibition against all tested microorganisms, with particularly strong activity against *B.subtilis*. These findings indicate that ethanol is a more effective solvent for extracting bioactive compounds responsible for antimicrobial activity compared to aqueous extraction.

DPPH Free Radical Scavenging Assay

The antioxidant activity of the *Nyctanthesarbor-tristis* leaf extracts was evaluated using the DPPH radical scavenging assay. The assay is based on the ability of antioxidant compounds to donate a hydrogen atom or electron to the DPPH radical, thereby reducing it to 1,1-diphenyl-2-picrylhydrazine(Dehpour, Et. Al.,2009 andSingleton.Et.al,1999). This reduction results in a color change from deep purple to pale yellow, indicating the scavenging potential of the tested samples (Sharma.Et.Al.,2009). The antioxidant activity of aqueous (H_2O) and ethanolic (EtOH) extracts, along with the standard ascorbic acid (AA), was assessed at concentrations ranging from 50 to 300 μg/mL, and the results are presented in Table 3. All samples exhibited a concentration-dependent increase in DPPH radical scavenging activity. The EtOH extract showed strong antioxidant activity, with percentage inhibition ranging from 89.53% to 93.89%, which was comparable to that of the standard ascorbic acid (94.57% to 95.80%). In contrast, the H_2O extract demonstrated moderate activity, with inhibition values ranging from 68.23% to 92.45%. The IC_{50} values were determined to be 36.6 μg/mL for the H_2O extract, 27.9 μg/mL for the EtOH extract, and 27.0 μg/mL for ascorbic acid. Since lower IC_{50} values indicate higher antioxidant activity, the EtOH extract exhibited excellent radical scavenging potential, comparable to the standard antioxidant. The aqueous extract, however, showed comparatively lower activity. Below table shows the IC_{50} values of the antioxidant's activities ofleaves ethanol extract in comparison with ascorbicacid for DPPH (2,2-Diphenyl-1- picryl hydrazyl) and FRAP (Ferric reducing antioxidant Powder) assays respectively.

Conclusion: -

Phytochemicals screening results, GC-MS analysis results and in Vitro biological activities study validate the ample amounts of bioactive compounds in NAT Leaves extract that places it in a position to be a potential source of natural antioxidants and anti-inflammation bio-active molecule. The biological activities observed in the present study appear closely associated with the phytochemical composition of the ethanolic extract. Phenolic compounds and flavonoids contribute substantially to antioxidant activity through hydrogen atom donation and electron transfer, while terpenoids such as β-caryophyllene, phytol, nerolidol, and farnesol contribute to antimicrobial and anti-inflammatory effects. Rather than acting independently, these metabolites are likely to function synergistically, producing greater biological activity than individual compounds alone. This synergistic effect is a characteristic feature of many medicinal plant extracts and may partly explain the broad pharmacological profile of N. arbor-tristis.

ACKNOWLEDGEMENT

The authors thanks to all the R&D department fellows who helped us incompleting all the biological activities and analysis

Competing interests / COI statement: -There is no conflict of interest between the authors.
Funding: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

ABSTRACT

Kombucha is a fermented tea beverage produced by a symbiotic culture of bacteria and yeasts (SCOBY), in which bacterial cellulose formation is strongly influenced by fermentation conditions. The present study investigated the effects of incubation temperature, carbon source type, and carbon source concentration on SCOBY development and bacterial cellulose production. Kombucha stock cultures were prepared from black tea and fermented under static aerobic conditions. The influence of refrigeration and room temperature on SCOBY formation was first evaluated using different carbon sources. Subsequently, dextrose, fructose, sucrose, jaggery, brown sugar, and honey were tested at concentrations of 1–5 g (honey: equivalent volume) to determine the optimum conditions for cellulose production. Room-temperature incubation supported active fermentation and the formation of a thick bacterial cellulose pellicle, whereas refrigeration completely inhibited SCOBY development. The type of carbon source significantly affected the rate of SCOBY initiation and cellulose production. Jaggery initiated SCOBY formation earliest (3 days), while dextrose, fructose, sucrose, and brown sugar-initiated growth after 4 days and honey after 5 days. The optimum carbon source concentrations for maximum bacterial cellulose production were 4 g dextrose, 5 g fructose, 2 g sucrose, 2 g jaggery, 2 g brown sugar, and 2 mL honey. The results demonstrate that bacterial cellulose production is dependent on both the nature and concentration of the carbon source, and that excessive substrate levels do not necessarily improve cellulose yield. Findings provide practical insights for optimizing kombucha fermentation and identify inexpensive natural carbon sources, particularly jaggery and brown sugar, as promising alternatives for efficient bacterial cellulose production. The study contributes to the development of cost-effective and sustainable fermentation strategies for food, biotechnological, and biomaterial applications.

Keywords: Kombucha, SCOBY, Bacterial cellulose, Carbon source, Fermentation, Jaggery, Brown sugar, Temperature optimization

INTRODUCTION

Kombucha is a low-alcohol beverage which contains a lot of bioactive substances from plant material(tea, juices, herbs, extracts) and microbe's metabolic activities (lactic acid bacteria, yeasts, and acetic acid bacteria). Nowadays, it attracts an increasing number people due to its health-promoting characteristics (Antolak, 2021).The Japanese term for this slightly fermented tea beverages is Germanized and used internationally as kombucha. Due to its therapeutic properties, it was initially utilized in East Asia. During the Tsin Dynasty (also known as "Ling Chi") in northeastern China (Manchuria), around 220 B.C., kombucha was highly valued for its stimulating and cleansing qualities. The tea fungus was brought to Japan in 414 A.D. by the doctor Kombu, who physician it to treat patients Inkyo's intestinal issues. Kombucha (formerly known as "Mo-Gu") first appeared in Russian of Eastern Europe as trade routes grew. Around the turn of the 20th century, it appeared in Germany (as Heldenpilz, kombuchaschwamm) (Jayabalan, 2014).
A symbiotic culture of acetic acid bacteria is used to make kombucha tea. (Acetic Acid Bacteria; *Komagataeibacter, Gluconobacter*and *Acetobacter* species)(De Roos& De Vuyst, 2018), lactic acid bacteria(*Lactobacillus, Lactococcus*) and yeasts (*Saccharomycodesludwigii, schizosaccharomyces pombe, Zygosacchromycesbailii, Kloeckera apiculate, Brettanomyces bruxellensis, Saccharomyces cerevisiae, Torulasporadelbrueckii*) (Coton *et al*., 2017; Vilarreal-Soto *et al*., 2018).Final sugar concentration can vary between fermentations, suggesting that the metabolic route is not always carried out in the same manner (Chen & Liu, 2000).Although there is currently no conclusive scientific proof of this beverage's effectiveness, it is said to have several therapeutic benefits, including the ability to treat metabolic disease, arthritis, psoriasis, constipation, indigestion, and hypertension (Sreeramulu*et al*., 2000). Kombucha tea is believed to lower blood and cholesterol, promote weight loss, enhance liver, glandular, immune, and gastric function, lessen kidney calcification, boost vitality, fight acne, get rid of wrinkles, purify the gall bladder, ease constipation, relieve arthritis pain, stop the growth of cancer, treat AIDS, and many more. There are some signs that drinking kombucha tea may help with health prophylaxis and recovery through detoxifying, anti-oxidation, revitalizing, and immune-stimulating actions, although the majority of these health advantages are unproven and based on individual observation and testimonials. (Laureys *et al*., 2013).

MATERIAL AND METHOD

Material: Kombucha SCOBY (Symbiotic Culture of Bacteria and Yeast), Black tea, Glucose (Dextrose anhydrous), fructose (levulose), Brown sugar, jiggery, honey, distilled water, sugar, sterile glass Viles (30 ml), glass jar, pipet, gloves, strainer and cotton muslin cloth were used in the study.

Method: Kombucha stock culture was prepared following the method described by Sievers and their team in 1995 with minor modification

Preparation of kombucha SCOBY stock culture:
The tea infusion was made by boiling distilled water, then adding sugar and black tea. The infusion was filtered into a sterile glass jar when it had cooled to room temperature after boiling. The filtrate was aseptically treated with an active kombucha SCOBY. In order to allow aerobic respiration, the jar was covered with sterile cotton muslin cloth. It was then incubated under static circumstances in a dry, dark and undisturbed setting, away from insects, dampness, and direct sunlight. The produced SCOBY was utilized as a stock culture for additional research after 15-20 days of fermentation.

Fermentation of kombucha at various temperatures and carbon sources:
Two temperature condition and various carbon sources were used for kombucha fermentation. 20 mL of kombucha stock culture was put into sterile 30 ml glass vials, which were then individually supplemented with 5 gm of dextrose anhydrous, 5 gm of levulose, 5 gm of brown sugar, 5 gm pf jiggery and 5 ml of honey. A culture without any

additional carbon source was used as the control. Every treatment was made in duplicate sets, one of which was kept at a low temperature (refrigeration) and the other at ambient temperature. For fifteen days, all culture were incubated in both static and aerobic conditions. To assess the impact of temperature and carbon supply on kombucha fermentation, the thickness and development of the upper SCOBY layer were measured.

Using Various Carbon Sources and Concentration for Kombucha Fermentation:

20 mL of kombucha stock culture was aseptically transferred into sterile 30 mL glass vials for each treatment. Levulose, sucrose, brown sugar, jiggery, and honey, and honey were added at quantities of 1, 2, 3, 4, and 5 gm per vial, and dextrose anhydrous at values of 1, 2, 3, 4, and 5 gm per vial. Additionally, a control with20 mL of kombucha culture and no addition carbon source was kept. Every vial kept out of direct sunlight, dampness, and insect contamination while being incubated at room temperature in both static and aerobic conditions. Throughout the fermentation process, SCOBY development and cellulose layer thickness were routinely monitored.

RESULTS AND DISCUSSION

SCOBY development and effect of temperature on kombucha fermentation

Temperature**s** impact on kombucha fermentation and SCOBY development within 15 to 20 days, a thick, gelatinous cellulose layer formed from static aerobic fermentation of kombucha, including the effective establishment of a new SCOBY appropriate for further experimental usage. The effective establishment of new SCOBY appropriate for further experimental usages. The fermented liquid that remained was used as an active kombucha stock media. Temperature was a crucial factor in the formation of SCOBY because, while all tested carbon sources promoted SCOBY development at room temperature, no SCOBY formation was seen at low (refrigeration) temperatures, indicating that microbial metabolic activity and cellulose synthesis were suppressed at lower temperatures.

Impact of carbon sources and their amount on the production of SCOBY

The rate of SCOBY initiation and growth at room temperature was greatly impacted by the type of carbon supply. The earliest SCOBY formation was supported by jiggery out of all the subtracted studied; on the third day of incubation, cellulose layer development was clearly visible. While honey showed delayed SCOBY formation starting on the fifth day of fermentation, dextrose anhydrous, levulose, sucrose, and brown sugar showed SCOBY initiation on the fourth day. The efficiency of SCOBY creation was also impacted by variations in the quantity of carbon sources; after ten days, the highest SCOBY formation was noted at 4 gm dextrose anhydrous, 5 gm levulose (fructose), 2 gm jiggery, 2 gm brown sugar, and 2 gm honey. Because of its quick SCOBY initiation and high cellulose production at relatively low concentrations, jiggery emerged as the most efficient carbon source. In contrast, honey consistently displayed slower fermentation kinetics. SCOBY production was directly proportional to fermentation rate and substrate utilization efficiency.

CONCLUSION

This study demonstrates that both carbon source type and concentration, together with incubation temperature, play critical roles in kombucha fermentation and bacterial cellulose (SCOBY) production. Room-temperature incubation supported active microbial metabolism and consistent cellulose biosynthesis, whereas refrigeration effectively inhibited SCOBY formation, highlighting the importance of appropriate fermentation temperature.Among the evaluated carbon sources, jaggery promoted the earliest SCOBY initiation, indicating rapid microbial adaptation and efficient substrate utilization. The optimal concentration for maximum bacterial cellulose production differed among carbon sources, with 4 g dextrose, 5 g fructose, 2 g sucrose, 2 g jaggery, 2 g brown sugar, and 2 mL honey producing the greatest cellulose formation under the experimental conditions. These findings demonstrate that increasing carbon concentration does not necessarily enhance cellulose production and that each carbon source possesses a distinct optimum concentration for efficient fermentation. Naturally derived carbon sources, particularly jaggery and

brown sugar, supported bacterial cellulose production comparable to or better than refined sugars while requiring relatively lower concentrations, suggesting their potential as economical and sustainable substrates for kombucha fermentation. The results provide a practical basis for optimizing fermentation media to improve bacterial cellulose yield and SCOBY development. Further investigations should quantify cellulose yield, evaluate physicochemical and mechanical properties of the produced bacterial cellulose, characterize changes in microbial community composition during fermentation, and validate these findings under larger-scale fermentation systems. Such studies will strengthen the application of optimized kombucha fermentation for sustainable bacterial cellulose production in food, biomedical, and biotechnological industries.

5	Brown sugar	4	2 gm
6	Honey	5	2 ml

Table 2: Effect of Different Carbon sources and their concentrations on bacterial cellulose production

No.	Observation	Experimental photograph
1	The glucose supplemented media showed a concentration dependent response when compared to the control (CTRL). Growth was lower in media with 1 gm and 2 gm of glucose than in the control. On the other hand, growth was improved by supplementing with 3 gm, 4 gm, and 5 gm of glucose. The 4 gm glucose supplemented medium was found to be the ideal condition since it generated the greatest growth response out of all the tested doses.	
2	Comparison with the control, the fructose media exhibited a concentration dependent response. Media containing 1 gm, 2 gm and 3 gm fructose showed a reduction in growth relative to the control. In contrast, supplementation with 4 gm, 5 gm fructose resulted in enhanced growth. Among all tested concentrations, the 5 gm fructose supplemented medium produced the highest growth response and was identified as optimal condition.	
3	Relative to the control, media supplement with higher sucrose concentration 3 gm, 4 gm and 5 gm significantly reduced cellulose growth compared to the control, whereas lower sucrose concentrations (1 gm, 2 gm) significantly increased bacterial cellulose production. Of all the treatments, the2 gm sucrose supplemented medium showed the best growth performance and was found to be the best concentration.	
4	When compared to the control bacterial cellulose synthesis was affected by jaggery supplement, 2 gm, 3gm and 4 gm jaggery media show considerably boosted bacterial cellulose production, while 1 gm and 5 gm jaggery media dramatically decreased cellulose growth in compare to control. The 2-gm jaggery supplemented medium was shownto be the best concentration amongall the treatments.	
5	Comparison to the control, a 1 gm less carbon concentration reduced bacterial cellulose layer. However, excessive carbon media like 2 gm, 3 gm, 4 gm and 5 gm enhanced bacterial cellulose layer, 2 gm brown sugar media show higher production of bacterial cellulose.	

6	A higher carbon concentration 2 gm, 3 gm, 4 gm, 5 gm encouraged increased bacterial cellulose synthesis as compared to the control, and 1gm honey concentrated media almost similar result show with control.

ABSTRACT

In this paper, a new term called Meta near rings was introduced. The role of meta near rings with regularity conditions, reversibility, regativity is being discussed. Meta near ring being adhering to regativity, booleanity and σ_1 property is strong S_1near ring. The structural framework of the meta near ring has been obtained with its algebraic structures.

Keywords: Meta near rings, Left-regular near ring, P_3property, Right transitive, R- near ring, Regative near ring, Cyclic weak commutative

INTRODUCTION

Meta near rings is a new notion in algbebraic structure in near ring theory. The near ring (N,+,.) defined on Klein's four group (N,+) with N = {0, a, b, c} where '.' is defined in the following table as per scheme 9, of Gunter Pilz, satisfies the condition of meta near ring. The role of intra-regularity and right strongly regularity is being intensely justified in meta near ring and thus yields another diverse algebraic substructure called Strong S2 near ring. The ideology behind meta near ring is to combine this new substructure into diverse other properties and substructures in near rings in order to come up with another prominent structures in near rings. The structural framework of meta near rings is being obtained which clearly illustrates the prominence of such structure.

Preliminaries

A (right) near ring [8] N is a set N together with two binary operations"." and "+" such that (N,+) is a group, (N, .) is a semi-group and $(n_1 + n_2)\, n_3 = n_1n_3 + n_2n_3$ for all $n_1, n_2, n_3 \in N$. A near ring N is said to be Regular [3] if $\forall\ a \in N, \exists\ x \in N$ such that axa = a. A near ring N is said to be Pseudo (m,n) power commutative near ring [6] if $x^my^nz = zy^mx^n \forall\ x, y, \in z$ and it is said to be reversible if ab = 0 ⇒ba = 0 ∀ a, b ∈ N. A regative near ring is defined as aba = ab and ab = ba∀a,b∈ N. A near ring N is said to be right strongly regular if $a = a^2x$, for all a,x in N. A near ring is said to be left transitive if xyxz = yz, ∀ x, y, z ∈ N. A near ring N is said to be intra regular [3] if $a = xa^2y$, ∀ a, x, y ∈ N and every regular near ring is intra regular near ring. A near ring is Strong S2 near ring if axa = ax, for all a,x in N and is said to be Strong S_1 near ring if axa = xa, for all a,x in N. A near ring N is said to be m-power commutative if $x^my = y^mx$, for all x,y in N and m is a positive integer. R- near ring is defined as for all 'a' in N, there exists 'x' in N such that xax = xa and P_3 property is defined as near ring satisfying weak commutative condition, which means xyz = xzy, for all x,y,z in N. Some of the basic properties of near ring include boolean, which means $a^2 = a$, for all 'a' in N and central if ae = ea, for all 'a' in N. Left singular property is defined as ab = a and right singular property is ab = b. Some of the prominent substructures in near ring theory include Strong δ near rings, strongly regular, σ_1 near rings and so on. Here comes the definition for the above substructures, when N is Strong δ it satisfies $axa = a^2x^2$, for all a,x in N; when N is Strongly regular it holds $a = xa^2$ and a = aax, for all a,x in N; and is σ_1 near ring, it adheres to $xy^2 = yxy$, for all x,yin N. Medial near ring is defined as xyzt = xzyt, for all x,yz,t in N. A near ring N is said to be I-quasi-weak commutative if xyz = yxz, for all x,y,z in E of N and called as I-quasi cyclic weak commutative if xyz = zxy, for all x,y,z in E of N.

Main Results

Definition 3.1

A right near ring N is called Meta near ring if $ab = ba^2b$, for all a,b in N.

Theorem 3.2

A right strongly and intra-regular meta near ring is a Strong S_2 near ring, whenever it holds pseudo commutativity and left transitivity.

Proof: Let N be a meta near ring, which means $ab = ba^2b$, ∀a,b∈ N—(1)

And N is intra-regular near ring. Then $a = ba^2y$ ∀a,b,y∈ N—(2).

Considering equation (2) in ab, we get: $ab = (ba^2y)\ b = baayb = ba(ayb) = ba(bya) = (baby)a$. Since, N is left transitive, we get ab = aya—(3). Similarly, make use of equation (2) in ba^2b, we get: $ba^2b = ba^2\ (ab^2y) = ba^2ab^2y = ba^3b^2y = ba(aab)by = ba(baa)by = (baba)by = ba(baby) = ba(ay) = ba^2y$.

Hence, for all a,b in N, $ba^2b = ba^2y$—(4).

Making use of equation (1) after comparing equation (3) and (4), we get:

$aya = ba^2y = baay = (baa)y = (aab)y = (a^2b)\ y$. And here since, N is right strongly regular, we get aya = ay, ∀a,y∈ N which completes the proof that N is Strong S_2 near ring.

Proposition 3.3

Every right strongly regular commutative near ring is meta near ring

Proof: Let N be a Strongly regular near ring.

Consider, $ba^2b = b(a^2b) = ba = ab \Rightarrow ab = ba^2b$ ∀a,b∈ N. Hence, N is a meta near ring.

Following this, here comes the structural theorem of Meta near rings along with its algebraic structures.

Theorem 3.4

Let N be a boolean meta near ring. Then, N holds the following:

(i) Every weak commutative near ring is central

(ii)Every regular near ring is right central

(iii)Every m-power commutative regular near ring is left singular

(iv)Every R- near ring is central

(v) Every regular near ring with P3 property is Strong δ near ring.

Proof: Let N be a meta near ring, which means $ab = ba^2b$, $\forall a,b \in N$.—(1)
(i) Considering the above equation, $ab = ba^2b = bab$.
Since N holds P_3 property, then we get $ab = bba = b^2a = ba \Rightarrow ab = ba \forall a,b \in N$.
(ii) Consider (1): $ab = ba^2b = bab$. Since, N holds regularity, we get $ab = b \Rightarrow ab = b$, $\forall a,b \in N$, which ends the proof that N is right singular near ring
(iii) Consider (1), $xy = yx^2y = y(x^2y) = y(yx^2)$ (since, N is m-power commutative) $= y^2x^2 = (y^2x)\,x = (x^2y)\,x = x(xyx)$.
Applying regular condition, the above equation becomes, $xy = xx = x^2 = x \Rightarrow xy = x$, $\forall x,y$ in N. Hence, N is left singular.
(iv) Let N be a R near ring. Then $xyx = yx^2y$, $\forall x,y \in N$ —(2) and $xy = yx^2y$.
Consider (1), $xy = yxxy = yx(xy)$. Now applying the condition of R near ring to the above equation, we get $xy = yx(xyx) = (yxx)yx = yx(xyx) = (yxy)(xyx) = y(xyx)yx = y(xy)yx$ (by (2)).
Now by using associativity, $xy = (yxy)yx = (yx)yx = (yx)^2 = yx$. $\Rightarrow\Rightarrow xy = yx$, $\forall x,y \in N$. Therefore, N is central.
(v) Consider, $a^2x^2 = aaxx = a(ax)x$.
Make use of equation (1), we get, $a^2x^2 = a(xa^2x)\,x = (axa)ax^2 = (axa)ax$.

Apply regular condition over the above equation: $a^2x^2 = a^2x = aax = axa$ which is obtained by P_3 property. Hence, $a^2x^2 = axa$, for all a,x in N, shows that N is strong δ near ring.

Theorem 3.5 A meta near ring is central whenever it adheres to strong regularity
Proof: Let N be a meta near ring. Consider, $yx^2y = yxxy = (yx)xy = (xy^2x)xy = (xy^2)(x^2y)$. Now by using, strongly regular condition, we get: $yx^2y = yx$
$\Rightarrow yx^2y = yx \Rightarrow\Rightarrow xy = yx$, $\forall x,y \in N$. Hence, N is central.
Proposition 3.6
Every meta near ring is reversible
Proof: Let N be a meta near ring. Now to prove that, $xy = 0 \Rightarrow yx = 0$, $\forall x,y \in N$.
Consider, $yx = xy^2x = xyyx = (xy)yx = 0.yx = 0 \Rightarrow\Rightarrow yx = 0$ $\forall x,y \in N$.
Hence, N is reversible.

Theorem 3.7
Meta near governed by regularity exhibiting P_3 property is commutative.
Proof: Let N be a meta near ring. Then $xy = yx^2y$ $\forall x,y \in N$— (1). Now using meta near ring over yxy: $yxy = y(xy) = y(yx^2y) = y^2x^2y = y^2x(xy) = y^2x(yx^2y) = y^2(xy)x^2y = y(yxy)x^2y = y^2(xyx)xy$. Since, N is regular, we get, $yxy = y^2xxy = (yyx)xy = (yxy)xy$ (by P_3 property). Again, by making use of P_3 property, we get $yxy = y(xyx)y = y(x^2y)\,y = (yx^2y)y = (xy)y = xy^2$. By right cancellation law, $yxy = xy^2$ becomes $yx = xy$, $\forall x,y \in N$. Hence, N is commutative.

Theorem 3.8
A meta near ring is Strong S_1 if it satisfies the following:
(i)Booleanity (ii)Regative σ_1 near ring.
Proof (i) Consider, $xa = ax^2a = axa \Rightarrow xa = axa$, $\forall a$, $x \in N$. So, N is Strong S_1 near ring.
(ii) Let N be a meta near ring and given that N is regative, which means $xyx = xy$ and $xy = yx$. Consider, $yx^2y = (yx)xy = (yxy)xy = y(xyx)y = y(xy)y = (yxy)y = (yx)y = (xy)y = (xyx)y = x(yxy) = xyx = (xy)x = yx^2 \Rightarrow yx^2y = yx^2 \Rightarrow xy = yx^2$ (Since, N is meta near ring) $\Rightarrow xy = xyx$ (by using σ_1 near ring) $\Rightarrow yx = xyx$, $\forall x,y \in N$. Hence, N is Strong S_1 near ring.

Theorem 3.9
Every Meta near ring adheres to regularity with P_3 property satisfies the multiplicative relation of 'a' on 'x' as 'y', for all x,y in N.
Proof: Let N be a meta near ring; then $xy = yx^2y$, for all x,y in N. Since, every regular near ring is intra-regular near ring, and using this, we get:
$xy = x(xy^2a) = x^2y^2a = x^2y^2(axa) = x^2(yya)xa = x^2(yay)xa$.
Now by using regularity, it becomes $xy = x^2axa = x^2a \Rightarrow\Rightarrow xy = x^2a$—(1).
Consider (1) and apply P_3 property and regularity, $yx^2y = yx^2(yxy) = yx(xyx)y = yxxy$

= y(xxy) = y(xyx) = yx ⟹ yx^2y = yx— (2).
From (1) and (2), it is clear that x^2a = yx⇒ x^2a − yx = 0 ⇒x(xa − y) = 0.
Either x = 0 (or) xa − y = 0 ⇒xa = y ∀ a, x, y ∈ N.
Hence, the multiplicative relation of 'a' on 'x' is 'y', for all a,x,y in N.

Theorem 3.10
An ideal in a meta near ring holds commutative property.
Proof: Let N be a meta near ring. Let z ∈ AB, where A and B are ideals of N. Then, for some x ∈ A and y ∈ B, z = xy = yx^2y
= yxxy∈ BA^2B ⊆ BA
⇒ AB ⊆ BA —>(1). Now, it is enough to prove that BA ⊆ AB.
Let w ∈ BA. Then, for some q ∈ B and r ∈ A,
w = qr = qr^2q
= qrrq∈ AB^2A ⊆ AB
⇒ BA ⊆ AB—(2).
Hence, AB = BA, where A and B are ideals of N. This completes the proof that every ideal in N is commutative.

CONCLUSION

The concept of meta near ring thus provides a wide-ranging framework and further broad openings for other prominent algebraic substructures which paves a way for theoretical application. The concept of I-meta near rings can be further extended to Boolean -like near rings and structural framework of I-meta near rings can be obtained. The role of meta near ring plays an ardent role when it comes to medial substructures dealing with four elements in near rings and when applied along with intra-regular and commutative substructures, many new notions of mediality can be obtained. Thus, role of meta near ring plays a significant role in enhancing the theoretical and applicational standards of near ring theory. Similarly, meta near rings can be further extended to some other new notions of algebraic structures by making modifications.

ABSTRACT

The rapid integration of generative AI tools such as ChatGPT in higher education has transformed students' approaches to reading, writing, and thinking, particularly within Outcome-Based Education (OBE) frameworks in India. While AI enhances linguistic fluency and efficiency, its unstructured use raises concerns regarding reduced cognitive engagement, weakened critical thinking, and increasing reliance on "shortcut" approaches to learning. Grounded in Flower and Hayes's Cognitive Process Theory of Writing, which conceptualises writing as a recursive and metacognitively guided process, this study examines how AI can be integrated without displacing the learner's cognitive work. The study addresses two research questions: how students use ChatGPT for academic purposes and perceive its impact on reading, writing, thinking, and participation, and whether a structured pedagogical framework can support responsible AI use while enhancing creative literacy and critical thinking. Adopting a mixed-method design, the study combines a large-scale descriptive survey of 627 undergraduate students across multiple institutions in India with a quasi-experimental classroom intervention involving 65 first-year Computer Engineering students enrolled in a communication course. Data were collected through a structured questionnaire and rubric-based assessment of pre- and post-intervention writing tasks, supported by qualitative analysis of student reviews and process notes. The study proposes the I-DEEE-O model (Ideate, Debate, Enrich, Examine, Evaluate, Original Work), developed by the author, as a process-oriented framework for responsible AI use in academic writing. Findings indicate that while students widely perceive AI as improving writing efficiency, it is also associated with reduced reading and increased procrastination. Notably, 73% of students demonstrated

improvement in at least two rubric dimensions after the intervention, showing enhanced critical thinking, textual engagement, and originality. The study concludes that structured pedagogical frameworks such as I-DEEE-O can reposition AI from a tool of convenience to a support for reflective and cognitively engaged learning, aligning its use with the goals of OBE.

Keywords: AI in education, ChatGPT, academic writing, cognitive process theory, creative literacy, digital pedagogy, learner autonomy, responsible AI use

INTRODUCTION

The rapid emergence of generative Artificial Intelligence (AI) tools, particularly ChatGPT, has begun to reshape academic practices in higher education. Students increasingly rely on such tools to explain concepts, summarise readings, and generate written responses, making AI an embedded part of everyday learning. While these tools offer advantages such as speed, accessibility, and linguistic support, their growing use raises important pedagogical concerns about the nature of student engagement with knowledge. In the context of Indian higher education, this transformation intersects with the implementation of Outcome-Based Education (OBE), which emphasises demonstrable competencies such as critical thinking, effective communication, creativity, and ethical responsibility. OBE frameworks require that learning outcomes be observable in student performance; however, when students depend heavily on AI-generated content, the visibility of their own cognitive processes becomes uncertain. The concern is not merely about academic integrity, but about whether students are meaningfully engaging with ideas or relying on algorithmic outputs as substitutes for thinking.

A central tension thus emerges between efficiency and engagement. AI enables students to produce grammatically sound and well-structured responses with minimal effort, but this convenience may reduce sustained interaction with texts, limit interpretive depth, and discourage independent problem-solving. Writing, particularly in academic contexts, is not only a means of communication but also a process through which thinking is developed and refined. If key stages of writing are outsourced to AI, the student's role risks being reduced to that of a surface-level editor rather than an active meaning-maker. This study responds to these concerns by exploring how AI can be integrated into classroom practices without displacing the learner's cognitive engagement. Rather than positioning AI as either a threat or a solution, the study approaches it as a pedagogical challenge that requires structured and reflective use. It proposes a process-oriented framework that encourages students to interact critically with AI outputs while retaining ownership of their thinking and writing.

LITERATURE REVIEW

Generative AI and Student Writing Practices

Recent scholarship indicates that generative AI tools such as ChatGPT are increasingly embedded in students' academic practices, supporting tasks such as idea generation, summarisation, and language refinement (Shuhaiberet al.; Kasneci et al.). For learners writing in English as a second language, these tools function as linguistic scaffolds, supporting improvements in grammatical accuracy and fluency (Dwivedi et al.; Cotton et al.). However, this apparent enhancement in writing quality has been critically examined. Studies suggest that while AI-generated texts are often coherent and well-structured, they may lack depth, specificity, and disciplinary engagement (Vieriu et al.; Bender et al.). In this sense, AI may facilitate surface-level improvement without necessarily fostering deeper cognitive processes involved in writing.

Scholars such as Selwyn and Zawacki-Richter et al. caution that such reliance may shift students from active knowledge construction to passive consumption. Thus, existing research presents a tension: AI simultaneously acts as a support for expression and a potential constraint on intellectual engagement.

AI and Cognitive Engagement: Support or Substitution?

The impact of AI on students' thinking remains a contested issue in current research. On one hand, studies argue that AI can enhance higher-order thinking by enabling reflection, revision, and comparison of ideas (Lee et al.;Mollick). When used interactively, AI can function as a cognitive partner that stimulates inquiry and iterative learning. On the other hand, research on cognitive offloading suggests that over-reliance on AI may reduce independent thinking, as learners may accept generated responses without critical evaluation (Kirschner and De Bruyckere; Carr). This tendency is closely linked to automation bias, where users place undue trust in machine-generated outputs (Goddard et al.). This divergence in perspectives highlights a key issue: AI does not inherently enhance or diminish thinking; rather, its impact depends on how it is used. The absence of structured guidance may lead to substitution of thinking, whereas guided use may support cognitive engagement.

AI within Outcome-Based Education (OBE) in India

Outcome-Based Education (OBE) frameworks in India emphasise demonstrable competencies such as critical thinking, communication, and ethical responsibility (University Grants Commission; Spady). These frameworks require that learning outcomes be visible in student performance, particularly in written and communicative tasks.

However, the integration of AI introduces a pedagogical challenge. While AI can help students meet surface-level criteria—such as grammatical correctness and organisation—it may obscure the cognitive processes underlying these outcomes. Holmes et al. and Luckin et al. describe this as a paradox within AI-driven education, where efficiency increases but engagement may decline. This tension aligns with findings by Andrews et al., who identify a "paradox of progress" in which technological assistance enhances output while potentially weakening deeper learning processes. Consequently, there is a need for pedagogical approaches that ensure AI use remains aligned with OBE goals rather than undermining them.

Writing as a Cognitive and Metacognitive Process

The theoretical foundation of this study is grounded in Flower and Hayes's Cognitive Process Theory of Writing, which conceptualises writing as a recursive process involving planning, translating, and reviewing. This model positions writing as a site of thinking, guided by metacognitive control rather than as a linear act of transcription.

Subsequent research reinforces this perspective, emphasising writing as a process of knowledge construction and self-regulation (Bereiter and Scardamalia; Zimmerman). From this viewpoint, the act of composing is integral to the development of critical thinking and interpretive ability. In AI-mediated contexts, however, parts of this process risk being outsourced. When students rely on AI-generated drafts, the stages of ideation, organisation, and revision may be partially bypassed, reducing their cognitive engagement. This raises concerns about whether AI-supported writing can still function as a process of meaning-making.

Toward Structured and Responsible AI Use: Identifying the Gap

Emerging policy frameworks and scholarly discussions emphasise the importance of responsible AI use in education, highlighting principles such as transparency, ethical awareness, and critical evaluation (UNESCO; OECD; Williamson and Eynon). While these frameworks provide conceptual guidance, they offer limited practical strategies for classroom implementation. Current research thus reveals a clear gap. Although the benefits and risks of AI in education are widely documented, there is a lack of structured, process-oriented pedagogical models that guide students in integrating AI without displacing their cognitive work.

Addressing this gap, the present study proposes the I-DEEE-O model (Ideate, Debate, Enrich, Examine, Evaluate, Original Work), developed by the author, as a framework for responsible AI use in academic writing. By embedding AI within a sequence of cognitively engaging stages, the model seeks to reposition AI from a tool of convenience to a support for reflective and independent learning.

Research Questions

1. How are students using ChatGPT for academic purposes, and how do they perceive its impact on reading, writing, thinking, and participation?
2. Can a structured framework support responsible AI use while enhancing creative literacy and critical thinking?

METHODOLOGY

Research Design

This study adopts a mixed-method research design, combining quantitative and qualitative approaches to examine students' use of generative AI and the effectiveness of a structured pedagogical intervention. The design is organised into two sequential phases:

- Phase 1 (Quantitative Survey): A descriptive, cross-sectional survey was conducted to identify patterns of ChatGPT use and students' perceptions of its impact on reading, writing, thinking, and participation.
- Phase 2 (Qualitative–Quantitative Classroom Intervention): A quasi-experimental classroom study was implemented to evaluate the effectiveness of the I-DEEE-O model in enhancing creative literacy and critical thinking. This phase integrates rubric-based quantitative assessment with qualitative analysis of student writing and process notes.

This mixed-method approach allows for both breadth (general patterns of AI use) and depth (changes in student performance and thinking processes).

Participants and Sampling Rationale

Phase 1: Survey Participants

A total of 627 undergraduate students from multiple higher education institutions across India participated in the survey. Participants were selected through convenience sampling, with a significant proportion drawn from Acropolis Institute of Technology and Research, Indore, and additional responses from government and private colleges.

The rationale for selecting a large and diverse sample was to:

- capture broad trends in AI usage across disciplines and institutions, and
- situate the study within the wider context of Indian Outcome-Based Education (OBE) practices.

Phase 2: Intervention Participants

The intervention involved 65 first-year Computer Engineering students enrolled in the BT-206 (English) course at Acropolis Institute of Technology and Research, affiliated with RGPV, Bhopal.

This group was selected purposively because:

- first-year students are at a transitional stage, adapting to academic writing in higher education;
- engineering students often prioritise technical subjects, making them an important group for examining creative literacy development in non-literary contexts;
- the BT-206 course provides a structured space for integrating language, thinking, and communication skills.

Data Collection Tools

Survey Instrument (Phase 1)

Data were collected using a structured Google Form questionnaire titled *"The Paradox of Progress: ChatGPT's Influence on Students and Its Clash with Outcome-Based Education."*

The instrument included:

- demographic details (name, institution);
- frequency of ChatGPT use;
- primary purposes of AI use (e.g., understanding concepts, writing assignments);

- perceived impact on writing, reading habits, thinking skills, participation, and procrastination.

All core items were closed-ended, enabling statistical analysis through frequencies and percentages.

Assessment Tools (Phase 2)

Writing Task

Students were asked to write a short-story review (800–1,000 words) based on The Cherry Tree.

Rationale for text selection:

- The story is linguistically accessible yet thematically rich, suitable for first-year learners.
- It allows scope for interpretation, symbolism, and personal reflection, aligning with creative literacy goals.
- Its brevity makes it feasible for close reading within classroom constraints.

Rubric-Based Evaluation

Student writing was assessed using a four-dimensional rubric:

- Creative literacy
- Critical thinking
- Textual and cultural engagement
- Academic integrity and process awareness

Process Documentation

Students submitted brief process notes explaining how they engaged with each stage of the I-DEEE-O model and how AI tools were used.

Structure of the Classroom Intervention

The intervention was conducted in two clearly defined stages to compare student performance before and after the introduction of the I-DEEE-O framework.

Stage 1: Initial Writing Task (Unstructured AI Use)

- Students read the prescribed short story and wrote a review independently.
- They were not given any specific framework for AI use; they could choose to use or avoid AI tools freely.
- This stage served as a baseline measure of students' natural writing practices and AI usage patterns.

Stage 2: Structured Writing with the I-DEEE-O Model

Students were introduced to the I-DEEE-O model (Ideate, Debate, Enrich, Examine, Evaluate, Original Work) through guided instruction and examples.

- Each stage was explained with reference to the same short story.
- Students were encouraged to:

1. generate their own ideas before consulting AI (Ideate),
2. discuss and question interpretations (Debate),
3. use AI selectively for vocabulary or background (Enrich),
4. critically examine AI outputs (Examine),
5. align their work with evaluation criteria (Evaluate),
6. and produce an original review in their own voice (Original Work).

Students then revised their earlier review or produced a new version, along with process notes documenting their engagement with each stage.

Data Analysis Methods

Quantitative Analysis

- Survey data (Phase 1) were analysed using descriptive statistics (frequencies and percentages) to identify patterns of AI usage and perceived impact.

- In Phase 2, pre- and post-intervention rubric scores were compared to observe improvement across the four dimensions.

Qualitative Analysis

Student reviews were analysed for:

- depth of interpretation,
- use of textual evidence,
- originality of voice,
- engagement with themes and context.

Process notes were examined to understand:

- how students interacted with AI,
- the extent to which they followed the I-DEEE-O stages,
- shifts in their writing approach.

Additionally, ten representative student cases were analysed to illustrate variations in learning trajectories across different proficiency levels.

Ethical Considerations

- Participation in both phases was voluntary.
- Student data were anonymised during analysis and reporting.
- AI use was not penalised; instead, students were encouraged to acknowledge and reflect on their use, promoting ethical awareness.

Summary

The methodology integrates large-scale survey data with a focused classroom intervention to examine both patterns of AI use and pedagogical possibilities. By combining statistical trends with detailed textual analysis, the study provides a comprehensive understanding of how structured frameworks like I-DEEE-O can support responsible and cognitively engaged AI use in higher education.

Results: Phase 1 – Patterns of AI Use

The findings from Phase 1 are based on descriptive statistical analysis (frequencies and percentages) of students' self-reported responses (N = 627).

Frequency of ChatGPT use for academic work (N = 627)

A substantial proportion of respondents (80.8%) reported using ChatGPT "sometimes," "often," or "always" for academic purposes, indicating that AI tools have become a routine part of their study practices. A relatively small proportion reported never using AI.

Perceived most helpful use-case for ChatGPT (N = 627)

The most frequently selected use-case was "understanding tricky topics" (34.3%), suggesting that many students experience ChatGPT primarily as a conceptual support tool. However, a combined 42.1% indicated that their main use was writing answers and assignments, which raises important concerns regarding academic integrity and independent thinking.

Perceived impact on writing skills (N = 627)

A majority of respondents (53.0%) reported that ChatGPT had improved their writing, while only 9.4% perceived a negative impact. These self-reported perceptions align with the view that AI tools support clarity, vocabulary, and organisation. However, such "improvement" may primarily reflect gains in surface-level fluency rather than deeper analytical or argumentative ability.

Perceived change in reading habits (N = 627)

A considerable proportion of respondents (45.4%) indicated that they now read less (either "a lot less" or "a little less") since using ChatGPT, while only 14.2% reported increased reading. This pattern supports the "paradox of progress," where students benefit from the speed and convenience of AI-generated summaries but may reduce sustained engagement with primary texts.

Perceived impact on thinking skills (N = 627)

In terms of thinking skills, 46.7% of respondents perceived a positive impact, whereas approximately 20.2% reported a negative effect. These responses reflect an ambivalent perception: while students find AI useful, there is also an awareness that it may reduce independent intellectual effort or originality.

Class participation and procrastination

With regard to class participation, 50% of respondents reported no noticeable change. Notably, a higher proportion indicated increased participation (26.6%) compared to those reporting a decrease (9.3%), suggesting that AI may enhance confidence, possibly by aiding preparation. In contrast, responses related to procrastination reveal a clearer trend. A substantial majority (72.6%, combining "Strongly agree" and "Agree") believed that over-reliance on ChatGPT encourages delaying tasks, with students depending on AI to complete work quickly at the last moment.

Results: Phase 2 – Implementing the I-DEEE-O Model

In the BT-206 intervention, all 65 first-year Computer Engineering students produced short-story reviews of The Cherry Tree before and after being introduced to the I-DEEE-O model. Reviews were assessed using the four-dimensional rubric described earlier, and findings are based on a rubric-based pre–post comparison.

Comparison of pre- and post-intervention scores indicated that:

- 73% of students progressed from basic/limited to competent or strong in at least two rubric dimensions.
- A smaller subset showed modest improvement in one dimension, often in organisation or textual engagement.
- A minority displayed little visible change, typically because they did not consistently follow the I-DEEE-O steps or continued to rely on AI-generated text with minimal adaptation.
- Overall, the pattern suggests that when the process framework is followed, students' reviews become more interpretive, text-focused, and reflective.

Qualitative tendencies

Teacher observations and student process notes revealed clear contrasts between Stage 1 (Initial Writing Task – Unstructured AI Use) and Stage 2 (Structured Writing with the I-DEEE-O Model).

In Stage 1, many reviews:

- were written in generic, moralising language, using stock phrases such as "very inspirational" and "teaches us many lessons," closely resembling typical "before" responses.
- relied heavily on plot summary, recounting events such as the planting of the seed, damage to the sapling, and eventual growth, with minimal interpretation.
- rarely cited specific lines or images; the cherry tree was often labelled a "symbol of hope" without reference to particular scenes.
- showed uneven paragraphing, with limited distinction between description, interpretation, and evaluation.

In Stage 2, after the I-DEEE-O model was introduced:

- students were more likely to begin with questions in the Ideate and Debate stages, such as "What does the cherry tree represent in my life?" or "Is the story primarily about nature or personal growth?"
- AI was used more selectively; for vocabulary, alternative interpretations, or contextual backgroundrather than for generating complete responses.
- reviews increasingly cited specific moments from the text, such as the repeated damage to the sapling, seasonal changes, and the final flowering scene shared by Rakesh and his grandfather.
- process notes indicated that several students critically evaluated AI-generated suggestions, deleting or revising them to better reflect their own voice.

Taken together, these patterns suggest that the I-DEEE-O framework helped reposition AI from a one-step answer generator to a resource that could be questioned, adapted, and refined. Students' engagement became more textual, analytical, and personal.

In Cycle 2, after the I-DEEE-O model was explicitly taught and practised:

- students were more likely to begin with questions in the Ideate and Debate stages, such as "What does the cherry tree stand for in my life?" or "Is this story mainly about nature or about growing up?"
- AI was used more selectively viz., to find vocabulary, explore alternative readings, or check background on Ruskin Bond and the hill settingrather than to generate full reviews.
- reviews began to cite concrete moments from the short story: the repeated damage to the sapling, the changing seasons, the final flowering scene shared by Rakesh and his grandfather.
- process notes recorded that several students deleted or heavily edited AI-suggested sentences because they sounded too formal or unlike their own voice.
- Taken together, these tendencies indicate that the I-DEEE-O framework helped reposition AI from a one-click answer generator to a resource that could be questioned, adapted, and overwritten. Students' engagement with "The Cherry Tree" became more textual and personal, rather than purely moral and generic.

Before–while–after I-DEEE-O: An illustrative case from "The Cherry Tree"

To further illustrate this shift, one representative sequence of drafts may be considered.

- The **pre-intervention review (Stage 1)** presents the story as a simple inspirational narrative focused on perseverance, relying largely on plot summary and generalised moral statements, with minimal attention to style or textual detail.
- The **process document (Stage 2)** consists of structured notes aligned with the I-DEEE-O stages. The student records initial questions, engages in peer discussion, gathers contextual vocabulary and background information, and reflects on using AI selectively for language support rather than content generation.
- The **post-intervention review (Stage 2)** demonstrates a more nuanced interpretation. It situates the story within its hill-town context, interprets the cherry tree as a symbol of gradual and fragile growth, comments on the author's style, and connects the theme of patience to personal experience.

Across this sequence, the stages of the I-DEEE-O model are clearly visible: independent ideation, dialogic exploration, selective enrichment, critical examination, and the production of original work with acknowledged AI support. This example illustrates how a short literary text can be used to develop both close reading and responsible AI practices.

Summary table

Given the modest sample size, the study reports broad trends based on rubric-based comparison rather than advanced statistical testing. Table 1 summarises the overall movement across rubric dimensions.

Ten anonymised student profiles and category-wise trajectories

To complement the overall rubric trends, the researcher also examined ten anonymised student cases (S1–S10) representing different initial language profiles and improvement patterns. Each case combined classroom evaluation

data on oral and written English with pre–post rubric scores for the "Cherry Tree" review and brief I-DEEE-O process notes. After the activity was completed (students were not informed of this grouping during the intervention), the ten cases were organised into three broad categories:

Category A – Strong baseline communicators (S1–S3): clear or fluent oral expression and strong or good writing.

Category B – Mixed profile (S4–S7): strength in either oral or written communication, but not both.

Category C – Developing communicators (S8–S10): noticeable need for improvement in both oral clarity and written expression.

Across these ten cases, a clear pattern emerges. Category A students, who already had relatively strong language command, tended to make high gains in critical thinking and textual engagement when they fully used the I-DEEE-O steps. Their "after" reviews of "The Cherry Tree" moved beyond moral lessons to discuss Bond's style, imagery, and hill setting in more detail. Category B students showed moderate but meaningful gains, especially when they engaged seriously with the Ideate and Debate stages and used AI mainly in Enrich for vocabulary and background checks. Their reviews began to balance plot summary with interpretation, citing more specific moments such as the repeated damage to the sapling and the final flowering scene. In Category C, improvement was more uneven. Two students (S8, S9) who treated AI as a shortcut, skipping early I-DEEE-O steps, showed only slight movement from basic to limited levels. In contrast, S10, who reported re-reading the story during the Ideate and Examine stages, showed stronger gains, suggesting that even developing communicators can benefit when they use the model as intended.

DISCUSSION

Interpreting the paradox: Efficiency versus engagement

The findings from Phase 1, based on students' self-reported perceptions, indicate that ChatGPT has become a routine academic tool, with a large proportion of students using it for understanding concepts and completing assignments. While a majority reported improvements in writing, a substantial proportion also indicated reduced reading habits and increased procrastination. This dual pattern reflects what this study conceptualises as the "paradox of progress"—a condition in which technological efficiency enhances output quality at a surface level while simultaneously weakening sustained cognitive engagement.

This finding aligns with earlier research suggesting that generative AI tools support linguistic fluency and accessibility (Dwivedi et al.; Cotton et al.) but may also encourage passive consumption of knowledge (Selwyn; Zawacki-Richter et al.). The reported decline in reading further resonates with concerns raised by Nicholas Carr, who argues that digital tools may fragment attention and reduce deep reading practices. Thus, while AI facilitates faster academic production, it may also reshape learning behaviours in ways that are not fully aligned with the goals of higher education.

Reclaiming the writing process in an AI-mediated context

From the perspective of Linda Flower and John R. Hayes's Cognitive Process Theory of Writing, writing is not merely a product but a recursive process involving planning, translating, and reviewing, guided by metacognitive control. The findings from Phase 2 suggest that unstructured use of AI may disrupt this process by enabling students to bypass key stages of idea generation and organisation, thereby reducing their cognitive engagement. However, the introduction of the I-DEEE-O model appears to restore this process orientation. The observed improvements in creative literacy, critical thinking, and textual engagement indicate that when students are required to ideate independently, debate interpretations, and critically evaluate AI outputs, they re-engage with writing as a meaning-making activity rather than a task of assembling ready-made content.

This supports the view that AI does not inherently diminish thinking; rather, its impact depends on how it is pedagogically structured. Studies of Mollick similarly suggest that AI can support higher-order thinking when used interactively and reflectively, rather than passively.

I-DEEE-O and Outcome-Based Education

Implications for Outcome-Based Education (OBE)

The findings have important implications for Outcome-Based Education (OBE) in the Indian context. OBE frameworks emphasise measurable competencies such as critical thinking, communication, and ethical responsibility. However, as indicated in Phase 1, heavy reliance on AI may obscure the learner's cognitive processes, making it difficult to assess whether these outcomes are genuinely achieved.

The I-DEEE-O model offers a practical way to bridge this gap by making the learning process visible and assessable. Each stage of the model aligns with specific OBE outcomes:

- Ideate and Debate promote independent thinking and analytical reasoning.
- Enrich and Examine support information literacy and critical evaluation.
- Evaluate and Original Work reinforce self-regulation, academic integrity, and authentic expression.

The improvements observed in the intervention suggest that structured frameworks can help ensure that AI use remains aligned with OBE goals, rather than undermining them. This reinforces arguments by UNESCO and OECD that AI in education must be integrated with ethical and pedagogical safeguards, not merely adopted for efficiency.

Differential impact across learner profiles

The analysis of ten representative student profiles further highlights that the effectiveness of the I-DEEE-O model is not uniform across all learners. Students with stronger baseline communication skills (Category A) were able to leverage the model more effectively, demonstrating significant gains in interpretation and textual engagement. Those in the mixed category (Category B) showed moderate improvement, particularly when they actively engaged in the Ideate and Debate stages. In contrast, students who treated AI as a shortcut and did not fully engage with the process (Category C) showed limited progress. This pattern supports the argument that cognitive engagement, not mere access to AI, determines learning outcomes. It also aligns with research on cognitive offloading (Kirschner and De Bruyckere), which suggests that over-reliance on external tools can reduce independent thinking when not accompanied by reflective practices.

At the same time, the improvement observed in at least one developing learner indicates that structured guidance can help even weaker students re-engage with reading and writing processes. This suggests that pedagogical frameworks like I-DEEE-O can function as scaffolding mechanisms, particularly in linguistically diverse classrooms.

From tool to thinking partner: Reframing AI in education

A key implication of this study is the need to reconceptualise AI not as a replacement for student effort but as a "thinking partner." In the absence of structure, students tend to use AI for quick answers, leading to superficial engagement. However, when guided through a process-oriented framework, they begin to question, adapt, and critically respond to AI-generated content. This shift is evident in the transition from generic, plot-driven reviews in Stage 1 to more interpretive and textually grounded responses in Stage 2. The findings suggest that the pedagogical value of AI lies not in its ability to generate content, but in its potential to stimulate inquiry, comparison, and revision when used responsibly.

Summary of implications

Overall, the study demonstrates that:

- AI use in higher education is widespread and perceived as beneficial but is associated with reduced reading and increased procrastination.
- Unstructured AI use may weaken cognitive engagement, particularly in writing.
- Structured frameworks like I-DEEE-O can significantly enhance creative literacy, critical thinking, and textual engagement.
- The effectiveness of such frameworks depends on students' active participation in the process.
- Integrating AI into pedagogy requires a shift from efficiency-driven use to process-oriented, reflective engagement.

Pedagogical Implications

Designing AI-aware assignments

The findings suggest that neither ignoring nor banning AI is realistic. Instead, teachers can:

- ask students to submit a brief process note explaining how they used the I-DEEE-O steps and where AI entered their workflow.
- set prompts that require textual evidence, local context, or personal reflection, elements that generic AI outputs often underplay.
- include reflective questions about how AI influenced students' understanding, reading, or confidence in a task.

Teaching creative literacy in technical programmes

In engineering and other technical programmes, English courses are often perceived as ancillary and focused mainly on correctness. The "Cherry Tree" intervention shows that AI can be integrated into such courses in ways that genuinely support creative literacy:

- students experimented with different narrative perspectives and tones in their reviews.
- AI suggestions were used as mirrors to think about style, not as final answers.
- paraphrasing and summarising practices were strengthened, which are crucial for ethical academic writing.

Rather than replacing creativity, AI became one of several tools' students were invited to question, shape, and ultimately fit into their own voice.

Institutional policy and AI literacy

The survey confirms that students are already using ChatGPT at scale and are aware of both benefits and risks. Institutions therefore need to:

- craft clear, context-sensitive AI use guidelines aligned with existing integrity and plagiarism policies.
- organise workshops on responsible AI use for both teachers and students, introducing models like I-DEEE-O.
- explicitly integrate AI literacy into OBE documentation and course outcomes, so that graduates are not only technically skilled but also able to use AI responsibly and reflectively.

CONCLUSION

This study explored the growing role of ChatGPT in higher education and examined how a structured framework can guide its responsible use within an Outcome-Based Education context. The findings reveal a clear tension: while students perceive AI as helpful for improving writing and completing tasks efficiently, its unstructured use is associated with reduced reading engagement, increased procrastination, and potential weakening of independent thinking. The classroom intervention demonstrates that the I-DEEE-O model can address this challenge by reintroducing a process-oriented approach, enabling students to engage more critically with texts and produce more original, reflective writing.

Limitations

The study is subject to certain limitations. First, the survey data are based on self-reported perceptions, which may not always reflect actual learning behaviour. Second, the participant pool is partially concentrated within a single institutional context, which may limit the generalisability of the findings. Third, the intervention was conducted with a relatively small sample (N = 65) and focused on a specific task—a short-story review—within an English course, which may not fully represent other disciplines or forms of academic writing. Finally, the study does not capture long-term effects of AI use on students' reading habits and cognitive development.

Future Directions

Future research can build on these findings in several ways. Studies may incorporate in-depth qualitative methods, such as interviews or think-aloud protocols, to better understand how students interact with AI during different stages of writing. The I-DEEE-O model can be tested across diverse disciplines and genres, including technical

writing, project-based learning, and research-oriented tasks. Longitudinal studies are needed to examine the sustained impact of structured AI use on critical thinking, reading practices, and learner autonomy. Further research may also explore the model's application in collaborative and digital learning environments, where AI use is increasingly embedded. In sum, the study suggests that the challenge is not whether students should use AI, but how they use it. With appropriate pedagogical frameworks, AI can be repositioned from a tool of convenience to a resource that supports deeper engagement, critical thinking, and responsible academic practice.

ACKNOWLEDGEMENTS

The researcher gratefully acknowledges Acropolis Institute of Technology and Research, Indore for institutional support. Sincere thanks are due to Dr. Sumitra Joshi, Head, Department of Humanities, and Dr. S. C. Sharma, Director, AITR, for their constant encouragement. Heartfelt appreciation is also extended to the BT-206 Computer Engineering students whose participation and honest responses made this study possible.

Table 1. Summary of improvement across rubric dimensions (BT-206, N = 65)

Dimension	Indicator of improvement	Approximate trend
Creative literacy	Stronger personal voice, more varied sentence structures, and richer reflective insights	Most students showed clear gains
Critical thinking	Deeper focus on themes, conflicts, and the writer's choices	Most students showed clear gains
Textual & cultural engagement	More frequent textual references and a sharper sense of setting, culture, and context	Most students showed clear gains
Academic integrity & process	More consistent mention of AI use and better articulation of the writing process	Noticeable but more limited improvement

Table 2. Snapshot of ten anonymised student profiles (BT-206, N = 65)

ID	Baseline profile (oral/written)	Category	Pre-review level	Post-review level	Brief I-DEEE-O process note (while using the model)
S1	Clear and expressive oral; well-structured writing	A	Limited	Strong	Used all I-DEEE-O steps; deleted generic AI lines and added own reflections.
S2	Clear oral command; writing strong but slightly formal	A	Competent	Strong	Used AI mainly for vocabulary; Ideate and Debate done fully with peers.
S3	Fluent oral skills; "writing good" in baseline sheet	A	Limited	Competent	Noted doubts about AI; rephrased most AI suggestions in simpler own language.
S4	Good oral clarity; "writing moderate"	B	Basic	Competent	Strong Ideate stage; used AI to check cultural references, not for full drafts.
S5	Needs fluency in oral; writing described as strong	B	Limited	Strong	Relied on Enrich and Examine; consciously added more textual evidence.
S6	Oral clarity needs work; writing understandable	B	Basic	Limited	Skipped Debate step; used AI for structure, made only small edits.
S7	Expresses ideas clearly; writing moderate	B	Limited	Competent	Group discussion in Debate stage led to clearer focus on themes.
S8	Weak oral clarity; writing moderate	C	Basic	Basic	Minimal process notes; copied large AI chunk; little use of Ideate/Examine.

S9	Needs improvement in clarity; "writing moderate"	C	Basic	Limited	Used I-DEEE-O partially; some new examples but still heavy plot summary.
S10	Needs focus on clarity and confidence; writing moderate	C	Limited	Competent	Reported that I-DEEE-O "forced me to read again" and add more specific scenes.

Book Review of "The Cherry Tree" by Ruskin Bond

"The Cherry Tree" is a very inspirational and beautiful short story written by Ruskin Bond. It teaches us many lessons about life, patience and nature. The story is about a boy named Rakesh who plants a cherry seed in his grandfather's garden. At first nothing happens, but slowly the plant starts to grow. Many problems come in the way of the plant, like the goat eating the leaves and the grass-cutter cutting it by mistake, but still the cherry tree survives.

The story shows how we should never give up in life. Even when there are many difficulties, we have to continue trying, just like the small tree continues to grow. The cherry tree is a symbol of hope and hard work. Ruskin Bond nicely describes the beauty of the hills and the garden, and we can easily imagine the scene in our mind.

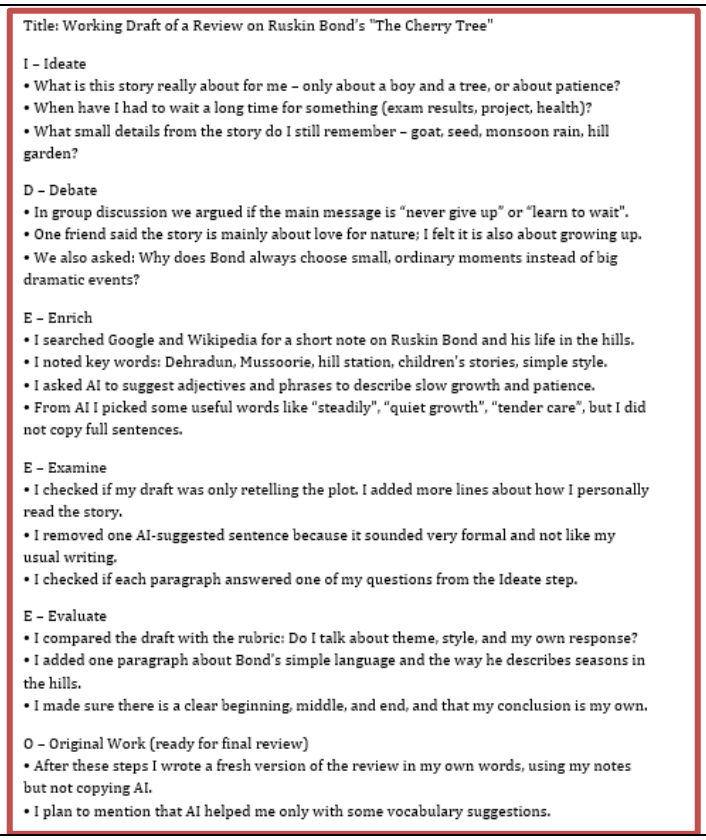
This story is also very motivating for students. It tells us that if we are patient and do not lose faith, we will get success at the right time. The language of the story is simple and easy to understand, so readers of all ages can enjoy it. I strongly recommend this inspirational story to everyone.

Shruti Shrivastava

CS4- AITR, Indore

Figure 7: 1st - Story Review

Book Review of Ruskin Bond's "The Cherry Tree" – After Using I-DEEE-O



When I first read Ruskin Bond's "The Cherry Tree", it looked like a very simple story about a boy, a seed, and a tree. After thinking about it more carefully, I realised that it quietly talks about patience, care, and the slow way in which both trees and people grow.

The story follows Rakesh, a young boy living in the hills with his grandfather. He plants a cherry seed almost casually, and then forgets about it. The small plant suffers again and again – the goat eats its leaves, the grass-cutter slices it by mistake, and the weather is not always kind. Still, the cherry tree keeps returning, putting out new shoots and leaves. This repeated growth makes the final moment, when Rakesh stands under the tree's pink blossoms, feel very special.

For me, the cherry tree becomes a symbol of long-term effort. It does not become tall in one season. It survives because of small, repeated acts: the boy watering it, the grandfather's quiet encouragement, and the simple decision not to give up. As a student who often wants fast results, I could connect this to my own experience of waiting for exam results or slowly improving in a subject. The story reminds me that some achievements need time and steady attention, not just quick hard work.

Bond's style is another reason the story stays in the mind. His language is clear and unpretentious. He does not use big philosophical speeches but instead describes small things, the feel of the garden soil, the goat wandering in, the change of seasons in the hill town. Through these details, he shows how nature moves at its own pace. The relationship between Rakesh and his grandfather is also gently drawn. There is respect, warmth, and shared wonder when they finally stand together under the flowering tree. In the end, "The Cherry Tree" is not just a moral lesson about "never giving up." It is a quiet reminder that growth, whether of a tree or a person, is usually slow, fragile, and beautiful. Reading it with the I-DEEE-O model pushed me to ask better questions, notice specific scenes, and relate the story to my own life, instead of just copying a ready-made review.

Figure 8: Story Review after using -IDEEEO method

Title: Working Draft of a Review on Ruskin Bond's "The Cherry Tree"

I – Ideate
• What is this story really about for me – only about a boy and a tree, or about patience?
• When have I had to wait a long time for something (exam results, project, health)?
• What small details from the story do I still remember – goat, seed, monsoon rain, hill garden?

D – Debate
• In group discussion we argued if the main message is "never give up" or "learn to wait".
• One friend said the story is mainly about love for nature; I felt it is also about growing up.
• We also asked: Why does Bond always choose small, ordinary moments instead of big dramatic events?

E – Enrich
• I searched Google and Wikipedia for a short note on Ruskin Bond and his life in the hills.
• I noted key words: Dehradun, Mussoorie, hill station, children's stories, simple style.
• I asked AI to suggest adjectives and phrases to describe slow growth and patience.
• From AI I picked some useful words like "steadily", "quiet growth", "tender care", but I did not copy full sentences.

E – Examine
• I checked if my draft was only retelling the plot. I added more lines about how I personally read the story.
• I removed one AI-suggested sentence because it sounded very formal and not like my usual writing.
• I checked if each paragraph answered one of my questions from the Ideate step.

E – Evaluate
• I compared the draft with the rubric: Do I talk about theme, style, and my own response?
• I added one paragraph about Bond's simple language and the way he describes seasons in the hills.
• I made sure there is a clear beginning, middle, and end, and that my conclusion is my own.

O – Original Work (ready for final review)
• After these steps I wrote a fresh version of the review in my own words, using my notes but not copying AI.
• I plan to mention that AI helped me only with some vocabulary suggestions.

Figure 9. pre-intervention review (Stage 1)

ABSTRACT

Ayurvedic embryology (GarbhaŚārīra) presents a comprehensive and holistic understanding of conception, fetal development, maternal health, and hereditary influences, integrating biological, psychological, and metaphysical dimensions. This review explores classical Ayurvedic concepts related to preconceptional care, embryogenesis, sex determination, fetal growth, constitutional inheritance (Prakruti), and factors responsible for fetal deformities, while correlating them with principles of modern developmental biology. Ayurveda emphasizes the essential role of Śukra (sperm), Śoṇita (ovum), Ātman (soul), and favorable conditions such as Kāla (time), Kṣetra (uterus), and Ambu (nutrition) in the formation of healthy progeny. Detailed descriptions of month-wise fetal development (MāsānumāsikaVṛiddhi), Garbhopaghatakara Bhava (harmful antenatal factors), and maternal conduct underscore the preventive and personalized nature of Ayurvedic reproductive science. Several classical observations, particularly those concerning maternal nutrition, emotional well-being, and environmental influences, show conceptual parallels with contemporary ideas of prenatal care, teratology, epigenetics, and personalized medicine. Although certain traditional doctrines, such as ancient theories of sex determination, lack modern scientific validation, Ayurvedic embryology remains significant for its preventive, constitutional, and holistic approach to reproductive health. Integrating Ayurvedic wisdom with modern embryological understanding may enhance preconception counseling, antenatal care, and

individualized healthcare strategies. Thus, GarbhaŚārīra continues to serve as an academically valuable and clinically relevant complementary framework in reproductive and developmental sciences.

Keywords: Ayurvedic embryology, GarbhaŚārīra, fetal development, preconception care, Garbhini Paricharya, Prakruti, Panchamahabhuta, Masanumasika Vriddhi, reproductive health

INTRODUCTION

Medical embryology, a scientific discipline devoted to investigating the mechanisms of organismal development at multiple levels—from genetic regulation to tissue interactions—constitutes a critical foundation for the advancement of regenerative medicine. Recent technological innovations, including in vitro blastocyst culture and stem cell–derived models of peri-implantation embryos, have substantially deepened our understanding of morphogenesis and the spatial arrangement of cells during early development.[1-2]Recent advances in Tissue Engineering, Synthetic Biology, biomaterials, and 3D cell culture technologies have enabled the development of organoids—miniaturized, three-dimensional tissue models that mimic certain structural and functional properties of real organs. These organoids can reproduce aspects of tissue architecture, cellular diversity, and limited physiological behavior. However, despite their increasing sophistication, they still do not achieve the full functional complexity and physiological performance of native human organs. [3]Intercellular communication is a particularly important field of study, as it regulates key processes such as cell proliferation, differentiation, and migration. When these signaling pathways are disrupted, it can result in developmental abnormalities and diseases, including cancer.[4]Advances in understanding these mechanisms are creating new opportunities for developing innovative therapies, especially in tissue engineering approaches designed to address congenital disorders such as esophageal atresia.[5]

Ayurvedic Perspective

In Ayurveda, conception and fetal development are viewed as sacred, well-ordered biological processes influenced by physical, psychological, and subtle metaphysical factors. GarbhaŚārīra elaborates on the origin of life, formation of organs, growth of the fetus, and maternal influences.[6] The concept of Garbha begins with the union of Śukra(sperm), Śoṇita (ovum), and Ātman, facilitated by appropriate Kāla (time), Kṣetra (uterus), and Ambu (nutrition). According to Acharya Charaka, Garbha is formed when Shukra and Shonita unite and are associated with the Jivatman.[7] When Shukra (male reproductive element) and Shoṇita (female reproductive element) are situated in the uterus and become integrated with the Atman (soul) along with Prakṛti and Vikāra (constitutional and modifying factors), this combined entity is called Garbha (embryo).[8]

Concept of Embryology

DISCUSSION

The present review highlights that Ayurvedic embryology (GarbhaŚārīra) offers a remarkably systematic and holistic understanding of conception, fetal development, and maternal care, paralleling several principles recognized in modern embryology while also incorporating metaphysical and constitutional dimensions. Classical Ayurvedic texts describe embryogenesis as a coordinated process involving Śukra (sperm), Śoṇita (ovum), Ātman, and favorable conditions such as Kāla, Kṣetra, and Ambu, emphasizing that healthy progeny depends not only on biological union but also on parental physical, mental, and behavioral status. This approach broadens embryology beyond anatomical development by integrating preventive reproductive health through pre conceptional care, Rutumaticharya, and GarbhiniParicharya. The concept of Panchamahabhuta in fetal organogenesis demonstrates Ayurveda's attempt to explain structural and functional development through elemental predominance, which can be interpreted as an early philosophical framework for physiological specialization. Similarly, the month-wise description of fetal growth (MasanumasikaVriddhi) reflects detailed observational knowledge regarding developmental milestones, from the undifferentiated embryonic stage to full-term maturation. Though expressed in traditional terminology, many of these descriptions symbolically correspond to sequential embryonic growth recognized in modern developmental biology. Ayurvedic explanations of fetal deformities, harmful antenatal factors (Garbhopaghatakara Bhava), and constitutional inheritance (Prakruti) further illustrate a preventive and personalized medical approach. The emphasis on maternal nutrition, emotional well-being, lifestyle, and environmental exposures aligns closely with contemporary understanding of teratogenic influences, epigenetics, and prenatal care. Furthermore, correlations between Prakruti and genetic/metabolic variations suggest emerging possibilities for integrating Ayurvedic constitutional concepts with personalized medicine and pharmacog enomics.

However, certain classical concepts such as sex determination based on predominance of Shukra or Aartava, or timing of intercourse, are not supported by modern scientific evidence and should be interpreted within historical and philosophical contexts rather than literal biological mechanisms. Therefore, while Ayurveda provides profound conceptual insights into reproductive health, integration with modern embryology requires critical scientific validation. Overall, Ayurvedic embryology contributes a comprehensive biopsychosocial model that emphasizes prevention, maternal care, and constitutional individuality. Its relevance in current healthcare may lie particularly in preconception counseling, antenatal lifestyle management, and holistic reproductive wellness rather than direct replacement of modern embryological science.

CONCLUSION

Ayurvedic embryology offers a comprehensive and all-encompassing view of human development that includes conception, foetal growth, mother behaviour, genetic effects, and preventive care. Ancient Ayurvedic scholars highlighted the significance of physical, psychological, and environmental variables in creating healthy kids and showed a comprehensive observational understanding of developmental processes. Many principles—such as preconception care, maternal health optimisation, and individualised constitutional assessment—remain highly relevant, even though certain classic concepts need to be reinterpreted in light of modern science. Ayurvedic principles combined with contemporary embryology may improve personalised medicine and preventive reproductive healthcare by providing a more comprehensive understanding of human development. As a complementing viewpoint in the reproductive and developmental sciences, Garbhaṅārīra thus maintains substantial scholarly and clinical importance.

Table 1: Preconception Factors [9-10]

Purpose of Preconceptional Care	Ayurveda emphasizes preconceptional care to achieve the goal of healthy offspring.
Guidelines for Menstruating Women (Rutumaticharya)	Specific instructions are prescribed for Rutumati (menstruating women) to prepare the body for healthy conception.
Lifestyle During Menstrual Period	From the first day of menstruation, women are advised to maintain celibacy and avoid day sleep along with other unsuitable activities.
Importance of Maternal Conduct	The mother's lifestyle, behavior, and regimen during the Rutumati period significantly influence the qualities and development of the future fetus.
Role of Parental Diet and Lifestyle	The embryo's physical and psychological traits are directly affected by both parents' diet and lifestyle before conception.
Overall Objective	To ensure optimal reproductive health and promote the birth of healthy, physically and mentally balanced progeny.

Table 2.Evolution and Body Parts [11]

Mahabhuta (Element)	Facilitated Characteristics / Functions in the Individual
Akash (Ether/Space)	Sound, auditory organ (hearing), all bodily orifices, distinctness
Vayu(Air)	Touch, tactile organ (skin), all activities (nervous system), movements/actions of all body parts, lightness
Tejas (Fire)	Vision, visual organ (eyes), complexion, heat, brilliance, digestion, intolerance, sharpness, courage
Aap (Water)	Taste, gustatory organ (tongue), fluidity, immensity, coldness, unctuousness, semen
Prithvi (Earth)	Smell, olfactory organ (nose), hardness, heaviness/weightness

Table 3: Sex Determination [12-14]

Aspect	**Ayurvedic Description**
Predominance of Shukra (semen)	Leads to conception of a male child
Predominance of Aartava (ovum)	Leads to conception of a female child
Equal proportion of Shukra and Aartava	May result in conception of a hermaphrodite child
Sexual interaction on even days	Believed to favor conception of a male child
Sexual interaction on odd days	Believed to favor conception of a female child

Table 4.Garbh Vigyaan [15-16] Formation of Embryo

Aspect	Ayurvedic Description
Definition of Garbha (Embryo)	Garbha is formed by the union of Shukra (sperm), Shonita (ovum), and Jiwa (Atma along with Sattwa) within the uterus
Essential components for embryo formation	Shukra (sperm), Shonita (ovum), Jiwa/Atma (soul), and Sattwa (mind/psyche)
Site of development	Uterus
Garbha Sambhav Bhava (Factors responsible for embryo development)	Six fundamental factors contribute to embryogenesis
Matrutaha	Maternal contribution
Pitrutaha	Paternal contribution

Aatmataha	Soul/self-contribution
Satmyataha	Suitability or adaptability
Rasataha	Nutritional factors
Satvataha	Psychological or mental factors

Table 5: Masanumasika-Vriddhi [17]

Gestational Month	Description According to Acharya Charaka
First Month	The embryo becomes mixed with all Dhatus (Mahabhutas) and appears as Khetabhuta (a jelly-like structure similar to Kapha), without distinct shape, with latent and undeveloped limbs.
Second Month	The embryo develops into a solid mass in one of three forms: Pinda (oval), Peshi (elongated), or Arbuda (circular). Pinda indicates male progeny, Peshi indicates female progeny, and Arbuda indicates hermaphrodite development.
Third Month	All Indriyas (sense organs) and Angavayava (body parts) become visible.
Fourth Month	The fetus attains stability, and the pregnant woman begins to feel increased heaviness
Fifth Month	Mamsa (muscle tissue) and Rakta (blood) increase, and the fetus receives enhanced nourishment.
Sixth Month	There is significant development of Bala (strength) and Varna (complexion) in the fetus.
Seventh Month	All fetal components become properly nourished and fully formed. Chakrapani interprets Mamsa, Shonita, etc., as indicating complete development of all bodily constituents.
Eighth Month	Due to fetal immaturity, Ojas continuously fluctuates between mother and fetus through the RasavahaSrotas, causing alternating pleasure and dullness in both. Birth during this month is considered risky because of unstable Ojas and uncertain survival.
Ninth to Tenth Month	The proper period of delivery begins from the first day of the ninth month and extends until the end of the tenth month. This is considered the ideal and safe period for childbirth.

Table 6: Diagnosis of sex of the foetus [18]

Maternal Signs / Indicators	**Predicted Foetal Sex**
First secretion appears in the right breast	Male child
Heaviness in the eyes	Male child
Walks with the right foot forward first	Male child
Desires articles having masculine names	Male child
Opposite of the above signs (left breast secretion first, opposite gait, feminine desires, etc.)	Female child
Middle part of the abdomen sinks inward like a saucer	Twins may be present

Table 7: Garbhopoghatkara Bhava [19]

Garbhopaghatakara Bhava (Harmful Factors)	Description / Effect on Pregnancy
UtkataVishamaKathina Asana Sevana	Sitting on hard, uneven, or uncomfortable seats
VataMutraPurisha Vega Dharana	Suppression of natural urges such as urination and defecation
DarunaAnuchitaMatraSevana	Excessive, strenuous, or inappropriate physical activity
TikshnaUshnaMatraSevana	Consumption of excessively hot, pungent, or inadequate food
Abhighata	Physical injury or trauma
Prapidana	Excessive compression or pressure on the body
ShvabhrukaKupaAvalokana	Looking into deep pits or wells
PrapataDeshaAvalokana	Traveling on jerky or uneven vehicles/roads

ApriyaMatraShravana	Hearing unpleasant, disturbing, or stressful words
UttanaShayana	Excessive sleeping in supine position
NabhyashrayaNadiKanthamanuveshatati	Umbilical cord complications, such as cord around fetal neck
VivrutaShayini	Sleeping in open or unprotected places
NaktaCharini	Wandering at night, believed to affect mental health of offspring
ShokaNityaBhrita	Constant grief, fear, or emotional distress leading to weak or short-lived progeny
Overall Ayurvedic Recommendation	Avoidance of these harmful factors as part of GarbhiniParicharya (antenatal care) for healthy fetal development

Table 8: Fetal Deformity [20-22]

Aspect	Ayurvedic Description
Cause of fetal deformity according to Charaka	Damage or defect in the reproductive seed (Shukra or ovum) during fertilization may lead to abnormalities in specific body parts
Genetic source involvement	If a body part's developmental source is impaired, that organ may develop abnormally or fail to develop
Influence of parental behavior	Unrighteous or improper actions of parents are believed to contribute to abnormal fetal forms
Examples of severe deformities described	Serpent-like, scorpion-like, pumpkin-shaped fetus
Role of vitiated Vata Dosha	Vata imbalance may lead to deformities such as Kubja (hunchback), Kuni (deformed hand), Pangu (lameness), Mook (dumbness), and Minmin (muffled voice)
Effect of neglecting maternal cravings	Failure to fulfill pregnant woman's desires (Dauhrida) may contribute to fetal abnormalities
Role of Doshas	Vitiated Doshas (Vata, Pitta, Kapha) can disturb fetal development
Classical analogy	Just as wood, stones, or water currents can distort a tree's growth in a river, Doshas can cause fetal anomalies during development

Table 9: Prakruti [23]

Aspect	**Ayurvedic Description / Modern Correlation**
Prakruti (Constitution)	Considered an Ayurvedic concept analogous to genetics, determined by maternal and paternal contributions
Formation of Prakruti	Homogeneous combination of maternal and paternal factors influencing offspring characteristics
Characteristics determined by Prakruti	Morphological (physical), functional (physiological), and mental traits
Sushruta's explanation	Prakruti is governed by the predominance of Tridosha (Vata, Pitta, Kapha)
Ayurvedic genetics concept	Prakruti reflects inherited constitutional patterns similar to genetic inheritance
CYP2C19 genotype association	Studies suggest links between Prakruti types and metabolic variations, including rapid or slow drug metabolism
Significance in modern	Implications for phenotype-genotype association, pharmacogenomics, personalized

science	medicine, and drug development
PGM1 gene association	Research by CCMB linked PGM1 gene with Pitta Dosha
Function of PGM1 gene	Plays a role in regulating basal metabolic rate (BMR), comparable to Pitta functions
Influencing factors during fertilization	Predominant Dosha at conception may be influenced by multiple internal and external factors

ABSTRACT

Economic strategy, information analysis, and dynamics all heavily rely on fuzzy numbers. Finding out where different fuzzy numbers are located is an important milestone in many numerical models. By using our recommended positioning method, we transform the hexagonal intuitionistic fuzzy transportation problem into a sophisticated and well-respected model. To get a fuzzy optimal solution, this transformation is then applied to another suggested method. The statistical example demonstrates how well the suggested approach uses fuzzy-based computations to solve transportation-related problems

Keywords: Fuzzy set, Intuitionistic fuzzy numbers, Centroid ranking method, Fuzzy transportation problem, Hexagonal fuzzy numbers

INTRODUCTION

There is usually some hesitancy and uncertainty while making decisions in many real-life circumstances due to a number of uncontrollable elements..According to the fuzzy set hypothesis, a part's membership point $\mu(x)$ falls between 0 and 1, and its non-membership point $\lambda(x)$ is $1-\mu(x)$. However, this is not practical in several real-world situations due to the degree of hesitancy. The membership and non-membership points are recognized concurrently in intuitionistic fuzzy set theory so that the sum of each of their values is not exceeding 1.Thus, the degree of hesitancy $\pi(x)$ is $1-\mu(x)-\lambda(x)$. More information about the problem was given by intuitionistic fuzzy set theory as opposed to fuzzy set theory. This has led to the use of intuitionistic fuzzy set theory by several academics across a variety of scientific fields [1–9]. Numerous circumstances make it impossible to fully explain the numerical data involved in a decision-making problem. Therefore, fuzzy numbers may serve as a representation. To represent fuzzy numbers, membership functions with triangular and trapezoidal shapes are commonly used in the literature [10–13]. To cope with arriving at a wholly ambiguous agreement. A two-stage cost-limiting fuzzy transportation problem has been investigated by R. Srinivasan and N. Karthikeyan [14–15] when requirements and inventory are both imprecise counts. in challenging circumstances that are not quite clear. Furthermore, Karthikeyan N et al. [16–17] have used a suggested approach that makes use of trapezoidal fuzzy numbers to address transportation-related problems. On the other hand, intuitionist fuzzy numbers signal considerable uncertainty and provide more information than fuzzy numbers in instances involving imprecise problems. Together with their membership and non-membership functions, the author of this paper provides hexagonal intuitionistic fuzzy numbers. A kind of arithmetic operation for hexagonal intuitionistic fuzzy numbers is proposed based on (α,β) cuts.

Primary Definitions

In this part, we review a number of important concepts that are also used in the work by R. Srinivasan and N. Karthikeyan [14]. Any collection with sudden or unclear boundaries is considered fuzzy. Because fuzzy set theory treats membership in a set as a matter of degree, it cannot be linked to the constraints of conventional set theory. A number between 0 and 1 represents the degree of membership in a set; values with a value of 0 completely vanish from the set, while values with a value of 1 are fully present. The numbers in between represent intermediate degrees of membership, while the number 0 denotes non-membership and the value 1 denotes membership. A membership function can be used to build a fuzzy set by mapping an element of a domain, such as the space of the cosmos of discourse X, to the unit interval. i.e .$Å = \{(x, \mu_{Å}(x); x \in X\}$. In this case, Å , $\mu_{Å}$(x)is referred to as the membership value of x ∈ X in a fuzzy set Å, and $\mu_{Å}: X \to J$ is a mapping termed the point of membership function of the fuzzy set Å. Real values between J are sometimes used to express these membership conditions.

Definition: Fuzzy Number

Let Å be a fuzzy set on R that is constrained by the following restrictions.

- Part by part $\mu_{Å}(x)$ is continuous.
- At least one $x_0 \in R$ exists such that $\mu_{Å}(x) = 1$.
- Å is both customary and convex.

Definition: Intuitionistic Fuzzy Number

$Å^{I} = \{< x, \mu_{Å^{I}}(x), \lambda_{Å^{I}}(x) >\}$ is a fuzzy intuitionistic set. A real line number R is referred to as an intuitionistic fuzzy number if the following requirements are satisfied:

- There is one $n \in R$ such that $\mu_{Å^{I}}(n) = 1$ and $\lambda_{Å^{I}}(n) = 1$ (where n is called the average of $Å^{I}$)
- The piecewise continuous functions $\mu_{Å^{I}}(x)$ and $\lambda_{Å^{I}}(x)$ are generated from $R \to [0,1]$ in such a way that $0 \le \mu_{Å^{I}}(x) + \lambda_{Å^{I}}(x) \le 1, \forall x \in R$
- The membership and non-membership functions of $A^{o^{I}}$ are as follows.

$$\mu_{\tilde{A}^I}(x)=\begin{cases} p_1(x) & n-\alpha \le x \le n \\ 1 & x=n \\ q_1(x) & n \le x \le n+\beta \\ 0 & otherwise \end{cases} \quad ------(2.1)$$

$$\lambda_{\tilde{A}^I}(x)=\begin{cases} p_2(x) & n-\alpha' \le x \le n \\ 0 & x=n \\ q_2(x) & n \le x \le n+\beta' \\ 1 & otherwise \end{cases}$$

Here

- $p_1(x)$ and $q_1(x)$ are piecewise continuous; strictly monotonic functions in $[n-\alpha,n]$ and $[n,n+\beta]$ correspondingly.
- $p_2(x)$ and $q_2(x)$ are piecewise continuous; strictly monotonic functions in $[n-\alpha',n]$ and $[n,n+\beta']$ correspondingly.
- α and β are the left and right spreads of the membership function $\mu_{A^{oI}}(x)$ respectively.
- α' and β' are the membership function's left and right spreads $\lambda_{A^{oI}}(x)$ respectively.
- $0 \le p_1(x)+p_2(x) \le 1$ and $0 \le q_1(x)+q_2(x) \le 1$ for all $x \in R$
- This is how the Intuitionistic fuzzy number $\tilde{A}^I$ is represented: $\tilde{A}^I=(n:\alpha,\beta:\alpha',\beta')$.

Hexagonal Intuitionistic Fuzzy Number

A hexagonal intuitionistic fuzzy number, or collection of intuitionistic fuzzy sets, is recognized by the subsequent membership and non-membership functions.

-

$$\mu_{A^{oI}}(x)=\begin{cases} \frac{1}{2}\left(\frac{x-a_1^o}{a_2^o-a_1^o}\right) & , \quad a_1^o \le x \le a_2^o \\ \frac{1}{2}+\frac{1}{2}\left(\frac{x-a_2^o}{a_3^o-a_2^o}\right), & a_2^o \le x \le a_3^o \\ 1 & , \quad a_3^o \le x \le a_4^o \\ 1-\frac{1}{2}\left(\frac{x-a_4^o}{a_5^o-a_4^o}\right), & a_4^o \le x \le a_5^o \\ \frac{1}{2}\left(\frac{a_6^o-x}{a_6^o-a_5^o}\right) & , \quad a_5^o \le x \le a_6^o \\ 0 & , \quad otherwise \end{cases} \quad ----------(2.2)$$ and

$$\lambda_{A^{oI}}(x)=\begin{cases} 1-\frac{1}{2}\left(\frac{x-a_1^{o'}}{a_2^o-a_1^o}\right) & , \quad a_1^{o'} \le x \le a_2^{o'} \\ \frac{1}{2}\left(\frac{a_3^{o'}-x}{a_3^{o'}-a_2^{o'}}\right), & a_2^{o'} \le x \le a_3^{o'} \\ 0 & , \quad a_3^{o'} \le x \le a_4^{o'} \\ \frac{1}{2}\left(\frac{x-a_4^{o'}}{a_5^{o'}-a_4^{o'}}\right), & a_4^{o'} \le x \le a_5^{o'} \\ \frac{1}{2}+\frac{1}{2}\left(\frac{x-a_5^{o'}}{a_6^{o'}-a_5^{o'}}\right) & , \quad a_5^{o'} \le x \le a_6^{o'} \\ 1 & , \quad otherwise \end{cases} \quad ---------- (2.3)$$

Where $a_1^{o'} \le a_2^{o'} \le a_3^{o'} \le a_4^{o'} \le a_5^{o'} \le a_6^{o'}$.The symbol for this fuzzy Intuitionistic hexagonal number is $A^{oI}{}_H = (a_1{}^0,,....,a_6{}^0; a_1^{o'},....,a_6^{o'})$. (Figure 1).

Principal Outcomes

Converting a Hexagonal Intuitionistic Fuzzy Number into a Hexagonal Fuzzy Number

If $a_1{}^0 = a_1^{o'}, a_2{}^0 = a_2^{o'}, a_5{}^0 = a_5^{o'} and\ a_6{}^0 = a_6^{o'}$ then the hexagonal Intuitionistic fuzzy number $A^{o\,I}{}_H = (a_1{}^0,,....,a_6{}^0; a_1^{o'},....,a_6^{o'})$. is transformed to a hexagonal fuzzy number $A_H^o = (a_1,,....,a_6)$.

Proof:

Put $a_1{}^0 = a_1^{o'}, a_2{}^0 = a_2^{o'}, a_5{}^0 = a_5^{o'} and\ a_6{}^0 = a_6^{o'}$ in 1 and 2 we get

$$\mu_{A^{oI}}(x) = \begin{cases} \frac{1}{2}\left(\frac{x-a_1^o}{a_2^o-a_1^o}\right) & , \quad a_1^o \le x \le a_2^o \\ \frac{1}{2}+\frac{1}{2}\left(\frac{x-a_2^o}{a_3^o-a_2^o}\right), & a_2^o \le x \le a_3^o \\ 1 & , \quad a_3^o \le x \le a_4^o \\ 1-\frac{1}{2}\left(\frac{x-a_4^o}{a_5^o-a_4^o}\right), & a_4^o \le x \le a_5^o \\ \frac{1}{2}\left(\frac{a_6^o-x}{a_6^o-a_5^o}\right) & , \quad a_5^o \le x \le a_6^o \\ 0 & , \quad otherwise \end{cases} \quad ------(3.1)$$

and

$$\lambda_{A^{oI}}(x) = \begin{cases} 1-\frac{1}{2}\left(\frac{x-a_1^o}{a_2^o-a_1^o}\right) & , \quad a_1^o \le x \le a_2^o \\ \frac{1}{2}\left(\frac{a_3^o-x}{a_3^o-a_2^o}\right), & a_2^o \le x \le a_3^{o'} \\ 0 & , \quad a_3^o \le x \le a_4^o \\ \frac{1}{2}\left(\frac{x-a_4^o}{a_5^o-a_4^o}\right), & a_4^o \le x \le a_5^o \\ \frac{1}{2}+\frac{1}{2}\left(\frac{x-a_5^o}{a_6^o-a_5^o}\right) & , \quad a_5^o \le x \le a_6^o \\ 1 & , \quad otherwise \end{cases} \quad ------(3.2)$$

It is evident from 3 and 4 that $\lambda_{A^{oI}}(x)$ is the complement of $\mu_{A^{oI}}(x)$ in each interval. *ie.* $\lambda_{A^{oI}}(x) = 1-\mu_{A^{oI}}(x)\ \forall x \in R$

As a result, it is a hexagonal fuzzy number or HFN. $A_H^o = (a_1,,....,a_6)$.

(α, β) – cuts of HIFN

Let $A^{oI}{}_H = (a_1{}^0,,....,a_6{}^0; a_1^{o'},....,a_6^{o'})$. be a hexagonal Intuitionistic fuzzy number, then (α, β) cuts of $A^{oI}{}_H$ are given by

$$A^{o^I}{}_H(\alpha)=\begin{cases}\left[a_1{}^0+2\alpha(a_2^0-a_1^0),a_6^0-2\alpha(a_{66}^0-a_5^0)\right] & \alpha\in[0,0.5)\\ \left[2a_2^0-a_3^0+2\alpha(a_3^0-a_2^0),2a_5^0-a_4^0-2\alpha(a_5^0-a_4^0)\right] & \alpha\in(0.5,1]\end{cases}$$

$$A^{o^I}{}_H(\beta)=\begin{cases}\left[a_3^{o'}+2\beta(a_3^{o'}-a_2^{o'}),a_4^{o'}-2\beta\,(a_5^{o'}-a_4^{o'})\right] & \beta\in[0,0.5)\\ \left[2a_2^{o'}{}'-a_1^{o'}+2\beta(a_2^{o'}-a_1^{o'}),2a_5^{o'}-a_6^{o'}-2\beta(a_6^{o'}-a_5^{o'})\right] & \beta\in(0.5,1]\end{cases}$$

Ranking of Hexagonal Intuitionistic Fuzzy Number

A centroid-based ranking approach is proposed for generalized hexagonal intuitionistic fuzzy numbers and hexagonal intuitionistic fuzzy numbers.

Let $A^{o^I}_{GH}=(a_1{}^0,,....,a_6{}^0;a_1^{o'},....,a_6^{o'}{}';u_a,w_a)$ represent a generalized hexagonal intuitionistic fuzzy number. A ranking framework based on the centroid technique is established for GHIFNs.

$$R\left[A^{o^I}_{GH}\right]=\frac{R[A^{o^I}{}_{GH}(\mu)]+R[A^{o^I}{}_{GH}(\lambda)]}{u_a+w_a}\qquad ------(3.3)$$

Where

$$R[A^{o^I}{}_{GH}(\mu)]=\left(\frac{2a_1{}^0+3a_2{}^0+4a_3{}^0+4a_4{}^0+3a_5{}^0+2a_6{}^0}{18}\right)\left(\frac{5u_a}{18}\right)$$

$$R[A^{o^I}{}_{GH}(\lambda)]=\left(\frac{2a_1^{o'}+3a_2^{o'}+4a_3^{o'}+4a_4^{o'}+3a_5^{o'}+2a_6^{o'}}{18}\right)\left(\frac{13+5w_a}{18}\right)$$

Using the Centroid Ranking technique for HIFNs, the ranking was introduced for $A^{o^I}_{GH}=(a_1{}^0,,....,a_6{}^0;a_1^{o'},....,a_6^{o'})$, which are hexagonal intuitionistic fuzzy numbers with the constraints $u_a=1$ and $w_a=0$.

$$R\left[A^{o^I}_{GH}\right]=\left(\frac{2a_1{}^0+3a_2{}^0+4a_3{}^0+4a_4{}^0+3a_5{}^0+2a_6{}^0}{18}\right)\left(\frac{5}{18}\right)+\left(\frac{2a_1^{o'}+3a_2^{o'}+4a_3^{o'}+4a_4^{o'}+3a_5^{o'}+2a_6^{o'}}{18}\right)\left(\frac{13}{18}\right)$$

Mathematical Formulation

The arithmetic structure of intuitionistic hexagonal fuzzy numbers is illustrated below for the case in which the total supply equals the total demand.

Min Z= $\sum_{i=1}^{k}\sum_{j=1}^{l}\hat{\tau}_{ij}\hat{x}_{ij}$

To the constraints

$\sum_{j=1}^{l}\hat{x}_{ij}=\hat{a}_i$, $j=1,2.....l$, $\sum_{i=1}^{k}\hat{x}_{ij}=\hat{b}_j$, $i=1,2.....k$

$\sum_{i=1}^{k}\hat{a}_i=\sum_{j=1}^{l}\hat{b}_j$; $i=1,2...k$; $j=1,2....l$ and $\hat{x}_{ij}\geq 0$, $i=1,2...k$; $j=1,2....l$

The following method, which is displayed in the table [1], is an open representation of the transportation problem (TP) of fuzzy

Transportation Problem

All of the restrictions in the transportation problem are typically of the equality kind. The observed data set needs to be modified in many transportation-related issues in order to meet certain correlations or requirements. The variables' observed values are frequently imprecise rather than precise, and in certain cases, they are approximated using the information at hand. Even with these approximations, the variables still need to meet a number of stringent constraints and relationships. The problem's various aims may clash with one another, complicating the decision

making process. Consequently, it is not always possible to compare or evaluate these goals directly. These circumstances are common in real-world transportation and optimization issues. Therefore, to get workable and trustworthy solutions, the right adjustment and balancing strategies are required (Table 1). Furthermore, variables like transportation cost, delivery time, journey distance, quantity of items moved, and underutilized capacity may be represented by the cost coefficients in transportation problems. Because there is sometimes limited or incomplete data available, these elements are ambiguous and imprecise. Many real-world scenarios make it impossible to identify precise numerical values. In order to deal with ambiguity and uncertainty in transportation models, fuzzy techniques are frequently employed.

This can be expressed mathematically as a TP (Transportation Problem):

$$\text{Min } Z= \sum_{i=1}^{k}\sum_{j=1}^{l} C_{ij} X_{ij} \quad ------(3.4)$$

Subject to

$$\left.\begin{array}{ll} \sum_{j=1}^{l} x_{ij} = a_i & i=1,2,.....k \\ \sum_{i=1}^{k} x_{ij} = j & j=1,2,.....l \\ x_{ij} \geq 0 & i=1,2,....k,\ j=1,2,...l \end{array}\right\} ------(3.5)$$

where x_{ij} is the quantity to be transferred from the origin (i) to the destination (j), and C is the cost of transporting a unit from the i^{th} source to the j^{th} terminal. It is evidently necessary and sufficient for the linear transportation problem given in (2.2) to have a solution that

$$\sum_{i=1}^{k} a_i = \sum_{j=1}^{l} b_j \quad ------(3.6)$$

(i.e)Note that the total supply and demand are assumed to be equal. If this condition does not hold, a dummy source or destination may be introduced to restore balance. The feasibility of solving the problem is verified only when condition (2.3) is fulfilled. The Transportation Problem (TP) is then formulated by controlling x_{ij} , with the objective of minimizing the total transportation cost.

Recommended Algorithm

Step 1: Confirm whether the given hexagonal intuitionistic fuzzy transportation problem is balanced. If an appropriate dummy row or column with hexagonal zero costs, having its supply or demand equal to the difference between the total fuzzy supply and total fuzzy demand, is not incorporated, the problem is considered unbalanced.

(ie) $$\sum_{i=1}^{k} a_i = \sum_{j=1}^{l} b_j$$

Step 2: Using the given HIFTP's centroid ranking value, create a clear transportation table. The purpose of this transformation is to express how supply and demand are ranked.

Step 3: For each row, identify the minimum cell value and subtract it from every corresponding cell value within that row, then insert the obtained results at the top-right corner of the relevant cost cells.

Step 4: For each column, identify the minimum cell value and subtract it from every corresponding cell value within that column, then insert the obtained results at the bottom-right corner of the relevant cost cells.

Step 5: Put the summation value in the appropriate cell value after adding the right-top and right-bottom values.

Step 6: Identify the highest value and allocate the least supply or demand quantity to the cell with the smallest element across all rows and columns. Eliminate the row or column in which the supply or demand has been completely fulfilled.

Step 7: Step six must be executed repeatedly until a total of (K+L-1) allocations have been assigned. If the number of allocated cells does not reach the required count, Modi's method should be applied to determine the optimal solution.

Step 8: The original transportation value should be replaced by the corresponding value of the fulfilled cell.

Step 9: Calculate the minimum cost.

Numerical Example

Refer to the table below and analyze a HIFTP with the corresponding data mentioned there in (Table 2). The fuzzy hexagonal intuitionistic numbers are transformed into a clear value using the centroid ranking algorithm (Table 3,4,5,6,7). There are $(3+4-1)=6$ cells allotted. The predicted Ranking algorithm might then be used to determine the best choice.

$$Min\ Z = 13(6) + 24(5) + 29(2) + 8(8) + 12(5) + 10(14)$$

$$Min\ Z = 520$$

A comparative analysis of the optimality conditions of NWCM, LCM, RMM, and MODI with the newly suggested ranking technique is shown in Figure 2. The findings reveal that the newly suggested ranking technique achieves the most optimal results (Figure 2).

CONCLUSION

The principal contribution of this research is to identify the most favorable feasible solution for a fuzzy transportation problem involving HIFN through the utilization of the recently proposed ranking algorithm. This method is universally applicable to any fuzzy transportation problem. The recently introduced ranking approach offers a simple and consistent framework that can be utilized to strengthen or diminish a targeted function across various types of problems. Additionally, this method has the potential to be broadened to tackle transportation-based challenges by making use of a second fuzzy algorithm.

ABSTRACT

The Western Dharwar Craton (WDC) in southern India is one of the best-preserved Archean terranes in the world and hosts an extensive network of Proterozoic mafic dyke swarms that record episodic mantle-plume activity, continental extensional tectonics, and super continental break-up. Despite their importance, mafic dykes in the WDC remain incompletely documented relative to those of the Eastern Dharwar Craton. This study presents a systematic geospatial mapping of fifteen mafic dyke intrusions across the Hassan, Tumkur (Tiptur area) and Chikmagalur districts of Karnataka using ArcGIS Pro and high-resolution Google Earth™ imagery. Field GPS data were integrated with satellite imagery, digitised as line features in a WGS 1984 UTM Zone 43N coordinate system, and analysed for spatial distribution, orientation, length and density. Collectively these results indicate at least four temporally and kinematically distinct episodes of mafic magmatism in the WDC, driven by changing mantle and plate-boundary conditions during the Paleoproterozoic. The systematic clockwise reorientation of dyke strikes records a progressive rotation of the regional extension direction over ~500 Myr. The geospatial workflow demonstrated here provides a cost-effective, scalable and reproducible framework for dyke-swarm mapping in other Precambrian terranes where field access is limited.

INTRODUCTION

Mafic dyke swarms are among the most geologically informative features of Precambrian cratons. Emplaced as discordant sheet intrusions during episodes of crustal extension, their compositions, ages and orientations preserve an integrated record of mantle dynamics, palaeogeographic configurations and the Wilson cycle of supercontinent assembly and dispersal (Ernst and Buchan, 2001; Halls, 1982; Srivastava, 2011; Srivastava and Gautam, 2018). Because dykes cross-cut all pre-existing lithologies and are datable by high-precision U–Pb baddeleyite geochronology, they serve as linear time-markers that constrain the relative and absolute chronology of Precambrian crustal evolution (French and Heaman, 2010; Hou et al., 2008). The Dharwar Craton of southern India comprises an extensive exposure of rocks ranging in age from approximately 3.6 to 2.5 Ga; it records the full spectrum of Archean crust-building processes, including tonalite–trondhjemite–granodiorite (TTG) magmatism, greenstone-belt evolution and dome-and-keel structural geometry (Naqvi and Rogers, 1987; Ramakrishnan and Vaidyanadhan, 2008; Meen et al., 1992). Following cratonisation at approximately 2.5 Ga, the craton was intruded by multiple generations of Paleoproterozoic mafic dyke swarms recording at least four major magmatic events between approximately 2.37 and 1.79 Ga (Halls et al., 2007; Kumar et al., 2012a, 2012b; French and Heaman, 2010).

The Dharwar Craton is classically divided into the Western Dharwar Craton (WDC) and the Eastern Dharwar Craton (EDC) by the Chitradurga Shear Zone (CSZ), a major sinistral transpressional structure (Swami Nath et al., 1976; Chadwick et al., 2000). More recently, a tripartite division into Western, Central and Eastern blocks has been proposed on the basis of geochronological and geochemical data (Peucat et al., 2013; Jayananda et al., 2018). Whereas mafic dyke swarms in the EDC have been extensively studied using field mapping, geochemistry, geochronology and palaeomagnetism (Srinivasa Sarma et al., 2020; Piispa et al., 2011; Srivastava et al., 2015), those of the WDC remain comparatively undocumented. This disparity limits our understanding of whether Paleoproterozoic dyke swarms extend uniformly across the craton or are partitioned along older tectonic boundaries. The rapid proliferation of satellite remote-sensing data and geographic information systems (GIS) has fundamentally transformed the scope and resolution of geological mapping in poorly accessible terranes. Google Earth™ provides sub-metre-resolution imagery that enables identification of linear dyke outcrops through tonal, morphological and textural contrasts with surrounding host rocks (Srivastava et al., 2015). ArcGIS supplies the analytical and visualisation infrastructure necessary to digitise, geo-reference, attribute and spatially analyse mapped features at regional scales. Together, these platforms facilitate systematic dyke-swarm mapping that can subsequently be integrated with field observations, geochemical data and geochronological constraints (Legg, 1994; Hou et al., 2008; Kumar et al., 2012a).

This study presents the first systematic geospatial mapping of mafic dykes in the Hassan, Tumkur (Tiptur area) and Chikmagalur districts of Karnataka, located within the WDC. Fifteen dyke intrusions were identified, located and digitised using a combined Google Earth™ and ArcGIS workflow, and their spatial distribution, trend groups and areal densities were analysed and correlated with known Paleoproterozoic dyke swarms. The objectives of the study are: (1) to document the distribution and orientation of mafic dykes in the study area; (2) to identify correlations between mapped dyke trends and known magmatic events in the WDC; (3) to evaluate the utility and limitations of geospatial methods for dyke mapping in Archean terranes; and (4) to provide a baseline dataset for future geochronological and geochemical investigation of WDC dyke swarms.

Geological Setting

The Dharwar Craton:

The Dharwar Craton forms the principal Archean nucleus of the Indian Peninsula and is bounded to the south by the Southern Granulite Terrain, to the east by the Eastern Ghats Mobile Belt, to the north by the Deccan Volcanic Province and the Bastar Craton, and to the west by the present-day western continental margin (Radhakrishna and Naqvi, 1986; Ramakrishnan and Vaidyanadhan, 2008). The craton exposes a continuous rock record spanning approximately 3.6–2.5 Ga and comprises three principal lithological associations: (i) the Peninsular Gneissic Complex

(PGC), an extensive sheet of TTG orthogneisses that forms the basement; (ii) two generations of supracrustal greenstone sequences (the Sargur Group and the Dharwar Supergroup); and (iii) late-tectonic K-rich granitoid batholiths emplaced between approximately 2.61 and 2.5 Ga (Jayananda et al., 2006, 2008; Chadwick et al., 2000; Rogers, 1988). The craton has traditionally been divided into the WDC and the EDC along the Chitradurga Shear Zone (Swami Nath et al., 1976; Swaminath and Ramakrishnan, 1981). However, Peucat et al. (2013) and Jayananda et al. (2018) proposed a tripartite crustal model in which a Central Dharwar Craton is distinguished between the WDC and EDC on the basis of distinct thermal histories, geochronological signatures and crustal thicknesses. The WDC is older, dominated by >3.0 Ga TTGs and Sargur Group enclaves; the CDC is a transitional block with mixed Meso- to Neoarchean crust; and the EDC is characterised by abundant 2.7–2.5 Ga juvenile tonalitic and granodioritic magmatism (Peucat et al., 2013; Jayananda et al., 2018; Singh et al., 2009).

The Western Dharwar Craton:

The WDC occupies a broad tract of Karnataka State and encompasses the study districts of Hassan, Tumkur (Tiptur area) and Chikmagalur. It is dominated by Meso- to Neoarchean lithologies and preserves some of the oldest basement rocks in the Indian Peninsula, including TTG gneisses with protolith ages of 3.4–3.0 Ga (Beckinsale et al., 1980; Taylor et al., 1984; Peucat et al., 1993; Jayananda et al., 2006, 2008). Two principal supracrustal cycles are preserved within the WDC. The older cycle, the Sargur Group (≥3.0–3.35 Ga), comprises dismembered greenstone belts tectonically interleaved within the PGC. These include ultramafic and mafic lavas (including komatiites), banded iron formations (BIFs) and pelitic metasediments. Principal exposures occur at Holenarsipur, Nuggihalli, Nagamangala, Sargur and Krishnarajpet (Swaminath and Ramakrishnan, 1981; Nutman et al., 1992; Peucat et al., 1995; Naqvi et al., 2009). The Holenarsipur belt is considered the oldest exposed supracrustal sequence in the Dharwar Craton, with ages exceeding 3.3 Ga (Radhakrishna and Naqvi, 1986).

The younger cycle, the Dharwar Supergroup (2.6–2.9 Ga), unconformably overlies both the PGC and the Sargur Group (Trendall et al., 1997; Nutman et al., 1996; Jayananda et al., 2008). In the WDC it is divided into the older Bababudan Group (predominantly mafic–ultramafic volcanic rocks and BIFs) and the younger Chitradurga Group (a mixed volcano-sedimentary succession). The greenstone belts of the WDC—including the Bababudan, Kudremukh, Shimoga and Chitradurga belts—host some of India's oldest supracrustal rocks (Chadwick et al., 1985a, 1985b; Ramakrishnan and Vaidyanadhan, 2008). A prominent metamorphic gradient characterises the WDC, with greenschist-facies conditions in the north, amphibolite-facies conditions in the central regions, and granulite-facies assemblages in the south, reflecting the northward tilt of the craton and the progressive exhumation of deeper crustal levels southward (Pichamuthu, 1965; Raith et al., 1982; Raase et al., 1986). The CSZ defines the eastern boundary of the WDC and represents a Late Archean sinistral transpressional collision zone active during final cratonisation between approximately 2.56 and 2.50 Ga (Chadwick et al., 2000; Chardon and Jayananda, 2008).

Mafic Dyke Swarms of the Western Dharwar Craton:

Following cratonisation at approximately 2.5 Ga, the WDC was intruded by multiple generations of mafic dykes recording prolonged Paleoproterozoic extensional tectonics. Several radiometrically dated swarms are recognised.

~2.37 Ga — Dharwar Giant Dyke Swarm (DGDS). This is the most voluminous and geographically extensive dyke swarm in the Dharwar Craton. Covering an area exceeding 140,000 km², the DGDS is interpreted as the product of a mantle plume and is characterised by ENE- to E-trending dykes in the north that rotate systematically to ESE–WNW directions further south (Halls et al., 2007; Kumar et al., 2012a). Baddeleyite U–Pb ages constrain emplacement to 2369 ± 2 Ma (Halls et al., 2007). ~2.22–2.21 Ga — Anantapur–Kunigal swarm. This NW–SE to N–S trending swarm is documented in both the WDC and EDC and is interpreted as a rift-related event (Kumar et al., 2012b; Nagaraju et al., 2018). Baddeleyite U–Pb ages constrain emplacement to 2209 ± 6 Ma (French and Heaman, 2010). ~1.89–1.88 Ga — Hampi (Southern Bastar–Cuddapah) swarm. N–S trending dykes of this age record the major extensional episode associated with the Southern Bastar–Cuddapah Large Igneous Province (French et al., 2008). Emplacement ages range from 1891 to 1883 Ma (French et al., 2008; French and Heaman, 2010). ~1.79 Ga — youngest Paleoproterozoic swarm. The youngest documented dyke generation in the Dharwar Craton trends NW–SE and has been linked to rifting associated with the Columbia (Nuna) supercontinent (Kumar et al., 2012b; Ernst and Srivastava, 2008). A

possible older Neoarchean swarm (~2.7 Ga) has been inferred from Rb–Sr whole-rock error chrons on E–W trending dykes in the southern WDC (Dawson and Hargraves, 1994), although this age requires confirmation by U–Pb geochronology.

Geology of the Study Districts

Hassan district

The Hassan district lies within the central WDC and is characterised by the dominance of the Peninsular Gneissic Complex, comprising TTG gneisses dated between 3.4 and 3.0 Ga (Beckinsale et al., 1980; Taylor et al., 1984). Subordinate exposures of Sargur Group supracrustals—including ultramafic bodies (komatiites, meta-peridotites and dunites), amphibolites and BIFs—occur as enclave-like remnants within the TTG gneisses. The mafic dykes in Hassan are distributed across the gneissic terrain and exhibit variable orientations. They intrude both the TTG basement and Sargur Group enclaves, often without discernible chilled margins owing to prolonged metamorphic overprinting at amphibolite-facies conditions (Raith et al., 1982; Raase et al., 1986). Dykes in this area occur as boulders, mounds or laterite-capped ridges extending from a few metres to several hundred metres in length.

Tiptur area (Tumkur district)

The Tiptur area, in the western part of Tumkur district, hosts one of the most notable mafic dyke concentrations in the WDC—the Tiptur Dyke Swarm. This area is underlain by a combination of TTG gneisses, Sargur Group supracrustals and Dharwar Supergroup greenstones. Two principal dyke generations are recognised (Murthy, 1995; Piispa et al., 2011): (1) older NE–SW trending metadolerite dykes, often intensely foliated and recrystallised to amphibolite facies, lacking primary igneous textures; and (2) younger NW–SE trending dolerite dykes, which are relatively unaltered and preserve ophitic to sub-ophitic textures, plagioclase laths and locally chilled margins. The compositional contrast and structural relationship between these two groups indicate distinct emplacement episodes separated by an interval of deformation or metamorphism. The dykes are basaltic to doleritic in bulk composition and exhibit tholeiitic affinities consistent with mantle-derived magmas (Chatterjee and Bhattacharji, 2001; Pandey et al., 1997).

Chikmagalur district

The Chikmagalur district straddles the transition between the WDC and the western margin of the Bababudan greenstone belt. The region is underlain by TTG gneisses of the PGC, Sargur Group enclaves comprising BIFs and ultramafic–mafic complexes, and the Bababudan Group of the Dharwar Supergroup, which is characterised by mafic volcanic rocks, shallow-marine sediments and BIFs (Chadwick et al., 1985a; Swaminath and Ramakrishnan, 1981). Mafic dykes in Chikmagalur are less densely distributed than at Tiptur but are geologically significant because they intrude both the older basement gneisses and the supracrustal sequences, providing cross-cutting age constraints. The district also lies within the zone of transition from greenschist to amphibolite facies, rendering some dykes variably metamorphosed (Raase et al., 1986). The Mudigere area falls within this district, where dykes are hosted in moderately hilly terrain with moderate vegetation cover, requiring integration of satellite imagery for effective mapping.

MATERIALS AND METHODS

The workflow comprised five sequential stages: (i) field data collection; (ii) GIS project set-up and coordinate-system definition; (iii) geo referencing of base maps; (iv) data import and digitisation; and (v) attribute population, symbolisation and spatial analysis. The complete workflow is summarised in Figure 2, and each stage is described in turn below.

Field Data Collection

Systematic field reconnaissance was conducted across the Hassan, Tumkur (Tiptur) and Chikmagalur districts to locate and document mafic dyke exposures. At each outcrop the following attributes were recorded: (i) GPS

coordinates (WGS 1984 datum) using a hand-held receiver with a nominal positional accuracy of ±5 m; (ii) strike and dip of the dyke plane, measured with a Brunton compass; (iii) dyke width, estimated by tape measure or pace-and-compass traverse; (iv) rock type (dolerite, metadolerite, amphibolite-facies mafic rock); (v) petrographic field observations, including grain size, texture (ophitic, sub-ophitic, granular), visible mineral assemblage, degree of alteration and the presence or absence of chilled margins; and (vi) host-rock type and cross-cutting relationships with adjacent lithologies. Field observations were logged on standardised sheets and transferred to Microsoft Excel for database management. Pre-field planning used Google Earth™ imagery to identify candidate outcrops from linear topographic and tonal anomalies, optimising the efficiency of field traverses in terrain characterised by dense vegetation and lateritic cover. Table 1 presents the GPS locations and principal attributes of the fifteen dyke outcrops documented in this study. The dataset spans a latitudinal range of approximately 12°55′ to 13°24′ N and a longitudinal range of approximately 75°39′ to 76°37′ E, covering an area of approximately 100 km (E–W) by 60 km (N–S). Coordinates are reported as recorded during the field survey.

GIS Project Set-up and Coordinate System:

A new project was created in ArcGIS Pro (version 3.x; ESRI, 2023), with the coordinate reference system set to WGS 1984 UTM Zone 43N (EPSG: 32643), which is optimal for Karnataka's geographic extent and minimises area and distance distortion at the regional scale of the study. The ESRI Geologic Mapping Template was employed as the base project framework, providing pre-configured feature-class definitions, topology rules and standard geological symbology that facilitate consistent representation of dykes, shear zones, contacts and lithological boundaries. Base-map rasters were sourced from the Bhukosh portal (bhukosh.gsi.gov.in), the online geological-mapping repository of the Geological Survey of India (GSI), which provides georeferenced 1:50,000-scale quadrangle sheets for the study area. Additional imagery was integrated from Google Earth™ and from USGS Landsat 8 OLI scenes accessed through Earth Explorer.

Georeferencing of Base Maps

Geological base maps downloaded from the Bhukosh portal were available as scanned raster images (TIFF or PDF) without embedded spatial-reference data. Georeferencing was performed in ArcGIS Pro using the Georeference tool. A minimum of eight well-distributed ground control points (GCPs) were identified on each raster by matching recognisable features—road intersections, river confluences and settlement boundaries—against their known coordinates from field surveys and Google Earth™. A first-order polynomial (affine) transformation, which corrects for translation, rotation and scale, was applied to each raster. The root-mean-square (RMS) error of all georeferencing operations was maintained below 10 m, consistent with the nominal positional accuracy of 1:50,000-scale maps. Georeferenced rasters were exported as GeoTIFFs and projected to WGS 1984 UTM Zone 43N prior to overlay with field GPS data.

Data Import and Digitisation

Field GPS coordinates were imported into ArcGIS Pro using the "Add XY Data" tool, with latitude and longitude assigned to the Y- and X-axes respectively and the spatial reference set to WGS 1984. The resulting point feature class was verified against Google Earth™ imagery to confirm accurate placement (Fig. 3). Mafic dykes were digitised as polyline features in a new line feature class within the project geodatabase, traced from field GPS waypoints and extended along their inferred strike using: (i) field-measured strike and dip; (ii) tonal and morphological lineaments visible in Google Earth™ imagery; and (iii) lithological contacts visible on the georeferenced GSI base maps. Snapping was performed with a tolerance of 5–10 m to ensure geometric continuity at dyke end-points and host-rock contacts. All polylines were digitised at a consistent on-screen scale of 1:10,000.

Attribute Population and Symbology

The attribute table of the dyke feature class was populated for each digitised dyke with the following fields: Dyke_ID, Locality, District, Strike_deg (0–360°), Dip_dir, Dip_angle, Width_m, Lithology, Metamorphic_grade, Texture (e.g. ophitic, granular, foliated), Trend_group (E–W, NE–SW, NW–SE, N–S) and Inferred_age_Ga. The Field Calculator was used to derive dip direction from strike, assuming a right-hand-rule convention. Symbology followed

the USGS FGDC Geologic Map Symbolisation Standard (FGDC-STD-013-2006, Section 1.3; U.S. Geological Survey, 2006). Unmetamorphosed dolerite dykes were symbolised as solid black lines, and metamorphosed metadolerite and amphibolite-facies dykes as dashed lines. Line thickness was graduated in proportion to estimated dyke width, from 0.5 pt for dykes narrower than 5 m to 2.0 pt for dykes wider than 50 m.

Spatial Analysis

Spatial analyses were performed to characterise the geometry and distribution of the mapped dyke network. The Linear Directional Mean tool (ArcGIS Spatial Statistics toolbox) was applied to compute the mean azimuth and angular variance of each trend group. Buffer analyses at radii of 2, 5 and 10 km around the Chitradurga Shear Zone were used to assess spatial clustering of dykes relative to the principal structural boundary. Kernel density estimation was applied to dyke mid-points to produce a continuous dyke-density surface. Rose diagrams of dyke strikes were compiled from the orientation data and plotted as circular frequency histograms (10° bins) using the ggplot2 package in R. Finally, proximity analysis quantified the minimum distance of each dyke to the nearest mapped greenstone-belt boundary and to the CSZ, providing a basis for evaluating structural controls on dyke emplacement.

RESULTS

Spatial Distribution and Coverage:

Fifteen mafic dyke outcrops were identified and digitised across the three study districts (Table 1; Figs 1 and 4). Seven dykes occur in Hassan district, six in the Tiptur area (Tumkur district) and two in Chikmagalur district. The mapped dykes span a combined outcrop length of approximately 48 km, with individual traceable lengths ranging from less than 1 km to approximately 12 km where continuous exposure permitted along-strike tracing. Dyke density is highest in the Tiptur area (~0.18 dykes km^{-2} within a 20 km radius of the township), intermediate in Hassan (~0.09 dykes km^{-2}) and lowest in Chikmagalur (~0.06 dykes km^{-2}). The low apparent density in Chikmagalur probably reflects a combination of genuinely sparser dyke abundance and reduced outcrop visibility beneath vegetation and laterite in the higher-relief terrain. Google Earth™ imagery was particularly effective in the Tiptur area, where dykes form prominent linear ridges and boulder trains visible in 30-cm-resolution imagery; in Hassan and Chikmagalur, several dykes were partly obscured by laterite and required field walking to delineate their full extent.

Dyke Orientations and Trend Groups

Four dominant trend groups are recognised in the dataset, consistent with the multi-swarm model established for the broader Dharwar Craton (Fig. 5). The relative proportions of these groups differ systematically between the three study districts: the Tiptur area (Tumkur) is dominated by the NE–SW set, Hassan preserves a mixed E–W, NE–SW and N–S population, and Chikmagalur is represented by only two dykes of contrasting NW–SE and N–S trend (Fig. 6). NE–SW trend (n = 7). Dykes JK, SH, DN, NL, BY, MN and KDG define a well-developed NE–SW trend with strikes ranging from approximately 042° to 055° (mean azimuth ~049°). This is the most frequently represented orientation in the dataset. These dykes are predominantly metadoleritic and exhibit variable amphibolite-facies overprinting, consistent with an earlier emplacement age than the relatively fresh dolerites. E–W trend (n = 4). Dykes GW, CP, AD and TP exhibit strikes between approximately 085° and 092° (mean azimuth ~089°). These dykes occur mainly in Hassan district and the Tiptur area and are predominantly doleritic, some with incipient foliation. NW–SE trend (n = 2). Dykes PN and KDH strike approximately 315°–320° (mean azimuth ~318°) and occur in Chikmagalur district and the Tiptur area respectively. Both are relatively unaltered dolerites, suggesting a younger emplacement age. N–S trend (n = 2). Dykes BR and MD strike near-N–S (000°–005°). Both are unfoliated dolerites with well-preserved igneous textures and are among the freshest dykes in the dataset.

Field and Petrographic Observations:

Mafic dykes in the study area occur in three principal morphological forms: (i) continuous ridges or wall-like outcrops rising 0.5–3 m above the surrounding lateritic plain; (ii) discrete boulder trains aligned along the dyke

strike; and (iii) inselberg-like mounds where the dyke is more resistant than the surrounding gneiss (Fig. 7). Width estimates from field measurement range from approximately 2 m for the narrowest dykes (e.g. CP, BY) to approximately 45 m for the widest (e.g. KDH, MD). Chilled margins are rarely preserved owing to prolonged exposure and amphibolite-facies overprinting; where observable (notably in dykes TP and MD) they occur as fine-grained zones ~5–10 cm wide against the TTG-gneiss contact. The older NE–SW trending metadolerites (e.g. SH, DN, MN) are dark greenish-grey, fine- to medium-grained, with a pervasive foliation defined by aligned amphibole and plagioclase; the primary ophitic texture is partially to wholly replaced by a granoblastic to nematoblastic metamorphic fabric. The younger dolerites (e.g. MD, BR, PN) are dark grey to black, medium-grained, with well-preserved ophitic to sub-ophitic textures defined by calcic plagioclase laths (labradorite, ~$An_{50–70}$) interlocked with clinopyroxene (augite), together with minor ilmenite, magnetite and interstitial chlorite. The E–W trending dykes (GW, CP, AD, TP) are intermediate in alteration state, showing partial development of a metamorphic foliation but local preservation of original igneous mineralogy.

ArcGIS Mapping Outputs and Spatial Statistics

The ArcGIS workflow produced three principal deliverables: (1) a georeferenced vector polyline dataset of the digitised dykes with fully populated attribute fields; (2) a kernel-density raster illustrating the spatial concentration of dyke mid-points across the study area; and (3) a publication-quality geological map in ArcGIS Layout View, incorporating the GSI 1:50,000 base map, digitised dykes symbolised by trend group, field GPS points, district boundaries, major greenstone belts and the trace of the CSZ. Outputs were exported as a 300-dpi PDF for print and as a GeoPackage (.gpkg) for open-format data sharing. The rose diagram (Fig. 5) clearly illustrates the NE–SW dominance, with a secondary E–W mode and minor NW–SE and N–S peaks. Buffer analysis shows that all NE–SW trending dykes lie within ~40 km of the CSZ trace, whereas N–S and NW–SE dykes are distributed more broadly across the craton interior. Google Earth™ imagery further demonstrates that the weathering-resistant dyke ridges locally control surface drainage and the siting of tanks and reservoirs (Fig. 7a), a geomorphic signature that aids remote identification of concealed dyke segments.

DISCUSSION

Correlation of Dyke Trends with Known Magmatic Events

The four trend groups identified in this study map onto four documented Paleoproterozoic (and possibly one late Neoarchean) magmatic events in the Dharwar Craton (Fig. 8). While the absence of direct radiometric ages for the dykes documented here precludes definitive chronological assignment, the combination of orientation, petrography, metamorphic grade and geographic position provides a basis for the following correlations, which are advanced as testable hypotheses rather than established ages. NE–SW dykes (~2.37 Ga, Dharwar Giant Dyke Swarm). The NE–SW trending metadolerites (JK, SH, DN, NL, BY, MN, KDG) are the most abundant dykes in the dataset and show the highest degree of metamorphic overprinting, consistent with affiliation to the ~2.37 Ga DGDS—the oldest and most voluminous well-dated dyke event in the Dharwar Craton (Halls et al., 2007; Kumar et al., 2012a). The DGDS is a radiating swarm centred in the northern EDC, with NE-trending members extending well into the WDC (Kumar et al., 2012a; Srinivasa Sarma et al., 2020). The NE–SW orientation observed here is consistent with the fan of the DGDS at approximately 13°N, and the amphibolite-facies overprint reflects the post-emplacement thermal history of the WDC basement (Borah et al., 2014). The clustering of NE–SW dykes within ~40 km of the CSZ is consistent with the shear zone acting as a zone of crustal weakness preferentially exploited by these magmas (Chadwick et al., 2000).

E–W dykes (~2.7 Ga or ~2.18 Ga?). The E–W trending dykes (GW, CP, AD, TP) are of intermediate preservation state, suggesting they are older than the NW–SE and N–S groups but possibly younger than the fully recrystallised NE–SW metadolerites. Dawson and Hargraves (1994) reported Rb–Sr whole-rock errorchron ages of approximately 2.7 Ga from E–W trending dykes near Harohalli in the southern Dharwar Craton; if confirmed by U–Pb geochronology, these could represent the oldest dyke generation in the study area. Alternatively, they may correlate with the ~2.18

Ga Mahbubnagar–Dandeli swarm, which also includes E–W members (Pandey et al., 1997). Geochemical and geochronological data are required to resolve this ambiguity.

NW–SE dykes (~2.21–2.22 Ga, Anantapur–Kunigal swarm). Dykes PN and KDH trend NW–SE and are relatively unaltered dolerites, consistent with a younger emplacement age than the NE–SW metadolerites. French and Heaman (2010) dated members of the Anantapur–Kunigal swarm to 2209 ± 6 Ma. NW–SE trending dykes of this age are documented in the WDC near Kunigal by Kumar et al. (2012b), and the PN and KDH dykes mapped here may represent a north-western extension of this swarm into Chikmagalur and the Tiptur area. Their fresh character implies emplacement after the main phase of Paleoproterozoic metamorphism in this part of the WDC. N–S dykes (~1.89–1.88 Ga, Hampi swarm). Dykes BR and MD trend approximately N–S and are the freshest and least metamorphosed in the dataset. N–S trending dykes of this orientation are consistently correlated with the 1891–1883 Ma Southern Bastar–Cuddapah Large Igneous Province (French et al., 2008), associated with plume-driven rifting of the Dharwar Craton from the Bastar Craton. The Hampi swarm is characterised by N–S trending tholeiites with an OIB-like enriched isotopic signature indicative of an enriched mantle-plume source (French et al., 2008; French and Heaman, 2010). A ~1.79 Ga age cannot be excluded for these dykes without U–Pb geochronology, as NW–SE to N–S trending dykes of that age are also documented in the region (Kumar et al., 2012b).

Tectonic and Stress-field Implications

Because a dyke opens against the least principal stress (σ_3) and propagates in the plane containing σ_1 and σ_2, the strike of each dyke generation constrains the orientation of the horizontal extension direction at the time of emplacement (extension is perpendicular to dyke strike). On this basis, the successive change in dyke orientation in the study area—from NE–SW (~2.37 Ga) to NW–SE (~2.21 Ga) to N–S (~1.89 Ga)—implies a progressive rotation of the regional σ_3 direction over approximately 500 Myr of Paleoproterozoic tectonism. This progressive reorientation of the extension direction is illustrated schematically in Figure 9. At ~2.37 Ga, the NE–SW striking DGDS dykes require a NW–SE directed extension ($\sigma_3 \approx 135°/315°$), potentially associated with the impingement of a mantle plume and the initial fragmentation of the Neoarchean supercraton Sclavia (Halls et al., 2007; Ernst and Srivastava, 2008; French and Heaman, 2010). By ~2.21 Ga, the NW–SE striking Anantapur–Kunigal dykes indicate a rotation of σ_3 to a NE–SW direction (≈ 045°/225°), consistent with a different plate-boundary configuration during the amalgamation of the Columbia (Nuna) supercontinent (French and Heaman, 2010; Hou et al., 2008). By ~1.89 Ga, the N–S striking Hampi dykes record an E–W directed extension ($\sigma_3 \approx 090°/270°$), consistent with the rifting of the Dharwar Craton from the Bastar Craton and the early break-up of Columbia (French et al., 2008). The E–W striking dykes, if genuinely older, would correspond to an approximately N–S extension. This clockwise sense of σ_3 rotation is compatible with the ~30° south-to-north swing in DGDS dyke trends documented across the craton by Srinivasa Sarma et al. (2020). The preferential clustering of NE–SW dykes near the CSZ supports the interpretation that the shear zone acted as a long-lived zone of crustal weakness repeatedly exploited by successive dyke-forming magmas. Reactivation of earlier structural fabrics as conduits for younger magmas is widely observed in Precambrian cratons (Halls, 1982; Ernst and Buchan, 2001). The relatively sparse dyke population in the Chikmagalur area, particularly within the Bababudan greenstone belt, may reflect the greater mechanical coherence of greenstone sequences relative to the more brittle TTG-gneissic basement, which preferentially accommodated extensional fracturing (Chatterjee and Bhattacharji, 2001).

Utility and Limitations of the Geospatial Approach

This study demonstrates that Google Earth™ imagery and ArcGIS are effective tools for reconnaissance-phase dyke mapping in the WDC, particularly for extending the coverage of known swarms into previously unsurveyed areas. The combination of high-resolution satellite imagery (capable of resolving metre-scale topographic and tonal contrasts), GPS-based field control and GIS spatial analysis provides a workflow that is cost-effective and reproducible in other Precambrian cratons (Srivastava et al., 2015; Legg, 1994). The demonstration that resistant dyke ridges locally control surface drainage (Fig. 7a) further shows how geomorphic proxies can be used to trace concealed dyke segments. Several limitations must nonetheless be acknowledged. First, the terrain is dominated by laterite-capped surfaces of variable vegetation cover, and dyke detection from imagery is restricted to areas where

erosion has exposed competent dyke rock; an unknown number of dykes may be entirely concealed beneath deep laterite, particularly in Chikmagalur. Second, orientation and length data alone are insufficient to uniquely identify the swarm affiliation of any individual dyke without supporting geochronology and geochemistry: multiple swarms may share similar orientations, and later deformation may have modified original trends. The age assignments in Table 1 and Section 5.1 are therefore explicitly tentative. Third, field width estimates are subject to error from incomplete exposure, oblique cross-sections and alteration halos that blur the dyke–host contact. These limitations collectively underscore the need for follow-up U–Pb baddeleyite geochronology, whole-rock and mineral geochemistry, and palaeomagnetic study to convert the spatial dataset established here into a robust chronostratigraphic framework.

CONCLUSIONS

- Fifteen mafic dyke intrusions were identified and digitised in the Hassan, Tumkur (Tiptur area) and Chikmagalur districts of the Western Dharwar Craton, exhibiting four dominant strike orientations: NE–SW (n = 7), E–W (n = 4), NW–SE (n = 2) and N–S (n = 2). Dyke density is highest in the Tiptur area and lowest in Chikmagalur.
- The NE–SW trending metadolerites are tentatively correlated with the ~2.37 Ga Dharwar Giant Dyke Swarm on the basis of orientation, amphibolite-facies overprinting and spatial association with the Chitradurga Shear Zone. The NW–SE dolerites are correlated with the ~2.21–2.22 Ga Anantapur–Kunigal swarm and the N–S dolerites with the ~1.89–1.88 Ga Hampi (Southern Bastar–Cuddapah) swarm. The E–W dykes may represent a Neoarchean (~2.7 Ga) generation or, alternatively, the ~2.18 Ga Mahbubnagar–Dandeli swarm.
- The successive change in dyke strike from NE–SW through NW–SE to N–S records a progressive rotation of the Paleoproterozoic extension (σ_3) direction—from NW–SE through NE–SW to E–W—reflecting changing mantle and plate-boundary conditions during the assembly and dispersal of Paleoproterozoic supercontinents.
- The combined Google Earth™–ArcGIS methodology provides an efficient, scalable and reproducible framework for dyke-swarm mapping in Precambrian terranes and is directly transferable to other cratonic regions.
- U–Pb baddeleyite geochronology, whole-rock geochemistry and palaeomagnetic study of the dykes documented here are essential next steps to confirm swarm affiliations, characterise magma-source compositions and integrate the WDC dyke record into global Paleoproterozoic palaeogeographic reconstructions.

Table 1: Field Attributes of the Fifteen Mafic Dyke Outcrops Documented in the Western Dharwar Craton, Karnataka

ID	Locality	District	Lat. (°N)	Long. (°E)	Trend	Rock Type	Inferred age (Ga)
GW	Gawrapura	Hassan	13°30′31″N	76°34′57″E	E–W	*Dolerite*	~2.7 / 2.18
CP	Channarayapatna	Hassan	12°55′29″N	76°22′13″E	E–W	*Metadolerite*	~2.7
AD	Ande(Honnehalli)	Hassan	13°08′39″N	75°56′43″E	E–W	*Dolerite*	~2.7 / 2.18
TP	Tiptur	Tumkur	13°16′02″N	76°25′49″E	E–W	*Dolerite*	~2.7
JK	Jakkanahalli	Tumkur	13°20′38″N	75°39′50″E	NE–SW	*Metadolerite*	~2.37
SH	Shettikere Road	Tumkur	13°18′07″N	76°31′49″E	NE–SW	*Metadolerite*	~2.37
DN	Danikanahalli	Hassan	13°11′29″N	75°52′51″E	NE–SW	*Metadolerite*	~2.37
NL	Nirlakatte	Tumkur	13°19′03″N	76°32′46″E	NE–SW	*Metadolerite*	~2.37
BY	Bayaravalli	Hassan	13°23′02″N	75°38′55″E	NE–SW	*Metadolerite*	~2.37
MN	Mallenahalli	Hassan	13°11′34″N	75°54′02″E	NE–SW	*Amphibolite dyke*	~2.37
PN	Panditnahalli	Chikmagalur	13°10′22″N	76°00′01″E	NW–SE	*Dolerite*	~2.21

KDH	Kedegahalli (D2)	Tumkur	13°24′06″N	76°36′23″E	NW–SE	*Dolerite*	~2.21
KDG	Kedegahalli (D1)	Tumkur	13°24′09″N	76°36′23″E	NE–SW	*Dolerite*	~2.37
BR	Basavarajapura	Hassan	13°12′48″N	75°58′01″E	N–S	*Dolerite*	~1.89
MD	Mudigere	Chikmagalur	13°15′57″N	76°25′36″E	N–S	*Dolerite*	~1.89

Inferred ages are tentative correlations based on orientation, petrography and spatial context. Note: the Kedegahalli locality (KDG, KDH) hosts two closely spaced dykes of contrasting orientation (NE–SW and NW–SE), providing a field cross-cutting relationship that is potentially valuable for relative-age determination.

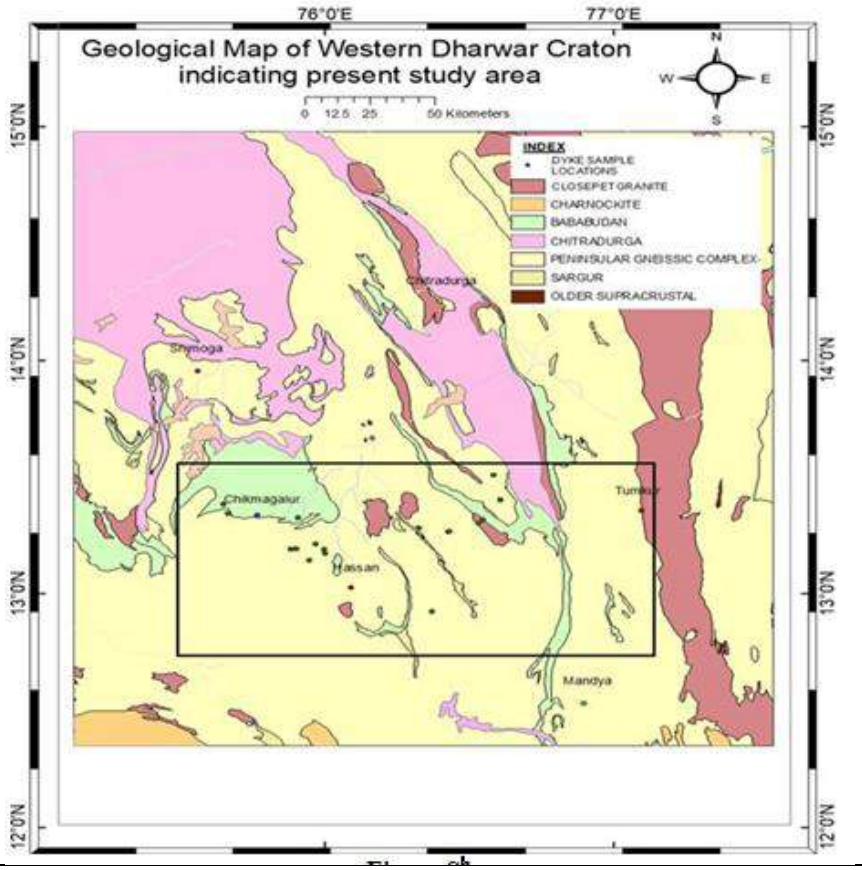

Figure 1. Geological map of the Western Dharwar Craton showing the principal lithological units and the location of the present study area (black rectangle), together with the documented dyke sample localities. Base geology after the Geological Survey of India; compiled in ArcGIS Pro.

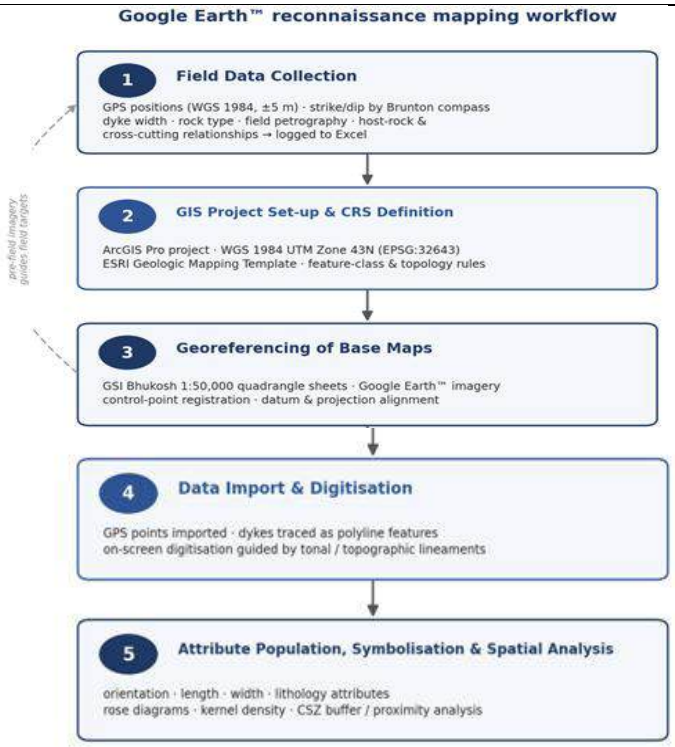

Figure 2. Workflow for the geospatial mapping of mafic dyke swarms in the Western Dharwar Craton, showing the five sequential stages from field data collection to spatial analysis. Pre-field Google Earth™ reconnaissance informs the selection of field targets (dashed feedback loop).

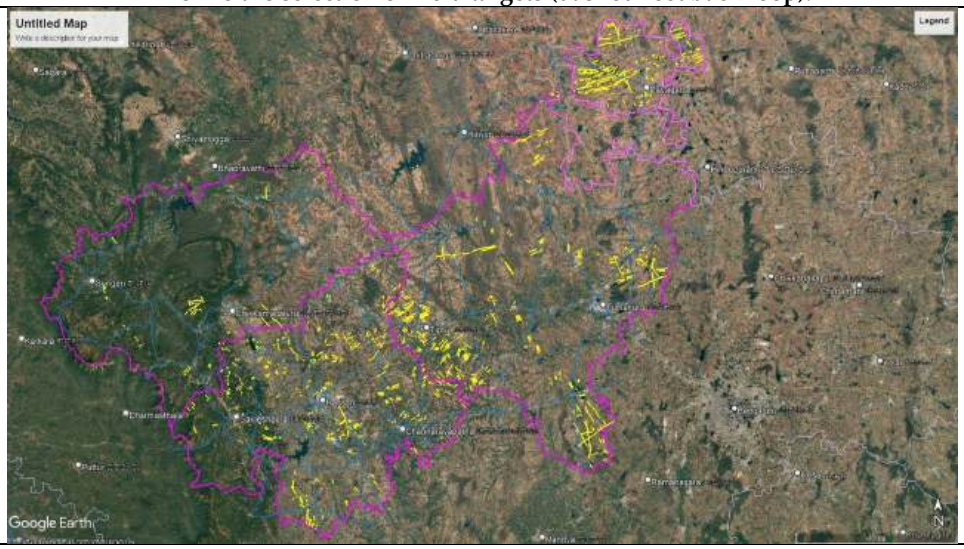

Figure 3. Google Earth™ workspace showing the district boundaries (magenta) of the study area and the KML/KMZ traces of digitised mafic dykes (yellow) prior to import into ArcGIS Pro. This dual-platform workflow enabled rapid visual validation of digitised features against high-resolution imagery.

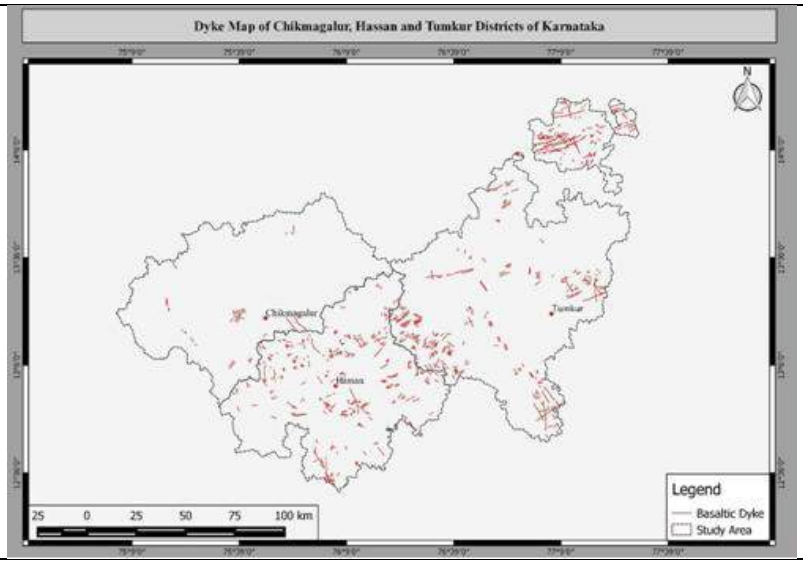

Figure 4. ArcGIS-derived dyke map of the study area (Chikmagalur–Hassan–Tumkur districts) showing the full network of digitised mafic dykes (red lines) within the study-area outline. The regional pattern reveals a dense, multi-directional dyke swarm; the fifteen field-verified dykes of Table 1 are a representative subset of this network.

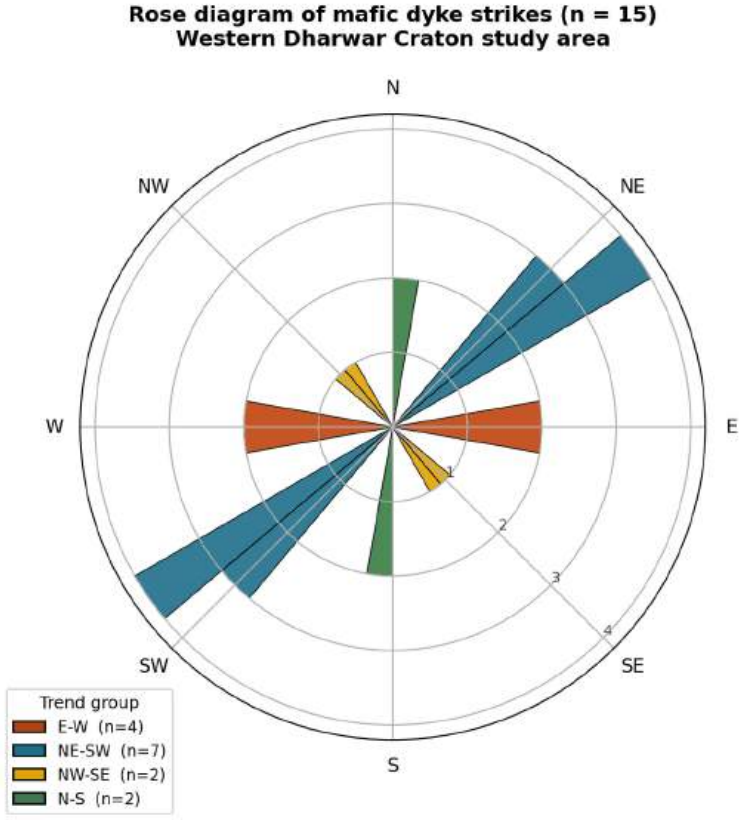

Figure 5. Rose diagram of mafic dyke strikes for the fifteen documented outcrops, plotted as an azimuth-frequency histogram (10° bins, bidirectional). The NE–SW maximum dominates, with a subordinate E–W mode and minor NW–SE and N–S populations.

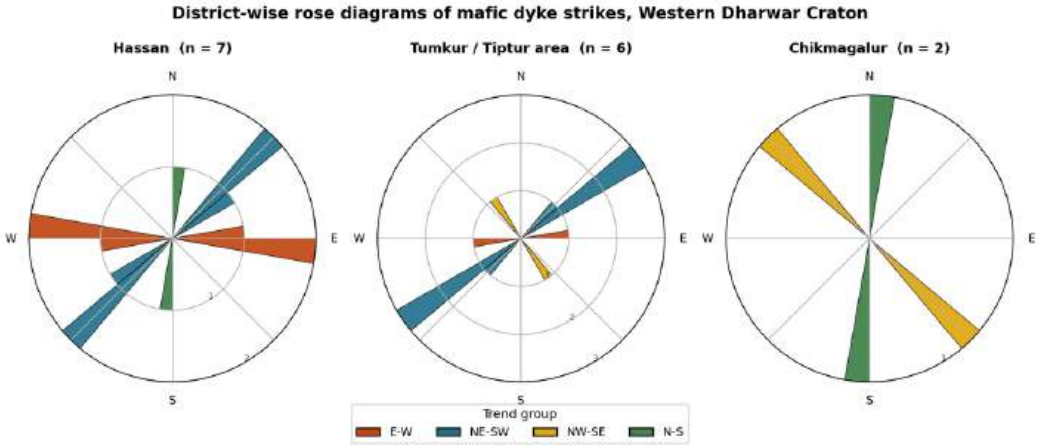

Figure 6. District-wise rose diagrams of mafic dyke strikes, plotted separately for the Hassan (n = 7), Tumkur / Tiptur (n = 6) and Chikmagalur (n = 2) districts (10° bins, bidirectional). The NE–SW-dominated Tiptur population contrasts with the more heterogeneous Hassan set; the small Chikmagalur sample reflects both genuinely sparser dyke abundance and reduced outcrop visibility.

Figure 7. Field and remote-sensing expression of mafic dykes in the study area. (a) Google Earth™ image of a prominent linear dyke ridge (yellow arrows) whose weathering-resistant trace locally controls surface drainage and a natural tank. (b) Boulder-train outcrop of a dolerite dyke rising above the lateritic plain (arrow) Dyke AD. (c) Close-up of a fresh dolerite dyke in sharp contact with host TTG gneiss; pencil for scale (arrow indicates dyke margin) Dyke CP.

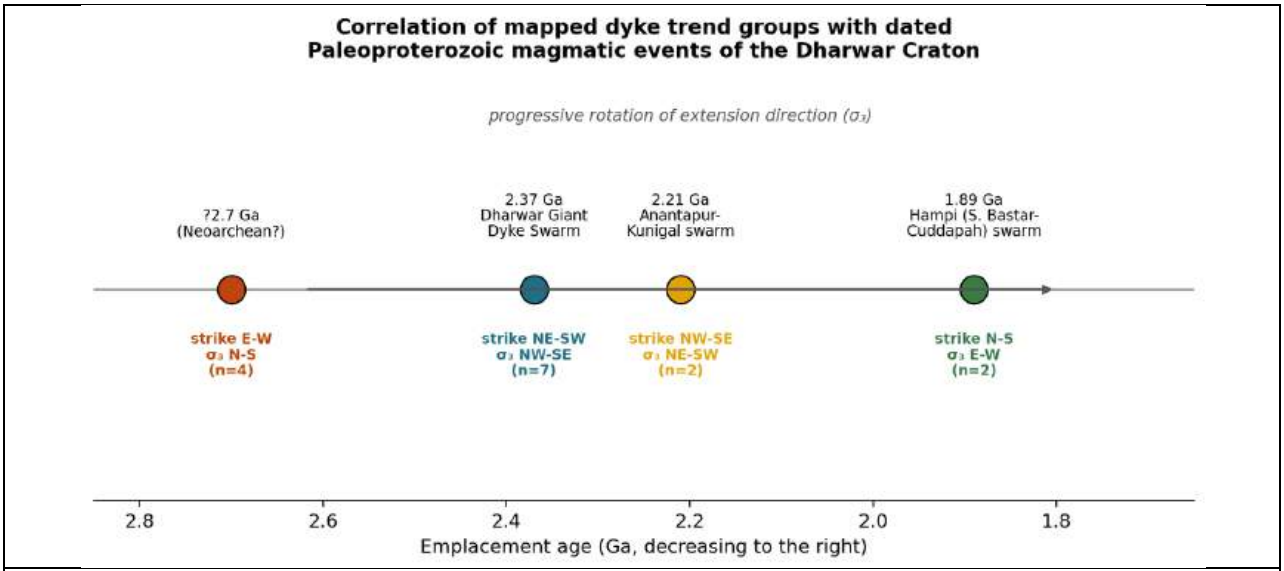

Figure 8. Schematic correlation of the four mapped dyke trend groups with dated Paleoproterozoic magmatic events of the Dharwar Craton. For each event the dyke strike and inferred least-principal-stress (σ_3, extension) direction are shown; note that σ_3 is oriented perpendicular to dyke strike in every case. The sequence records a progressive rotation of the extension direction over ~500 Myr.

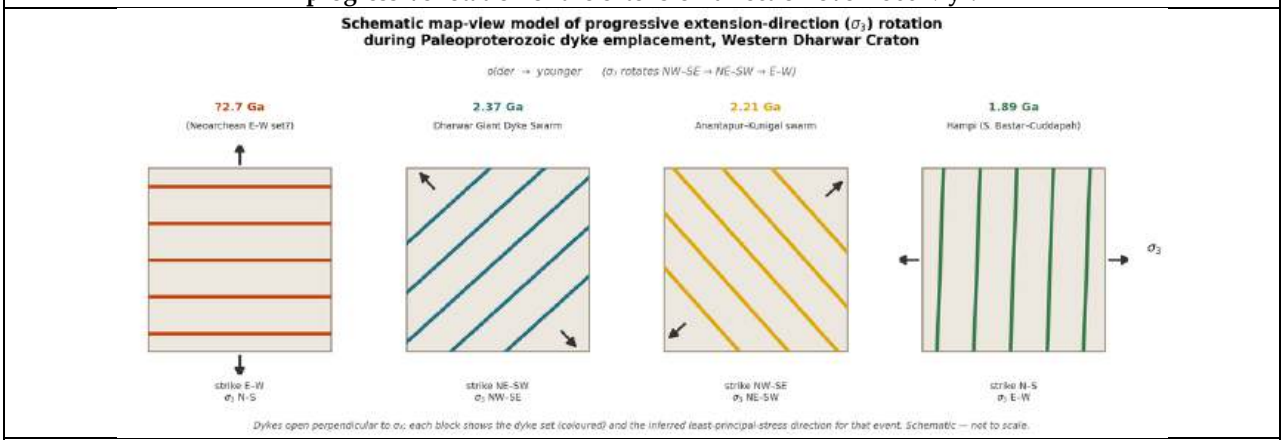

Figure 9. Schematic map-view model of the progressive rotation of the least-principal-stress (σ_3, extension) direction during Paleoproterozoic dyke emplacement in the Western Dharwar Craton. Each block shows a dyke set at its characteristic strike together with the inferred σ_3 direction, which is perpendicular to strike in every case. Not to scale; the ?2.7 Ga E–W event is shown as a tentative early stage.

ABSTRACT

This paper presents a novel class of matrices called Symmetric Penta partitioned Neutrosophic Fuzzy Matrices (SPNFM) and explores their foundational properties. We further define two specific types within this framework: the Range-Symmetric PNFM (RS-PNFM) and the Kernel-Symmetric PNFM (KS-PNFM), which exhibit characteristics analogous to EP-matrices in the unitary setting. Initially, we provide equivalent formulations for identifying RS-type matrices. Subsequently, we establish necessary and sufficient conditions under which an SPNFM qualifies as a KS matrix. To support our theoretical findings, we offer illustrative examples introducing the concepts of kernel symmetry and range symmetry within the SPNFM framework.

Keywords: SPNFM, RS-PNFM, KS-PNFM, SPNFPM, Adjacency Matrices

INTRODUCTION

The concept of uncertainty has long been an intrinsic element of real-world systems, particularly in contexts involving imprecise, incomplete, or inconsistent information. To address such uncertainty, Zadeh [22] introduced the pioneering concept of *FS*, which laid the foundation for representing vagueness through degrees of membership rather than binary logic. Building upon this idea, Atanassov [1] proposed the notion of *intuitionistic fuzzy sets (IFS)*, extending the classical fuzzy framework by incorporating both membership and non-membership degrees, thereby enhancing flexibility in handling indeterminate information. Subsequent advancements in fuzzy set theory led to several important generalizations. Bhowmik and Pal [4,5] introduced *generalized interval-valued intuitionistic fuzzy sets*, enabling representation of uncertainty through interval values instead of precise numbers. Similarly, Khan and Pal [13] and Khan and A. Pal [14] explored the algebraic structures of *intuitionistic fuzzy matrices*, including tautological matrices and their generalized inverses. These developments significantly enriched the theoretical and computational aspects of fuzzy matrix theory. Parallel to these theoretical advancements, the study of *fuzzy matrices* evolved through investigations into their algebraic and structural properties. Cen [7,8] examined generalized inverses and partial ordering in fuzzy matrices, while Shyamal and Pal [20,21]presented new operators and IVFM, expanding their applicability in complex computational environments. Mitra [16] unified the concept of matrix partial order through generalized inverses, offering a foundational framework for matrix theory in fuzzy environments. To bridge fuzzy logic with soft computing, Cagman and Enginoglu [6] and Borah et al. [3]established*fuzzy soft matrix theory*, combining *soft sets* with *fuzzy logic* to handle parameterized uncertainty.

Extending this, Muthukumar and Krishnan [17] proposed *GRFM*, which integrate fuzzy, soft, and rough set theories to enhance decision-making under uncertain conditions. The concept of *neutrosophy* introduced by Smarandache [18] generalized fuzzy and intuitionistic fuzzy sets by incorporating the three components of truth, indeterminacy, and falsity. This framework was further extended to *hypersoft* and *plithogenichypersoft sets* by Smarandache [19], enriching the expressive power of Neutrosophic modeling in multi-attribute and multi-parameter domains. These contributions stimulated extensive research into hybrid and matrix-based neutrosophic structures. In this direction, various authors explored matrix formulations within the neutrosophic environment. Das et al. [9] integrated neutrosophic and rough sets to form *neutrosophic soft rough sets*, while Kamacı [12] investigated *hybrid hypersoft–rough structures*. Al-Quran et al. [2]future a *neutrosophic soft rough set* approach to manage dual-layer uncertainty in decision systems. More recently, Jafar and Saeed [10] introduced the *matrix theory for neutrosophichypersoft sets* and demonstrated its applications in *multi-attributive multicriteria decision-making problems*. Likewise, Jayasudha and Raghavi [11] developed operations on *neutrosophichypersoft matrices*, showcasing their practical relevance in complex systems. Further hybridization of neutrosophic, fuzzy, soft, and rough frameworks led to advanced matrix structures designed for robust decision analysis. Martina and Deepa [15] studied *rough neutrosophic matrices* and demonstrated their potential applications in multi-criteria decision-making contexts. Such hybrid models effectively manage vagueness, incompleteness, and indeterminacy simultaneously, thereby providing more powerful tools for decision-support systems.

Anandhkumar et al. [23] presented the *determinant theory* of QPNFMs and established its applicability to multi-criteria decision-making (MCDM), marking a significant advancement in the integration of neutrosophic matrix theory with real-world decision-based systems. Complementing this direction, Radhika et al. [24] expanded the framework to interval-valued secondary k-range symmetric QPNFMs, incorporating enhanced flexibility in representing interval uncertainty within decision-making environments. Another important line of research is the investigation of various inverse forms of neutrosophic fuzzy matrices. Anandhkumar et al. [25] examined multiple inverse types—such as generalized and pseudo-inverses—thereby enabling deeper algebraic characterizations and computational applications. This was further complemented by studies on pseudo similarity transformations in neutrosophic fuzzy matrices [26], paving the way for spectral and structural analysis analogous to classical matrix theory. Parallel to these developments, researchers have explored Schur complements, kernel-based structures, and symmetry properties in neutrosophic and intuitionistic fuzzy matrices. Radhika et al. [27] analyzed the Schur

complement in *k-kernel symmetric block QPNFMs*, offering new insights into block-structured neutrosophic systems. In related works, the concepts of *kernel* and *k-kernel symmetric matrices* have been extended to intuitionistic fuzzy settings [33], thus broadening the theoretical foundation across different uncertainty-based matrix classes. The integration of interval-valued uncertainty with generalized inverses has also gained attention. Prathab et al. [28] investigated IV secondary k-RSFM with generalized inverses, highlighting their computational role in systems with bounded uncertainty. Meanwhile, research on partial orderings within both intuitionistic and IFM has become an important tool in ranking, optimization, and structural analysis. Reverse Tilde and Minus partial orders in intuitionistic fuzzy matrices were studied in [29], while Reverse Sharp and Left-T Right-T partial orders were examined both in the intuitionistic fuzzy domain [30] and later extended to neutrosophic fuzzy matrices [34]. These ordering mechanisms contribute to a deeper understanding of dominance relations in uncertain environments. Further advancements include the introduction of secondary k-RSNFM [31] and the development of k-idempotent NFM along with their characterizations and generalizations [32]. These works provide essential algebraic foundations for matrix operations, decomposition theories, and iterative processes within neutrosophic frameworks.

Notations

$R\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$: Row space of $\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$,

$C\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$: Column space of $\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$,

$N\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$: Null Space of $\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$.

Preliminaries

Definition 2.1 Let X be a universe. A Pentapartitioned neutrosophic Fuzzy Matrices A on X is an object of the form

$\left[P_{ij}\right]=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$

Where $0\le T_{ij}^{P}+C_{ij}^{P}+I_{ij}^{P}+U_{ij}^{P}+F_{ij}^{P}\le 5$

T_{ij}^{P} = Truth membership, C_{ij}^{P} =Contradiction membership

I_{ij}^{P} = Ignorance membership, U_{ij}^{P} = Unknown membership

F_{ij}^{P} = False membership

Definition: 2.2 Let $P=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$ be a PNFM, if

$\mathrm{R}\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\mathrm{R}\left[\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right]$ then $P=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$ is called as Range symmetric.

Example: 2.1 Consider a SPNFM

$$\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\begin{bmatrix} <0.4,0,1,0.5,0.8> & <1,0,1,0.2,0.5> & <0.2,0.3,0.4,0.6,0.9> \\ <1,0,1,0.2,0.5> & <1,0,1,0.5,0.4> & <1,0,1,0.9,0.8> \\ <0.2,0.3,0.4,0.6,0.9> & <1,0,1,0.9,0.8> & <1,0,1,0.7,0.8> \end{bmatrix}$$

Here, $\mathrm{R}\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\mathrm{R}\left[\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right]$

$$\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\begin{bmatrix} <0.4,0,1,0.5,0.8> & <1,0,1,0.2,0.5> & <0.2,0.3,0.4,0.6,0.9> \\ <1,0,1,0.2,0.5> & <1,0,1,0.5,0.4> & <1,0,1,0.9,0.8> \\ <0.2,0.3,0.4,0.6,0.4> & <1,0,1,0.9,0.8> & <1,0,1,0.7,0.8> \end{bmatrix}$$

$$\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}=\begin{bmatrix} <0.4,0,1,0.5,0.8> & <1,0,1,0.2,0.5> & <0.2,0.3,0.4,0.6,0.4> \\ <1,0,1,0.2,0.5> & <1,0,1,0.5,0.4> & <1,0,1,0.9,0.8> \\ <0.2,0.3,0.4,0.6,0.9> & <1,0,1,0.9,0.8> & <1,0,1,0.7,0.8> \end{bmatrix}$$

$$\left[(0.4,0,1,0.5,0.8)\ (1,0,1,0.2,0.5)\ (0.2,0.3,0.4,0.6,0.9)\right]\in R\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right),$$

$$\left[(0.4,0,1,0.5,0.8)\ (1,0,1,0.2,0.5)\ (0.2,0.3,0.4,0.6,0.9)\right]\notin R\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right),$$

$$\left[(1,0,1,0.2,0.5)\ (1,0,1,0.5,0.4)\ (1,0,1,0.9,0.8)\right]\in R\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right),$$

$$\left[(1,0,1,0.2,0.5)\ (1,0,1,0.5,0.4)\ (1,0,1,0.9,0.8)\right]\in R\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right),$$

$$\left[(0.2,0.4,0.4,0.6,0.4)\ (1,0,1,0.9,0.8)\ (1,0,1,0.7,0.8)\right]\in R\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right),$$

$$\left[(0.2,0.4,0.4,0.6,0.4)\ (1,0,1,0.9,0.8)\ (1,0,1,0.7,0.8)\right]\notin R\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right),$$

$$R\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)\neq R\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right).$$

Note: 2.1 For SPNFM R with det $\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)>(0,0,0,1,1)$ has non- zero rows and non-columns, here after $\mathrm{N}\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=(0,0,0,1,1)$

$=\mathrm{N}\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right)$. Furthermore, a symmetric matrix $\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$

$=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}$ that is $\mathrm{N}\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\mathrm{N}\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right)$.

Definition: 2.5 Let $P=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)\in\left(PNFM\right)_{n}$, if

$\mathrm{N}\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\mathrm{N}\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right)$ and then P is called Kernel symmetric where

$\mathrm{N}\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\{x/x\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=(0,0,0,1,1)$ and $x\in F_{1\times n}\}$.

Theorems and Results

Theorem: 3.1 For an NHSRFM

$P=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right), Q=\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)\in PNFM_{nn}$ and K be a PNFMPM

$$N\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=N\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)\Leftrightarrow N\left(K\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)K^{T}\right)$$

$$=N\left(K\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)K^{T}\right).$$

Proof: Let $w \in N\left(K\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right)K^{T}\right)$

$\Rightarrow w\left(K\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right)K^{T}\right) = (0,0,0,1,1)$

$\Rightarrow yK^{T} = (0,0,0,1,1)$ where $y = wK\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right)$

$\Rightarrow y \in N(K^{T})$

$\det K = \det K^{T} > (0,0,0,1,1)$ (By Note: 2.1)

Therefore, $N(K^{T}) = (0,0,0,1,1)$

Hence, $y = (0,0,0,1,1)$

$\Rightarrow wK\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right) = (0,0,0,1,1)$

$\Rightarrow wK \in N\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right) = N\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)$

$\Rightarrow wK\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)K^{T} = (0,0,0,1,1)$

$\Rightarrow w \in N\left(K\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)K^{T}\right)$

$N\left(K\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right)K^{T}\right) \subseteq N\left(K\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)K^{T}\right)$

Similarly, $N\left(K\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)K^{T}\right) \subseteq N\left(K\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right)K^{T}\right)$

Therefore,

$N\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right) = N\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)$

$\Rightarrow N\left(K\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right)K^{T}\right) = N\left(K\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)K^{T}\right)$

Conversely, if $N\left(K\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right)K^{T}\right) = N\left(K\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)K^{T}\right)$,

$N\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right) = N\left(K^{T}\left(K\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right)K^{T}\right)K\right)$

$= N\left(K^{T}\left(K\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)K^{T}\right)K\right)$

$N\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right) = N\left(T_{ij}^{Q}, C_{ij}^{Q}, I_{ij}^{Q}, U_{ij}^{Q}, F_{ij}^{Q}\right)$

Example: 3.1 Consider a PNFM

$$\left(T_{ij}^{P}, C_{ij}^{P}, I_{ij}^{P}, U_{ij}^{P}, F_{ij}^{P}\right) = \begin{bmatrix} <0.3,0.3,0.4,0.5,0.3> & <0.5,0.3,0.6,0.7,0.8> & <0.2,0.3,0.4,0.4,0.7> \\ <0.4,0.7,0.6,0.4,0.6> & <0.4,0.8,0.1,0.3,0.2> & <0.2,0.5,0.1,0.5,0.7> \\ <0.2,0.4,0.4,0.1,0.4> & <0.4,0.4,0.5,0.6,0.4> & <0.4,0.5,0.6,0.5,0.6> \end{bmatrix}$$

$$K = \begin{bmatrix} (1,1,1,0,0) & (0,0,0,1,1) & (0,0,0,1,1) \\ (0,0,0,1,1) & (1,1,1,0,0) & (0,0,0,1,1) \\ (0,0,0,1,1) & (0,0,0,1,1) & (1,1,1,0,0) \end{bmatrix}$$

$$\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)=\begin{bmatrix}<0.5,0.3,0.7,0.6,0.5> & <0.4,0.3,0.6,0.9,1> & <0.3,0.4,0.4,0.5,0.7>\\ <0.5,0.7,0.5,0.1,0.5> & <0.4,0.8,0.2,0.3,0.8> & <0.2,0.5,0.2,0.4,0.6>\\ <0.2,0.4,0.4,0.5,0.1> & <0.4,0.4,0.5,0.5,0.9> & <0.4,0.5,0.6,0.7,0.9>\end{bmatrix}$$

Theorem: 3.2 For a kernel symmetric PNFM $P=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$ and K be a PNFPM

$$N\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=N\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right)$$

$$\Leftrightarrow N\left(K\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)K^{T}\right)=N\left(K\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}K^{T}\right).$$

Proof: The proof is similar to Theorem 3.1

Theorem: 3.3 For $P=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$ is kernel symmetric PNFM, then

$$N\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right)=$$

$$N\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)\right)=N\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$$

Proof: The proof is similar to Theorem 3.1

Example: 3.3 Consider a PNFM

$$\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\begin{bmatrix}<0.1,0.3,0.5,0.6,0.9> & <0.4,0.3,0.6,0.8,0.7> & <0.2,0.3,0.4,0.3,0.4>\\ <0.4,0.7,0.6,0.2,0.5> & <0.4,0.7,0.1,0.5,0.8> & <0.2,0.5,0.1,0.2,0.4>\\ <0.2,0.3,0.5,0.6,0.7> & <0.4,0.3,0.5,0.9,0.2> & <0.4,0.2,0.1,0.9,0.9>\end{bmatrix}$$

Theorem: 3.4 For a SPNFM $P=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right),Q=\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)\in PNFM_{nn}$ and K PNFPM, $R\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=R\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)\Leftrightarrow R\left(K\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)K^{T}\right)$

$$=R\left(K\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)K^{T}\right).$$

Proof: The proof is similar to theorem 3.1

Example: 3.4 Consider a PNFM

$$\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\begin{bmatrix}<0.1,0.3,0.5,0.4,0.7> & <0.4,0.3,0.6,0.8,0.9> & <0.2,0.3,0.4,0.3,0.2>\\ <0.4,0.3,0.6,0.5,0.6> & <0.4,0.7,0.1,0.8,0.9> & <0.2,0.5,0.1,0.7,0.8>\\ <0.2,0.3,0.4,0.1,0.2> & <0.2,0.5,0.1,0.4,0.8> & <0.4,0.2,0.1,0.8,0.9>\end{bmatrix}$$

$$\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)=\begin{bmatrix}<0.2,0.3,0.4,0.1,0.2> & <0.2,0.5,0.1,0.4,0.8> & <0.4,0.2,0.1,0.8,0.9>\\ <0.4,0.3,0.6,0.5,0.6> & <0.4,0.7,0.1,0.8,0.9> & <0.2,0.5,0.1,0.7,0.8>\\ <0.1,0.3,0.5,0.4,0.7> & <0.4,0.3,0.6,0.8,0.9> & <0.2,0.3,0.4,0.3,0.2>\end{bmatrix}$$

$$K=\begin{bmatrix}(1,1,1,0,0) & (0,0,0,1,1) & (0,0,0,1,1)\\ (0,0,0,1,1) & (1,1,1,0,0) & (0,0,0,1,1)\\ (0,0,0,1,1) & (0,0,0,1,1) & (1,1,1,0,0)\end{bmatrix}$$

$$R\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=R\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)\Leftrightarrow R\left(K\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)K^{T}\right)$$

$$=R\left(K\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)K^{T}\right).$$

Theorem: 3.5 For $P=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$ be the SPNFM and K be a PNFPM, $R\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)$

$$=R\left(\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}\right)\Leftrightarrow R\left(K\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)K^{T}\right)$$

$$=R\left(K\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)^{T}K^{T}\right).$$

Example: 3.5 Consider a PNFM

$$\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\begin{bmatrix}<0.2,0.1,0.3,0.9,0.1> & <0.3,0.3,0.2,0.4,0.3> & <0.4,0.5,0.6,0.9,0.8>\\ <0.3,0.3,0.2,0.4,0.3> & <0.4,0.7,0.1,0.9,0.4> & <0.4,0.5,0.2,0.1,0.2>\\ <0.4,0.5,0.6,0.9,0.8> & <0.4,0.5,0.2,0.1,0.2> & <0.3,1,1,0.9,0.2>\end{bmatrix}$$

$$K=\begin{bmatrix}(1,1,1,0,0) & (0,0,0,1,1) & (0,0,0,1,1)\\ (0,0,0,1,1) & (1,1,1,0,0) & (0,0,0,1,1)\\ (0,0,0,1,1) & (0,0,0,1,1) & (1,1,1,0,0)\end{bmatrix}$$

Theorem: 3.6 For a SPNFM $P=\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right),Q=\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)\in PNFM_{nn}$ and K PNFPM $C\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=C\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)\Leftrightarrow C\left(K\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)K^{T}\right)$

$$=C\left(K\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)K^{T}\right).$$

Example: 3.6 Consider a PNFM

$$\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=\begin{bmatrix}<0.1,0.1,0.2,0.7,0.8> & <0.3,0.3,0.2,0.8,0.3> & <0.4,0.5,0.6,0.7,0.8>\\ <0.2,0.3,0.4,0.3,0.2> & <0.4,0.7,0.1,0.3,0.4> & <0.4,0.5,0.1,0.9,0.8>\\ <0.4,0.5,0.6,0.4,0.7> & <0.4,0.5,0.2,0.5,0.5> & <0.4,0.1,0.1,0.4,0.7>\end{bmatrix}$$

$$\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)=\begin{bmatrix}<0.4,0.5,0.6,0.7,0.8> & <0.3,0.3,0.2,0.8,0.3> & <0.1,0.1,0.2,0.7,0.8>\\ <0.4,0.5,0.1,0.9,0.8> & <0.4,0.7,0.1,0.3,0.4> & <0.2,0.3,0.4,0.3,0.2>\\ <0.4,0.1,0.1,0.4,0.7> & <0.4,0.5,0.2,0.5,0.5> & <0.4,0.5,0.6,0.4,0.7>\end{bmatrix}$$

$$C\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)=C\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)\Leftrightarrow C\left(K\left(T_{ij}^{P},C_{ij}^{P},I_{ij}^{P},U_{ij}^{P},F_{ij}^{P}\right)K^{T}\right)$$

$$=C\left(K\left(T_{ij}^{Q},C_{ij}^{Q},I_{ij}^{Q},U_{ij}^{Q},F_{ij}^{Q}\right)K^{T}\right).$$

$$K = \begin{bmatrix} (1,1,1,0,0) & (0,0,0,1,1) & (0,0,0,1,1) \\ (0,0,0,1,1) & (1,1,1,0,0) & (0,0,0,1,1) \\ (0,0,0,1,1) & (0,0,0,1,1) & (1,1,1,0,0) \end{bmatrix}$$

Application

Mr. X is looking to purchase a laptop from the following options: M_1, M_2, M_3, M_4, and M_5, each of which has certain properties S_1, S_2, S_3, S_4 and S_5.

- Laptop M1 features properties S_3, S_4 and S_5, Laptop M_2 includes properties S_1, S_2, S_4 and S_5.
- Laptop M_3 has property S_1, S_2, S_3, S_4 and S_5, Laptop M_4 also includes property S_1, S_2, S_3, and S_4.
- Laptop M_5 comes with properties S_1, S_2, S_3, and S_4, what would be the best laptop choice for optimal performance?
  First, make a graph based on the providing problem as described.
  Replace M by v and S by z.
  First, generate a graph based on the providing problem as defined.

If V ={ M_1, M_2, M_3, M_4, M_5, S_1, S_2, S_3, S_4}, select A={ M_1, M_2, M_3, M_4, M_5}, describe S(x) = {z ∈ V : d(x, z) ≤ 1}, T(x)= {xu ∈ E : u ∈ S(x)} and F(x)=(S(x), T(x)), F(v_1) = { v_1, z_3, z_4, z_5}, F(v_2) = { v_2, z_1, z_2, z_4, z_5}, F(v_3) = { v_3, z_1, z_2, z_3, z_4, z_5}, F(v_4) = { v_4, z_1, z_2, z_3, z_4}, F(v_5) = { v_5, z_1, z_2, z_3, z_4}. Thus (F, A) is a soft graph. The corresponding adjacency matrix for the soft graph constructed in the previous steps is presented below. In the adjacency matrix, the value in the final column of each row corresponds to the degree of the associated vertex in the soft graph (F, A). Since the entry (Mi, S2) is (1,0,0), (1,0,0) for all i=1,2,3,4,5 parameter S2 does not provide any discriminatory value. Therefore, the second column should be removed from the matrix. By inspecting the row totals in the final column of the matrix for laptops M1, M2, M3, M4, and M5, it is observed that M3 has the highest value. Consequently, M3 is identified as the most suitable option.

CONCLUSION AND FUTURE WORK

In this paper, we introduced and developed the concept of SPNFM, establishing a comprehensive foundation for their theoretical study. Two significant subclasses—Range-Symmetric PNFMand Kernel-Symmetric PNFM—were formally defined and investigated. Through well-constructed examples. Future work may focus on extending the theory of SPNFM to higher-dimensional tensor representations and exploring their applications in complex decision-making systems, pattern recognition, and artificial intelligence. Additionally, further research can investigate the stability, decomposition, and spectral properties of SPNFM, as well as develop efficient computational algorithms for handling large-scale problems involving neutrosophic and rough-fuzzy uncertainty. Applying these matrix structures in fields such as medical diagnosis, financial modeling, and image processing also presents a promising direction for practical implementations.

ABSTRACT

The integration of artificial intelligence (AI) into healthcare has revolutionized medical diagnosis by enabling highly accurate and efficient predictions. However, the widespread adoption of AI, particularly machine learning (ML) models, faces challenges due to their opaque decision-making processes. This paper explores the potential of Explainable AI (XAI) to address this critical gap by enhancing the interpretability of ML models, fostering trust, and ensuring ethical deployment in healthcare. We propose a comprehensive framework that incorporates XAI techniques such as SHAP (Shapley Additive Explanations), LIME (Local Interpretable Model-Agnostic Explanations), and attention-based mechanisms to clarify the reasoning behind model predictions. Using real-world datasets, including medical imaging and electronic health records, we demonstrate how these techniques can provide actionable insights for clinicians while maintaining high diagnostic accuracy. The experimental results show that integrating XAI not only improves transparency but also supports clinical decision-making by highlighting the most relevant features influencing predictions. Additionally, this study delves into the ethical implications of XAI, including fairness, bias mitigation, and patient-centric care, while addressing challenges like scalability and interpretability-accuracy tradeoffs. The findings emphasize that explainability is a cornerstone for the responsible adoption of AI in healthcare, paving the way for transparent, accountable, and trustworthy systems that empower both clinicians and patients. This research serves as a step forward in advancing interpretable AI systems, offering pathways for future enhancements in real-time, multimodal, and universally interpretable healthcare applications.

Keywords: Machine learning, Explainable AI, Shapley Additive Explanations, Local Interpretable Model-Agnostic Explanations

INTRODUCTION

Artificial Intelligence (AI) has transformed the landscape of healthcare by enabling breakthroughs in medical diagnostics, predictive modeling, and treatment planning. Machine learning (ML) models, in particular, have shown remarkable success in domains such as medical imaging, genomics, and electronic health records (EHR) analysis, achieving levels of accuracy often comparable to, or surpassing, human experts (Esteva et al., 2017; Topol, 2019). Despite these advancements, a significant barrier to the widespread adoption of AI in clinical settings remains: the lack of transparency in ML decision-making processes, commonly referred to as the "black-box" nature of these models. Explainable AI (XAI) has emerged as a vital field to address this challenge by enhancing the interpretability and transparency of ML models. XAI aims to bridge the gap between complex algorithmic operations and human understanding, enabling stakeholders—clinicians, patients, and regulatory bodies—to comprehend and trust AI-driven predictions. Techniques such as SHAP (Shapley Additive Explanations) and LIME (Local Interpretable Model-Agnostic Explanations) have been widely recognized for their ability to provide insights into model behavior by identifying the contribution of individual features to predictions (Lundberg & Lee, 2017; Ribeiro et al., 2016). Furthermore, attention-based mechanisms, particularly in deep learning, have proven instrumental in highlighting critical regions in medical imaging and textual data, making the decision-making process more interpretable (Vaswani et al., 2017).

This paper explores the integration of XAI techniques into ML workflows for healthcare applications, focusing on their role in providing actionable insights for clinicians while maintaining high diagnostic accuracy. Using real-world datasets such as chest X-rays and EHR data, we evaluate the performance and interpretability of these models in predicting medical outcomes. Our findings highlight how XAI facilitates clinical decision-making by identifying relevant features influencing predictions, thereby ensuring alignment with clinical reasoning. In addition to the technical contributions, this study delves into the ethical and practical considerations of deploying XAI in healthcare. Issues such as fairness, bias mitigation, and patient-centric care are critical to ensuring that AI systems are not only accurate but also equitable and transparent (Floridi et al., 2018). Challenges such as the scalability of XAI techniques, the tradeoff between interpretability and accuracy, and the potential misinterpretation of explanations by non-expert users are also discussed. By emphasizing explainability as a cornerstone for trustworthy AI, this research aims to pave the way for the responsible deployment of AI systems in healthcare. Furthermore, it highlights the need for collaborative efforts among AI researchers, clinicians, ethicists, and policymakers to advance the development of real-time, multimodal, and universally interpretable healthcare solutions.

LITERATURE REVIEW

The adoption of artificial intelligence (AI) in healthcare has significantly advanced the field of medical diagnosis and treatment, enabling precise and efficient predictive models. However, the lack of interpretability in these models, often termed as "black-box" models, poses a significant challenge to their widespread adoption in clinical practice. This literature review explores the advancements and challenges of Explainable AI (XAI) in addressing this issue, focusing on the techniques and applications highlighted in the abstract.

Advancements in AI for Medical Diagnosis

AI has demonstrated remarkable capabilities in various healthcare domains, such as medical imaging, electronic health records (EHR) analysis, and personalized medicine. Convolutional Neural Networks (CNNs) and recurrent models have achieved state-of-the-art performance in image-based diagnosis, including detecting diseases like diabetic retinopathy and cancer from imaging datasets[1][2]. Similarly, ML models such as random forests and gradient boosting are employed for predictive tasks like patient outcome forecasting and disease progression

tracking [3]. Despite these achievements, their decision-making processes often remain opaque, leading to concerns about trust and adoption [4].

The Role of Explainable AI (XAI)

XAI aims to bridge the gap between model accuracy and interpretability, making AI systems more transparent and trustworthy. Techniques such as SHAP (Shapley Additive Explanations) and LIME (Local Interpretable Model-Agnostic Explanations) are widely recognized for their ability to provide feature-level explanations of model predictions. SHAP leverages game theory to attribute feature importance for each prediction, while LIME creates local surrogate models to explain specific predictions [5][6]. Attention-based mechanisms in neural networks, which highlight the most critical input regions for a given output, are particularly useful in healthcare applications like radiology and pathology, where interpretability is crucial [7]. These tools not only help clinicians understand the reasoning behind model outputs but also enable validation of AI predictions against clinical expertise [8].

Applications in Medical Imaging and EHR

XAI techniques have been applied extensively in medical imaging to visualize and interpret the decisions of deep learning models. For example, saliency maps and Grad-CAM (Gradient-weighted Class Activation Mapping) have been used to identify disease-specific regions in radiographic images, enhancing clinician trust in AI predictions [9][10]. In the context of EHRs, XAI has been employed to explain temporal models, allowing clinicians to track how patient history contributes to outcomes [11].

Ethical Implications and Challenges

The ethical deployment of AI in healthcare necessitates fairness, accountability, and transparency. Bias in AI models, arising from imbalanced datasets or flawed training processes, can exacerbate healthcare disparities [12]. XAI provides a mechanism to detect and mitigate these biases by exposing the underlying factors driving predictions [13]. However, challenges remain, such as the scalability of XAI techniques for complex multimodal data and the tradeoff between interpretability and accuracy [14].

Future Directions

Research continues to explore real-time explainability, which is critical in applications like emergency care. Moreover, there is a growing interest in developing universally interpretable models that provide inherent transparency without compromising performance [15]. Multimodal XAI, which integrates data from diverse sources such as imaging, genomics, and clinical notes, represents another promising avenue for advancing patient-centric care [16].

Proposed Framework

Develop a framework that incorporates XAI techniques into the ML pipeline for healthcare applications to enhance model interpretability and usability. The diagram illustrates the integration of data collection, preprocessing, and advanced AI models for medical diagnosis. The system involves data gathering from patients, preprocessing for standardization, and processing through a diagnostic system consisting of a machine learning (ML) engine, explainable AI (XAI) methods, and a large language model (LLM) engine. The results are evaluated and presented through a user interface for healthcare workers, enabling informed clinical decisions with inputs from medical experts and cloud storage for efficient data management. Explainable AI (XAI) in healthcare focuses on enhancing the interpretability and transparency of machine learning (ML) models used for medical diagnosis. This ensures that healthcare practitioners understand the reasoning behind model predictions, thereby improving trust, accountability,

Model Predictions and Importance Scores

ML models often produce predictions based on a learned function:

$$\hat{y} = f(x) \quad (1)$$

Where

$\hat{y}$is the predicted diagnosis,

$x = [x_1, x_2, \dots, x_n]$is the feature vector

$\boldsymbol{f}$is the trained model

Feature importance helps identify the contribution of each input feature to prediction. For example, in tree-based models like Randam Forests, feature importance $\boldsymbol{I_j}$ for feature $\boldsymbol{j}$ can be computed as:

$$\boldsymbol{I_j = \frac{1}{T}\sum_{t=1}^{T} \Delta G_t(j)} \quad (2)$$

Where:

$T$is the total number of trees,

$\Delta G_t(j)$is the reduction in the Gini Index or entropy for feature j in tree t

SHAP Values (Shapley Additive exPlanations)

SHAP values offer a unified measure of feature importance by attributing a models prediction to individual features based on cooperative game theory. The SHAP value for feature $\boldsymbol{j}$ is given as:

$$\boldsymbol{\emptyset_j = \sum_{S \subseteq N \setminus \{j\}} \frac{|S|!(|N|-|S|-1)!}{|N|!} [f(S \cup \{j\}) - f(S)]} \quad (3)$$

Where:

$S$is a subset of all features N excluding j

$f(S)$is the models output using only the features in subset S.

LIME (Local Interpretable Model-Agnostic Explanations)

LIME explains individual predictions by approximating the model locally with a simple interpretable model, such as a linear regression. The local model g(x) is defined as:

$$\boldsymbol{g(x) = w.x + b} \quad (4)$$

Where:

- w is the weight vector,
- $b$is the bias term.

The weights w indicate feature contributions to the prediction.

Saliency Maps and Gradients

For deep learning models, saliency maps use the gradient of the model output with respect to input features to visualize important regions in medical images. The saliency map S is computed as:

$$\boldsymbol{S_{i,j} = \left|\frac{\partial \hat{y}}{\partial x_{i,j}}\right|} \quad (5)$$

Where:

$\boldsymbol{x_{i,j}}$is the pixel intensity at location $(\boldsymbol{i}, \boldsymbol{j})$

$\hat{\boldsymbol{y}}$is the model output.

RESULTS ANALYSIS

An accuracy of 88.3% indicates that the model performs reliably for risk prediction. Interpretability- SHAP provides a high interpretability score by attributing precise importance values to each feature, making it highly suitable for clinicians to understand the contribution of risk factors like age, BMI, or glucose levels. Time Complexity - Medium computational demand, as SHAP calculates feature contributions across multiple permutations, making it feasible for moderate-sized datasets. Application: Used for Diabetes Risk Prediction on the PIMA Diabetes dataset. Application: Applied to Skin Cancer Classification using the HAM10000 dataset. Performance: With an accuracy of 92.5%, LIME performs exceptionally well, especially for complex image classification tasks. Interpretability: The moderate interpretability score reflects LIME's localized approach, which explains individual predictions but may lack a holistic view of the model's behavior. Time Complexity: High time complexity due to the need to train local surrogate models for each explanation, making it resource-intensive for large datasets. Application: Deployed for Chest X-ray Anomaly Detection using the ChestX-ray14 dataset. Performance: Achieves the highest accuracy of

94.2%, demonstrating robust performance in identifying anomalies in medical imaging. Interpretability: With a moderate interpretability score, Grad-CAM effectively highlights regions in the X-ray images that influenced the model's prediction, aiding radiologists in confirming AI findings. Time Complexity: Low computational demand makes Grad-CAM suitable for real-time and large-scale diagnostic tasks. Application: Used for Retinopathy Detection with the Kaggle Diabetic dataset. Performance: Delivers an accuracy of 91.8%, demonstrating effectiveness in detecting diabetic retinopathy. Interpretability: A high interpretability score is achieved due to the model's ability to focus on relevant image regions, aligning well with the decision-making process of ophthalmologists. Time Complexity: Medium complexity reflects the additional computation for generating attention maps, balancing explainability and performance.

Performance

- The CNN + Grad-CAM model outperforms others in AUC-ROC, precision, and recall, making it ideal for tasks requiring high diagnostic accuracy.
- XGBoost + SHAP provides a balance of strong performance and high interpretability for structured data-based diagnostics.
- Random Forest + LIME performs slightly lower in all metrics but remains a viable option for moderately complex tasks.

Interpretability

- XGBoost + SHAP leads with 90% interpretability, making it highly trusted for clinical decision-making.
- CNN + Grad-CAM, though slightly lower at 85%, compensates with intuitive visual explanations.
- Random Forest + LIME, while providing interpretability, ranks lowest due to its localized and less holistic nature.

Task Suitability

- CNN + Grad-CAM is tailored for image-based diagnostics (e.g., pneumonia detection).
- XGBoost + SHAP is optimal for structured data requiring actionable insights (e.g., cardiovascular risk prediction).
- Random Forest + LIME suits simpler classification tasks like diabetes detection where computational efficiency is secondary.

CONCLUSION

The conclusion of the document emphasizes the critical role of Explainable AI (XAI) in transforming healthcare diagnostics. By integrating XAI techniques such as SHAP, LIME, and attention mechanisms, the study demonstrates enhanced interpretability in machine learning models, making them more transparent, trustworthy, and aligned with clinical decision-making. The findings underscore how explainability supports ethical AI deployment by addressing issues like fairness, bias, and patient-centric care, while maintaining high diagnostic accuracy. Furthermore, the study highlights the importance of real-time and multimodal interpretability, paving the way for the responsible adoption of AI in healthcare. This research sets a foundation for advancing transparent and accountable AI systems that empower both clinicians and patients.

ABSTRACT

Autism Spectrum Disorder commonly affects the children of 18-24 months of age. The disease lacks social interaction and communication skills in the children often presenting with restricted interests and repetitive actions. The treatment focuses on individualized approach with multidisciplinary involvement mainly behavioral therapy. Ayurveda treatment modalities can be an option of treatment results in improved concentration and decreased hyperactivity. A 5 year old boy presented with complaints of poor eye contact, aggressive nature, and poor communication. He presented with hyperactive nature such that he didn't sit at one place for more than 3 minutes. The child showed limited interaction with other people and got frustrated and angry in little things. He was treated with Internal medications and Procedures like *Thalam, Shirodhara ,Sarvanga Abhyanga* along with *Matra Basti.* After 90 days of therapy, there was improvement in hyperactivity along with eye control and interaction. Mild improvement was observed in Speech and communication skills. The main *Dosha* affected in the disease *Unmada* (Correlated with ASD) is *Vata dosha*, So the treatment was planned as per the *Chikitsa Sutra* of the *Vataja Unmada.* Regular *Matra Basti* and other procedures helps in controlling *Vata* and relieves anxiety which helps in reducing the hyperactive nature. The treatment principles described in Ayurveda Classics can be helpful in treating ASD. There was moderate improvement in patient after 90 days of treatment.
Abstract is summarized in Figure 1.

Keywords: Ayurveda, Autism Spectrum Dosorder, Internal Medicine , Panchkarma, Hyperactivity

INTRODUCTION

Autism commonly known as Autistic Spectrum disorder is the disease affecting the communication skills and reciprocal social interaction in the children. The children presents with stereotype behaviors, as well as restricted interests and activities. The disease is found in among 40% of the children.(1)The hyperactivity in the children not only affects the development of children but also affects the life of parents and surrounding people. The etiology of the disease contains no single and definite cause, with probable causes including genetic factors and environmental factors with prenatal causes. The children presents with repetitive behavior along with low social interactions. (2) This treatment focuses on individualized approach along with behavioral therapy. Noticing its effect on society, it is the need of time to develop an interdisciplinary approach towards the disease. In Ayurveda, the symptoms of autism resembles to the disease *Unmada,* as described in classical texts. It refers to *Mano Vibhrama*(Disturbance of *Manasa* (mind) along with *Sangya Vibhrama* (disturbance in consciousness) (3) Particularly *Vata Dosha* can be said to be predominant along with *Mano DoshaRajas* and *Tamas* in *Unmada*. The treatment focuses on *Mrudu shodhan* (Mild Purification therapies) and *snehapana* particularly in *Vataj Unmada (4)* The case study presented here represents a single report of a 5 year old boy diagnosed with ASD before 3 years treated with Ayurveda principles.

MATERIALS AND METHODS

Case Introduction

A 5 year old boy was brought to OPD with complaints of poor eye contact, aggressive nature, and poor communication. He presented with hyperactive nature such that he didn't sit at one place for more than 3 minutes. The child showed limited interaction with other people and got frustrated and angry in little things. The child was with birth weight – delivered full term via Caesarean Section. The mother had multiple abortions before the last pregnancy. Also, the child had 15 days NICU admission for Hypoglycemia after birth. He had no family history with similar illness or any other major lifestyle disorders.

Developmental history: The developmental milestones were achieved at proper time except for Eye control and language. At the age of 8 moths, he was able to speak mono-bisyllable, but by the later time, it regressed. At present the child is not able to form a sentence and speak properly.

Personal History: The child has normal appetite with regular micturition and defecation. The child had sound sleep. He had pulse rate of 75 / min, respiratory rate of 19 / minute. The CNS examination revealed lack of communication and social interaction along with poor eye control. Other systemic examination were unremarkable.

Assessment criteria and past history: - The child was diagnosed as ASD as per DSM IV TR and had undergone behavioral therapy and is on medication Resperidone HS.

RESULTS

After 90 days, moderate improvement was observed in hyperactive nature, aggressive behavior with mild improvement in speech. The patient improved mild in its social interaction and eye control.

DISCUSSION

Unmada is the disease of *Manovaha Srotas* affecting the *Manasa* (Mind) and Sangya (Consciousness) of the children. The treatment mainly focuses here to control the *Vata*, the predominant *Dosha*. As it is suggested in *Chikitsa sutra* of *Vataj Unmada*, *Snehan* and *Mrudu Shodhan* was adopted here. Among the procedures, *Thalam, Sarvanga Abhyanga,*

Shirodhara and *Basti* were given to patient on regular basis. *Thalam*, application of *Kshirabala Taila* on Bregma region, as this layer is combination of multiple connective tissues, medicine applied here, gets absorbed and helps in nourishment of the nervous tissues (5) *Shirodhara* with *Mamsyadi Kwatha* helps relieve anxiety and insomnia. (6) *Vata* is the main *Dosha* responsible of the proper functioning of mind (7). 2 procedures namely *Sarvanga Abhyanga* and *Matra Basti* were administered to patient for nourishment of body and *Vata* control. *Lakshadi Taila* is *Balya* (gives strength) and works effectively in *Unmada*disease (8) As, Basti is considered to be the *ShreshthaChikitsa* (best treatment) for *Vata(9)*, *Basti* with *Bala Ashvagandhadi Taila* was given to patient for 90 days. Along with that, as *Snehan Dravya,Jivantyadi Ghrita* was given HS along with *Manas Mitra Vati*. *Manasa Mitra vati* helps in reducing the neuro-inflammation and contains antioxidant property. (10) Overall, the treatment was planned keeping in mind the *dosha* affected (*Vata* predominant), site of *dosha* (*Shirah Pradesh* – *Manasa* – mind) and condition of patient. Main improvement was noted in hyperactive nature of the patient.

CONCLUSION

ASD is the disorder affecting the communication and social life of the children. Keeping in view, the limitations in treatment, Ayurveda can contribute in improving the quality of life of such patietns. The present case study shows improvement in the hyperactive nature of the child along with mild improvement in the eye contact and social behavior. This opens the door for new research in developing a effective treatment plan in the ASD disorders.

ABSTRACT

The Gompertz distribution is widely used in survival analysis, reliability engineering, and life data analysis due to its ability to replicate aging and wear-out processes. It is an essential lifespan distribution for describing systems with monotonically increasing failure rates, which are commonly observed in engineering and biological systems in the real world. Depending on the settings of its parameters, the Gompertz distribution can properly represent a range of component lifespan characteristics

Keywords:

INTRODUCTION

Reliability analysis plays a major role in engineering system design, evaluation, and maintenance. In many practical applications, such as biological systems, mechanical assemblies, and electrical systems, a system is composed of several components connected in series. In series systems, the failure of any one component results in the failure of the system as a whole, whereas in parallel systems, the failure of any one component does not cause the whole to fail. This makes the study of system dependability very important. The Gompertz distribution has been used in reliability engineering, actuarial science, demography, and medical survival analysis because of its capacity to accurately describe aging processes. It is especially appropriate for components that undergo wear-out failures rather than random failures because its hazard function grows exponentially with time. Series and parallel systems are two basic configurations. In a parallel system, the system keeps running as long as at least one component is working, however in a series system, any component failure results in system failure. In engineering applications including power grids, communication systems, and safety-critical systems, parallel systems are frequently utilized.

Reliability engineering is essential for evaluating the performance, availability, and dependability of engineering systems. Several researchers have developed reliability models for series and parallel systems under different failure distributions, particularly Weibull models [1–8]. Recent studies have extended these approaches to non-series–parallel systems and fuzzy failure environments, enhancing the accuracy of system reliability assessment and supporting more effective engineering design and maintenance planning [9–11]. In this paper, we examine a parallel and series system whose parts adhere to separate Gompertz failure laws. The reliability function, hazard rate, mean time to failure (MTTF), and system failure rate are some of the reliability metrics that are derived. The effect of component parameters on overall system performance is investigated, demonstrating the Gompertz model's utility in series system dependability assessment.

Gompertz Distribution

Let Tbe a continuous random variable representing the lifetime of a component.

T is said to follow a Gompertz distribution with parameters:

- $a > 0$: scale (initial failure level) parameter
- $b > 0$: shape (aging rate) parameter

Probability Density Function (PDF)

$$f(t) = a\, b\, e^{bt} \exp[-a(e^{bt} - 1)], t > 0$$

Cumulative Distribution Function (CDF)

$$F(t) = 1 - \exp[-a(e^{bt} - 1)]$$

This represents the probability that failure occurs by time t.

Reliability (Survival) Function

$$R(t) = P(T > t) = \exp[-a(e^{bt} - 1)]$$

It gives the probability that the component survives beyond time t.

Hazard Rate Function$h(t) = \frac{f(t)}{R(t)} = abe^{bt}$

Interpretation

- The hazard rate increases exponentially with time.
- This captures aging and wear-out behaviour.

Mean Time to Failure (MTTF)

$$\text{MTTF} = \int_0^\infty R(t)\, dt = \int_0^\infty \exp[-a(e^{bt} - 1)]dt$$

System Description

For Series System

We have considered 'n' components series system. The failure of any one component connected in series leads to the system failure. Figure 1 represents the state

The system reliability is given by$R(t) = \prod_{i=1}^{n} R_i(t)$

The Mean time to system failure is given by$MTSF = \int_0^\infty \prod_{i=1}^{n} R_i(t)\, dt$

Notations

$R(t)$: Reliability of the system

$R_i(t)$: Reliability of the i^{th} component

Failure Distribution of the Series System

The cumulative distribution function (CDF) of the system failure time is :

$$F_s(t) = 1 - R_s(t)$$

$$F_s(t) = 1 - exp\left[-\sum_{i=1}^{n} a_i(e^{b_i t} - 1)\right]$$

Failure Rate (Hazard Function) of the Series System

The hazard rate of series system is the sum of component hazard rate:

$$h_s(t) = \sum_{i=1}^{n} h_i(t)$$

Substituting the Gompertz hazard function:

$$h_s(t) = \sum_{i=1}^{n} a_i b_i \, e^{b_i t}$$

Special Case: Identical Components

If all components are identical with parameter a and b System Reliability

$$R_s(t) = \exp[-na(e^{bt} - 1)]$$

System Failure Rate is $h_s(t) = nabe^{bt}$

Reliability Measures of a Series System with Gompertz Distribution

Gompertz distribution for a component:

i. For the i^{th} component

The failure rate is given by $h_i(t) = a_i b_i e^{b_i t}$

The component reliability is given by $R_i(t) = \exp[-a_i(e^{b_i t} - 1)]$

Gompertz distribution for the system

Now, the system reliability is given by

$$R_s(t) = \prod_{i=1}^{n} R_i(t) = \prod_{i=1}^{n} \exp[-a_i(e^{b_i t} - 1)]$$

$$R_s(t) = exp\left[-\sum_{i=1}^{n} a_i(e^{b_i t} - 1)\right] \quad (1)$$

ii. For identical Components :

If all the components are identical then System failure rate is given by

$$h_s(t) = nabe^{bt}$$

system reliability is given by

$$R_s(t) = \exp[-na(e^{bt} - 1)]$$

Illustrations

1. For a single component, the system reliability is given by

$$R_s(t) = \prod_{i=1}^{1} R_i(t) = \prod_{i=1}^{1} \exp[-a_1(e^{b_1 t} - 1)]$$

For identical components, we have

System failure rate is given by

$$h_s(t) = abe^{bt}$$

system reliability is given by

$$R_s(t) = \exp[-a(e^{bt} - 1)]$$

If system has two components, then the system reliability is given by

$$R_s(t) = \prod_{i=1}^{2} R_i(t) = \prod_{i=1}^{2} \exp[-a_i(e^{b_i t} - 1)]$$

$$R_s(t) = exp\left[-\sum_{i=1}^{2} a_i(e^{b_i t} - 1)\right]$$

$$R_s(t) = exp[-\{a_1(e^{b_1 t} - 1) + a_2(e^{2t} - 1)\}]$$

For identical components, we have

System failure rate is given by

$$h_s(t) = 2abe^{bt}$$

system reliability is given by

$$R_s(t) = \exp[-2a(e^{bt} - 1)]$$

In similar way, we can obtain reliability of a system having three or more components connected in series.

Numerical Illustrations

The reliability of the system has been analysed for arbitrary choices of the number of components (n), failure rate(a), operating time (t), and shape parameter (b). The outcomes are illustrated using both numerical evaluations and graphical representations.

For Parallel System

A parallel system with "n" components has been examined. As long as at least one component is operating, a parallel system can function. Figure 5 represents the state

The reliability of the system is given by

$$R(t) = 1 - \prod_{i=1}^{n} (1 - R_i(t))$$

The Mean time to system failure is given by

$$MTSF = \int_0^{\infty} \left[1 - \prod_{i=1}^{n} (1 - R_i(t))\right] dt$$

Notation

$R(t)$: Reliability of the system

$R_i(t)$: Reliability of the ith component

$h_i(t)$: Failure rate of the ith component

Failure Distribution of the Parallel System

The cumulative distribution function (CDF) of the system failure time is :

$$F_p(t) = 1 - R_p(t)$$

$$F_p(t) = \left[1 - \exp[-a(e^{bt} - 1)]\right]^n$$

Failure Rate (Hazard Function) of the Parallel System

The hazard rate of parallel system is define as:

$$h_p(t) = \frac{f_p(t)}{R_p(t)}$$

Substituting the Gompertz hazard function:

$$h_p(t) = \frac{nabe^{bt}\, e^{-a(e^{bt}-1)}\left[1 - e^{-a(e^{bt}-1)}\right]^{n-1}}{1 - \left[1 - e^{-a(e^{bt}-1)}\right]^n}$$

Special Case: Identical Components

If all components are identical with parameter a and b

System Reliability

$$R_p(t) = 1 - \left[1 - e^{-a(e^{bt}-1)}\right]^n$$

System Failure Rate

$$h_p(t) = \frac{nabe^{bt}\, e^{-a(e^{bt}-1)}\left[1 - e^{-a(e^{bt}-1)}\right]^{n-1}}{1 - \left[1 - e^{-a(e^{bt}-1)}\right]^n}$$

Reliability Measures of a Parallel System with Gompertz Distribution

Gompertz distribution for a component:

i. For the i^{th} component

The failure rate is given by

$$h_i(t) = a_i b_i e^{b_i t}$$

where i= 1 to n
The component reliability is given by

$$R_i(t) = \exp[-a_i(e^{b_i t} - 1)]$$

ii. For identical Components :
If all the components are identical then
System failure rate is given by

$$h_p(t) = \frac{nabe^{bt}e^{-a(e^{bt}-1)}\left[1 - e^{-a(e^{bt}-1)}\right]^{n-1}}{1 - \left[1 - e^{-a(e^{bt}-1)}\right]^{n}}$$

system reliability is given by

$$R_p(t) = 1 - \left[1 - e^{-a(e^{bt}-1)}\right]^{n}$$

Illustrations
1. For a single component, the system reliability is given by $R_p(t) = R(t)$
For identical components, we have
System failure rate is given by $h_p(t) = abe^{bt}$
system reliability is given by $R_p(t) = 1 - \left[1 - e^{-a(e^{bt}-1)}\right]$
2. If the system has two components, then the reliability of a system is given by

$$R_p(t) = 1 - (1 - R(t))^2$$

$$R_p(t) = 1 - \left[1 - e^{-a(e^{bt}-1)}\right]^2$$

The reliability of a system with three or more parallel-connected components can also be determined in a similar manner.

Numerical Illustrations
The reliability of the parallel system has been analysed for arbitrary choices of the number of components (n), failure rate (a) , operating time (t), and shape parameter (b). The outcomes are illustrated using both numerical evaluations and graphical representations

RESULT

The reliability of series systems with Gompertz-distributed components declines sharply as the number of components increases from 1 to 10. Table 1 shows that the shape parameter a (0.01 to 0.05, fixed b=0.1, t=10) reduces reliability progressively across all n, with the steepest drops at larger n. While table 2 indicates that on increasing the scale parameter b (0.1 to 0.5, fixed a=0.01, t=10) causes dramatic reliability collapse. While longer mission time t i.e. table 3 (5 to 25, fixed a=0.01, b=0.1) shows the steady reliability decay, more pronounced for higher n.
The reliability of the parallel system with Gompertz-distributed components improves markedly as the number of components increases from 1 to 10. Table 4 shows that increasing the failure rate parameter a (0.01–0.05), while keeping b = 0.1 and t = 10, reduces reliability for systems with fewer components. However, reliability rapidly approaches unity as more components are added in parallel. Table 5 shows that while more component redundancy considerably lessens the effect, increasing the shape parameter b (0.1–0.5) reduces dependability. Table 6 illustrates that longer mission lengths (t = 5–25) significantly reduce reliability, particularly for small systems. However, systems with more parallel components maintain reliability ratings close to one. Overall, the results show that parallel redundancy successfully reduces the adverse effects of greater failure rate, form parameter, and operating length, hence improving overall system dependability.

CONCLUSION

Assuming that component lifetimes are distributed according to the Gompertz distribution, this paper investigates dependability metrics for both parallel and serial systems. The exponential hazard function of the Gompertz

distribution makes it an effective model for systems with wear-out and aging characteristics. The results demonstrate that series system reliability decreases with the number of components and operating conditions, but parallel system reliability rises due to redundancy. Parallel configuration is a more robust and reliable design for engineering systems governed by the Gompertz distribution because it effectively mitigates the effects of higher failure rates, shape parameters, and mission time. The study demonstrates that the Gompertz distribution offers greater flexibility than traditional lifetime models when it comes to imitating real-world failure behaviors. Engineers and reliability analysts may find the data useful in system design, maintenance planning, and risk assessment in systems where component deterioration accelerates with time.

ABSTRACT

This comprehensive review examines the formulation strategies for developing taste-masked iodoquinol β-cyclodextrin complexes specifically designed for incorporation into oral medicated jellies. Iodoquinol, an effective anti-amoebic agent, presents significant challenges for oral administration due to its poor aqueous solubility and unpleasant taste profile, limiting patient compliance particularly among paediatric and geriatric populations. The formation of inclusion complexes with β-cyclodextrin offers a promising approach to overcome these pharmaceutical obstacles by enhancing solubility, masking bitter taste, and potentially improving bioavailability without compromising therapeutic efficacy. This review systematically analyses various complexation techniques, characterization methods, jelly formulation strategies, and evaluation parameters while highlighting the pharmaceutical advantages of medicated jelliesas an innovative dosage form. The findings suggest that optimized β-cyclodextrin complexation followed by incorporation into appropriately formulated jellies can effectively mask the objectionable taste of iodoquinol while providing a patient-friendly alternative to conventional dosage forms.

Keywords: iodoquinol, beta-cyclodextrin, taste-masking, oraljelly, inclusion complex

INTRODUCTION

Iodoquinol (5,7-Diiodo-8-quinolinol), also known as diiodohydroxy quinoline, is a halogenated hydroxyquinoline derivative primarily used as an anti-amoebic agent for treating intestinal infections. The compound exists as

yellowish-brown crystals with a melting point range of 200- 215°C and demonstrates extremely poor water solubility, which poses significant challenges for its formulation into conventional oral dosage forms. The inherent bitter taste and poor organoleptic properties of iodoquinol further compound the problem of patient compliance, particularly among paediatric and geriatric populations who often struggle with swallowing conventional dosage forms. These limitations necessitate the development of innovative formulation strategies aimed at improving both the palatability and patient acceptability of iodoquinol preparations. Taste masking has emerged as a critical consideration in pharmaceutical development, with various techniques being employed to mitigate the unpleasant taste of medications, including polymer coating, complexation, microencapsulation, and the use of sweeteners and flavouring agents. Among these approaches, cyclodextrin complexation presents a particularly promising strategy for addressing both solubility and taste issues simultaneously through the formation of inclusion complexes.

Pharmaceutical Properties and Therapeutic Applications of Iodoquinol

Iodoquinol is classified pharmacologically as an anti-amoebic agent with a molecular weight of 396.95 and chemical formula $C_9H_5I_2NO$. The compound's structural characteristics include two iodine atoms at positions 5 and 7 of the 8-hydroxyquinoline ring, which contribute to its therapeutic efficacy but also influence its physicochemical properties. Despite its sparingly solubility in common organic solvents like alcohol, ether, and acetone, it demonstrates practically no solubility in water, which significantly affects its dissolution characteristics and subsequently its bioavailability when administered orally. The primary therapeutic application of iodoquinol lies in its ability to treat intestinal amoe biasis, a parasitic infection commonly found in tropical and subtropical regions affecting millions worldwide. Traditional formulations of iodoquinol include tablets and suspensions, which often suffer from poor patient acceptability due to the compound's bitter taste and limited aqueous solubility. These inherent limitations highlight the necessity for developing novel dosage forms that can overcome the challenges associated with conventional formulations while maintaining therapeutic efficacy. The development of taste-masked formulations becomes particularly important considering that patient compliance significantly impacts treatment outcomes in parasitic infections where complete eradication requires consistent medication adherence over the prescribed course of therapy.

Cyclodextrins as Taste-Masking Excipients

Cyclodextrins represent a group of cyclic oligosaccharides composed of glucose units linked by α-1,4-glycosidic bonds, forming a truncated cone-shaped structure with a hydrophobic central cavity and hydrophilic exterior. This unique structural arrangement allows cyclodextrins to form inclusion complexes with various hydrophobic drug molecules, effectively encapsulating them within the central cavity. The formation of such inclusion complexes can significantly modify the physicochemical properties of the guest molecules, including enhanced solubility, improved stability, and notably, taste-masking effects. The taste-masking capability of cyclodextrins stems from their ability to sequester the bitter-tasting drug molecules within their hydrophobic cavity, thereby preventing direct interaction with taste receptors on the tongue. Among the naturally occurring cyclodextrins, β-cyclodextrin has gained particular prominence in pharmaceutical applications due to its appropriate cavity size, commercial availability, and relatively lower cost compared to its derivatives. The application of cyclodextrins for taste-masking purposes has been extensively investigated, with systematic evaluations revealing both successful and unsuccessful implementations depending on factors such as the choice of appropriate cyclodextrin type, guest-host molar ratio, and complexation methods. While cyclodextrin complexation offers significant advantages in terms of safety, effectiveness, and cost-efficiency, it's important to note that successful implementation requires careful consideration of various factors specific to the drug molecule being complexed.

Mechanism of Taste Masking Using B-Cyclodextrin

The taste-masking effect of β-cyclodextrin operates through several complementary mechanisms that collectively contribute to reduced perception of bitter taste. The primary mechanism involves physical entrapment of the drug molecule within the hydrophobic cavity of the cyclodextrin, creating a barrier that prevents direct contact between the bitter compound and taste receptors located on the tongue. This physical sequestration effectively shields the

bitter-tasting functional groups of the drug from interacting with gustatory receptors, thereby reducing taste perception. Additionally, the formation of inclusion complexes can alter the drug's solubility characteristics in saliva, which further contributes to decreased concentration of free drug available for taste receptor activation. In the specific case of iodoquinol, the aromatic quinoline structure with hydrophobic regions makes it a suitable candidate for inclusion complex formation with β- cyclodextrin. The complexation process typically involves the penetration of the hydrophobic portions of iodoquinol into the cyclodextrin cavity, while the more hydrophilic regions remain oriented toward the external aqueous environment. Nuclear magnetic resonance (NMR) studies have demonstrated that for similar compounds, the aromatic portions typically insert into the β-cyclodextrin cavity while functional groups like the piperazinyl group tend to remain positioned outside the cavity. This structural arrangement effectively masks the bitter taste while potentially improving dissolution characteristics due to the hydrophilic outer surface of the complex. The efficacy of taste masking ultimately depends on the stability of the complex formed and the extent to which the bitter-tasting portions of the drug molecule are shielded from taste receptors.

Methods for Preparation of Iodoquinol-B-Cyclodextrin Complexes

The development of effective iodoquinol-β-cyclodextrin complexes requires careful selection of preparation methods that maximize inclusion efficiency while maintaining the drug's therapeutic properties. Multiple techniques for preparing cyclodextrin inclusion complexes have been reported in the literature, each with specific advantages and limitations that influence the characteristics of the resulting complex. The co-precipitation method represents one of the most widely employed techniques, involving the addition of the drug to an aqueous solution of β-cyclodextrin under controlled conditions of temperature and pH, followed by precipitation of the complex through cooling or solvent removal. This method often yields complexes with high inclusion efficiency but may require significant amounts of water and energy for the precipitation and drying processes. Alternatively, the kneading method offers a more environmentally friendly approach, where the drug and cyclodextrin are mixed together with a small amount of water or hydroalcoholic solution to form a paste, which is then kneaded thoroughly to promote complexation before drying. The spray-drying technique provides another viable option, particularly suitable for industrial-scale production, wherein the drug and cyclodextrin solution or suspension is atomized and dried in a hot air stream, resulting in fine particles of the inclusion complex. This method offers advantages in terms of processing time, being a single-step process with excellent scale-up capability and flexibility in solvent selection. For iodoquinol specifically, the selection of an appropriate complexation method must consider the compound's poor water solubility and thermal stability characteristics.

Characterization Techniques for Iodoquinol-B-Cyclodextrin Complexes

Comprehensive characterization of iodoquinol-β-cyclodextrin complexes is essential to confirm successful complexation and understand the interaction mechanisms between the drug and cyclodextrin. Fourier Transform Infrared Spectroscopy (FTIR) represents a fundamental analytical technique for identifying complex formation through the observation of characteristic shifts in absorption bands corresponding to functional groups involved in the complexation process. For compounds similar to iodoquinol, FTIR analysis typically reveals significant changes in carboxyl carbonyl stretching vibrations and hydroxyl bending vibrations upon complexation with β-cyclodextrin, indicating the formation of hydrogen bonds and other non-covalent interactions. Nuclear Magnetic Resonance (NMR) spectroscopy provides more detailed structural information about the inclusion complex, with 1H NMR showing clear changes in the signal pattern for β-CD protons, particularly those positioned within the cyclodextrin cavity (protons in positions 3 and 5). These changes in chemical shifts confirm the inclusion of the aromatic portion of the guest molecule within the cyclodextrin cavity. Additional characterization techniques include Differential Scanning Calorimetry (DSC), which demonstrates changes in melting, boiling, and sublimation points upon complex formation; X-ray diffractometry (XRD), which reveals alterations in crystallinity patterns; and Phase solubility studies, which quantify improvements in aqueous solubility resulting from complexation. Scanning Electron Microscopy (SEM) provides visual confirmation of morphological changes in the complex compared to pure drug and cyclodextrin. For iodoquinol-β-cyclodextrin complexes, these characterization techniques collectively

provide comprehensive evidence of successful complexation and insights into the structural arrangement of the complex, which directly influences its taste-masking efficacy and dissolution properties.

Formulation of Oral Medicated Jellies Containing Iodoquinol-B-Cyclodextrin Complexes

Oral medicated jellies represent an innovative and patient-friendly dosage form that offers significant advantages in terms of palatability, ease of administration, and patient compliance, particularly for populations with swallowing difficulties. The formulation of jellies containing iodoquinol-β-cyclodextrin complexes involves a methodical approach starting with the selection of appropriate gelling agents that provide optimal texture and mouth feel. Common gelling agents include gelatin, which produces firm jellies with thermally reversible properties; pectin, which yields softer jellies suitable for sensitive populations; and combinations of gums like xanthan and carrageenan, which offer diverse textural properties. The preparation process typically follows the heating and congealing method, wherein the gelling agent is dispersed in water, heated until completely dissolved, followed by the addition of the drug-cyclodextrin complex under continuous stirring, and finally allowed to cool and set in appropriate molds. Sweeteners and flavoring agents play a crucial role in enhancing palatability and providing additional taste-masking effects, with common choices including sucralose and aspartame for sweetening, and fruit flavors like orange or mint for flavoring. Preservatives such as sodium benzoate or potassium sorbate are essential to maintain microbiological stability, particularly important considering the high-water content of jellies. The incorporation of the iodoquinol-β-cyclodextrin complex into the jelly matrix provides dual taste-masking mechanisms: the cyclodextrin complex shields the bitter taste of iodoquinol, while the sweet and flavoured jelly base further masks any residual unpleasant taste.

Optimization of Jelly Formulation Parameters

The development of optimal jelly formulations containing iodoquinol-β-cyclodextrin complexes requires careful consideration and adjustment of various formulation parameters that directly influence the quality, stability, and patient acceptability of the final product. The concentration of gelling agents represents a critical parameter that determines the textural properties of the jellies, with higher concentrations generally producing firmer jellies that maintain their shape but may be less palatable, while lower concentrations yield softer jellies with improved mouth feel but potentially reduced physical stability. Experimental studies have demonstrated that combinations of gelling agents, such as gelatin with xanthan gum, often produce jellies with superior characteristics compared to single gelling agents, with one study reporting optimal drug content (98.95%) in formulations utilizing such combinations. The pH of the formulation significantly impacts both the stability of the iodoquinol-β-cyclodextrin complex and the setting properties of most gelling agents, necessitating careful pH adjustment typically within the range of 3.5-6.5 using buffering agents like citric acid and sodium citrate. The incorporation of humectants such as glycerine or sorbitol at concentrations between 5-15% helps prevent moisture loss during storage, thereby maintaining the desired consistency of the jellies over their shelf life. The selection and concentration of sweeteners and flavouring agents require optimization through sensory evaluation studies to ensure maximum taste-masking effectiveness while maintaining acceptable organoleptic properties. Additionally, the processing parameters including heating temperature, duration, and cooling rate must be carefully controlled to ensure complete dissolution of the gelling agent, uniform distribution of the drug-cyclodextrin complex, and appropriate setting of the jellies without affecting the stability of the complex.

Evaluation Parameters for Iodoquinol-B-Cyclodextrin Containing Jellies

Comprehensive evaluation of medicated jellies containing iodoquinol-β-cyclodextrin complexes is essential to ensure product quality, stability, and efficacy. Physical appearance and organoleptic properties constitute the initial evaluation parameters, assessing colour, clarity, texture, and overall appearance, which significantly influence patient acceptability. The pH determination represents another critical parameter, typically measured using a digital pH meter, with optimal values generally falling between 5.0-7.0 to ensure product stability while minimizing potential irritation upon oral administration. Viscoelastic properties, including viscosity and spread ability, directly

impact the mouth feel and administration characteristics of the jellies, with studies reporting acceptable viscosity ranges between 53,000-62,000 cps for similar medicated jelly formulations. Drug content uniformity testing ensures consistent dosing across the prepared batch, typically achieved through spectrophotometric analysis after appropriate sample preparation, with acceptable limits generally ranging between 90-110% of the labelled claim. In vitro dissolution testing provides crucial information regarding the release pattern of iodoquinol from the complex and subsequently from the jelly matrix, typically conducted using USP dissolution apparatus with appropriate dissolution media that simulate oral conditions. The moisture content determination helps assess the physical stability of the jellies, with excessive moisture potentially leading to microbial contamination or altered textural properties. Syneresis, the phenomenon of water separation from the gel matrix during storage, requires evaluation as it can significantly impact product quality and stability. Additionally, microbial testing ensures product safety throughout the shelf life, particularly important considering the high-water content of jellies which potentially supports microbial growth.

Taste Evaluation Methodologies

The evaluation of taste-masking effectiveness represents a critical aspect in the development of iodoquinol-β-cyclodextrin containing jellies, requiring both subjective human panel assessments and objective analytical methods. Human taste panel studies remain the gold standard for taste evaluation, typically involving trained panellists who assess the formulations using standardized rating scales for parameters such as bitterness, sweetness, mouth feel, and overall palatability. To minimize subjective variations, these studies often employ a crossover design with sufficient washout periods between sample evaluations. However, human taste assessment presents challenges including ethical considerations, especially when evaluating pharmaceutical formulations containing active ingredients. Electronic taste sensing systems, also known as electronic tongues, offer an objective alternative to human panels by utilizing potentiometric sensors to detect and quantify taste attributes based on molecular interactions with sensor membranes. These systems generate taste patterns that can be correlated with human sensory data through multivariate statistical analysis. In vitro drug release in simulated saliva represents another indirect method for taste assessment, based on the principle that taste perception correlates with the concentration of dissolved drug in saliva, with lower dissolution rates in the first few minutes indicating better taste-masking. Drug-release studies specifically focusing on the initial time points (0-5 minutes) provide valuable insights into potential taste perception upon oral administration. Additionally, in vitro evaluation of drug-receptor interactions using cell-based assays that express taste receptors offers another promising approach for objectively assessing taste-masking efficiency. For iodoquinol-β-cyclodextrin containing jellies, a combination of these methodologies provides comprehensive understanding of taste-masking effectiveness from both subjective patient experience and objective analytical perspectives.

Stability Studies and Storage Considerations

Stability assessment of iodoquinol-β-cyclodextrin containing jellies constitutes a fundamental aspect of formulation development, ensuring that the product maintains its physical, chemical, and microbiological integrity throughout its intended shelf life. Stability studies should be conducted in accordance with International Conference on Harmonisation (ICH) guidelines, which typically recommend both accelerated (40°C/75% RH) and long-term (25°C/60% RH) stability testing protocols. Physical stability parameters requiring monitoring include appearance, texture, pH, viscosity, and syneresis, with significant changes potentially indicating instability issues that could affect product quality and patient acceptability. Chemical stability focuses primarily on drug content analysis at predetermined time intervals, with acceptable limits typically allowing no more than 5% degradation of the active ingredient throughout the proposed shelf life. The stability of the cyclodextrin complex itself merits special attention, as dissociation of the complex could compromise taste-masking effectiveness and potentially expose the bitter-tasting iodoquinol. Microbiological stability testing ensures that the product remains free from microbial contamination, with particular emphasis on total aerobic microbial count, yeast and Mold count, and the absence of specified pathogens. The high-water content of jellies necessitates effective preservation systems and appropriate packaging materials to maintain product integrity. Packaging considerations for iodoquinol-β-cyclodextrin containing jellies include the use of moisture-resistant, light-protective, and airtight containers, typically utilizing aluminium foil

laminates or blister packs that provide adequate protection against environmental factors that could accelerate degradation. Storage recommendations derived from stability studies should be clearly indicated on product labels, typically advising storage at controlled room temperature away from direct light and excessive heat.

Patient Compliance and Acceptability Studies

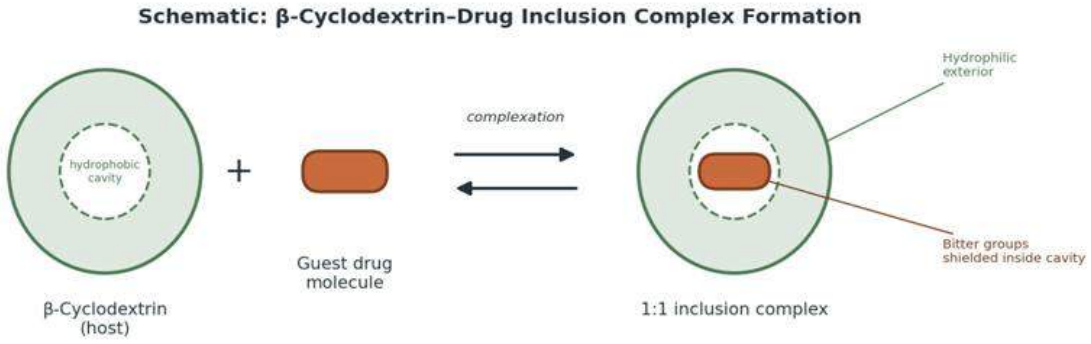
The ultimate success of iodoquinol-β-cyclodextrin containing jellies as an alternative dosage form heavily depends on patient acceptability and compliance, necessitating comprehensive evaluation through structured studies. Patient preference studies typically employ questionnaire-based approaches to assess subjective parameters including taste, mouth feel, ease of administration, and overall satisfaction compared to conventional dosage forms containing iodoquinol. These studies often utilize visual analogue scales or Likert scales to quantify preferences, with statistical analysis of the collected data providing insights into the relative acceptability of the jelly formulations. Specific demographic considerations must be addressed in these studies, particularly focusing on paediatric and geriatric populations who generally experience greater difficulties with conventional oral medications and therefore stand to benefit most significantly from alternative formulations. Swallowability assessments evaluate the ease with which patients can consume the medicated jellies, an especially important consideration for patients with dysphagia or those experiencing difficulty in swallowing conventional solid dosage forms. Compliance monitoring in clinical settings provides valuable real-world data regarding patient adherence to prescribed regimens when medications are administered as jellies compared to conventional formulations. Studies have consistently demonstrated superior patient compliance with medicated jellies compared to traditional dosage forms, attributable to their appealing organoleptic properties, ease of administration without water, and elimination of swallowing difficulties. Quality of life assessments further evaluate the impact of the dosage form on overall treatment experience, particularly important for medications like iodoquinol that may require prolonged administration periods. The collective findings from these acceptability studies provide crucial information for formulators to optimize jelly characteristics that maximize patient compliance while maintaining therapeutic efficacy.

Advantages and Limitations of Cyclodextrin-Based Taste-Masked Jellies

The incorporation of iodoquinol-β-cyclodextrin complexes into medicated jellies offers numerous pharmaceutical advantages that collectively enhance patient experience and therapeutic outcomes. The dual taste-masking mechanism, combining cyclodextrin complexation with the sweet, flavoured jelly base, provides superior palatability compared to conventional taste-masking approaches, particularly important for bitter drugs like iodoquinol. Enhanced drug solubility and dissolution represent significant advantages of the cyclodextrin complex, potentially improving bioavailability of the poorly water-soluble iodoquinol, while the jelly matrix provides a hydrophilic environment that further promotes dissolution. The jellies offer exceptional patient compliance benefits, particularly for paediatric, geriatric, and dysphagic patients, as they eliminate the need for swallowing intact tablets or capsules and can be administered without water. From a manufacturing perspective, the formulation process is relatively straightforward and scalable, typically requiring standard equipment already available in pharmaceutical manufacturing facilities. The flexible dosing options represent another advantage, as jellies can be easily moulded into different sizes corresponding to various dose strengths, facilitating personalized dosing regimens particularly valuable in paediatric applications. Despite these considerable advantages, certain limitations must be acknowledged, including the relatively higher moisture content of jellies which potentially impacts stability and necessitates effective preservation systems and appropriate packaging. The additional manufacturing steps involved in preparing the cyclodextrin complex before incorporation into jellies potentially increase production costs and complexity. The loading capacity limitations of cyclodextrins must also be considered, as β-cyclodextrin typically accommodates only 25-30% w/w of guest molecules, potentially restricting the maximum achievable dose in the final formulation. Additionally, the use of multiple excipients in jellies raises concerns regarding potential interactions that could affect complex stability or drug release characteristics.

Regulatory Considerations and Market Potential

The regulatory landscape for cyclodextrin-based medicated jellies presents both opportunities and challenges that must be carefully navigated during product development and commercialization. From a regulatory perspective, β-cyclodextrin enjoys generally recognized as safe (GRAS) status and is approved as a pharmaceutical excipient in various jurisdictions worldwide, including by the FDA and EMA, facilitating the regulatory approval process. The classification of medicated jellies as a pharmaceutical dosage form follows established regulatory frameworks, with specific requirements regarding quality control parameters, stability testing, and good manufacturing practices. Dissolution testing methodologies for non-conventional dosage forms like jellies may require development and validation in accordance with regulatory guidelines, potentially involving discussions with regulatory authorities to establish appropriate specifications. Intellectual property considerations present significant opportunities for innovation and market exclusivity, with numerous patentable aspects including specific cyclodextrin complex preparation methods, jelly formulation compositions, and manufacturing processes. The market potential for iodoquinol-β-cyclodextrin containing jellies appears promising, particularly considering the growing demand for patient-centric dosage forms that enhance compliance and treatment outcomes. The global antiparasitic drug market, including anti-amoebic agents like iodoquinol, continues to expand, driven by increasing prevalence of parasitic infections in developing regions and growing awareness regarding appropriate treatment options. The paediatric medication market represents a particularly attractive segment for medicated jellies, with healthcare providers and caregivers actively seeking alternatives to conventional dosage forms that children often refuse due to taste issues or swallowing difficulties. Additionally, the growing geriatric population worldwide presents another significant market opportunity, as elderly patients frequently experience dysphagia and may benefit substantially from easy-to-swallow dosage forms like medicated jellies. The commercial viability of the product ultimately depends on balancing manufacturing costs, including those associated with cyclodextrin complexation, against the premium pricing potential justified by enhanced patient compliance and therapeutic outcomes.



CONCLUSION

The development of taste-masked iodoquinol-β-cyclodextrin complexes for incorporation into oral medicated jellies represents a significant advancement in addressing the pharmaceutical challenges associated with this anti-amoebic agent. The systematic approach outlined in this review demonstrates how cyclodextrin complexation effectively addresses the dual challenges of poor solubility and bitter taste of iodoquinol, while the jelly dosage form provides an innovative solution to administration difficulties, particularly for paediatric, geriatric, and dysphagic patients. The comprehensive evaluation parameters discussed ensure product quality, stability, and efficacy, while taste assessment methodologies confirm the success of the taste-masking strategy. Despite certain limitations related to moisture content, complex loading capacity, and manufacturing complexity, the advantages of enhanced palatability, improved patient compliance, and potentially better bioavailability make this approach particularly promising for clinical applications. Future research directions should focus on optimizing complexation methods specific to iodoquinol's physicochemical properties, developing innovative jelly bases with enhanced stability characteristics, and conducting clinical studies to quantify improvements in bioavailability and patient compliance compared to conventional formulations. Additionally, exploration of modified cyclodextrins with higher complexation efficiency and investigation of synergistic taste-masking approaches could further enhance the formulation. The integration of quality-by-design principles into the development process would strengthen the scientific understanding of critical formulation and process parameters affecting product quality. Ultimately, the successful development of taste-masked iodoquinol-β-cyclodextrin containing jellies has the potential to significantly improve therapeutic outcomes in the treatment of amoebic infections by enhancing patient acceptability and medication adherence.

ABSTRACT

Neurodegenerative disorders arise from progressive neuronal dysfunction driven by oxidative stress, cholinergic impairment, and neuro inflammation. Aluminium chloride ($AlCl_3$) is a widely employed neurotoxicant that mimics Alzheimer's disease-like pathology by generating reactive oxygen species (ROS) and disrupting antioxidant defence mechanisms. *Trigonella foenum-graecum* (fenugreek), particularly in its sprouted form, is enriched in bioactive compounds including diosgenin, trigonelline, flavonoids, and polyphenols possessing potent antioxidant and anti-inflammatory properties. This study investigates the neuroprotective effects of sprouted fenugreek extract in an $AlCl_3$-induced neurotoxicity model using adult zebrafish (*Danio rerio*). Phytochemical screening confirmed the presence of phenols, flavonoids, alkaloids, tannins, saponins, and terpenoids. Anti-inflammatory activity was demonstrated via protein denaturation and proteinase inhibition assays. In vivo biochemical assays on brain homogenates revealed that $AlCl_3$ significantly elevated lipid peroxidation (TBARS) and reduced catalase, glutathione reductase, and acetylcholinesterase (AChE) activities in a dose-dependent manner. Treatment with sprouted fenugreek extract dose-dependently restored these parameters toward control levels. Behavioural studies confirmed amelioration of anxiety-like behaviour. These findings establish sprouted *Trigonella foenum-graecum* as a promising phytotherapeutic candidate against neuro degeneration.

Keywords: $AlCl_3$, zebrafish, neuro protection, neuro degeneration, sprouted fenugreek, acetylcholinesterase, antioxidants, oxidative stress, *Danio rerio*, diosgenin, trigonelline

INTRODUCTION

Neurodegenerative diseases represent a rapidly growing global public health crisis, with Alzheimer's disease (AD) alone affecting over 55 million people worldwide and projected to exceed 100 million by 2050 [1]. These disorders are characterised by progressive, irreversible neuronal loss, oxidative stress, neuroinflammation, and cholinergic dysfunction, resulting in cognitive decline and motor impairment [2]. Despite decades of research, no disease-modifying therapies exist, underscoring the urgency for novel neuroprotective strategies [3]. Aluminium is the most abundant metal in the Earth's crust and a well-documented neurotoxicant with no known biological function. It penetrates the blood-brain barrier (BBB) via transferrin receptor-mediated endocytosis and calcium channel mimicry, accumulating preferentially in the cortex and hippocampus — regions critical for learning and memory [4]. $AlCl_3$ reproduces key biochemical hallmarks of AD in experimental models: elevated lipid peroxidation, inhibition of antioxidant enzymes (catalase, glutathione reductase, SOD), cholinergic impairment through AChE dysregulation, and neuroinflammatory cascades [5, 6].

Human exposure to aluminium occurs via food, drinking water treated with aluminium sulphate, aluminium cookware, antacids, and occupational dust inhalation [7]. Zebrafish (*Danio rerio*) share approximately 70% genetic homology with the human genome, including orthologues of major neurodegeneration-associated genes (PSEN1, SNCA, HTT, PINK1). Their well-characterised nervous system, conserved neurotransmitter systems (dopaminergic, cholinergic, serotonergic), rapid reproductive cycle, cost-effectiveness, and suitability for high-throughput behavioural assays make them an ideal vertebrate model for neurotoxicological studies [8, 9]. Sprouted *Trigonella foenum-graecum* offers substantially enhanced pharmacological activity compared to unsprouted seeds. Germination activates phenylalanine ammonia-lyase, increasing total phenolic content; degrades anti-nutrients such as phytic acid and enzyme inhibitors; and elevates concentrations of diosgenin, quercetin, vitexin, trigonelline, and 4-hydroxyisoleucine [10, 11]. These bioactives collectively exert antioxidant, anti-inflammatory, and cholinesterase-modulatory effects relevant to neuroprotection [12, 13]. Although fenugreek's antidiabetic, hypocholesterolaemic, and hepatoprotective properties are extensively documented, its neuroprotective potential against $AlCl_3$-induced neurotoxicity — specifically using the sprouted form in a zebrafish model — remains largely unexplored. This gap forms the central focus of the present study.

MATERIALS AND METHODS

Chemicals

All chemicals used were of analytical grade. Aspirin, bovine serum albumin (BSA), phosphate buffer saline, trypsin, Tris-HCl buffer, ovalbumin, trichloroacetic acid (TCA), thiobarbituric acid (TBA), Ellman's reagent (DTNB: 5,5'-dithiobis-(2-nitrobenzoic acid)), acetylthiocholine iodide, EDTA, oxidized glutathione (GSSG), NADPH, aluminium chloride ($AlCl_3$), quercetin, catechol, Folin-Ciocalteu reagent, sodium carbonate, diosgenin, vanillin, perchloric acid, ascorbic acid, and DPPH (2,2-diphenyl-1-picrylhydrazyl) were procured from standard commercial suppliers (SRL, Sigma-Aldrich, HiMedia).

Preparation of Sprouted Fenugreek Extracts

Seeds of *T. foenum-graecum* were cleaned thoroughly and soaked in distilled water for 8 h. The soaked seeds were wrapped in a sterile moist cloth and incubated at room temperature (25–28°C) for 2–3 days until uniform sprouting was observed. The germinated seeds were collected and immediately used for extraction to preserve bioactive integrity. Aqueous extract: 50 g of fresh sprouts were homogenized in 100 mL of distilled water using a sterile mortar and pestle and centrifuged at 10,000 rpm for 10–15 min. The supernatant was collected as the crude aqueous extract. Methanolic extract (cold maceration method): 50 g of fresh sprouts were macerated in 100 mL of analytical-grade methanol for 12–16 h at room temperature, with continuous magnetic stirring for 1 h. The mixture was filtered through Whatman No. 1 filter paper and the filtrate volume adjusted to 100 mL with methanol. Both extracts were stored at 4°C until use [14].

Phytochemical Screening

Standard qualitative phytochemical tests were performed on both extracts as described by Chandan and Krishna (2024) [15]. Alkaloids were detected by Dragendorff's Mayer's, and Wagner's tests; flavonoids by lead acetate test; phenols and tannins by ferric chloride test; saponins by froth test; glycosides by Keller-Killiani test; phytosterols and terpenoids by Salkowski test; carbohydrates by Molisch's, Benedict's, and Fehling's tests; proteins by Biuret test; and amino acids by ninhydrin test.

Quantitative Estimation of Phyto constituents

Total phenolic content (TPC) was determined by the Folin-Ciocalteu method using catechol as standard; absorbance was measured at 650 nm [16]. Total flavonoid content (TFC) was measured by the aluminium chloride colorimetric method using quercetin as standard (415 nm) [17]. Diosgenin content was quantified by the vanillin-perchloric acid colorimetric method (540 nm) [18]. Antioxidant activity was assessed by the DPPH radical scavenging assay against ascorbic acid as standard [19], and the percentage scavenging activity was calculated as:

$$\% \text{ Scavenging Activity} = [(A_{control} - A_{sample}) / A_{control}] \times 100$$

Anti-inflammatory Assays

Protein denaturation inhibition assay: Varying aliquots (0.2–1.0 mL) of aqueous and methanolic extracts were tested against heat-induced denaturation of 0.2% bovine serum albumin (BSA) in phosphate buffer saline (pH 6.4). Tubes were incubated at 37°C for 15 min followed by 70°C for 5 min. After cooling, absorbance was measured at 660 nm. Aspirin (10 mg/mL) served as the positive control [20]. Proteinase inhibition assay: Trypsin (0.06 mg/mL) was incubated with 0.1 mg/mL aspirin or extract for 5 min at 37°C. Ovalbumin (4%) was added and incubated further. Reactions were terminated with 70% perchloric acid and centrifuged at 3,000 rpm for 10 min; absorbance was read at 280 nm [21]. For both assays:

$$\% \text{ Inhibition} = [(A_{control} - A_{sample}) / A_{control}] \times 100$$

Experimental Animals and Design

Healthy adult zebrafish (*Danio rerio*), 3–6 months old, were obtained from a certified supplier (Hachi's Aqua, Mathikere, Bengaluru) and acclimatized for 7 days under standard conditions (26 ± 1°C, 14 h light: 10 h dark cycle, aerated dechlorinated water, pH 7.0–7.4). Fish were fed commercial low-fat pellet feed once daily. Five experimental groups (n = 10 per group) were established: Group I — untreated normal control; Group II — $AlCl_3$ exposure (500 μg/L); Group III — $AlCl_3$ exposure (1 mg/L); Group IV — $AlCl_3$ (500 μg/L) + D-galactose (100 mg/L) + sprouted fenugreek extract (25 mg/L); Group V — $AlCl_3$ (500 μg/L) + D-galactose (100 mg/L) + sprouted fenugreek extract (50 mg/L). Chemicals were directly dissolved in dechlorinated aquarium water. Exposure was maintained for 7 days with daily water renewal [22].

Brain Homogenate Preparation

After the 7-day experimental period, fish were anaesthetized by cold immersion (ice water, 2–4°C) and sacrificed. Whole brains were dissected carefully and homogenized using a sterile mortar and pestle in 5 mL of 0.1 M phosphate buffer (pH 7.2). The homogenate was centrifuged at 5,000 rpm for 15 min at 4°C and the resulting supernatant was collected. This supernatant served as the enzyme source for all in vivo biochemical assays [23].

In Vivo Biochemical Assays

Lipid peroxidation (TBARS method): MDA levels were estimated by the thiobarbituric acid reactive substances assay [24]. Brain homogenate (0.5 mL) was combined with 10% TCA (1 mL) and 0.67% TBA (1 mL), incubated in a boiling water bath for 30–45 min, cooled, and centrifuged at 3,000 rpm for 10 min. Absorbance of the pink-coloured MDA-TBA complex was measured at 532 nm. Elevated TBARS in $AlCl_3$-exposed groups reflects increased oxidative damage to neuronal membrane lipids. Acetylcholinesterase (AChE) activity: Quantified by Ellman's colorimetric method [25]. The reaction mixture contained 2.6 mL of 0.1 M phosphate buffer (pH 7.4), 0.1 mL of 3.3 mM DTNB, and 0.1 mL of brain homogenate. After 20 min incubation, 0.02 mL of 75 mM acetylthiocholine iodide was added to

initiate the reaction. Absorbance change at 412 nm was recorded every minute for 3 min. Catalase activity: The rate of H_2O_2 decomposition was monitored spectro photo metrically at 240nm at 15-sec intervals over 2 min. Enzyme activity was expressed as the rate constant (s^{-1}) following Aebi (1974) [26]. Glutathione reductase activity: NADPH oxidation was monitored spectrophotometrically at 360nm. The reaction mixture contained 0.1 M phosphate buffer (pH 7.4), 1 mM EDTA, 1 mM GSSG, 0.1 mM NADPH, and brain homogenate. Absorbance was recorded at 30-sec intervals over 2 min. Activity was expressed as M/min/mL (Stahl et al., 1963) [26].

Behavioural Studies

Novel tank diving test (NTDT): Individual fish were transferred into a novel glass tank (24 cm × 15 cm × 20 cm) filled with dechlorinated water, clearly demarcated into upper and lower zones. The tank was placed on a plain white surface and the fish was allowed to acclimatise for 30 sec before recording. Time spent in the upper and lower zones and the frequency of freezing episodes were recorded over a 10-min observation period. Increased bottom-dwelling and freezing behaviour indicates anxiety-like stress [27]. Light-dark preference test (LDP): One half of the tank was covered with black opaque material to create a dark zone, while the other half remained illuminated. Each fish was introduced individually and its behaviour was recorded over 10 min. Number of transitions between zones and time spent in each compartment were documented. A pronounced preference for the dark compartment and reduced transitions is indicative of anxiety-like behaviour [28].

RESULTS AND DISCUSSION

Phytochemical Screening

Qualitative phytochemical analysis of sprouted *T. foenum-graecum* confirmed the presence of a broad spectrum of bioactive secondary metabolites in both aqueous and methanolic extracts (Table 1). The methanolic extract demonstrated stronger profiles for alkaloids and phytosterols, consistent with the higher methanol solubility of trigonelline and diosgenin [29]. The aqueous extract showed stronger profiles for saponins, carbohydrates, proteins, and amino acids. The polyphenolic compounds — phenols, flavonoids, and tannins — are established free radical scavengers and metal chelators, directly relevant to counteracting $AlCl_3$-mediated oxidative neuronal damage [30]. The presence of alkaloids (trigonelline) and steroidal saponins (diosgenin) is pharmacologically significant: trigonelline has documented neuroprotective functions through mitochondrial protection and antioxidant enzyme modulation, while diosgenin exerts anti-inflammatory activity by downregulating pro-inflammatory cytokine pathways [12, 13]. The amino acids and proteins identified may contribute indirectly to antioxidant defence and cellular metabolism support.

Quantitative Phytochemical Estimation

The DPPH radical scavenging activity was evaluated against ascorbic acid as a positive control. The ascorbic acid standard exhibited a dose-dependent increase in scavenging activity (0.27% at 0.1 mL to 17.46% at 0.4 mL), confirming assay validity. The methanolic extract of sprouted fenugreek (0.2 mL, diluted 1:10 from 50% crude) demonstrated an average DPPH scavenging activity of **50.27%** (replicates: 69.96% and 30.58%). The inter-replicate variation is attributable to the crude nature of the extract and potential pipetting variability during sample preparation, as has been noted in previous DPPH assay studies. The moderate-to-good antioxidant activity (≈50%) is consistent with the high phenolic and flavonoid content identified, since these compounds donate hydrogen atoms to DPPH radicals, causing the characteristic colour shift from purple to yellow. The results strongly support the in vitro antioxidant potential of sprouted fenugreek.

Anti-inflammatory Activity

Protein Denaturation Inhibition

Sprouted fenugreek extracts inhibited heat-induced BSA denaturation in a concentration-dependent manner (Table 2, Fig. 2). The methanolic extract demonstrated 35% inhibition and the aqueous extract 28.3% inhibition, compared to 40% inhibition by aspirin (10 mg/mL, positive control). Protein denaturation is a key event in the pathogenesis of

inflammation and a hallmark of the neuro inflammatory response triggered by $AlCl_3$ accumulation in brain tissue [30]. The ability of fenugreek phytochemicals — particularly tannins, flavonoids, and alkaloids — to stabilise protein native conformation suggests a mechanistic basis for its anti-neuro inflammatory action [29].

Proteinase Inhibition

The methanolic extract inhibited trypsin-mediated proteinase activity by 38.88% and the aqueous extract by 35.25%, versus 57.61% inhibition by aspirin (Table 3, Fig. 3). Proteinase overexpression in neurodegenerative conditions contributes to extracellular matrix degradation and progressive neuronal damage. Fenugreek's inhibitory activity against trypsin-mediated proteolysis suggests suppression of this pathological pathway, attributable to tannins, glycosides, and saponins that form complexes with proteinase active sites [20, 21].

In Vivo Antioxidant Assays

Lipid Peroxidation (TBARS Assay)

Malondialdehyde (MDA) is a stable end-product of polyunsaturated fatty acid (PUFA) peroxidation and a reliable marker of oxidative membrane damage. As expected, $AlCl_3$ exposure dose-dependently and significantly elevated TBARS levels: control 1.12 ± 0.00 μg/L; $AlCl_3$ 500 μg/L group 2.84 ± 0.18 μg/L; $AlCl_3$ 1 mg/L group 3.21 ± 0.22 μg/L ($p < 0.01$ vs control; Table 4, Fig. 4). This substantial elevation reflects Al^{3+}-mediated mobilisation of redox-active iron from transferrin and ferritin, which generates hydroxyl radicals via Fenton reactions that oxidise neuronal membrane PUFAs — including arachidonic acid and DHA — producing cytotoxic aldehydes such as MDA and 4-hydroxynonenal [5, 32]. The brain is particularly vulnerable because of its exceptionally high lipid content and relatively weak antioxidant defences. Sprouted fenugreek treatment dose-dependently attenuated lipid peroxidation: 25 mg/L group 2.01 ± 0.14 μg/L; 50 mg/L group 1.48 ± 0.09 μg/L ($p < 0.05$ vs $AlCl_3$ 500 μg/L group). This protective effect is attributable to the radical chain-breaking capacity of quercetin, vitexin, polyphenols, and the iron-chelating activity of tannins in sprouted fenugreek, which collectively suppress Fenton reaction-driven lipid peroxidation cascades [10, 33].

Acetylcholinesterase (AChE) Activity

AChE is the principal enzyme terminating cholinergic neurotransmission by hydrolysing acetylcholine (ACh) at synapses. $AlCl_3$ exposure dose-dependently reduced AChE activity: control 0.545 ± 0.018 μmol/min/mL; 500 μg/L 0.410 ± 0.026; 1 mg/L 0.375 ± 0.026 ($p < 0.01$; Table 5, Fig. 5). This inhibition leads to ACh accumulation at synapses, causing prolonged cholinergic overstimulation, receptor desensitisation, and ultimately synaptic dysfunction — a pattern consistent with early-stage AD-like neuro degeneration and previously reported in $AlCl_3$-exposed zebrafish [33, 34]. Treatment with sprouted fenugreek extract partially but significantly restored AChE activity in a dose-dependent manner: 25 mg/L 0.421 ± 0.020; 50 mg/L 0.462 ± 0.165 μmol/min/mL ($p < 0.05$ vs $AlCl_3$ group). This modulation is consistent with the documented inhibitory and regulatory effects of trigonelline, diosgenin, and polyphenolic flavonoids on cholinergic pathways [12, 13, 35]. By partially restoring AChE to near-normal activity, fenugreek treatment re-establishes balanced cholinergic neurotransmission

Catalase Activity

Catalase catalyses the decomposition of H_2O_2 to water and oxygen, forming a critical first-line antioxidant defence. $AlCl_3$ produced a consistent, dose-dependent suppression of catalase activity: control 6.32 ± 0.41 s^{-1}; 500 μg/L group 4.01 ± 0.28 s^{-1}; 1 mg/L group 3.12 ± 0.24 s^{-1} ($p < 0.01$; Table 6, Fig.6). This inhibition is mediated by Al^{3+}-induced down regulation of the Nrf2 transcription factor — the master regulator of antioxidant gene expression — and by direct interference with mitochondrial electron transport chain (ETC) complexes I and IV, amplifying intracellular ROS load [5, 6]. The dose-dependent relationship (lower activity at higher $AlCl_3$ concentration) confirms that the 1 mg/L group experienced greater oxidative burden. Sprouted fenugreek treatment dose-dependently restored catalase activity: 25 mg/L 4.78 ± 0.22 s^{-1}; 50 mg/L 5.68 ± 0.31 s^{-1} ($p < 0.05$ vs $AlCl_3$ group). The 50 mg/L treatment restored catalase to approximately 90% of control activity, consistent with Nrf2/ARE pathway activation by quercetin and polyphenolic compounds in sprouted fenugreek [33, 36].

Glutathione Reductase Activity

Glutathione reductase (GR) regenerates reduced glutathione (GSH) from oxidized glutathione (GSSG) using NADPH as cofactor — a critical step in maintaining the cellular redox buffer. $AlCl_3$ dose-dependently suppressed GR activity: control 0.0041 ± 0.0002 M/min/mL; 500 μg/L group 0.0032 ± 0.0003; 1 mg/L group 0.0024 ± 0.0002 ($p < 0.01$; Table 7, Fig. 7). The progressive depletion at higher concentrations confirms dose-dependent oxidative exhaustion of the GSH redox cycle. This depletion reflects Al^{3+}-mediated mitochondrial membrane potential collapse (via mPTP opening), NADPH consumption by compensatory antioxidant responses, and direct inhibition of mitochondrial Mn-SOD, collectively exhausting the glutathione regeneration pathway [5, 6]. Fenugreek treatment at 50 mg/L restored GR activity to 0.0038 ± 0.0002 M/min/mL, approaching control levels ($p < 0.05$); the 25 mg/L group showed partial recovery to 0.0031 ± 0.0003 M/min/mL — above the $AlCl_3$ 500 μg/L group value, confirming concentration-dependent neuroprotective efficacy. The restoration is attributed to the NADPH-sparing effect of fenugreek antioxidants, which reduce the oxidative burden and allow GSH recycling to resume [33, 36].

Behavioural Studies

$AlCl_3$-exposed zebrafish exhibited pronounced anxiety-like behaviour in both the novel tank diving test (NTDT) and the light-dark preference (LDP) test. In the NTDT, $AlCl_3$-exposed fish spent significantly greater time in the bottom zone with frequent freezing episodes and markedly reduced exploratory movement toward the upper zone. In the LDP test, these fish showed a strong preference for the dark compartment with minimal transitions to the illuminated zone. Both patterns are consistent with oxidative neuronal damage, cholinergic dysfunction, and neuroinflammation caused by aluminium toxicity [27, 28, 37]. Zebrafish treated with sprouted fenugreek extract demonstrated dose-dependent behavioural improvement. Fish in the 50 mg/L treatment group explored the upper tank zones more frequently, exhibited shorter freezing latency, and spent a greater proportion of time in the light compartment with increased inter-zone transitions — reflecting reduced anxiety and enhanced exploratory behaviour. These improvements strongly correlate with the biochemical restoration of AChE activity and antioxidant enzyme levels observed in the same group, confirming that the neuroprotective effects of sprouted fenugreek are functionally meaningful. The anxiolytic improvement is mechanistically consistent with fenugreek's restoration of cholinergic neurotransmission balance and its modulatory effects on dopaminergic and serotonergic pathways reported in rodent models [38, 39].

CONCLUSION

This study provides comprehensive experimental evidence that sprouted *Trigonella foenum-graecum* extract exerts significant, dose-dependent neuro protective effects in an $AlCl_3$-induced zebrafish model of neurotoxicity, addressing a previously underexplored research gap. $AlCl_3$ produced characteristic neurodegenerative hallmarks — elevated lipid peroxidation, depleted catalase and glutathione reductase activities, reduced AChE activity, and pronounced anxiety-like behaviour — in a consistent dose-dependent pattern. Sprouted fenugreek extract, enriched through germination in polyphenols, flavonoids, and steroidal saponins, dose-dependently restored all measured biochemical and behavioural parameters. The sprouting process confers pharmacological superiority over unsprouted seeds by amplifying bioactive content while degrading anti-nutritional factors. These findings support the incorporation of sprouted *T. foenum-graecum* as a dietary neuroprotective strategy. Future investigations should elucidate the molecular signalling pathways involved (Nrf2/ARE, Akt/GSK3β, NF-κB), perform gene expression analyses, and validate therapeutic efficacy and safety in mammalian models and clinical settings.

ACKNOWLEDGEMENT

The authors gratefully acknowledge Dr. Kavitha G Singh, for her invaluable guidance, encouragement and support. The authors also thank the Principal, Dr. George Lekha and the Department of Biochemistry, Mount Carmel College, Autonomous, Bengaluru, for their institutional support and encouragement.

Conflict of Interest

The authors declare no conflict of interest associated with this manuscript.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

ABSTRACT

A set D of vertices in a splitted graph $S(G) = (V, E)$ is called a dominating set if every vertex in $V - D$ is adjacent to some vertex in D. A dominating set D of a graph $S(G)$ is said to be a non split dominating set of $S(G)$ if the subgraph induced by V−D is connected. The minimum cardinality among all non split dominating sets is called the non-split domination number of $S(G)$ and is denoted as $\gamma_{ns}[S(G)]$.

Keywords: Domination, Splitted Graph, Non Split Domination

INTRODUCTION

[6] By a graph, we mean a finite simple and undirected graph. The vertex set and edge set of a graph G denoted are by V (G) and E(G) respectively. Let G be a graph. For each vertex v of a graph G, take a new vertex u. Join u to those vertices of G adjacent to v. The graph thus obtained is called the splitting graph of G. It is denoted by S(G) . For a graph G, the splitting graph S of G is obtained by adding a new vertex v corresponding to each vertex u of G such that N(u) = N(v) and it is denoted by S(G). The notions of splitting graphs were studied and investigated of many more authors for Example [3,4,5,9, 10, 11,12,]

Preliminaries

Definition: [7, 13]
A set D of vertices in a splitted graph $S(G) = (V, E)$ is called a dominating set if every vertex in $V - D$ is adjacent to some vertex in D. The *domination number γ [S(G)] of S(G) is minimum cardinality of a domination set of S(G).*

Definition:
A dominating set D of a graph $S(G)$ is said to be a non split dominating set of $S(G)$ if the subgraph induced by $V - D$is connected. The minimum cardinality among all non split dominating sets is called the non split domination number of $S(G)$ and is denoted as $\gamma_{ns}[S(G)]$.

Main Results
Theorem 3.1 Non Split domination number of the splitted graph S(P_m) is
$\gamma_{ns}[S(P_m)] = m$.

Proof: Let S(P_m) be splitted graph of P_m . Let V [S(P_m)] = {d_j , h_j : 1≤j≤m }, Let E[S(P_m)] = {($d_j\, d_{j+1}$) ∪ ($h_j\, d_{j+1}$) ∪ ($d_j\, h_{j+1}$) ; 1≤j≤m-1}. In$S(P_m)$, vertexh_{j+1} is adjacent tod_{j+2}, d_j where as h_1 is adjacent to $d_2$and h_m is adjacent to d_{m-1},by definition h_j $1 \le j \le m$, is all vertices satisfy the Non Split dominating set condition but other all vertices $V - D$ is connected. Hence, $\gamma_{ns}[S(P_m)] = m$
For example $\gamma_{ns}[S(P_7)]$ = {h_1 , h_2 , h_3 , h_4, h_5, h_6, h_7}=7 as shown in the figure 3.2.

Theorem 3.3 Non Split domination number of the Splitted graph S(H_m)],is
$$\gamma_{ns}[S(H_m)] = 2m$$

Proof: Let S(H_m) be splitted graph of H_m .
Case (i): m is odd
Let V [S(H_m)] = {d_j , h_j ,$d_j^{'}$, $h_j^{'}$: 1≤j≤m },Let E[S(H_m)] = {($d_j\, d_{j+1}$) ∪ ($h_j\, d_{j+1}$) ∪ ($d_j\, h_{j+1}$) ∪ ($d_{\frac{m+1}{2}} d_{\frac{m+1}{2}}^{'}$) ∪ ($d_{\frac{m+1}{2}} h_{\frac{m+1}{2}}^{'}$) ∪ ($h_{\frac{m+1}{2}} d_{\frac{m+1}{2}}^{'}$)∪($d_j^{'} d_{j+1}^{'}$)∪ ($h_j^{'} d_{j+1}^{'}$) ∪ ($d_j^{'} h_{j+1}^{'}$); 1≤j≤m-1}.
In S(H_m), vertex h_{j+1} is adjacent to $d_{j+2}, d_j$where as h_1 is adjacent to $d_2$and h_m is adjacent to d_{m-1} ,by definition h_j and $h_j^{'}$, $1 \le j \le m$, is all vertices satisfy the Non Split dominating set condition but other all vertices $V - D$ is connected. The same process applicable for the set of vertex $h_{j+1}^{'}$, $h_1^{'}$ *and* $h_m^{'}$.

Case (ii): m is even
Let V [S(H_m)] = {d_j , h_j ,$d_j^{'}$, $h_j^{'}$: 1≤j≤m },LetE[S(H_m)] = {($d_j\, d_{j+1}$) ∪ ($h_j\, d_{j+1}$) ∪ ($d_j\, h_{j+1}$) ∪ ($d_{\frac{m}{2}} d_{\frac{m}{2}+1}^{'}$) ∪ ($d_{\frac{m}{2}} h_{\frac{m}{2}+1}^{'}$) ∪ ($h_{\frac{m}{2}} d_{\frac{m}{2}+1}^{'}$) ∪ ($d_j^{'} d_{j+1}^{'}$) ∪ ($h_j^{'} d_{j+1}^{'}$) ∪ ($d_j^{'} h_{j+1}^{'}$); 1≤j≤ $m-1$}.
In S(H_m), vertex h_{j+1} is adjacent to d_{j+2}, d_j where as h_1 is adjacent to $d_2$and h_m is adjacent to d_{m-1} ,by definition h_j and $h_j^{'}$, $1 \le j \le m$, is all vertices satisfy the Non Split dominating set condition but other all vertices $V - D$ is connected. The same process applicable for the set of vertex $h_{j+1}^{'}$, $h_1^{'}$ *and* $h_m^{'}$.

Hence $\gamma_{ns}[S(H_m)] = 2m$
For example $\gamma_{ns}[S(H_6)]$={h_1, h_2 , h_3 , h_4 , h_5, h_6, $h_1^{'}$, $h_2^{'}$, $h_3^{'}$, $h_4^{'}h_5^{'}$, $h_6^{'}$}=12and
$\gamma_{ns}[S(H_5)]$={h_1, h_2 , h_3 , h_4 , h_5, $h_1^{'}$, $h_2^{'}$, $h_3^{'}$, $h_4^{'}$, $h_5^{'}$}=10as shown in the figure 3.4 and 3.5.

Theorem 3.6 Non Split domination number of the splitted graph$S(P_m^+)$,is
$\gamma_{ns}\ [S(P_m^+)]$ = m

Proof. Let S(P_m^+) be splitted graph of P_m^+. Let V[S(P_m^+)] = {d_j , h_j ,$d_j^{'}$, $h_j^{'}$: 1≤j≤m }, Let

E[S(P_m^+)] = { [$(d_j d_{j+1})$; 1≤j≤m-1]∪[$(d_j d_j^{'}) \cup (d_j h_j^{'})$; 1≤j≤m] ∪ [$(h_j d_{j-1}) \cup (h_j d_j^{'})$
$\cup (h_j d_{j+1})$; 2≤j≤m-1] ∪ $(h_1 d_1^{'}) \cup (h_1 d_2) \cup (h_m d_m^{'}) \cup (h_m d_{m-1})$ }
In S(P_m^+), vertex h_{j+1} is adjacent to $d_{j+2}, d_j, d_{j+1}^{'}$ where as h_1 is adjacent to $d_2, d_1^{'}$and h_m is adjacent to $d_{m-1}, d_m^{'}$ and also pendent vertices $h_j^{'}$ is adjacent to $d_j$by definitionh_j and $h_j^{'}$ $1 \leq j \leq m$, is all vertices satisfy the Non Split dominating set condition but other all vertices $V - D$ is connected.

Hence,$\gamma_{ns}\ [S(P_m^+)] = m$
For example $\gamma_{ns}\ [S(P_5^+)]$ ={$h_1, h_2, h_3, h_4, h_5, h_1^{'}, h_2^{'}, h_3^{'}, h_4^{'}, h_5^{'}$}= 10 as shown in the figure 3.7

Theorem 3.8 Non Split domination number of the splitted graph$S(P_m^+)$,is
γ_{ns}[S($P_m \circ NK_1$)] = $m(1+N)$

Proof: Let S($P_m \circ NK_1$) be splitted graph of $P_m \circ NK_1$.

Let V[S($P_m \circ NK_1$)] = {d_j, h_j, d_{jl}, h_{jl} ; $1 \leq j \leq m$, $1 \leq l \leq N$},
Let E[S($P_m \circ NK_1$)] = { [$(d_j d_{j+1})$; 1≤j≤m-1] ∪[$(d_i d_{jl}) \cup (h_j d_{jl})$; $1 \leq j \leq m, 1 \leq l \leq N$] ∪[$(h_j d_{j-1}) \cup (h_j d_{j+1})$; 2 ≤j≤m-1]∪ [$(h_1 d_2) \cup (h_m d_{m-1})$] } In S($P_m \circ NK_1$) ,vertex h_j is adjacent to d_{jl}, d_j, d_{j+1}, where as all pendent verticesh_{jl} is adjacent to d_j by definitionh_j and h_{jl} $1 \leq j \leq m, 1 \leq l \leq N$, is all vertices satisfy the Non Split dominating set condition but other all vertices $V - D$ is connected. Hence γ_{ns}[S($P_m \circ NK_1$)] = $m(1+N)$ For example γ_{ns}[S($P_4 \circ 2K_1$)] ={$h_1, h_2, h_3, h_4, h_{11}, h_{12}, h_{21}, h_{22}, h_{31}, h_{32}, h_{41}, h_{42}$}= 12 as shown in the figure 3.9.

Theorem 3.10 Let G be a path splitted graph. Let k be minimum degree. Then $G - k$ is non split dominating set.
Proof: Let G be a path splitted graph. Let k be maximum degree. Now, a cut vertices k of path splitted graph G, k is a point whose removal increases the number of components. So $G - k$ is connected graph. Then $G - k$ is non split dominating set is zero.

Theorem 3.11. For any splitted graph G, $P = 2\ (\gamma_{ns}\ (G))$
Proof: Let G be a path splitted graph. Then non split dominating set of G is m, but any path splitted graph total number of vertices is 2m. Hence $P = 2\ (\gamma_{ns}\ (G))$.

Theorem 3.12. Every independent dominating set is need not be non split dominating set.
Proof: Let D be an independent dominating set of G. Let $v \in D$. since v is a cut point of G. therefore $G - v$ is disconnected. Hence $G - v$ has atleast two Component, So $G - D = S$ is not a nonsplit dominating set.

Theorem 3.13. $\gamma_{ns}[S(C_m)] = m$
Proof: Let S(C_m) be cycle splitted graph of C_m .
Let V[S(C_m)] = {$d_j, h_j : 1 \leq j \leq m$ } ,
Let E[S(C_m)] = [{$(d_j d_{j+1}) \cup (h_j d_{j+1}) \cup (d_j h_{j+1})$; $1 \leq j \leq m-1$}] ∪ [$(h_1 d_m) \cup (h_m d_1) \cup (d_1 d_m)$] .
First, all vertices h_j must be selected. Then all the remaining vertices become connected. Thus the $< D >$ − set satisfies the conditions of a non – split dominating set.
Hence, $\gamma_{ns}[S(C_m)] = m$
For example, $\gamma_{ns}[S(C_5)]$ = { h_1, h_2, h_3, h_4, h_5 } = 5. as shown in the figure 3.13.

Observation 3.13 For any Splitted graph (G) , $\gamma(S(G)) \leq \gamma_{ns}(S(G))$
Observation 3.14 For any Splitted graph (G) ,$\gamma_c(S(G)) \leq \gamma_{ns}(S(G))$
Observation 3.15 For any Splitted graph (P_m) , $\gamma_c(S(P_m)) + \chi(S(P_m)) = \gamma_{ns}(P_m)$
Observation 3.16 For any Splitted graph (G), $\gamma^{-1}(S(G)) \leq \gamma_{ns}(S(G))$
Observation 3.17 For any Splitted graph (G) , $\gamma(S(G))\chi(S(G)) > \gamma_{ns}(S(G))$

ABSTRACT

Diabetes mellitus is a chronic metabolic disorder characterized by hyperglycemia, insulin resistance, β-cell dysfunction, and impaired insulin secretion. Hence, the aim of this study was to formulate and standardize moringa-enriched diabetic-friendly crackers using a composite flour base comprising wheat flour, quinoa flour, and jackfruit flour, incorporated with moringa leaf powder, these ingredients were selected for their complementary nutritional properties, including high dietary fiber content, antioxidant activity, and potential contribution to glycemic control, making the product suitable for individuals with diabetes.Four formulations were prepared, namely a control (T0) and three diabetic friendly crackers (T1, T2, and T3) by progressively varying the proportion of moringa powder (0 g, 2 g, 3 g, and 5 g, respectively) while maintaining the other ingredients at constant levels. Wheat flour (38–40 g) served as the structural base; quinoa flour (28 g) was incorporated to enhance protein quality and micronutrient density, and jackfruit flour (19 g) was included for its resistant starch and dietary fiber content, which aid in attenuating postprandial glycemic response. Flavoring and textural agents, likechilli powder (0.5 g), pepper powder (0.48 g), sesame seeds (4 g), jeera (10 g), salt (2 g), oil (10 ml), and water (10 ml), were added uniformly across all formulations to ensure palatability and consumer acceptability.Sensory evaluation by 30 panelists affirmed the high consumer acceptability of T3, with the most favourable hedonic frequency distribution and the highest mean scores across all sensory attributes, and substantiated that the T3 formulation of moringa enriched diabetic friendly crackers is nutritionally superior and sensorially the most acceptable product among all tested formulations. The T3 crackers demonstrated significantly higher protein (11.8 g/100g), crude fibre (3.8 g/100g), ash (2.6 g/100g), iron (6.5 mg/g), and calcium (120 mg/g) content, alongside a significantly reduced carbohydrate content (58.8

g/100g), which are beneficial for blood glucose management in diabetic individuals. Shelf-life analysis confirmed microbiological safety for 7 days, with TPC and yeast/mold counts within permissible limits and a complete absence of *E. Coli*i n both formulations. These findings substantiate the potential of *Moringa oleifera* leaf powder as a functional ingredient in the formulation of nutritionally enhanced, safe, and acceptable diabetic friendly cracker which are an effective, safe, palatable functional ingredient and a healthier alternative to conventional snacks, offering balanced energy, gluten-free composition, and potent bioactive benefits for blood sugar control.

Keywords: Moringa leaf, Wheat flour, Quinoa flour, Jackfruit flour, Diabetic friendly cracker, Low glycemic index

INTRODUCTION

India is often referred to as the "Diabetes capital of the world". Diabetes mellitus is a chronic metabolic disorder characterized by hyperglycemia, developing insulin resistance, β-cell dysfunction, and impaired insulin secretion. In India, the prevalence of T2DM has risen sharply over the past two decades, with an estimated 77 million adults currently diagnosed, a figure that is projected to cross 134 million by 2045 (IDF, 2023). Chronic hyperglycemia contributes to oxidative stress, low-grade inflammation, endothelial dysfunction, and impaired glucose metabolism, ultimately leading to serious microvascular and macrovascular complications like nephropathy, neuropathy, retinopathy, and cardiovascular diseases (Sun et al., 2021). These complications significantly reduce life expectancy and quality of life. Dietary management forms the cornerstone of diabetes prevention and control. Levy et al. (2021) stated that modern dietary patterns increasingly include refined carbohydrates and ultra-processed foods that are energy-dense but nutritionally poor; such foods contribute to rapid glucose spikes, increased insulin demand, and metabolic dysregulation. In recent years, there has been growing scientific and consumer interest in functional foods that provide health benefits beyond basic nutrition. The strategic incorporation of bioactive plant ingredients into everyday food formulations offers a promising avenue for diabetes-friendly product development to manage glycemia, oxidative stress, and inflammation through everyday dietary choices.

Gómez-Martínez et al. (2022) stated that people with prediabetes who received 2.4 g/day of *Moringa oleifera* leaf powder observed significant reductions in fasting blood glucose and HbA1c compared with placebo, while no adverse effects on liver or kidney function were observed, making Moringa an ideal functional food development targeted towards control in diabetes management. Quinoa is one of the gluten-free foods and contains functional ingredients such as bioactive peptides, polysaccharides, saponins, polyphenols, flavonoids, and other compounds. The active ingredients in quinoa have different health effects, including antioxidant, antidiabetic, antihypertensive, anti-inflammatory, and anti-obesity activities. (Ren et al., 2023). Jackfruit flour has a low glycaemic index and exhibits antidiabetic properties, significantly reducing HbA1c, fasting blood glucose and postprandial blood glucose (Rao et al 2021).The global and national prevalence of diabetes mellitus continues to increase at an alarming rate, placing an extraordinary burden on healthcare systems and individuals, creating an urgent need for effective dietary interventions. According to the International Diabetes Federation (2023), the number of people living with diabetes is projected to rise substantially in the coming decades, with India bearing one of the largest shares of this burden. Rapid urbanization, the pervasive shift toward refined and ultra-processed food consumption, and increasingly sedentary lifestyles have collectively contributed to deteriorating glycemic control across populations.

Most commercially available snack products are rich in refined carbohydrates, added sugars, and unhealthy fats, which contribute to rapid postprandial glucose spikes and long-term metabolic complications. There is a growing need to develop functional snack products incorporating nutrient-dense, low glycemic index ingredients that can support glycemic control without compromising sensory acceptability. Hence, the investigator felt the need to formulate, standardize, the incorporation of functional ingredients such as *Moringa oleifera* , quinoa, jackfruit flour,

and wheat flour blends, which provides an opportunity to enhance protein quality, dietary fiber, micronutrient density, and antioxidant capacity as a novel and comprehensive dietary approach for management of type 2 diabetes, aligning with dietary recommendations emphasizing plant-based, fiber-rich, and low-GI foods.

Objectives

General Objective: To formulate and nutritionally evaluate Moringa-enriched diabetes-friendly crackers

Specific Objectives

- To formulate diabetes-friendly crackers incorporating Moringa leaf powder, quinoa flour, jackfruit flour, and wheat flour in varying proportions.
- To standardize and optimize the formulation of diabetes-friendly crackers.
- To assess the overall sensory quality and acceptability of the formulated crackers.
- To analyse the proximate nutritional composition of the developed crackers.
- To determine and compare the dietary fiber and mineral content (calcium and iron) of the formulated crackers
- To evaluate the microbiological shelf-life and storage stability of the optimized product.

MATERIALS AND METHODS

The present study adopts an experimental research design, specifically a product formulation developed and assessed for moringa-enriched diabetes-friendly crackers. This research design enables controlled modification of ingredient proportions, scientific evaluation of nutritional composition, and sensory analysis to determine the overall acceptability of the developed product. The study begins with the procurement and processing of raw materials, where fresh leaves of *Moringa oleifera* are carefully cleaned, shade-dried, and ground into fine moringa leaf powder. In addition, other functional ingredients such as quinoa, jackfruit flour, and wheat flourwere procured from the supermarket and used for the preparation of the crackers. Using these ingredients, different cracker formulations were developed by varying the level of moringa leaf powder while maintaining the proportions of the base ingredients within acceptable limits. Sensory evaluation of the developed crackers was conducted using a panel of thirty semi-trained panellists aged 20–45 years. The samples were evaluated using a nine-point hedonic scale based on the attributes of appearance, colour, flavour, texture, taste, crispness, and overall acceptability. Energy and carbohydrates content of the control and standardized samples of the cracker was determined using the CTL/SOP/FOOD/262 test method, Protein was assessed using the test method AQAC 992.23, Fat was assessed using the test method AOAC 992.23, Crude fiber was assessed using the test method AOAC 978.10, Ash was assessed using the test method AOAC 942.05, Moisture was assessed using the test method AOAC 930.15, Iron and calcium were assessed using the Atomic Absorption Spectrophotometer. The total plate count was conducted using the test method IS 5402. The shelf -life study on standardized (T3) was conducted by carrying out a shelf-life analysis where the product was stored under accelerated conditions for 1 week, which is equivalent to 1month

- The moisture content of both control and T3 was analyzed using the test method IS 5402: Part 1 :2021
- Yeast and mold count were analyzed using IS 5403:1999(RA2018)
- E.coli was assessed using IS 5401 : Part 1 ; 2012 (RA 2018)

Development of Moringa Enriched Diabetes Friendly Crackers

The moringa-enriched diabetes-friendly crackers were prepared by first combining the dry ingredients, namely wheat flour, quinoa flour, jackfruit flour, and moringa leaf powder, in a mixing bowl. To this mixture, chilli powder, pepper powder, sesame seeds, salt, and baking powder were added and mixed thoroughly to ensure uniform distribution. Oil was then incorporated into the dry mixture to improve the texture and crispness of the crackers. Water was added gradually while kneading until a smooth and firm dough was obtained. The dough was allowed to rest for 10–15 minutes to facilitate proper hydration of the flour. After resting, the dough was rolled into a thin sheet on a lightly floured surface using a rolling pin and cut into uniform cracker shapes using a knife or cutter. Small holes were pricked on the surface of each cracker with a fork to prevent puffing during baking. The crackers were

then arranged on a greased baking tray and baked in a preheated oven at 180°C for 12–15 minutes until they became crisp and developed a light golden-brown colour.

Statistical Analysis

After collection of data, the analysis of data was done using SPSS. Descriptive statistical analysis method (mean, median, standard deviation) was used to describe the data while ONE WAY ANOVA and TWO -WAY ANOVA were the inferential statistical methods that were used for data inference.

RESULTS

Standardization of Moringa enriched- diabetes friendly crackers

The formulation of moringa-enriched diabetes friendly crackers was carried out using composite flour consisting of wheat flour, quinoa flour, jackfruit flour, and moringa leaf powder, which were procured from the local market in Chennai, selected due to their nutritional benefits, particularly their high fiber content, antioxidant activity, and potential role in glycemic control. Four formulations were prepared, namely a control (T0) and three diabetic-friendly crackers (T1, T2, and T3), by progressively varying the proportion of moringa powder (0 g, 2 g, 3 g, and 5 g, respectively) while keeping the other ingredients constant. Wheat flour (38–40 g) served as the base ingredient, providing structure and texture to the crackers; quinoa flour (28 g) was incorporated to enhance protein quality and micronutrient density, and jackfruit flour (19 g) was included for its resistant starch and dietary fiber content, which aid in attenuating postprandial glycemic response. Flavoring and textural agents, like chilli powder (0.5 g), pepper powder (0.48 g), sesame seeds (4 g), jeera (10 g), salt (2 g), oil (10 ml), and water (10 ml), were added uniformly across all formulations to ensure palatability and consumer acceptability. All formulations were prepared under the same processing conditions and baked at 180°C for 12–15 minutes. The crackers were removed from the oven, allowed to cool at room temperature, and then stored in airtight containers to preserve their quality and crispness.

Sensory Analysis-- 9-Point Hedonic Scale

Sensory evaluation was conducted to determine the consumer acceptability of all four cracker formulations (Control, T1, T2, and T3) using the nine-point Hedonic Scale, a validated instrument for measuring the degree of liking or disliking of food products (Peryam & Pilgrim, 1957). Thirty untrained panellists independently evaluated each formulation for appearance, taste/flavour, smell/odour, texture, and overall acceptability. Values expressed as Mean ± SD. Statistical significance determined using one-way ANOVA at $p < 0.001$. Fat: Marginally higher in T3 (18.5 g/100g vs. 18.0 g/100g, $p = 0.004$), with no adverse nutritional implications. Sensory evaluation of the developed moringa enriched diabetic friendly crackers by 30 panellists is presented in Table 2. One-way ANOVA revealed statistically significant differences among the four formulations for all five sensory attributes evaluated ($p \leq 0.001$ in all cases), confirming that moringa concentrationinfluenced the sensory profile of the cracker products. The T3 formulation recorded the highest mean scores across all attributes; appearance (8.53 ± 0.68), taste/flavour (8.23 ± 1.09), smell/odour (8.33 ± 1.12), texture (8.53 ± 0.86), and overall acceptability (8.41 ± 0.94). Appearance scores for T3 (8.53 ± 0.68) were the highest among all formulations, including the control (8.13 ± 0.86), indicating that the characteristic green colouration imparted by moringa leaf powder at the T3 concentration did not negatively affect visual acceptability, which is a common concern in moringa-fortified products.

The highest score for taste/flavour in T3 (8.23 ± 1.09, comparable to the control at 8.20 ± 0.96) further confirms that moringa's characteristic grassy flavour was well-integrated at the T3 level without eliciting negative perception. The T1 formulation recorded the lowest scores for taste/flavour (6.83 ± 2.02), smell/odour (6.40 ± 2.12), and texture (6.43 ± 2.26), with the highest standard deviations across all attributes, suggesting imbalance at the lower moringa concentration. The T2 formulation exhibited intermediate scores across all attributes. Overall, T3 demonstrated consistent superiority in all sensory dimensions, confirming its suitability as the optimal formulation for a diabetic friendly moringa enriched cracker product. Table 3: Proximate composition of the control and T3 moringa enriched diabetic friendly crackers demonstrates significant nutritional improvements with moringa enrichment. The T3

formulation showed significantly higher protein content (11.8 g/100g) compared to the control (9.5 g/100g) ($t = 21.64$, $p < 0.001$), attributable to the rich amino acid profile of *Moringa oleifera* leaf powder. Mineral analysis demonstrated highly significant enhancements in both iron and calcium content in the T3 formulation compared to the control (Table 4).

Moisture Content During Storage

Moisture content was monitored at each storage interval to assess physicochemical stability, as it is a primary determinant of texture degradation and microbial susceptibility in baked cracker products. The results of Two-Way ANOVA, examining the effects of sample type and storage time, are presented in Table-5. Moisture content in both formulations increased progressively over the 7-day storage period, from 4.0% and 4.5% at Day 0 to 5.8% and 6.4% at Day 7 for the control and T3, respectively (Table 5). Two-way ANOVA revealed that storage time had a highly significant effect on moisture content ($F = 354$, $p< 0.001$). The effect of sample type was also significant ($F = 144$, $p = 0.006$), with T3 consistently exhibiting slightly higher moisture values, likely due to the hygroscopic nature of moringa leaf powder. Despite this increase, both samples remained within acceptable moisture limits for cracker products throughout the storage period, confirming product stability. Despite the progressive moisture increase, both formulations remained well within the acceptable moisture limit for baked crackers. These findings confirm the physicochemical stability of both formulations and validate adequate product shelf-life under the tested conditions.

Shelf-Life Analysis

Shelf-life analysis was conducted to evaluate the microbiological stability and chemical changes in both control and T3 cracker formulations over a 7-day storage period. Tests included Moisture Content, Total Plate Count (TPC), Yeast and Mold Count, and E.Coli testing using standard spread plate methods

Total Plate Count (TPC) During Storage

100 mg of sample transferred aseptically to 9 ml of 0.9% sterile saline. Serial dilution up to 10^3. Inoculated 0.1 ml on Plate Count Agar, incubated at 37°C for 24 hrs. Colonies counted and expressed in CFU/g.
Method: Plate Count Method — Spread Plate Method (IS 5402). Values expressed as CFU/g.

Total Plate Count increased significantly with storage duration in both formulations, as indicated by Two-Way ANOVA that storage time was the primary driver of microbial growth ($F = 413.5$, $p < 0.001$), with a significant effect of sample type also observed ($F = 17$, $p = 0.025$). The T3 sample showed slightly higher microbial counts compared to the control at each time point, which may be linked to its marginally higher moisture content. Despite this incremental increase, all TPC values across both formulations remained well within the permissible limit of $\leq 10^5$ CFU/g specified by the Food Safety and Standards Authority of India (FSSAI) for baked snack products throughout the 7-day storage period. These results confirm acceptable microbiological quality and product safety over the assessed shelf-life.

Yeast and Mold Count During Storage

Yeast and mould counts were determined using the Spread Plate Method on Rose Bengal Agar (IS 5403:1999 RA 2018), incubated at 37°C for 72 hours. Yeast and mould enumeration is specifically relevant for baked cereal products, as fungal spoilage is a primary mode of quality deterioration in such matrices during storage. The Two-Way ANOVA results are presented in (Table 7) Mac Conkey Agar was used for *E. Coli*detection—Spread Plate Method, incubated at 37°C for 24 hrs. *E. Coli*was entirely absent (NIL CFU/g) in both the control and T3 formulations at all four storage time points (Day 0, 3, 5, and 7) (Table 8). This finding is of significant public health importance, as *E. Coli*contamination in food products is a critical indicator of poor hygiene or cross-contamination during processing.

DISCUSSION

The T3 diabetic friendly crackers contained significantly higher protein than the control. The results are consistent with Gómez-Martínez et al. (2022), who attributed the increase to the naturally high protein content due to*Moringa oleifera* leaves. Crude fibre content was markedly elevated in T3 Vs Control (3.8 g/100g Vs. 2.0 g/100g, $p < 0.001$).Dietary fibre increased with increasing levels of quinoa, jackfruit flour, and moringa. This finding agrees with Ren et al. (2023), who described quinoa as a rich source of dietary fibre and bioactive compounds. Ash content was significantly higher in T3 Vs Control (2.6 g/100g Vs. 1.8 g/100g, $p < 0.001$), indicating enhanced micronutrient richness from moringa fortification. Carbohydrate content was significantly reduced in T3 (58.8 g/100g Vs. 64.7 g/100g, $p < 0.001$), making it more appropriate for glycaemic management. Energy content showed a marginal but significant reduction in T3 (449 kcal Vs. 452 kcal, $p < 0.05$). These findings confirm the nutritional superiority of T3 for diabetic-friendly food formulation. Iron content increased more than twofold, from 2.8 mg/g in the control to 6.5 mg/g in T3 ($t = 62.41$, $p < 0.001$). This substantial increase is directly attributable to the exceptionally high iron content of moringa leaf powder, which has been reported to contain 28.2 mg of iron per 100 g on a dry weight basis (Seshadri & Nambiar, 2003; Gopalakrishnan et al., 2016; Gómez-Martínez et al. (2022)). Adequate iron intake is essential for prevention of anaemia, while calcium supports bone mineral density. The T3 formulation, therefore, offers a meaningful dietary strategy for addressing this nutritional gap confirms that moringa fortification substantially increases the micronutrient value of the diabetic friendly crackers. Calcium content rose dramatically from 45 mg/g in the control to 120 mg/g in T3 ($t = 68.73$, $p < 0.001$). *Moringa oleifera* leaves are among the most calcium-rich plant sources, with a reported calcium content of approximately 440 mg per 100 g dry weight, exceeding that of cow's milk on an equal weight basis (Fuglie, 2001). Adequate dietary calcium is essential for maintaining bone mineral density, which is compromised in individuals with diabetes due to insulin deficiency, poor glycaemic control, and associated alterations in calcium-phosphate metabolism (Janghorbani et al., 2007). The significant elevation of both minerals in T3 confirms that moringa fortification substantially enhances the micronutrient density of the cracker formulation, augmenting its potential as a functional food for diabetic populations

The T3 sample showed slightly higher microbial counts compared to the control at each time point, which may be linked to its marginally higher moisture content. Despite this incremental increase, all TPC values across both formulations remained well within the permissible limit of $\leq 10^5$ CFU/g specified by the Food Safety and Standards Authority of India (FSSAI) for baked snack products throughout the 7-day storage period. These results confirm acceptable microbiological quality and product safety over the assessed shelf-life.Despite the slight increase over storage, all yeast and mold counts remained within acceptable food safety limits throughout the study period, confirming that both formulations had adequate microbiological shelf-life stability. The antimicrobial bioactive constituents of *M. oleifera*, including isothiocyanates and phenolic acids, may have additionally contributed to limiting fungal proliferation in the T3 formulation. The results state that both the control and T3 moringa-enriched crackers were prepared under hygienic conditions and are entirely safe for human consumption. Additionally, the well-documented antimicrobial activity of *M. oleifera* leaf bioactives — including 4-(α-L-rhamnopyranosyloxy)-benzyl isothiocyanate — against Gram-negative enteric pathogens (Fahey, 2005) may have contributed to the sustained pathogen-free status of the T3 formulation throughout storage.

CONCLUSION

The present study formulated and validated moringa-enriched diabetes-friendly crackers and found thatT3 diabetic-friendly crackersexhibited the most desirable nutritional profile, with enhanced protein, dietary fibre, mineral content, and antioxidant potential, while maintaining high sensory acceptability and satisfactory microbiological stability. The incorporation of moringa leaf powder, quinoa flour, jackfruit flour, and wheat flour produced a nutritionally balanced functional snack with the potential to support glycaemic management and serve as a healthier alternative to conventional crackers. These findings demonstrate that the synergistic combination of these ingredients

can improve the nutritional quality of bakery products and highlight their potential for the development of value-added functional foods.

ABSTRACT

The aim of this paper is introducing the notions of neutrosophic implicative and positive implicative filters of Monidal t-norm based Logic algebras (MTL-algebras). Also, investigate some relevant properties with illustrations.

Keywords: MTL-algebra; Filter; Neutrosophic filter; Neutrosophic implicative filter; Neutrosophic positive implicative filter.

INTRODUCTION

To formalize the many-valued logics induced by continuous t- norms on the real unit interval [0,1], Hájek published Basic Logic [4], a highly generic many-valued logic, in 1998.The well-known conclusion that a t-norm has a residumm if and only if the t-norm is left-continuous shows that Basic Logic is not the most general t-norm-based logic. Filter theory is essential to the understanding of these algebras. Distinct sets of proven equations logically correspond to distinct filters. Hájek introduced the concepts of filters and prime filters in BL-algebras [4], and BL-algebras defined the concepts of implicative, positive, and fantastic filters [5]. The first person to thoroughly study filter theory in BL-algebras, including maximal, Boolean, and prime filters, was Turunen [14]. To emphasize that these filters are closed with respect to Modus Ponens and relate to sets of proved equations, they are called deductive systems. Furthermore, deductive systems were shown by [15]. Additionally, it was demonstrated in [14] that Hájek's filters align with deductive systems. Several definitions and theorems that follow

identical axioms from BL-algebras can be extended to MTL- algebras without any modifications as any BL-algebra is an MTL-algebra. The authors [14] introduced a notion of neutrosophic filter of MTL- algebras and investigated some of its related properties with illustrations. Here, we present a few novel filters with unique properties in MTL-algebras. We define positive implicative and neutrosophic implicative filters of MTL-algebras.

Preliminaries

To advance the main conclusions, various definitions and findings from the literature are cited in this section.

Definition 2.1[2]: A residuated lattice is a lattice $\mathcal{L}= (\mathcal{L}, \leq, \wedge, \vee, \otimes, \mapsto, 0, 1)$ containing the least element 0 and the largest element 1, and endowed with two binary operations $\otimes$ (called product) and $\mapsto$ (called residuum) such that

- $\otimes$ is associative, commutative and isotone.
- $\zeta \otimes 1 = \zeta$, for all $\zeta \in \mathcal{L}$
- The Galois correspondence holds,

That is, $\zeta \otimes \varpi \leq \varrho \Leftrightarrow \zeta \leq \varpi \mapsto z$, for all $\zeta, \varpi, \varrho \in \mathcal{L}$

In a residuated lattice, the following are true

- $\zeta \leq \varpi \Leftrightarrow \zeta \mapsto \varpi = 1$.
- $0 \mapsto \zeta$
- $\zeta = 1, 1 \mapsto = \zeta, \zeta \mapsto (\varpi \mapsto \zeta) = 1$.
- $\varpi \leq (\varpi \mapsto \zeta) \mapsto \zeta$.
- $\zeta \mapsto (\varpi \mapsto \varrho) = (\zeta \otimes \varpi) \mapsto \varrho = \varpi \mapsto (\zeta \mapsto \varrho)$.
- $\zeta \mapsto \varpi \leq (\varrho \mapsto \zeta) \mapsto (\varrho \mapsto \varpi)$,
- $(\zeta \mapsto \varpi) \leq (\varpi \mapsto \varrho) \mapsto (\zeta \mapsto \varrho)$.
- $\varpi \leq \zeta \Rightarrow \zeta \mapsto \varrho \leq \varpi \mapsto \varrho, \varrho \mapsto \varpi \leq \varrho \mapsto \zeta$.
- $(\vee_{i \in r} \varpi_i) \mapsto x = \wedge_{i \in r} (\varpi_i \mapsto \zeta)$.

Definition 2.2[10]: An MTL-algebra is a residuated lattice $\mathcal{M}= (\mathcal{M}, \leq, \wedge, \vee, \otimes, \mapsto, 0, 1)$ satisfying the pre-linearity equation $(\zeta \mapsto \varpi) \vee (\varpi \mapsto \zeta) = 1$.

In an MTL-algebra, the following are true for all $\zeta, \varpi, \varrho \in \mathcal{M}$,

- $\zeta \mapsto (\varpi \vee \varrho) = (\zeta \mapsto \varpi) \vee (\zeta \mapsto \varrho)$
- $\zeta \otimes \varpi \leq \zeta \wedge \varpi$.
-

Definition 2.3[10]: Let $\mathcal{M}$ be an MTL-algebra. A non-empty subset F of $\mathcal{M}$ called a filter of $\mathcal{M}$, if it satisfied the following for all $\zeta, \varpi \in \mathcal{M}$,

(i) $\zeta \otimes \varpi \in F$

(ii) $\zeta \leq \varpi \Rightarrow \varpi \in F$.

Proposition 2.4[10]: A nonempty subset F of an MTL-algebra $\mathcal{M}$ is a filter of $\mathcal{M}$ if and only if it satisfies the following for all $\zeta, \varpi \in \mathcal{M}$,

(i) $1 \in F$.

(ii) $\zeta \mapsto \varpi \in F \Rightarrow \varpi \in F$.

Definition 2.5 [5] A nonempty subset F of an MTL-algebra $\mathcal{M}$ is a implicative filter of $\mathcal{M}$, if it satisfies the following for all $\zeta, \varpi, \varrho \in \mathcal{M}$,

(i) $1 \in F$

(ii) $\zeta \mapsto (\varpi \mapsto \varrho) \in F$ and $\zeta \mapsto \varpi \in F$ imply $\zeta \mapsto \varrho \in F$.

Definition 2.6 [5]A nonempty subset F of an MTL-algebra $\mathcal{M}$ is a positive implicative filter of $\mathcal{M}$, if it satisfies the following for all $\zeta, \varpi, \varrho \in \mathcal{M}$,

(i) $1 \in F$

(ii) $\zeta \mapsto ((\varpi \mapsto \varrho) \mapsto \varpi) \in F$ and $\zeta \in F$ imply $\varpi \in F$.

Definition 2.7[1,12] A neutrosophic subset $\mathcal{N}$ of the universe U is a triple $(\mathbb{T}_{\mathcal{N}}, \mathbb{I}_{\mathcal{N}}, \mathbb{F}_{\mathcal{N}})$ where $\mathbb{T}_{\mathcal{N}}: U \to [0,1]$, $\mathbb{I}_{\mathcal{N}}: U \to [0,1]$ and $\mathbb{F}_{\mathcal{N}}: U \to [0,1]$ represents truth membership, indeterminacy and false membership functions respectively where $0 \leq \mathbb{T}_{\mathcal{N}}(\alpha_5) + \mathbb{I}_{\mathcal{N}}(\alpha_5) + \mathbb{F}_{\mathcal{N}}(\alpha_5) \leq 3$ for all $\alpha_5 \in U$.

Definition 2.8[14] A neutrosophic set $\mathcal{N}$ in $\mathcal{M}$ is called a neutrosophic filter of a MTL-algebra $\mathcal{M}$, if it satisfied the following for all $\zeta, \varpi \in \mathcal{M}$,

(i) $\mathbb{T}_{\mathcal{N}}(\zeta) \leq \mathbb{T}_{\mathcal{N}}(1), \mathbb{I}_{\mathcal{N}}(\zeta) \leq \mathbb{I}_{\mathcal{N}}(1)$ and $\mathbb{F}_{\mathcal{N}}(\zeta) \geq \mathbb{F}_{\mathcal{N}}(1)$

(ii) $\mathbb{T}_{\mathcal{N}}(\zeta \otimes \varpi) \geq \min\{\mathbb{T}_{\mathcal{N}}(\zeta), \mathbb{T}_{\mathcal{N}}(\varpi)\}$, $\mathbb{I}_{\mathcal{N}}(\zeta \otimes \varpi) \geq \min\{\mathbb{I}_{\mathcal{N}}(\zeta), \mathbb{I}_{\mathcal{N}}(\varpi)\}$ and $\mathbb{F}_{\mathcal{N}}(\zeta \otimes \varpi) \leq \max\{\mathbb{F}_{\mathcal{N}}(\zeta), \mathbb{F}_{\mathcal{N}}(\varpi)\}$.

MAIN RESULTS

Neutrosophic Implicative Filter

Here, we discuss the notion of neutrosophic implicative filter and investigates some properties with illustrations.

Definition 3.1.1. A neutrosophic filter $\mathcal{N}_1$ of MTL- algebra $\mathcal{M}_1$ is called a neutrosophic implicative filter of $\mathcal{M}_1$, if it contents the below requirements for all $r, s, t \in \mathcal{M}_1$,

(i) $\mathbb{T}_{\mathcal{N}_1}(r) \leq \mathbb{T}_{\mathcal{N}_1}(1), \mathbb{I}_{\mathcal{N}_1}(r) \leq \mathbb{I}_{\mathcal{N}_1}(1)$ and $\mathbb{F}_{\mathcal{N}_1}(r) \geq \mathbb{F}_{\mathcal{N}_1}(1)$;

(ii) $\mathbb{T}_{\mathcal{N}_1}(r \mapsto t) \geq \min\{\mathbb{T}_{\mathcal{N}_1}(r \mapsto (s \mapsto t)), \mathbb{T}_{\mathcal{N}_1}(r \mapsto s)\}$,

$\mathbb{I}_{\mathcal{N}_1}(r \mapsto t) \geq \min\{\mathbb{I}_{\mathcal{N}_1}(r \mapsto (s \mapsto t)), \mathbb{I}_{\mathcal{N}_1}(r \mapsto s)\}$, and

$\mathbb{F}_{\mathcal{N}_1}(r \mapsto t) \leq \max\{\mathbb{F}_{\mathcal{N}_1}(r \mapsto (s \mapsto t)), \mathbb{F}_{\mathcal{N}_1}(r \mapsto s)\}$.

Example 3.1.2. Let $\mathcal{M}_1 = \{0, i_1, j_1, 1\}$ be a set, where $0 < i_1 < j_1 < 1$ The product $' \otimes '$ and a residuum $' \mapsto '$ on $\mathcal{M}$ defined by the tables 3.1.1 and 3.1.2 as follows

Let $' \wedge '$ and $' \vee '$ be defined on $\mathcal{M}_1$ by 'min' and 'max', respectively.

Then $(\mathcal{M}_1, \wedge, \vee, \otimes, 0,1\}$ is an MTL-algebra.

Consider

$$\mathcal{N}_1 = \{(0, [0.7, 0.4, 0.1]), (i_1, [0.5, 0.4, 0.2]), (j_1, [0.4, 0.5, 0.1]), (1, [0.7, 0.6, 0.1])\}$$

It is evident that $\mathcal{N}$ assures definition 3.1. Thus, $\mathcal{N}_1$ is a neutrosophic filter of $\mathcal{M}_1$.

Proposition 3.1.3. Any neutrosophic implicative filter of MTL-algebra $\mathcal{M}_1$ is a neutrosophic filter. But, the converse is not true.

Proof. Let $\mathcal{N}_1$ be a neutrosophic implicative filter of $\mathcal{M}_1$.

To Prove: $\mathcal{N}_1$ is a neutrosophic filter of $\mathcal{M}_1$

Replace r as 1 in the definition 3.1.1, we have

$\mathbb{T}_{\mathcal{N}_1}(1 \mapsto t) \geq \min\{\mathbb{T}_{\mathcal{N}_1}(1 \mapsto (s \mapsto t)), \mathbb{T}_{\mathcal{N}_1}(1 \mapsto s)\}$ for all $r, s, t \in \mathcal{M}$

$\mathbb{T}_{\mathcal{N}_1}(t) \geq \min\{\mathbb{T}_{\mathcal{N}_1}((s \mapsto t)), \mathbb{T}_{\mathcal{N}_1}(s)\}$ for all $s, t \in \mathcal{M}$.

Similarly, $\mathbb{I}_{\mathcal{N}_1}(1 \mapsto t) \geq \min\{\mathbb{I}_{\mathcal{N}_1}(1 \mapsto (s \mapsto t)), \mathbb{I}_{\mathcal{N}_1}(1 \mapsto s)\}$ for all $r, s, t \in \mathcal{M}$

$\mathbb{I}_{\mathcal{N}_1}(t) \geq \min\{\mathbb{I}_{\mathcal{N}_1}((s \mapsto t)), \mathbb{I}_{\mathcal{N}_1}(s)\}$ for all $s, t \in \mathcal{M}$.

$\mathbb{F}_{\mathcal{N}_1}(1 \mapsto t) \leq \max\{\mathbb{F}_{\mathcal{N}_1}(1 \mapsto (s \mapsto t)), \mathbb{F}_{\mathcal{N}_1}(1 \mapsto s)\}$ for all $r, s, t \in \mathcal{M}$

$\mathbb{F}_{\mathcal{N}_1}(t) \leq \max\{\mathbb{F}_{\mathcal{N}_1}((s \mapsto t)), \mathbb{F}_{\mathcal{N}_1}(s)\}$ for all $s, t \in \mathcal{M}$.

Then from the definition of neutrosophic filter $\mathcal{N}_1$ is a neutrosophic filter of $\mathcal{M}_1$. ■

The converse part may not be true. This can be proved by an illustration.

Example 3.1.4: Let $\mathcal{M}_1 = \{0, \eta_1, \xi_1, 1\}$ be a set, where $0 < \eta_1 < \xi_1 < 1$ The product $' \otimes '$ and a residum $' \mapsto '$ on $\mathcal{M}_1$ by the tables (3.1.3) and (3.14).

Now, consider

$\mathcal{N}_1 = (0,[0.9,0.2,0.1]),(\eta_1,[0.5,0.3,0.1]),(\xi_1,[0.5,0.3,0.1]),(1,[0.9,0.2,0.1])\}$.
Here, $\mathcal{N}_1$ is not a neutrosophic implicative filter.
Since,$\mathbb{T}_{\mathcal{N}}(\xi_1 \longmapsto 1) = \mathbb{T}_{\mathcal{N}}(\xi_1) = 0.5 \not\geq 0.9 = \mathbb{T}_{\mathcal{N}}(0)$

Proposition 3.1.5: Let$\mathcal{N}_1$ be a neutrosophic filter of an MTL-algebra $\mathcal{M}_1$. The following are equivalent for all $\zeta_1, \varpi_1, \varrho_1 \in \mathcal{M}$.

(i) $\mathcal{N}_1$is a neutrosophic implicative filter.
(ii) $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \geq \mathbb{T}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$,
$\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \geq \mathbb{I}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$,
$\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \leq \mathbb{F}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$.
(iii) $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) = \mathbb{T}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$,
$\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) = \mathbb{I}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$,
$\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) = \mathbb{F}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$.

Proof: (i)⇒(ii)
Suppose$\mathcal{N}_1$ is a neutrosophic implicative filter of $\mathcal{M}_1$.
Put $\varrho_1 = \varpi_1$, $\varpi_1 = \zeta_1$in the definition 3.1.1,
we get
$\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \geq \min\{\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)), \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \zeta_1)\}$for all $\zeta_1, \varpi_1 \in \mathcal{M}$.
$\geq \min\{\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)), \mathbb{T}_{\mathcal{N}_1}(1)\}$
$= \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1))$
Therefore,
$\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \geq \mathbb{T}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$for all $\zeta_1, \varpi_1 \in \mathcal{M}$.
Similarly, $\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \leq \min\{\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)), \mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto \zeta_1)\}$
Therefore, $\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \leq \mathbb{I}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$for all $\zeta_1, \varpi_1 \in \mathcal{M}$.
$\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \leq \min\{\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)), \mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto \zeta_1)\}$
Therefore, $\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \leq \mathbb{F}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$for all $\zeta_1, \varpi_1 \in \mathcal{M}$.
Hence (ii) holds.
(ii)⇒(iii)
Let$\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \geq \mathbb{T}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$for all $\zeta_1, \varpi_1 \in \mathcal{M}$.
Since$\zeta_1 \longmapsto \varpi_1 \leq \zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)$ and,
we have $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \leq \mathbb{T}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$ for all $\zeta_1, \varpi_1 \in \mathcal{M}$, and
from (ii) we get, $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) = \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1))$ for all$\zeta_1, \varpi_1 \in \mathcal{M}$.
Similarly, we have $\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) \geq \mathbb{I}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$.
Therefore, $\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) = \mathbb{I}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$for all $\zeta_1, \varpi_1 \in \mathcal{M}$.
Similarly, we have $\mathbb{F}_{\mathcal{N}_1}\big(\zeta_{1_1} \longmapsto \varpi_1\big) \geq \mathbb{F}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$.
Therefore, $\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) = \mathbb{F}_{\mathcal{N}_1}\big(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1)\big)$for all $\zeta_1, \varpi_1 \in \mathcal{M}$.
Hence (iii) holds.
(iii)⇒(i)
Let $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1) = \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\zeta_1 \longmapsto \varpi_1))$for all $\zeta_1, \varpi_1 \in \mathcal{M}$.
If$\mathcal{M}_1$ is a neutrosophic filter of $\mathcal{S}$, then from the proposition 2.2.9,
$\min\{\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\varpi_1 \longmapsto \varrho_1)), \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1)\} \leq \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varrho_1)$for all $\zeta_1, \varpi_1, \varrho_1 \in \mathcal{M}$
Similarly, $\min\{\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\varpi_1 \longmapsto \varrho_1)), \mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1)\} \geq \mathbb{I}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varrho_1)$, and
$\min\{\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto (\varpi_1 \longmapsto \varrho_1)), \mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varpi_1)\} \geq \mathbb{F}_{\mathcal{N}_1}(\zeta_1 \longmapsto \varrho_1)$for all $\zeta_1, \varpi_1, \varrho_1 \in \mathcal{M}$.
Hence, $\mathcal{N}_1$ is a neutrosophic implicative filter of $\mathcal{M}_1$. ■
Next, we demonstrate the extension theorem for neutrosophic implicative filter.

Proposition 3.1.6: Let $\mathcal{M}_1$ and $\mathcal{N}_1$ be two neutrosophic filters of $\mathcal{S}$. Let $\mathcal{M}_1 \subseteq \mathcal{N}_1, \mathbb{T}_{\mathcal{N}_1}(1) = \mathbb{T}_{\mathcal{N}_1}(1)$, $\mathbb{I}_{\mathcal{N}_1}(1) = \mathbb{I}_{\mathcal{N}_1}(1)$, $\mathbb{F}_{\mathcal{N}_1}(1) = \mathbb{F}_{\mathcal{N}_1}(1)$. If $\mathcal{M}_1$ is a neutrosophic implicative filter, then so is $\mathcal{N}_1$.

Proof: Let $\mathcal{M}_1$ and $\mathcal{N}_1$ be two neutrosophic filters of $\mathcal{S}$.
From the proposition 4.2.5,
we only prove that $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto \varpi_1) \geq \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1))$,
$\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \mapsto \varpi_1) \leq \mathbb{I}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1))$,
$\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \mapsto \varpi_1) \leq \mathbb{F}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1))$ for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
Let $\zeta_1 = \zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)$
Then, $\zeta_1 \mapsto (\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) = \zeta_1 \mapsto (\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) = 1$.
Suppose, $\mathcal{M}_1$ is a neutrosophic implicative filter of $\mathcal{S}$, then from (iii) of the proposition 4.2.5, and since $\mathcal{M}_1 \subseteq \mathcal{N}_1, \mathbb{T}_{\mathcal{M}_1}(1) = \mathbb{T}_{\mathcal{N}_1}(1)$,

$$\begin{aligned}\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) &= \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) \\ &\geq \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) \\ &= \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1))) \\ &= \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1))) \\ &= \mathbb{T}_{\mathcal{M}_1}(1) \\ &= \mathbb{T}_{\mathcal{N}_1}(1)\end{aligned}$$

Thus, $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) \geq \mathbb{T}_{\mathcal{N}_1}(1)$ for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
This together with (i) of the definition 4.2.1, $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) \leq \mathbb{T}_{\mathcal{N}_1}(1)$
imply that $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) = \mathbb{T}_{\mathcal{N}_1}(1)$ for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
Since, $\mathcal{N}_1$ is a neutrosophic filter then by the definition 2.2.1,
we have $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto \varpi_1) \geq \min\{\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)), \mathbb{T}_{\mathcal{N}_1}(\zeta_1)\}$ for all $\zeta_1, \varpi_1 \in \mathcal{S}$.

$$\begin{aligned}&= \min\{\mathbb{T}_{\mathcal{N}_1}(1), \mathbb{T}_{\mathcal{N}_1}(\zeta_1)\} \\ &= \mathbb{T}_{\mathcal{N}_1}(\zeta_1) \\ &= \mathbb{T}_{\mathcal{N}}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1))\end{aligned}$$

Hence, $\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto \varpi_1) \geq \mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1))$ for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
Similarly, $\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) \leq \mathbb{I}_{\mathcal{N}_1}(1)$ for all $\zeta_1, \varpi_1 \in \mathcal{S}$, and
we have $\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \mapsto \varpi_1) \leq \min\{\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)), \mathbb{I}_{\mathcal{N}}(\zeta_1)\}$

$$= \mathbb{I}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) \text{ for all } \zeta_1, \varpi_1 \in \mathcal{S}.$$

Also, $\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) \leq \mathbb{F}_{\mathcal{N}_1}(1)$ for all $\zeta_1, \varpi_1 \in \mathcal{S}$, and
we have $\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \mapsto \varpi_1) \leq \min\{\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)), \mathbb{F}_{\mathcal{N}}(\zeta_1)\}$

$$= \mathbb{F}_{\mathcal{N}_1}(\zeta_1 \mapsto (\zeta_1 \mapsto \varpi_1)) \text{ for all } \zeta_1, \varpi_1 \in \mathcal{S}.$$

Therefore, from (ii) of the proposition 4.2.5,
$\mathcal{N}_1$ is a neutrosophic implicative filter. ■

Neutrosophic Positive Implicative Filter

In this section, we discuss the notion of neutrosophic positive implicative filter and investigate some properties with illustrations.

Definition 3.2.1: A neutrosophic set $\mathcal{N}_1$ is called a neutrosophic positive implicative filter of MTL-algebra $\mathcal{M}_1$ if it persuades the succeeding for all $\zeta_1, \varpi_1, \varrho_1 \in \mathcal{S}$,

(i) $\mathbb{T}_{\mathcal{N}_1}(\zeta_1) \leq \mathbb{T}_{\mathcal{N}_1}(1)$, $\mathbb{I}_{\mathcal{N}_1}(\zeta_1) \geq \mathbb{I}_{\mathcal{N}_1}(1)$ and $\mathbb{F}_{\mathcal{N}_1}(\zeta_1) \geq \mathbb{F}_{\mathcal{N}_1}(1)$.

(ii) $\min\{\mathbb{T}_{\mathcal{N}_1}(\zeta_1 \mapsto ((\varpi_1 \mapsto \varrho_1) \mapsto \varpi_1), \mathbb{T}_{\mathcal{N}_1}(\zeta_1)\} \leq \mathbb{T}_{\mathcal{N}_1}(\varpi_1)$;
$\min\{\mathbb{I}_{\mathcal{N}_1}(\zeta_1 \mapsto ((\varpi_1 \mapsto \varrho) \mapsto \varpi_1), \mathbb{I}_{\mathcal{N}_1}(\zeta_1)\} \leq \mathbb{I}_{\mathcal{N}_1}(\varpi_1)$;
$\min\{\mathbb{F}_{\mathcal{N}_1}(\zeta_1 \mapsto (\varpi_1 \mapsto \varrho_1) \mapsto \varpi_1), \mathbb{F}_{\mathcal{N}_1}(\zeta_1)\} \geq \mathbb{F}_{\mathcal{N}_1}(\varpi_1)$.

Example 3.2.2: Let $\mathcal{M}_1 = \{0, \alpha_{11}, \beta_{11}, \gamma_{11}, 1\}$. The bi-fold operations are specified by the tables (3.2.1) and (3.2.2).
Now consider a neutrosophic set

$\mathcal{M}_1 = \{(0,[0.4,0.6,0.6]), (\alpha_{11},[0.5,0.6,0.6]), (\beta_{11},[0.5,0.6,0.6]),$
$(\gamma_{11},[0.5,0.6,0.6]), (1,[0.6,0.6,0.6])\}$.
Hence, from the definition 5.2.1 $\mathcal{M}_1$is a neutrosophic positive implicative filter of$\mathcal{S}$.

Proposition 3.2.3: Any neutrosophic positive implicative filter is a neutrosophic filter. But, the adverse may not be true.
Proof: Let $\mathcal{M}_1$be a neutrosophic positive implicative filter of$\mathcal{S}$.
To prove:$\mathcal{M}_1$ is a neutrosophic filter of $\mathcal{S}$.
Then, putting $\varrho_1 = \varpi_1$ in (ii) of the definition 3.2.1, we get
$\mathbb{T}_{\mathcal{M}_1}(\varpi_1) \geq \min\{\mathbb{T}_{\mathcal{M}_1}\big((\zeta_1 \longmapsto (\varpi_1 \longmapsto \varpi_1) \longmapsto \varpi_1), \mathbb{T}_{\mathcal{M}_1}(\zeta_1)\big\}$for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
$\mathbb{T}_{\mathcal{M}_1}(\varpi_1) \geq \min\{\mathbb{T}_{\mathcal{M}_1}\big(\zeta_1 \longmapsto (1 \longmapsto \varpi_1), \mathbb{T}_{\mathcal{M}_1}(\zeta_1)\big)\}$
$\mathbb{T}_{\mathcal{M}_1}(\varpi_1) \geq \min\big\{\mathbb{T}_{\mathcal{M}_1}\big(\zeta_1 \longmapsto \varpi_1\big), \mathbb{T}_{\mathcal{M}_1}(\zeta_1)\big\}$for all $\zeta_1, \varpi_1 \in \mathcal{S}$.

Similarly, $\mathbb{I}_{\mathcal{M}_1}(\varpi_1) \leq \min\{\mathbb{I}_{\mathcal{M}_1}\big((\zeta_1 \longmapsto (\varpi_1 \longmapsto \varpi_1) \longmapsto \varpi_1), \mathbb{I}_{\mathcal{M}_1}(\zeta_1)\big\}$for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
$\mathbb{I}_{\mathcal{M}_1}(\varpi_1) \leq \min\{\mathbb{I}_{\mathcal{M}_1}\big(\zeta_1 \longmapsto (1 \longmapsto \varpi_1), \mathbb{I}_{\mathcal{M}_1}(\zeta_1)\big)\}$
$\mathbb{I}_{\mathcal{M}_1}(\varpi_1) \leq \min\big\{\mathbb{I}_{\mathcal{M}_1}\big(\zeta_1 \longmapsto \varpi_1\big), \mathbb{I}_{\mathcal{M}_1}(\zeta_1)\big\}$for all $\zeta_1, \varpi_1 \in \mathcal{S}$, and
$\mathbb{F}_{\mathcal{M}_1}(\varpi_1) \leq \min\{\mathbb{F}_{\mathcal{M}_1}\big((\zeta_1 \longmapsto (\varpi_1 \longmapsto \varpi_1) \longmapsto \varpi_1), \mathbb{F}_{\mathcal{M}_1}(\zeta_1)\big\}$for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
$\mathbb{F}_{\mathcal{M}_1}(\varpi_1) \leq \min\{\mathbb{F}_{\mathcal{M}_1}\big(\zeta_1 \longmapsto (1 \longmapsto \varpi_1), \mathbb{F}_{\mathcal{M}_1}(\zeta_1)\big)\}$
$\mathbb{F}_{\mathcal{M}_1}(\varpi_1) \leq \min\big\{\mathbb{F}_{\mathcal{M}_1}\big(\zeta_1 \longmapsto \varpi_1\big), \mathbb{F}_{\mathcal{M}_1}(\zeta_1)\big\}$for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
Therefore, by the definition 2.2.1, $\mathcal{M}_1$ is a neutrosophic filter of $\mathcal{S}$.
The adverse part can be proved by an example. ■

Example 3.2.4: Let $\mathcal{S} = \{0, \alpha_{11}, \beta_{11}, \gamma_{11}, 1\}$. The bi-fold operations are specified by the tables (3.2.1) and (3.2.2).
Now consider a neutrosophic set
$\mathcal{M}_1 = \{(0,[0.6,0.4,0.4]), (\alpha_{11},[0.6,0.4,0.4]), (\beta_{11},[0.6,0.4,0.4]),$
$(\gamma_{11},[0.6,0.4,0.4]), (1,[0.8,0.3,0.3])\}$
Here, $\mathcal{M}_1$ is not a neutrosophic positive implicative filter.
Because,$\mathbb{T}_{\mathcal{M}_1}(\beta_{11}) = 0.4 \ngeq 0.5 = \mathbb{T}_{\mathcal{M}_1}(\alpha_{11})$.

Proposition 3.2.5: Let $\mathcal{M}_1$ be a neutrosophic filter of$\mathcal{S}$. Then, $\mathcal{M}_1$ is a neutrosophic positive implicative filter of $\mathcal{S}$if and only if it persuades
$\mathbb{T}_{\mathcal{M}_1}(\zeta_1) \geq \mathbb{T}_{\mathcal{M}_1}\big((\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1\big)$,
$\mathbb{I}_{\mathcal{M}_1}(\zeta_1) \leq \mathbb{I}_{\mathcal{M}_1}\big((\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1\big)$,
$\mathbb{F}_{\mathcal{M}_1}(\zeta_1) \leq \mathbb{F}_{\mathcal{M}_1}\big((\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1\big)$for all $\zeta_1, \varpi_1 \in \mathcal{S}$.

Proof: Let $\mathcal{M}_1$ be a neutrosophic positive implicative filter of $\mathcal{S}$.

Then,$\mathbb{T}_{\mathcal{M}_1}(\zeta_1) \geq \min\big\{\mathbb{T}_{\mathcal{M}_1}(1 \longmapsto (\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1), \mathbb{T}_{\mathcal{M}_1}(1)\big\}$for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
$= \min\{\mathbb{T}_{\mathcal{M}_1}\big((\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1\big), \mathbb{T}_{\mathcal{M}_1}(1)\}$
$= \mathbb{T}_{\mathcal{M}_1}\big((\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1\big)$
Therefore, $\mathbb{T}_{\mathcal{M}_1}(\zeta_1) \geq \mathbb{T}_{\mathcal{M}_1}((\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1)$ for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
Similarly,$\mathbb{I}_{\mathcal{M}_1}(\zeta_1) \leq \mathbb{I}_{\mathcal{M}_1}((\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1)$, and
$\mathbb{F}_{\mathcal{M}_1}(\zeta_1) \leq \mathbb{F}_{\mathcal{M}_1}((\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1)$for all$\zeta_1, \varpi_1 \in \mathcal{S}$.
Conversely, suppose that $\mathbb{T}_{\mathcal{M}_1}(\zeta_1) \geq \mathbb{T}_{\mathcal{M}_1}((\zeta_1 \longmapsto \varpi_1) \longmapsto \zeta_1)$for all $\zeta_1, \varpi_1 \in \mathcal{S}$.
Then, for any $\zeta_1, \varpi_1, \varrho_1 \in \mathcal{S}, \mathbb{T}_{\mathcal{M}_1}(\varpi_1) \geq \mathbb{T}_{\mathcal{M}_1}((\varpi_1 \longmapsto \varrho_1) \longmapsto \varpi_1)$
$\geq \min\{\mathbb{T}_{\mathcal{M}_1}\big(\zeta_1 \longmapsto (\varpi_1 \longmapsto \varrho_1)\big), \mathbb{T}_{\mathcal{M}_1}(\zeta_1)\}$
[By the definition 2.2.1]
Similarly, $\mathbb{I}_{\mathcal{M}_1}(\varpi_1) \leq \mathbb{I}_{\mathcal{M}_1}((\varpi_1 \longmapsto \varrho_1) \longmapsto \varpi_1)$

$\leq \min\{\mathbb{I}_{\mathcal{M}_1}(\zeta_1 \mapsto (\varpi_1 \mapsto \varrho_1)), \mathbb{I}_{\mathcal{M}_1}(\zeta_1)\}$ for all $\zeta_1, \varpi_1, \varrho_1 \in \mathcal{S}$, and

$\mathbb{F}_{\mathcal{M}_1}(\varpi_1) \geq \mathbb{F}_{\mathcal{M}_1}((\varpi_1 \mapsto \varrho_1) \mapsto \varpi_1)$

$\geq \min\{\mathbb{F}_{\mathcal{M}_1}(\zeta_1 \mapsto (\varpi_1 \mapsto \varrho_1)), \mathbb{F}_{\mathcal{M}_1}(\zeta_1)\}$ for all $\zeta_1, \varpi_1, \varrho_1 \in \mathcal{S}$.

Therefore, $\mathcal{M}_1$ is a neutrosophic positive implicative filter of $\mathcal{S}$. ■

ABSTRACT

Alzheimer's Disease Alzheimer's Disease (AD) is the leading cause of dementia worldwide and constitutes a formidable and emerging public health burden. It is an inexorable progressive neurodegenerative disease caused by the complex convergence of Aβ deposition, aberrant tau phosphorylation and neurofibrillary formation, synaptic dysfunction, neuronal degeneration, neuroinflammation, oxidative stress and vascular and metabolic pathology. The onset and pathogenesis of AD proceed along a progressive continuum involving a prodromal preclinical period, the phase of Mild Cognitive Impairment and finally Dementia. Substantially, the pathogenic and molecular cascade events precede the onset of a clinically identifiable cognitive decline for years or even decades. Both genetic and non-genetic factors affect the susceptibility for developing AD and the ApoE4 genetic allele is considered to the strongest factor contributing to late-onset AD. Cardiovascular diseases, diabetes, physical inactivity, lack of sleep as well as other potential modified risk factors can contribute to the pathogenesis and development of AD. Symptomatic pharmacological treatment consists in acetylcholine inhibitors and memantine and recently Aβ -modifying therapeutic strategies, such as lecanemab and donanemab, add to this option in a part of early stage of AD patients. However, the deficiencies of therapeutic effectiveness, safety, accessibility and disease heterogeneity have paved the ground for seeking new therapeutic avenues. Promising interventions directed toward the modulation of tau pathology, neuro inflammation, oxidative stress, impaired synapses, metabolic changes, and others have emerged as actively explored innovative methods of managing AD. Life style modifications including cognitive stimulation, physical exercises and the regulation of vascular and metabolic risk factors also

play an important role for disease prevention and reduction of AD risk. Therefore, thorough knowledge regarding multi factorial pathogenesis and continuum development characteristics of AD provides a basis for unveiling new target sites for drugs, individualized prevention strategies and disease modification approaches.

Keywords: Alzheimer's disease, amyloid-beta, tau protein, neurodegeneration, risk factors, biomarkers, treatment, prevention

INTRODUCTION

Alzheimer's disease (AD) is the most prevalent neurodegenerative disorder and the leading etiology of dementia in subjects aged 65 years or older. First described by Alois Alzheimer in 1906, it has progressed from an obscure clinical entity to a global health problem that affects health systems, economies, and cultures worldwide. Alzheimer's disease has a progressive clinical manifestation of cognitive and behavioural decline, as well as a functional deterioration ultimately leading to a terminal state [1]. Traditional pathological markers diagnostic for AD include extracellular deposition of amyloid-beta (A) protein in senile plaques and intracellular accumulation of hyperphosphorylated tau protein in neurofibrillary tangles (NFTs). Presently, it is recognized that AD is an even more complex disease process composed of many interwoven pathomolecular mechanisms including mitochondrial dysfunction, oxidative stress, neuroinflammation, synaptic loss, blood-brain barrier dysfunction, dysregulated metabolism, among many others [2]. The global social and economic burden of AD are staggering; current figures state that there are 55 million people with dementia worldwide with AD being the underlying cause in 60-80% of them and projections show these numbers rising to 152 million by 2050 as the world population ages with the global economic burden alone exceeding $1 trillion US dollars per year in 2018 [3]. The immense emotional and psychological toll on affected individuals, caregivers, and families is incalculable [3]. Beyond years of extensive research and countless clinical trials there remain a dearth of therapeutic treatments for the disease. Most previously available treatments only had the potential to impact the symptoms of the disease but had no direct effect on its course. In 2023, approval of lecanemab, and in 2024 of donanemab by the FDA were a breakthrough as they were described as the first disease-modifying agents which caused a slight deceleration in cognitive decline [4].

Pathophysiology of Alzheimer's Disease

The Amyloid Cascade Hypothesis

The amyloid cascade hypothesis has served as the predominant framework for Alzheimer's disease research for almost three decades, positing that the buildup of Ab peptides is the primary catalyst for AD pathogenesis. Ab is produced thru the stepwise cleavage of amyloid precursor protein (APP) by the enzymes β-secretase (BACE1) and γ-secretase. This processing produces different variants of Ab peptide, with A40 and A42 being the predominant forms, the latter being more prone to aggregation and neurotoxicity. In typical physiological conditions, the generation and elimination of Ab maintain a homeostatic equilibrium, which is disrupted in AD, resulting in the accumulation, oligomerization, and creation of insoluble Ab plaques. It is believed that the soluble Ab oligomers are the neurotoxic entities accountable for impairing synaptic function, triggering oxidative stress, and provoking inflammatory responses prior to plaque development. Recent studies have modified the amyloid hypothesis to suggest that amyloid-beta pathology alone may not entirely capture all facets of Alzheimer's disease. The 2024 updated Alzheimer's Association standards demonstrate this by employing a biological stage framework that incorporates amyloid and tau biomarkers, while considering heterogeneity, co-pathologies, and cognitive resiliency.[5],[6]

Tau Pathology and Neurofibrillary Tangles

Tau Protein and Neurofibrillary Tangles: Tau is a protein associated with microtubules that plays a crucial role in maintaining neuronal cytoskeletal structure, facilitating intracellular signaling, and aiding axonal transport. In

Alzheimer's disease, tau undergoes excessive hyper phosphorylation, dissociates from microtubules, and aggregates into paired helical filaments, which are characteristic of neurofibrillary tangles (NFTs). In contrast to the essentially unchanging characteristics of A disease, tau pathology progressively extends to physically linked regions of the brain in a systematic and foreseeable manner (Braak staging). The spatial distribution of tau accumulation and its spread throughout the brain is significantly associated with cognitive deterioration and neuronal degeneration, surpassing the impact of amyloid load. While A probably triggers the illness cascade, tau pathology is likely responsible for the ensuing neurode generation, resulting in clinical advancement. Recent studies indicate that A oligomers might enhance the phosphorylation and transmission of tau in a cyclical manner. P-tau is acknowledged as a pivotal biomarker for Alzheimer's disease, with particular phosphorylated tau variants, p-tau217, p-tau181, and p-tau231, demonstrating considerable promise for diagnostic and monitoring purposes. Significantly, these p-tau indicators are now consistently identifiable in both cerebrospinal fluid and blood.[7],[8],[9]

Neuroinflammation and Microglial Dysfunction

Neuroinflammation plays a crucial role in the development of Alzheimer's disease, with microglia serving as its primary cellular mediators. The brain's resident immune cells, known as microglia, often perform a safeguarding role, including the removal of cellular waste by phagocytosis, synaptic pruning, and providing neuroprotection. Nevertheless, persistently active microglia adversely affect the brain in Alzheimer's disease, perpetuating a prolonged inflammatory response that contributes to neurodegeneration. Activated microglia have been observed to cluster around amyloid plaques and release pro-inflammatory cytokines (including IL-1, IL-6, and TNF-) as well as generate reactive oxygen species (ROS), which contribute to neurotoxicity. This persistent inflammatory reaction establishes a self-perpetuating cycle that fosters the buildup of A, tau phosphorylation, and neuronal damage. Numerous Alzheimer's disease risk genes have been identified that play a role in microglial activities and innate immune responses, such as TREM2, CD33, and CR1. Emerging research suggests that microglia are heterogeneous and exhibit many activation patterns beyond the conventional M1/M2 polarization. Microglia enter a particular condition referred to as disease-associated microglia (DAM) during neurodegenerative processes, characterized by a unique gene expression profile and functionally different attributes. The examination of the variety of microglial states and their fluctuating alterations offers potential therapeutic approaches for managing neuroinflammation.[10],[11]

Mitochondrial Dysfunction and Energy Metabolism

Mitochondrial impairment and disrupted energy metabolism are prominent and early characteristics of Alzheimer's disease. Neurons have a significant energy requirement owing to the substantial metabolic needs of the brain, making them particularly vulnerable to mitochondrial impairment. Various facets of mitochondrial functionality are impaired in Alzheimer's disease, encompassing oxidative phosphorylation, ATP synthesis, calcium equilibrium, and mitochondrial dynamics (fission, fusion, and mitophagy).Reduced cerebral glucose metabolism can be identified by FDG-PET several years before the clinical onset of Alzheimer's disease. Glucose hypometabolism in Alzheimer's disease is particularly evident in the temporoparietal regions, resulting in synaptic impairment and increased neuronal vulnerability to apoptosis. Mitochondrial impairment causes heightened reactive oxygen species generation, resulting in oxidative harm to lipids, proteins, and DNA, hence worsening disease progression. A reciprocal association between mitochondrial malfunction and Alzheimer's disease pathogenesis has also been apparent. An oligomer and hyperphosphorylated tau can provoke mitochondrial impairment, which in turn can exacerbate A production and tau hyperphosphorylation. This detrimental cycle will consequently intensify the progression of AD. Mitochondrial augmentation presents prospective therapeutic avenues.[12],[13],[14]

Synaptic Dysfunction and Neuronal Loss

Synaptic loss seems to be the most significant neuropathological indicator of cognitive impairment in Alzheimer's disease, occurring prior to neuronal demise. Dendritic spines, which serve as the postsynaptic locations for excitatory synapses, are particularly vulnerable to impairment in Alzheimer's disease. They are recognized for displaying particular patterns of correlation with tau pathology, indicating tau-mediated synaptic damage.[15]. Aß oligomers, particularly the soluble variants, exhibit a pronounced attraction to synapses, contributing to the impairment of long-

term potentiation, modifications in neurotransmitter release, and alterations in receptor trafficking. They exert a disruptive influence on synaptic plasticity, which underpins learning and memory, and the expression and positioning of various proteins in the postsynaptic density (PSD-95, neurogranin), presynaptic area (synaptophysin, SNAP-25), and adhesion molecules are modified in Alzheimer's disease.[16]The factors that render specific neuronal populations and brain regions more vulnerable to harm than others are intricate and probably linked to metabolic requirements, neuronal interconnectivity, and the varied expression of susceptibility genes, among other elements. Neurons within the hippocampus and entorhinal cortex are among the first to sustain damage, which corresponds to the characteristic early manifestation of Alzheimer's disease as episodic memory deficits. Clarifying the processes of neuronal susceptibility and resilience offers a promising therapeutic pathway for neuroprotection.[17]

Vascular Contributions and Blood-Brain Barrier Dysfunction

Vascular pathology frequently co-exists with AD neuropathology and makes a considerable contribution to cognitive dysfunction. Cerebrovascular dysfunction is characterized by decreases in cerebral blood flow and impairment in neurovascular coupling, breakdowns in the blood brain barrier (BBB) and cerebral amyloid angiopathy. These cerebrovascular changes can develop early in AD and synergize with AD pathology.[19]BBB breakdown allows peripheral immune cells and inflammatory factors to enter the brain and promote neuroinflammation. In addition, disruption of A clearance across the BBB will promote an accumulation. The relationship between vascular risk factors (hypertension, diabetes and atherosclerosis) and AD is well established, and they may advance the disease process by inducing changes such as hypoxia, inflammation, and metabolic perturbations.The glymphatic system is a newly identified pathway for waste clearance within the brain, which provides another avenue through which brain vascular function, sleep, and AD can be linked. Glymphatic clearance operates most effectively during sleep and is responsible for removing A as well as other metabolic wastes. It can be disturbed by aging, cerebrovascular disease and sleep disruption, which may consequently play a role in the accumulation and the development of AD. [18]

Disease Progression and Clinical Stages

The Alzheimer's Continuum

Currently, Alzheimer's disease is considered a progressive phenomenon that unfolds along a spectrum, commencing with preclinical Alzheimer's and culminating in dementia, with mild cognitive impairment situated in the intermediate stage. This has been revised to incorporate the 2024 Alzheimer's Association criteria, indicating that brain pathology can exist for 15-20 years before any clinical manifestation. The advancement is then categorized as: Preclinical Alzheimer's Disease - The person exhibits the pathological markers for Alzheimer's Disease (accumulation of amyloid, tau, or both) yet demonstrates no cognitive deficits. Nonetheless, individuals with preclinical Alzheimer's disease may report perceived cognitive deficits (SCD) despite lacking demonstrable impairment on cognitive assessments. According to biomarker evidence, approximately 20-40% of cognitively intact older individuals exhibit preclinical Alzheimer's disease. Prodromal Alzheimer's Disease (MCI attributable to Alzheimer's Disease): The individual exhibits measurable cognitive deterioration (often characterized by a deficit in episodic memory) while maintaining independence in daily tasks. Approximately 10-15% of individuals with Mild Cognitive Impairment (MCI) progress to Alzheimer's Disease (AD) dementia annually, although this rate is highly varied and influenced by biomarkers. Alzheimer's dementia: The deterioration is sufficiently pronounced to result in considerable dysfunction and the forfeiture of autonomy in everyday tasks. AD dementia manifests in mild, moderate, and severe stages; the typical life expectancy post-diagnosis ranges from 4 to 8 years, albeit with considerable variability. (20)

Biomarker Staging and Disease Trajectory

ATN biomarkers can define stages based on the status of amyloid (A), tau (T), and neurodegeneration (N) for an individual and gives a biological stage that does not correlate directly with the clinical stage.21 This is useful to identify individuals in the preclinical state and for prediction of progression.22 Studies involving staged cohorts have shown that the biomarkers develop in a relatively consistent order (the A, T, N, and finally cognitive changes).[23]Although this general pattern exists, an individual's course is likely to be very heterogeneous. [24] Some

individuals possess high pathology with little or no clinical signs of dementia, displaying cognitive reserve. Others with little pathology can show remarkably fast disease progression. [25] This heterogeneity is likely due to factors such as genes, cognitive reserve, pathologies (vascular, LBD, TDP-43), etc. (26)(27)(28)

Cognitive and Functional Decline

Early AD will typically show a profile of episodic memory loss, the earliest involvement of regions being the hippocampus and entorhinal cortex. (29) The range of impairment widens in later disease and also affects language, visuospatial abilities, executive function and attention. (30) The presence of BPSD is common in the majority of sufferers and include depression, anxiety, apathy, aggression, agitation, psychosis and sleep disturbances. (31) The decline in functional abilities follows the typical pattern: in the early stages, impairment is seen in IADLs such as financial affairs, medication management and use of transport, (32), (33). As the disease progresses, impairment occurs in the ADLs; eating, dressing, bathing and toileting need assistance, (34). The advanced stage patient becomes completely dependent, eventually losing the ability to ambulate or swallow which can lead to infection, aspiration and pneumonia (35)

Risk Factors for Alzheimer's disease

Genetic Risk Factors

APOE genotype: Genetic risk factor that shows the greatest effect on late-onset AD. Carriers of the APOE 4 allele are 3-4 times more likely to develop AD compared to non-carriers in heterozygous state, 8-12 times more likely when homozygous. Protective effect seen in the 2 allele. 65% of patients with AD carry at least one copy of APOE 4[36-38]. The APOE4 genotype is implicated in many disease mechanisms including clearance of A, tau pathology, neuro inflammation, lipid metabolism, BBB function, mitochondrial function [39-41]. Recent research has revealed that APOE4 carriers develop pathology earlier and have a faster disease progression and characteristic regional distribution of brain atrophy compared to non-carriers[42,43], the difference in the former appears to be sex-specific and that women are more susceptible to APOE4 associated neurodegeneration [44]. APOE genotype has an impact on therapeutic intervention; APOE4 carriers exhibit increased rates of ARIA with anti-amyloid monoclonal therapy [45, 46]. The identification of APOE mechanisms in disease has identified new targets for therapy and the criteria to treat in AD [47].

Rare genetic variants: Family members of families affected by autosomal dominant forms of EOAD, where a person inherits a mutation in one of APP, PSEN1, or PSEN2 that results in the development of AD before age 65 typically in<1% of cases[48,49]. These mutations result in deterministic AD. Study of EOAD families has been invaluable in understanding AD pathology and the trajectory of biomarkers in AD [50].

Polygenic risk: As well as the effect of APOE on risk of developing AD, GWAS studies have identified >75 genes whose associated variations correlate to the risk of developing AD[51,52]. Many of these are genes implicated in biological mechanisms such as immunity (TREM2,CD33, CR1) lipid metabolism (CLU, ABCA7) endocytosis (PICALM, BIN1) and tau biology (MAPT)[53-55]. The use of polygenic risk scores combining many small effects on risk will increase predictive ability beyond that provided by APOE alone [56].

Cardiovascular and Metabolic Risk Factors

Hypertension: Midlife hypertension is a major modifiable risk factor for AD and increases risk for AD by 40-60% in several studies. [57-59] The mechanisms by which hypertension affects AD pathogenesis include BBB damage, impaired cerebral blood flow, vascular damage and the development of vascular pathology and AD neuropathology. [60,61] With progression of the disease blood pressure changes. It has been demonstrated that late-life hypotension is associated with more rapid decline and this is suspected to represent effects on the autonomic nervous system by the disease. [62,63]

Diabetes Mellitus: Type 2 diabetes increases AD risk by approximately 1.5-2-fold. [64,65]. The proposed mechanisms involve insulin resistance and changes in A and tau metabolism, inflammation, oxidative stress and vascular complications.[66- 68]This has led to the suggestion that AD is "type 3 diabetes" because of insulin resistance occurring in the brain. Management of diabetes and the administration of insulin-sensitizing medications are possible prevention strategies. [69,70]

Obesity and Metabolic Syndrome: Midlife obesity increases AD risk, andal though associations are somewhat conflicting with late-life obesity appearing protective possibly due to effects of weight loss due to the disease [71-73]. Combined with obesity, metabolic syndrome, which is characterized by a constellation of dyslipidemia, hypertension, and insulin resistance, carries a greater risk of dementia as each feature contributes cumulatively to the development of dementia and involves inflammatory and oxidative mechanisms. [74,75]

Dyslipidemia: The associations between cholesterol and AD are still complex and controversial. Midlife hypercholesterolemia is thought to increase the risk of AD, whereas associations with late-life may be less convincing. [76,77] Results for the use of statins for prevention are mixed among observational and intervention studies. [78,79] The biochemical associations between cholesterol metabolism and the processing of APP and A metabolism add to the mechanistic plausibility. [80,81]

CONCLUSION

Alzheimer's disease (AD) constitutes a significant challenge in the medical field, impacting millions worldwide in profoundly detrimental personal and societal manners. The previous ten years have witnessed a transformation in our comprehension of the pathophysiology of Alzheimer's Disease, elucidating the intricate connections among genetic predispositions, aging mechanisms, metabolic impairments, vascular anomalies, inflammatory responses, and lifestyle factors. These elements collectively determine an individual's susceptibility to AD and influence the speed of its progression. Significant progress has been made. We are nearer than ever to attaining readily accessible and scalable identification of Alzheimer's Disease thru the advancement of blood-based biomarkers. The recent FDA endorsements of lecanemab and donanemab provide evidence that the progression of the disease can be modified by eliminating amyloid plaques, albeit with a limited therapeutic impact, indicating that significant enhancements in treatment are both necessary and attainable. Moreover, the acknowledgment of numerous modifiable risk factors for Alzheimer's Disease indicates that mitigating these risks will soon be an attainable objective via lifestyle changes and the management of cardiovascular risk factors. Notable obstacles, meanwhile, persist. Current disease-modifying treatments exhibit limited efficacy and encounter numerous challenges, such as ARIA and its related hazards, exorbitant expenses, and the necessity for early-stage administration.

Numerous recent setbacks have occurred in drug development initiatives, particularly for tau-targeting medicines, and the chasm between encouraging pre-clinical research and effective clinical application remains considerable. Health equity continues to be a significant issue, as minority groups are inadequately represented in clinical studies and encounter obstacles in diagnosis and treatment. The successful progression of the discipline in the forthcoming years will probably stem from multifaceted strategies. Employing combination therapy that concurrently addresses many disease mechanisms will be an essential approach. Addressing Alzheimer's Disease in earlier, pre-clinical phases necessitates inventive and ethical trial design methodologies, potentially incorporating more tailored strategies that leverage an individual's unique risk factors, disease sub-type, and biomarker profile. Lifestyle alterations will be crucial for the widespread prevention of Alzheimer's Disease. Significant funding for research, innovative clinical trial methodologies, technological progress, fair treatment approaches, and cross-sector collaboration among academic, industrial, governmental bodies, and patient advocacy organizations are essential. Although it remains a catastrophic disease, there is now optimism for an effective strategy to prevent, mitigate, or even halt the onset and advancement of Alzheimer's disease.

ABSTRACT

Brucellosis is reported as a re-emerging anthropozoonotic disease characterized by a complex epidemiology and considerable socio-economic consequences globally. The infection caused by *Brucella canis* is the most prevalent reason for reproductive issues in dogs, occurring more frequently in stray dogs compared to pet dogs. Besides *B. canis*, dogs may also be vulnerable to infections from *B. abortus*, *B. melitensis*, and *B. suis*. This study aimed to assess the seroprevalence of brucellosis in dogs that attended the Veterinary Clinical Complex at the Veterinary College and Research Institute, Orathanadu of Thanjavur district. A total of 320 serum samples were collected and analyzed using the Rose Bengal Plate Agglutination test (RBPT), Standard Plate Agglutination Test (SPAT), and i-Enzyme-linked Immunosorbent Assay (i-ELISA) to identify the presence of anti-*Brucella* antibodies. The seroprevalence rates of brucellosis in dogs were determined to be 7.4%, 6.2%, and 10.5% according to RBPT, SPAT, and i-ELISA, respectively. These findings underscore the potential risk of reproductive losses in dogs and the related public health concerns, especially in regions with significant human-dog interactions. The results highlight the necessity for ongoing

surveillance, enhanced control strategies, and educational initiatives to mitigate the transmission of *Brucella* infections in both animals and humans.

Keywords: Seroprevalence, dogs, brucellosis, Cauvery delta region, RBPT, i-ELISA

INTRODUCTION

Brucellosis is a significant zoonotic bacterial disease characterized by intricate epidemiological patterns and considerable implications for veterinary medicine, public health, and socio-economic conditions globally. It impacts a diverse array of domestic and wild animals, leading to reproductive issues, production losses, and economic repercussions in livestock, while also representing a notable public health threat (Corbel *et al*., 2006; Lopes *et al*., 2010). In canines, *Brucella canis* serves as the primary causative agent of canine brucellosis. This disease is mainly marked by reproductive complications such as abortion, stillbirth, infertility, epididymitis, and orchitis. Additional clinical signs may encompass lymphadenopathy, disco-spondylitis, and various osteoarticular disorders. Nevertheless, dogs that are infected may either show no clinical signs or develop chronic infections, which complicates detection and management efforts (Greene and Carmichael, 2012; Santos *et al*., 2021) While *B. canis* is the species most frequently linked to canine brucellosis, dogs can sometimes contract infections from other *Brucella* species, such as *B. abortus*, *B. melitensis*, and *B. suis*, especially after coming into contact with infected livestock, wildlife, or contaminated substances (Corbel *et al*., 2006; Hensel *et al*., 2018). These infections are particularly alarming as several of these *Brucella* species are significant zoonotic pathogens.

Canine brucellosis holds significant importance for both veterinary and public health. The primary mode of transmission for *B. canis* is through reproductive and genital secretions, which includes venereal transmission, contact with aborted fetuses, placental tissues, and vaginal discharges. Additionally, vertical transmission and spread through contaminated environments or fomites can also occur (Greene and Carmichael, 2012; Santos *et al*., 2021). The disease can manifest as a subclinical or chronic infection, which allows for silent transmission among canine populations, complicating both diagnosis and epidemiological control (Hensel *et al*., 2018; Santos *et al*., 2021). The zoonotic potential of *B. canis* amplifies the importance of canine brucellosis. While human infections are deemed rare, there have been recorded instances following direct contact with infected dogs, their reproductive fluids or tissues, as well as through laboratory exposure. Human infections can present as a nonspecific febrile illness, characterized by symptoms such as fever, chills, malaise, and lymphadenopathy (Lucero *et al*., 2005; Hensel *et al*., 2018). As a result, veterinarians, breeders, laboratory staff, animal handlers, and individuals who frequently interact with infected dogs may constitute groups of particular occupational or exposure concern.

Despite its significance in veterinary and zoonotic contexts, canine brucellosis is often overlooked in numerous areas due to the presence of asymptomatic infections, chronic conditions, and challenges related to definitive diagnosis (Hensel *et al*., 2018; Santos *et al*., 2021). Consequently, comprehensive epidemiological studies are crucial to ascertain the prevalence and distribution of the infection, identify potential risk factors, and enhance the understanding of transmission dynamics. Specifically, epidemiological data from particular geographical areas is vital for formulating effective surveillance and control measures. Nevertheless, there is a scarcity of information concerning the incidence and clinical manifestations of canine brucellosis in dogs that are also suffering from other illnesses. Therefore, region-specific sero-epidemiological research is necessary to deepen the understanding of the impact and public health implications of canine brucellosis. In India, various regional studies have indicated differing seroprevalence rates of canine brucellosis, which can be attributed to disparities in awareness, surveillance, and control measures. Nonetheless, information from the Cauvery Delta region of Tamil Nadu is scarce, despite the area's high dog population and significant human-animal interactions. Evaluating the seroprevalence of canine brucellosis in this region is crucial for comprehending its epidemiological trends and potential zoonotic risks. Consequently, the aim of the current study was to determine the seroprevalence of canine brucellosis in the Cauvery Delta region of Tamil Nadu.

MATERIALS AND METHODS

Sample collection and processing

Blood samples were obtained from 320 dogs that attended the Veterinary Clinical Complex at the Veterinary College and Research Institute in Orathanadu over the last year. The collected blood was permitted to clot for approximately two to three hours at room temperature before being centrifuged at 2500 rpm for 15 minutes. The serum samples were then aseptically transferred into sterile microcentrifuge tubes. These samples were subsequently stored at -80ºC for future analysis (Sowmiya *et al*., 2024).

Reagents

The reagents utilized in this study comprise the Rose Bengal Plate Test antigen (Indian Veterinary Research Institute, Izatnagar, Uttar Pradesh), the Brucella abortus colored (plate) reagent (Institute of Veterinary Preventive Medicine, Ranipet, Tamil Nadu), and the Asur Dx ELISA Kit (Biostone Animal Health). Serum samples were analyzed using RBPT and SPAT according to the standard protocol established by Alton *et al*. (1988), and i-ELISA was performed following the instructions provided by the kit manufacturer. Prior to commencing the procedure, the stored serum samples and reagents were allowed to reach room temperature for 30 minutes (Sowmiya *et al*., 2024).

Rose Bengal Plate Test (RBPT)

Serum samples underwent the RBPT following the established protocol (Alton *et al.,* 1988). In summary, 30 µl of RBPT antigen was combined with an equal volume of serum on a clean white tile, and the mixture was agitated using a glass rod while rotating the tile. After duration of four minutes, the results were interpreted based on the presence (positive) or absence (negative) of agglutination (Sowmiya *et al*., 2024) and it is illustrated in figure 2.

Standard Plate Agglutination Test (SPAT)

Serum samples were processed using SPAT according to the established protocol (Alton *et al.,* 1988). An equal volume of serum was combined with Brucella abortus colored (plate) antigen, and the results were evaluated based on the presence of agglutination after four minutes (Sowmiya *et al*., 2024) and it is illustrated in figure 3.

Indirect Enzyme Linked Immuno-Sorbent Assay (i-ELISA)

Serum samples were analyzed using i-ELISA according to the protocol provided by the kit manufacturer, utilizing an antigen-coated plate for antibody detection. The optical density (OD) value was measured with an ELISA reader (Sowmiya *et al*., 2024).

The Percent Positivity value was calculated using the following formula: Percent positivity = [(OD450 of test sample) / (Mean OD450 of positive control)] × 100. Samples exhibiting a Percent Positivity value exceeding 40 were classified as positive.

RESULTS AND DISCUSSION

A total of 320 serum samples collected from dogs in the Cauvery Delta region of Tamil Nadu were screened for antibodies against *Brucella* spp. using Rose Bengal Plate Test (RBPT), Serum Plate Agglutination Test (SPAT) and indirect Enzyme-Linked Immunosorbent Assay (i-ELISA). The seroprevalence observed by the three diagnostic tests is presented in Figure 1.The overall seroprevalence was **7**.40% by RBPT, 6.20% by SPAT and 10.50% by i-ELISA. Among the three tests, i-ELISA detected the highest proportion of seropositive animals, followed by RBPT and SPAT. Based on the i-ELISA results, approximately one in ten dogs examined showed evidence of antibodies against *Brucella*, indicating that exposure to canine brucellosis may be present in the study region. The seroprevalence detected by RBPT was 7.40%, whereas SPAT identified 6.20% positive animals. The relatively close positivity rates obtained with these two agglutination tests indicate comparable patterns of antibody detection in the sampled

population. However, the higher positivity recorded by i-ELISA suggests that this assay was able to detect a greater proportion of sero-reactive animals than the conventional agglutination tests.

The present study demonstrated serological evidence of *Brucella* exposure among dogs in the Cauvery Delta region of Tamil Nadu, with seroprevalence estimates ranging from 6.20% to 10.50%**,** depending on the diagnostic test used. The highest seroprevalence was detected by i-ELISA (10.50%), whereas lower values were obtained by RBPT (7.40%) and SPAT (6.20%). Differences in seroprevalence obtained by different diagnostic assays are well recognized in canine brucellosis because individual tests differ in their sensitivity, specificity, antigenic composition and ability to detect antibodies at different stages of infection (Santos *et al.,* 2021; Perletta *et al*., 2023). The relatively higher positivity observed with i-ELISA in the present study may be related to the greater analytical sensitivity of ELISA-based assays compared with conventional agglutination tests. Sharma *et al.* (2011) examined 527 canine serum samples using several serological assays and reported seroprevalences of 2.27% by 2-mercaptoethanol tube agglutination test, 1.50% by agar gel immunodiffusion, 3.03% by dot-ELISA and 16.12% by i-ELISA. Their findings demonstrated a marked difference in seroprevalence according to the diagnostic method and suggested that i-ELISA was highly sensitive for detecting antibodies against *Brucella canis*.

The usefulness of ELISA for canine brucellosis has also been demonstrated through assay validation studies. Oliveira *et al*. (2011) evaluated an ELISA using heat-soluble *B. canis* antigen and reported a sensitivity of 91.18% and specificity of 100%, supporting its application as a practical method for serological diagnosis and sero-epidemiological investigations. Similarly, the review by Santos *et al.* (2021) reported that ELISA can be more sensitive than several conventional agglutination and immune diffusion methods and may detect antibodies in chronically infected dogs that can be negative by some other serological tests. The lower seroprevalence observed with RBPT and SPAT compared with i-ELISA may therefore reflect differences in the ability of these assays to detect low antibody concentrations. However, the results should not be interpreted as evidence that i-ELISA-positive dogs are necessarily infected, because serological positivity indicates antibody response rather than direct demonstration of viable organisms. Perletta *et al.* (2023) emphasized those serological tests for canine brucellosis may produce both false-positive and false-negative reactions and recommended combining serological testing with bacterial isolation and/or molecular methods when definitive diagnosis is required.

The 10.50% seroprevalence detected by i-ELISA in the present study is epidemiologically significant. A recent global meta-analysis by Dadar *et al*. (2025) involving 175,675 canine samples from 134 studies estimated the overall pooled prevalence of canine brucellosis at 7.96%**,** although considerable geographical variation was observed. Nevertheless, direct comparison should be made cautiously because prevalence is influenced by geographical location, dog population, sampling strategy, epidemiological characteristics and diagnostic methodology. The observed prevalence may also be influenced by differences in the characteristics of the sampled dog population. Factors such as age, sex, reproductive status, breeding practices, contact with other dogs, kennel conditions and previous reproductive disorders may influence exposure to *Brucella*. The recent meta-analysis by Dadar *et al*. (2025) reported substantial geographical variation and found higher infection rates among farm dogs, females and symptomatic dogs. Therefore, characterization of potential risk factors in the study population would be valuable for understanding the epidemiology of canine brucellosis in the Cauvery Delta region. Canine brucellosis is particularly important because infection can be associated with abortion, infertility, reproductive failure, neonatal mortality and reproductive tract abnormalities. Although reproductive disease is a prominent manifestation, infected dogs may also remain clinically inapparent, making serological surveillance important for identifying exposed animals (Santos *et al*., 2021; Perletta *et al*., 2023).

The present findings also have One Health significance. *Brucella canis* has zoonotic potential, and human infection may occur following exposure to infected dogs or their reproductive and biological secretions. Veterinarians, breeders, laboratory personnel, animal handlers and individuals with close contact with infected dogs may consequently be at increased risk (Santos *et al*., 2021). The detection of seropositive dogs in the present study therefore highlights the need for increased awareness of canine brucellosis among veterinarians and dog owners.

The results further emphasize the importance of using an appropriate diagnostic algorithm rather than relying on a single serological test. The combination of screening tests with a more sensitive or specific confirmatory assay can improve interpretation, while bacteriological isolation and molecular detection provide stronger evidence of active infection (Perletta *et al.,* 2023; Santos *et al*., 2021). Overall, the present study revealed serological evidence of *Brucella* exposure in dogs in the Cauvery Delta region of Tamil Nadu**,** with seroprevalence of 7.40% by RBPT, 6.20% by SPAT and 10.50% by i-ELISA. The findings support the need for continued surveillance of canine brucellosis in Tamil Nadu and suggest that positive serological findings should preferably be evaluated using complementary serological, bacteriological and/or molecular methods.

ABSTRACT

Strength, sprinting speed, acceleration, and explosive power are central to athletic performance. Although weight training and plyometric training each target important neuromuscular qualities, combined and complex resistance formats may provide a broader transfer to dynamic sport actions. This study compared changes in leg strength, back strength, speed, acceleration, vertical explosive power, and horizontal explosive power across weight training, plyometric training, combined training, and complex resistance training groups. A secondary analysis was conducted on a de-identified pre-test and post-test dataset containing 40 collegiate male athletes, with 10 participants in each training group. Within-group changes were examined with paired-samples t-tests. Post-test differences were evaluated using analysis of covariance, with the corresponding pre-test value as the covariate. Bonferroni-adjusted comparisons located significant group differences. Cohen's dz and partial eta squared quantified effect magnitude. Every group improved significantly in all six outcomes, $p < .05$. Adjusted between-group differences were not significant for leg strength, $F(3,35) = 0.28$, $p = .841$, partial eta squared = .023, or back strength, $F(3,35) = 1.21$, $p = .319$, partial eta squared = .094. Significant differences emerged for speed, $F(3,35) = 33.75$, $p < .001$, partial eta squared =

.743; acceleration, F(3,35) = 47.50, p < .001, partial eta squared = .803; vertical explosive power, F(3,35) = 41.18, p < .001, partial eta squared = .779; and horizontal explosive power, F(3,35) = 18.44, p < .001, partial eta squared = .613. Complex resistance training produced the best adjusted speed, acceleration, and horizontal-power scores. Complex and combined training produced statistically comparable vertical-power scores after multiplicity correction. All four methods improved performance, but complex resistance training showed the broadest advantage for rapid and explosive actions. The absence of a non-training control group prevents causal claims relative to no training.

Keywords: resistance training; plyometric training; complex training; muscular strength; sprint performance; acceleration; explosive power

INTRODUCTION

Strength and power underpin many decisive actions in sport. Greater force-producing capacity supports sprint acceleration, jumping, change of direction, collision tolerance, and the ability to repeat high-intensity efforts. Maximal strength is not identical to sport performance, but it raises the force ceiling from which rapid force production can develop. Reviews have therefore emphasized both the direct importance of strength and the need to translate strength gains into task-specific high-velocity performance [1-5]. Traditional weight training develops force capacity through progressive external loading. Its effects depend on exercise selection, intensity, volume, frequency, movement quality, and progression. Programs using multi-joint exercises can increase neural drive, inter muscular coordination, muscle cross-sectional area, and the capacity to express force against high resistance [1,2,18-21,24-27]. These adaptations support athletic preparation, but transfer to sprinting and jumping is influenced by contraction velocity, force orientation, range of motion, and the similarity between training and performance tasks [3-6]. Plyometric training emphasizes rapid eccentric-concentric coupling. A fast stretch followed by an immediate concentric action can improve use of elastic energy, reflex contribution, musculotendinous stiffness, and rate of force development. Meta-analytical evidence indicates that plyometric training improves vertical jump, horizontal jump, linear sprinting, and other explosive outcomes across athletic populations [7-10,22,23]. However, plyometric work does not always provide the high-force stimulus needed to maximize strength, particularly in athletes with a limited strength base.

Combined training integrates conventional resistance and plyometric exercises within the same program but not necessarily as closely paired exercises. This structure seeks to develop force and velocity qualities concurrently. In male volleyball players, combined strength and plyometric training improved sprinting and muscular power and produced broader benefits than plyometric training alone [11]. More generally, strength and plyometric combinations may be time-efficient when athletes need multiple adaptations within a restricted preparation period.
Complex resistance training pairs a higher-load resistance exercise with a biomechanically related ballistic or plyometric exercise. A typical sequence may combine a squat with a jump or a heavy press with an explosive throw. The acute rationale is that a conditioning contraction may transiently enhance subsequent high-velocity performance when potentiation exceeds fatigue. The chronic rationale is broader: repeated exposure to paired force- and velocity-oriented tasks may improve the athlete's ability to express newly developed strength rapidly [12-15]. Evidence supports complex training as an acceptable approach for improving strength, jump performance, and sprinting. A meta-analysis of 33 studies and 1,064 participants found improvements in countermovement jump, squat jump, one-repetition maximum squat, and sprint times following complex training [12]. A recent comparison of complex training with resistance training alone reported broadly similar strength effects but possible advantages for selected sprint, change-of-direction, and countermovement-jump outcomes [13]. The certainty of those comparative effects was low to very low, which makes well-described primary studies valuable. Direct comparisons among weight, plyometric, combined, and complex resistance training are useful because each method occupies a different position on the force-velocity continuum. Weight training emphasizes high force, plyometrics emphasize rapid stretch-shortening actions, combined training distributes the two modes across a program, and complex resistance training

links them within the same training sequence. The present dataset permits a controlled statistical comparison of changes across these four formats for six practical performance outcomes.

Purpose of the study

The purpose was to compare the effects associated with four recorded training conditions on leg strength, back strength, speed, acceleration, vertical explosive power, and horizontal explosive power. The analysis addressed both within-group improvement and baseline-adjusted differences among groups.

Hypotheses

- Each training group would show significant pre-test to post-test improvement.
- Weight training would produce strong gains in leg and back strength.
- Combined and complex resistance training would produce greater improvements in speed, acceleration, and explosive power than single-mode training.
- Complex resistance training would show the broadest performance advantage because of its paired high-force and high-velocity structure.

MATERIALS AND METHODS

Study design and data source:

This article reports a secondary statistical analysis of a de-identified performance workbook containing pre-test and post-test measurements. The available dataset used a four-group pre-test and post-test structure. It did not contain a non-training control group. Accordingly, the analysis compares the relative performance of four training conditions and does not estimate the effect of training compared with no intervention.

Participants and group structure:

The analytical sample comprised 40 collegiate male athletes. Ten participants were included in each of four groups: weight training group (WTG), plyometric training group (PTG), combined training group (CTG), and complex resistance training group (CRTG). All 40 records contained complete pre-test and post-test values for all six outcomes, so no observations were excluded and no missing-value imputation was required.

Training conditions:

The workbook identified four training conditions but did not provide the exercise schedule, intervention duration, session frequency, intensity, set and repetition structure, recovery periods, progression criteria, or supervision arrangements. The group labels were therefore retained exactly as recorded. In conceptual terms, WTG represents conventional external-load resistance exercise, PTG represents stretch-shortening-cycle exercise, CTG represents a program containing both weight and plyometric work, and CRTG represents a paired or closely sequenced resistance-plus-explosive format. These conceptual descriptions should be replaced with the original intervention prescription when available.

Outcome measures:

Exact test names, equipment, warm-up procedures, trial numbers, rest intervals, and reliability information were not present in the workbook. Consequently, the article reports the recorded outcome labels and units without inventing unsupported test-administration details.

Statistical analysis:

Means and sample standard deviations summarized pre-test and post-test performance. Baseline equivalence was examined using one-way analysis of variance. Within each group, paired-samples t-tests evaluated pre-test to post-test change. Improvement was defined as post-test minus pre-test for strength and power outcomes and pre-test minus post-test for timed outcomes so that positive values consistently represented improvement. Cohen's dz was

calculated as the mean paired change divided by the standard deviation of paired changes. Between-group post-test differences were tested using analysis of covariance (ANCOVA), with the corresponding pre-test score entered as the covariate. The group effect was tested with 3 and 35 degrees of freedom. Partial eta squared was calculated as the group sum of squares divided by the group plus error sums of squares. Significant omnibus effects were followed with six Bonferroni-adjusted pairwise comparisons. Statistical significance was set at $p < .05$, and confidence in the practical interpretation was based on effect magnitude, consistency across outcomes, and the study design rather than p-values alone [29,30]. Diagnostics examined the normality of ANCOVA residuals, equality of residual variance, and homogeneity of regression slopes. These assumptions were acceptable for most outcomes. Acceleration residuals showed a modest departure from normality; because the design was balanced, ANCOVA estimates were retained, but this result should be checked with a robust or permutation sensitivity analysis in a final submission.

Ethical and reporting considerations:
The spreadsheet contained no names or direct identifiers. However, ethical approval, consent procedures, approval number, trial registration, funding, and conflicts of interest were not included in the analytical file. These items cannot be reconstructed statistically and require confirmation by the investigators before external dissemination.

RESULTS

Data completeness and baseline comparability:
All 40 participants had complete data for every outcome. Baseline one-way ANOVA showed no significant group differences for leg strength, back strength, speed, acceleration, vertical explosive power, or horizontal explosive power. The four groups were therefore statistically comparable on the recorded pre-test outcomes.

Within-group changes:
All four groups improved significantly on all six outcomes. The largest numerical strength gains occurred in WTG, whereas the largest gains in speed, acceleration, and both explosive-power outcomes occurred in CRTG. CTG generally ranked second on the rapid and explosive outcomes.

Note. For speed and acceleration, improvement is the reduction in time. dz is the paired-samples standardized mean change. The unusually large dz values reflect highly consistent changes and small change-score variability in groups of only 10 participants; they should not be generalized without replication.

Baseline-adjusted between-group differences:
ANCOVA was used to compare post-test performance after adjustment for the corresponding pre-test value. The adjusted means and omnibus group effects are reported in Table 4.

After adjustment for baseline, group effects were not significant for leg strength or back strength. Large group effects occurred for speed, acceleration, vertical explosive power, and horizontal explosive power. CRTG had the lowest adjusted times and the highest adjusted power values.

Bonferroni-adjusted comparisons
WTG and PTG did not differ significantly on speed or acceleration. CTG and CRTG did not differ significantly in vertical explosive power after Bonferroni adjustment, despite a larger numerical gain in CRTG. For horizontal power, CRTG exceeded WTG, PTG, and CTG. No post hoc testing was interpreted for leg or back strength because the omnibus group effects were not significant.

Percentage improvement
The percentage pattern reinforces the ANCOVA results. Strength gains were similar across groups. In contrast, the separation among groups increased for speed, acceleration, and explosive power. CRTG improved speed by 8.42%, acceleration by 9.05%, vertical power by 17.89%, and horizontal power by 7.34%.

DISCUSSION

The main finding was a clear outcome-specific pattern. All four groups improved, yet the adjusted post-test differences were concentrated in speed, acceleration, and explosive power rather than leg and back strength. Complex resistance training produced the most favorable overall profile for rapid and explosive actions. Combined training also outperformed single-mode weight and plyometric training on several outcomes. These findings support the principle that adaptations depend on the force and velocity characteristics of the training stimulus. The similar adjusted strength results require careful interpretation. WTG showed the largest numerical improvements in leg strength and back strength, but the between-group effects were not statistically significant. This suggests that all four programs provided a sufficient strength stimulus or that the tests were not sensitive enough to distinguish small differences in adaptation. It also indicates that adding plyometric or complex elements did not reduce strength development within the limits of this dataset. The absence of a strength advantage for CRTG is consistent with recent comparative evidence. Thapa and colleagues reported that complex and traditional resistance training produced broadly similar changes in one-repetition maximum squat and bench press, while complex training showed possible advantages for selected sprint and countermovement-jump outcomes [13]. Complex training should therefore not be described as universally superior. Its benefit appears more specific to the expression of force at high velocity.

Speed and acceleration showed the clearest separation among groups. CRTG improved speed by 0.61 s and acceleration by 0.40 s, compared with smaller reductions in WTG and PTG. CTG also performed better than both single-mode groups after baseline adjustment. Sprint performance depends on applying high force within short ground-contact periods. Heavy resistance work can raise available force, while plyometric and ballistic tasks can improve rapid force expression. Their integration may therefore provide a more complete stimulus than either mode alone [3,5,6,12,13]. The complex format may add value through exercise sequencing. Pairing a high-load action with a biomechanically related explosive movement creates repeated opportunities to express force rapidly after substantial motor-unit recruitment. Acute post-activation performance enhancement is influenced by strength level, loading, recovery interval, and fatigue [14-16]. Across a training period, the repeated force-to-velocity transition may strengthen coordination between maximal force capacity and sport-relevant rate of force development. The present dataset cannot identify the mechanism, but the outcome pattern is compatible with this explanation. Vertical explosive power improved most in CRTG and CTG. Their numerical gains were 8.10 cm and 6.90 cm, respectively, and both exceeded WTG and PTG after adjustment. However, the 1.20 cm adjusted difference between CRTG and CTG did not remain significant after Bonferroni correction. The practical interpretation is that both integrated approaches were effective for vertical power, with insufficient evidence to declare one superior in this sample.

The vertical-power result aligns with research showing that strength and plyometric training both improve jumping and that programs combining force and velocity stimuli can be effective [7-12]. A network meta-analysis of 83 studies found that complex formats ranked highly for selected jump outcomes but also showed that the optimal method differed across tests [17]. This outcome specificity is important. Coaches should select a method according to the athlete's deficit and the mechanical demands of the target task rather than assuming that one program dominates every outcome. Horizontal explosive power produced a stronger comparative conclusion. CRTG achieved an adjusted mean of 220.56 cm and exceeded WTG, PTG, and CTG. The improvement of 15.00 cm was more than three times the gain in WTG. Horizontal jumping and acceleration share a need for effective forward-oriented impulse [28]. The paired high-force and explosive structure may have enhanced the ability to redirect force rapidly into horizontal displacement, although force-platform or kinetic measurements would be needed to test this mechanism directly.

PTG improved every variable but did not match CTG or CRTG on most rapid-performance outcomes. This does not mean plyometric training was ineffective. Its within-group changes were significant, and large bodies of evidence support improvements in jump and sprint performance [7-10]. The comparative result suggests that plyometrics alone may be less comprehensive when athletes also require a stronger high-force stimulus. Training status may moderate this relationship, but participant training history was unavailable. WTG produced strong and consistent

strength gains but smaller improvements in explosive performance. This pattern reflects the specificity of traditional loading. Heavy resistance training may improve sprinting through increased lower-body force capacity, and meta-analytic evidence supports a positive transfer between strength gains and sprint performance [6]. Transfer is not automatic, however. Athletes may need ballistic intent, plyometric exposure, sprint practice, or combined programming to express added force under the time constraints of explosive movement. The statistical effect sizes were large, particularly for acceleration and vertical power. Those estimates describe strong separation in this dataset, but they should not be treated as precise population effects. Each group contained only 10 participants, and the raw scores showed unusually consistent changes. Small samples can produce unstable standardized effects, especially when variability is low. Confidence should therefore come from replication, complete intervention reporting, and convergence with external evidence rather than from effect-size magnitude alone.

Practical applications

- Use weight training when the main goal is increasing general force capacity and the athlete requires a stronger strength base.
- Use plyometric training to emphasize rapid stretch-shortening-cycle actions, jumping, and reactive performance.
- Use combined training when the program must develop strength and explosive qualities within the same training phase.
- Consider complex resistance training when speed, acceleration, and horizontal power are priority outcomes and the athlete can perform both the heavy and explosive exercises safely.
- Match paired exercises by movement pattern, force direction, and technical competence. Avoid pairing exercises only because they use the same muscles.
- Manage fatigue carefully. Heavy loading followed too quickly by explosive work may reduce movement quality instead of enhancing performance.
- Track both high-force and high-velocity outcomes. Strength tests alone may miss meaningful improvements in rapid force expression.

Strengths

The analysis used participant-level pre-test and post-test values with complete data across four active training conditions. Baseline adjustment reduced bias from initial score differences. Bonferroni correction limited false-positive pairwise conclusions. Reporting both within-group change and between-group ANCOVA prevented the common error of interpreting a significant change in one group and a non-significant change in another as proof that the groups differed.

Limitations

- The study had no non-training control group. Improvements cannot be separated from familiarization, concurrent sport practice, maturation, or other time-related influences.
- Each group contained only 10 participants, limiting precision, power for smaller effects, and generalizability.
- The dataset did not record demographics, sport, training age, or competitive level. Subgroup effects could not be examined.
- The intervention duration, frequency, exercise prescription, progression, attendance, and compliance were unavailable.
- Exact test protocols and measurement reliability were unavailable. Measurement error and smallest worthwhile change could not be evaluated.
- Group allocation was not documented. The analysis cannot assume randomization or rule out selection bias.
- Acceleration residuals showed some non-normality, so a robust sensitivity analysis is advisable.
- Multiple outcomes increase analytical complexity. Although Bonferroni correction was used for pairwise comparisons, the primary outcome was not pre-specified in the workbook.

Directions for future research:
Future studies should use adequately powered randomized designs with a non-training or usual-training control condition. The protocol should define training duration, intensity, volume, exercise sequence, recovery, progression, adherence, and adverse-event monitoring. Researchers should pre-specify a primary outcome, report confidence intervals and smallest worthwhile changes, and include force-velocity or kinetic measures that can test why complex training affects rapid performance. Longer follow-up is also needed to establish retention and sport-specific transfer.

CONCLUSION

Weight, plyometric, combined, and complex resistance training were each associated with significant improvement in strength, speed, acceleration, and explosive power. After adjustment for baseline, the four groups did not differ in leg or back strength. Clear differences favored integrated training for rapid and explosive performance. Complex resistance training produced the best adjusted speed, acceleration, and horizontal explosive-power outcomes, while complex and combined training produced comparable vertical-power results after multiplicity correction. These findings support complex resistance training as a useful option when the training objective emphasizes rapid force expression. They do not establish superiority for every outcome or efficacy compared with no training.

ABSTRACT

Mechanical Low Back Pain (MLBP) is among the most prevalent musculoskeletal disorders worldwide, accounting for nearly 90–95% of all low back pain cases. This study aimed to compare the effectiveness of McKenzie Exercises, Maitland Mobilization, and conventional physiotherapy consisting of Short-Wave Diathermy (SWD) and Core Stabilization in individuals with chronic MLBP. A three-arm randomized controlled trial was conducted among 210 participants aged 20–40 years with chronic Mechanical Low Back Pain. Participants were randomly assigned to one of three groups: Group A received McKenzie Exercises with SWD and Core Stabilization, Group B received Maitland Mobilization with SWD and Core Stabilization, and Group C received SWD and Core Stabilization alone. Interventions were delivered three times weekly for four weeks. Outcome measures included pain intensity, lumbar mobility, muscle strength, muscle endurance, and functional disability, assessed using the Numeric Pain Rating Scale (NPRS), Modified Schober Test (MST), Manual Muscle Testing (MMT), Biering–Sorensen Test (BST), and Oswestry Disability Index (ODI). All groups demonstrated significant post-intervention improvements. However, the McKenzie group showed superior outcomes across most measures. Post-treatment NPRS scores were significantly lower in Group A (2.27 ± 0.88) compared with Group B (3.34 ± 0.88) and Group C (4.13 ± 1.24). Similarly, functional disability measured by ODI was lowest in Group A (4.89 ± 4.02), followed by Group B (14.63 ± 9.17) and Group C (24.74 ± 15.53) ($p < 0.001$). Significant between-group differences were also observed for lumbar mobility, muscle strength, and endurance. The findings

suggest that McKenzie Exercises demonstrated favourable short-term improvements in pain and functional disability compared with Maitland Mobilization and conventional physiotherapy, while improvements in lumbar mobility were comparable to those achieved with Maitland Mobilization in individuals with chronic Mechanical Low Back Pain. These results support the use of McKenzie Mechanical Diagnosis and Therapy as an effective and evidence-based rehabilitation approach for chronic MLBP.

Keywords: Mechanical Low Back Pain, McKenzie Exercises, Maitland Mobilization, Core Stabilization, Rehabilitation, Oswestry Disability Index.

INTRODUCTION

Mechanical Low Back Pain (MLBP) is one of the most prevalent and disabling musculoskeletal disorders worldwide. It is typically associated with pain arising from the lumbar vertebrae, intervertebral discs, facet joints, ligaments, or paraspinal muscles in the absence of inflammatory, systemic, infectious, or malignant pathology.[1,2] MLBP accounts for approximately 90–95% of all low back pain cases and affects nearly 84% of adults at some point during their lifetime.[3] According to the Global Burden of Disease Study, low back pain remains the leading cause of years lived with disability globally, affecting an estimated 619 million individuals in 2020, with projections exceeding 843 million by 2050. [3,5] In India, the prevalence of MLBP ranges from 23% to 60%, particularly among manual labourers, agricultural workers, and office employees.[5] Beyond its clinical burden, MLBP imposes substantial socioeconomic consequences through increased healthcare expenditure, work absenteeism, reduced productivity, and diminished quality of life.[6] Consequently, identifying effective and accessible physiotherapy interventions remains a major clinical priority. The etiology of MLBP is multi factorial and involves a complex interaction of biomechanical, physiological, and psychosocial factors. Structural changes such as intervertebral disc degeneration, facet joint dysfunction, ligament laxity, and weakness of stabilizing muscles, particularly the transversus abdominis and multifidus, may contribute to lumbar instability and persistent pain. [7,8] Inflammatory mediators and central sensitization mechanisms may further amplify pain perception beyond the initial tissue injury, while psychological factors such as fear-avoidance beliefs, pain catastrophizing, depression, and occupational dissatisfaction are recognized contributors to chronic pain and disability.[10,11]

Conservative physiotherapy is widely recommended as the first-line management approach for MLBP. [12,13] Among the available interventions, McKenzie Mechanical Diagnosis and Therapy (MDT) and Maitland Mobilization are commonly employed in clinical practice. McKenzie MDT emphasizes mechanical assessment, directional preference, and symptom centralization through repeated movement strategies, whereas Maitland Mobilization utilizes graded passive oscillatory techniques to reduce pain, restore joint mobility, improve biomechanics, and enhance proprioceptive function. [14, 17] Although both interventions have demonstrated clinical effectiveness, direct comparisons across multiple functional outcomes remain limited. [18, 20] Furthermore, previous studies have primarily focused on pain reduction and disability, while outcomes such as lumbar mobility, muscle strength, muscle endurance, and functional performance have received comparatively less attention. Variations in study design and the absence of standardized control interventions have also limited the ability to determine the relative effectiveness of these treatment approaches. Therefore, the present three-arm randomized controlled trial was designed to compare the effectiveness of McKenzie Exercises, Maitland Mobilization, and a standardized control intervention comprising Short-Wave Diathermy (SWD) with Core Stabilization in individuals with Mechanical Low Back Pain. The primary objective was to evaluate changes in pain intensity, lumbar mobility, muscle strength, extensor muscle endurance, and functional disability following four weeks of intervention, thereby providing evidence to guide the selection of effective physiotherapy strategies for the management of MLBP.

MATERIALS AND METHODS

Study Design and Ethical Considerations

This study employed a three-arm, parallel-group, pre-test/post-test randomized controlled trial (RCT) design to compare the effectiveness of McKenzie Exercises, Maitland Mobilization, and a control intervention in individuals with chronic Mechanical Low Back Pain (MLBP). Ethical approval was obtained from the Research Ethics Committee of Baba Mastnath University, Rohtak, Haryana, India (REC/BMU/FPT/2024/212). Written informed consent was obtained from all participants prior to enrolment. The study was conducted in accordance with the ethical principles of the Declaration of Helsinki (2013 revision) and reported following the Consolidated Standards of Reporting Trials (CONSORT 2010) guidelines. Data collection was carried out between February 2023 and December 2024 at the Outpatient Physiotherapy Department, Panipat, Haryana, India.

Study Architecture and Trial Flow

A total of 225 individuals with Mechanical Low Back Pain were screened for eligibility. Following assessment based on predefined inclusion and exclusion criteria, 15 participants were excluded. The remaining 210 eligible participants were enrolled and randomly allocated into three equal groups (n = 70 per group). Group A received McKenzie Exercises combined with Short-Wave Diathermy (SWD) and Core Stabilization, Group B received Maitland Mobilization combined with SWD and Core Stabilization, and Group C received SWD with Core Stabilization only.
All participants underwent supervised treatment sessions three times per week for four consecutive weeks. Clinical outcomes were assessed at baseline and immediately after completion of the intervention period. The overall study process is illustrated in the CONSORT flow diagram (Figure 1).

Sample Size and Randomization

Sample size estimation was performed using G*Power software (Version 3.1.9.7). Based on an effect size (f) of 0.25, a significance level of 0.05, and a statistical power of 95%, the minimum required sample size was calculated as 207 participants. To ensure equal group allocation and maintain adequate statistical power, 210 participants were recruited and equally distributed among the three study groups (70 participants per group). The final sample exceeded the minimum required sample size, thereby strengthening the statistical robustness of the study. Participants were randomly allocated into the three study groups using a lottery-based simple randomization procedure. Each participant had an equal probability of assignment, ensuring unbiased group allocation.

Inclusion and Exclusion Criteria

Participants aged 20–40 years with chronic Mechanical Low Back Pain of at least three months' duration, pain intensity ranging from 4 to 7 on the Numeric Pain Rating Scale (NPRS), reduced lumbar muscle endurance, and functional disability were included in the study. Individuals with a history of recent spinal surgery, vertebral fractures, spinal tumors, infections, pregnancy, severe spinal deformities, osteoporosis, spondylolisthesis, inflammatory spinal disorders, or any other serious medical condition affecting lumbar function were excluded.

Intervention Protocols

Participants in Group A received McKenzie Mechanical Diagnosis and Therapy (MDT) exercises in combination with SWD and Core Stabilization. The MDT programme was individualized according to directional preference and included extension in prone lying, extension in standing, flexion in supine lying, and flexion in sitting. Each exercise was performed for 10 repetitions per set and progressed according to symptom response and the principle of pain centralization. Treatment sessions were conducted three times per week for four weeks under physiotherapist supervision. Participants in Group B received Maitland Mobilization in combination with SWD and Core Stabilization. Oscillatory mobilization techniques (Grades I–IV) were applied to lumbar vertebral segments (L1–L5) for approximately 12–15 minutes per session. The grade of mobilization was selected according to pain severity, symptom response, and tissue irritability. Continuous Short-Wave Diathermy (27.12 MHz) was administered to all participants for 15 minutes before treatment to facilitate pain reduction, tissue relaxation, and improved circulation.

A progressive Core Stabilization programme was also provided to all groups and included tummy-tuck exercises, cat-camel stretch, hip bridge, dead bug, unilateral leg extension, and Superman exercises. Each exercise was performed with a 10-second hold, 10 repetitions, and 3 sets. All interventions were delivered by qualified physiotherapists under direct supervision throughout the study period.

Outcome Measures

Clinical outcomes were assessed at baseline and after completion of the four-week intervention period using standardized and validated assessment tools. Pain intensity was measured using the Numeric Pain Rating Scale (NPRS), lumbar mobility using the Modified Schober Test (MST), muscle strength using Manual Muscle Testing (MMT), muscle endurance using the Biering–Sorensen Test (BST), and functional disability using the Oswestry Disability Index (ODI). The psychometric properties and clinical applications of the outcome measures used in the study are presented in Table 2. All instruments were selected based on their established reliability, validity, and widespread use in low back pain research and clinical practice. Table 3 presents the baseline demographic characteristics of participants in the three study groups. No statistically significant baseline differences were observed among the three groups for demographic or clinical variables (all $p > 0.05$), indicating successful randomization and baseline comparability.

Statistical Analysis

Data were analysed using IBM SPSS Statistics Version 18.0. Descriptive statistics were expressed as mean ± standard deviation (Mean ± SD). Normality of data distribution was assessed using the Shapiro–Wilk test. Within-group differences between pre- and post-intervention assessments were analysed using paired t-tests. Post-treatment differences among the three groups were examined using one-way analysis of variance (ANOVA), followed by Tukey's Honest Significant Difference (HSD) post-hoc test for pairwise comparisons where appropriate. A p-value of less than 0.05 was considered statistically significant for all analyses.

RESULTS AND ANALYSIS

Participant Flow and Baseline Characteristics

A total of 225 participants were screened for eligibility, of whom 210 met the inclusion criteria and were enrolled in the study (70 participants per group). Fifteen participants were excluded because they did not meet the eligibility criteria or declined participation prior to randomization. No post-randomization dropouts were recorded. Baseline demographic and clinical characteristics were comparable among the three groups, with no statistically significant differences observed across baseline variables (Table III), indicating successful randomization and baseline homogeneity.

Pain Outcomes (NPRS)

Pain intensity measured using the Numeric Pain Rating Scale (NPRS) was comparable at baseline across all groups. Following four weeks of intervention, significant improvements were observed in all groups; however, Group A (McKenzie Exercises) demonstrated the greatest reduction in pain scores. The post-intervention NPRS score was 2.27 ± 0.88 in Group A, compared with 3.34 ± 0.88 in Group B and 4.13 ± 1.24 in Group C ($F = 58.993$, $p < 0.001$). Tukey's post-hoc analysis revealed significant differences between all groups ($p < 0.001$), confirming the superior effectiveness of McKenzie Exercises in pain reduction.

Lumbar Range of Motion (MST)

The Modified Schober Test (MST) showed similar baseline values among the three groups. After intervention, Group A achieved the highest lumbar mobility score (4.86 ± 1.21 cm), followed by Group B (4.67 ± 1.24 cm) and Group C (4.16 ± 1.10 cm). Statistical analysis demonstrated significant differences between active intervention groups and the control group ($F = 6.588$, $p = 0.003$). However, no significant difference was observed between Groups A and B ($p =$

0.620), suggesting that both McKenzie Exercises and Maitland Mobilization were similarly effective in improving lumbar flexibility.

Muscle Strength (MMT) and Endurance (BST)

All groups showed comparable baseline muscle strength scores. Following treatment, Groups A and B demonstrated significantly greater improvements in Manual Muscle Testing (MMT) grades than the control group. The mean post-treatment MMT grades were 4.06 ± 0.51 for Group A, 4.03 ± 0.61 for Group B, and 3.53 ± 0.72 for Group C ($F = 16.176$, $p < 0.001$). For muscle endurance assessed using the Biering–Sorensen Test (BST), Group A achieved the greatest improvement with a mean score of 84.46 ± 21.47 seconds, followed by Group B (78.89 ± 18.07 seconds) and Group C (65.33 ± 20.52 seconds). Significant differences were observed between the active treatment groups and the control group ($F = 16.823$, $p < 0.001$), indicating superior endurance enhancement with McKenzie and Maitland interventions.

Functional Disability (ODI)

At baseline, Oswestry Disability Index (ODI) scores were statistically similar across all groups. After four weeks, Group A achieved substantial functional improvement, reducing disability from 24.29% to 4.89%, which corresponds to the "minimal disability" category. Group B improved to 14.63%, while Group C showed limited improvement, remaining at 24.74%. One-way ANOVA demonstrated highly significant differences among groups ($F = 60.627$, $p < 0.001$). Improvements were observed across all ten ODI domains, including pain intensity, personal care, lifting, walking, sitting, standing, sleeping, social life, and travelling, with Group A consistently demonstrating the greatest benefit. Table 4 presents the baseline and post-intervention outcome measures across the three study groups. Baseline values were comparable among the groups for all outcome measures. Following four weeks of intervention, significant improvements were observed in all groups; however, Group A (McKenzie Exercises) demonstrated the most favourable outcomes in pain reduction, lumbar mobility, muscle strength, muscle endurance, and functional disability compared with Group B (Maitland Mobilization) and Group C (Control). Significant between-group differences were observed for all outcome measures ($p < 0.05$). Table 5 presents the pre- and post-intervention ODI sub-domain scores across the three study groups. Baseline scores were comparable among the groups. Following four weeks of intervention, significant improvements were observed across all domains of daily living, with Group A (McKenzie Exercises) demonstrating the greatest reduction in disability scores compared with Group B (Maitland Mobilization) and Group C (Control). The most pronounced improvements were observed in pain intensity, lifting, standing, social life, and travelling domains, indicating superior functional recovery following McKenzie-based rehabilitation.

DISCUSSION

In the present study, the comparative effectiveness of McKenzie Exercises, Maitland Mobilization, and Short-Wave Diathermy (SWD) plus Core Stabilization was studied in people with chronic Mechanical Low Back Pain (MLBP). All three treatments showed a significant improvement after the 4 weeks period of treatment, but the group treated with the McKenzie exercise showed better results in reducing pain and functional disability and improving lumbar extensor muscle endurance disability. This increased pain reduction for the McKenzie group could be explained by the principles of directional preference and symptom centralization presented in McKenzie Mechanical Diagnosis and Therapy (MDT). Movement performed repeatedly in the "right" direction can help decrease mechanical stress on painful spinal tissues, optimize movement patterns, and aid in symptom resolution. Maitland Mobilization also resulted in significant pain and mobility improvements, but the level of improvement was not as great as with McKenzie Exercises. Lumbar mobility and muscle strength were significantly improved with both McKenzie Exercises and Maitland Mobilization compared with the control intervention. The group who did the McKenzie Exercises, however, showed higher gains in the muscle endurance of the extensor muscles of the lumbar spine. Greater muscle endurance can lead to better spinal stability, increased function and a decrease in the likelihood of having the low back pain episode again. The results of this study point to the positive outcomes of McKenzie Exercises which could potentially help with long-term functional recovery. There was a significant reduction in

functional disability in all groups as measured by Oswestry Disability Index (ODI), most significantly in the McKenzie group. Participants showed a clinically significant improvement in daily functioning and quality of life from moderate disability at baseline to minimal disability after treatment. The present study's results align with Long et al.[15] who showed that, when it comes to low back pain, exercises that focus on the direction of movement yielded better results. Likewise, pain and functional improvements after MDMT were reported to be significant by Machado et al.[19]. The findings of the present study further reinforce the effectiveness of McKenzie based rehabilitation in people with chronic Mechanical Low Back Pain. Results indicate that McKenzie Exercises offer higher clinical benefits than Maitland Mobilization and conventional physiotherapy (SWD and Core Stabilization). McKenzie Mechanical Diagnosis and Therapy appears to be more comprehensive in improving functional recovery, reducing disability and in promoting self-management in a person with chronic Mechanical Low Back Pain (cMLBP), while Maitland Mobilization is still effective for improving pain and mobility. The self-directed and active aspect of McKenzie Exercises could also increase patient involvement and adherence, potentially contributing to better clinical outcomes.

Limitations

The present study has several limitations that should be considered when interpreting the findings. First, the intervention period was limited to four weeks, which may not adequately reflect the long-term effectiveness of the treatment approaches. Second, participants were restricted to the 20–40 years age group, limiting the generalizability of the findings to adolescents and older adults. Third, the study was conducted at a single clinical center, which may affect the external validity of the results. In addition, no long-term follow-up assessments were performed; therefore, the sustainability of treatment effects and recurrence rates could not be evaluated. Some outcome measures, particularly the Numeric Pain Rating Scale (NPRS) and Oswestry Disability Index (ODI), relied on patient self-report and may have been influenced by response bias. Furthermore, advanced objective assessment methods such as electromyography, motion analysis, and imaging-based evaluations were not utilized. The study focused exclusively on individuals with Mechanical Low Back Pain, and the findings may not be applicable to patients with inflammatory, traumatic, or neurological spinal disorders. Psychosocial factors, including fear-avoidance beliefs, anxiety, stress, and depression, were not separately assessed despite their recognized influence on low back pain outcomes. Treatment adherence outside supervised sessions was also not objectively monitored. Although the sample size was adequate, larger multicenter studies with longer follow-up periods are recommended to further validate these findings across diverse populations.

CONCLUSION AND FUTURE SCOPE

The present study revealed that patients with Mechanical Low Back Pain (MLBP) had a significant improvement after McKenzie Exercises, Maitland Mobilization and SWD with Core Stabilization. McKenzie Exercises demonstrated favourable short-term improvements in pain and functional disability, while improvements in lumbar mobility were comparable to those achieved with Maitland Mobilization. The magnitude of the improvement seen with Maitland Mobilization was not as great as that seen with McKenzie, but was clinically significant. These results provide evidence for using the McKenzie exercise as an effective treatment approach for functional outcomes and self-management in people with chronic Mechanical LBP. Future studies should be conducted on larger, multicenter, randomized controlled trials with longer follow-up time to assess treatment effectiveness and sustainability over the long-term. Combined McKenzie and Maitland approaches should also be explored in follow up studies, objective biomechanical assessment methods should be evaluated and the effect of psychosocial factors on treatment response should be explored. New technologies, such as telerehabilitation, wearable monitoring devices, and the use of AI for rehabilitation could also present exciting options for personalizing and optimizing the management of Mechanical Low Back Pain.

ABSTRACT

Halophytic plants are essential sources of natural compounds that beneficial to human health and possess significant promise for the development of novel pharmaceuticals. Halophytes are exposed to high heat and salinity stress, which stimulates the synthesis of secondary metabolites that reduce the stress. The current work commenced with the HPTLC (High-performance thin-layer chromatography) fingerprinting analysis of flavonoid and phenolic compounds derived from the methanolic extracts of various plant sections of the halophytic species *Suaeda fruticosa* Forssk ex. J. F. Gmel. The chromatographic examination of methanol extracts was conducted on TLC plates of Silica gel 60 F254 (Merck) HPTLC aluminium sheets using a CAMAG Linomat 5 applicator. The plates were formulated with a mobile phase of ethyl acetate: glacial acetic acid: formic acid: water at a ratio of 16.26:0.81:0.81:2.11 (v/v/v/v). Flavonoid and phenolic compounds were identified at 254 nm, 366 nm, and 540 nm (subsequent to derivatization). The application of derivatization reveals fluorescent bands at 366 nm (R_f values at 0.10, 0.14, 0.35, 0.65 and 0.82) and blue colour bands at 540 nm (R_f values at 0.11, 0.24, 0.40 and 0.55), signifying the presence of flavonoid and phenolic compounds respectively. The results based on FT-IR analysis revealed the presence of functional groups like alcohol, phenol, aliphatic, anhydrides, aromatics, and aliphatic amines. The presence of the phenolic compounds, flavonoids and several functional groups render good antioxidant activity (lowest IC_{50} values at 38.98±0.94 µg/mL) of the extracted compounds was evaluated using standard assays, revealing significant free radical scavenging potential. The HPTLC fingerprints provided a comprehensive phytochemical profile, highlighting the

distribution of bioactive compounds across different plant parts. This validated approach offers a reliable tool for quality control and further exploration of *S.fruticosa* as a source of natural antioxidants for pharmaceutical and nutraceutical applications.

Keywords: *Suaeda fruticosa*, TLC, CAMAG, FT-IR,antioxidant activity, bioactive compounds

INTRODUCTION

Plants have historically provided remedies for various diseases in numerous traditional medicine systems and continue to offer new solutions for humanity across the entire world[1]. Medicinal plants contain a numerous bioactive compound with therapeutic properties. The plant has anti-inflammatory, antiviral, antitumor, anticancer, antimalarial and analgesic qualities, among other medicinal possibilities[2].Secondary metabolism produces bioactive chemical molecules, which provides plants their biological activities, including the ability to treat infectious diseases[3].Various plants, including halophytes, were identified as containing polyphenols and bioactive compounds, which may be beneficial for medicinal application and hold significant interest in the therapeutic and cosmetic sectors[4].*Suaeda*,(family Amaranthaceae) is a succulent perennial halophytic shrub known for its excellent salt tolerance, commonly found in terrestrial and coastal salt marshes[5].Halophytes possess an effective antioxidant system, comprising both enzymatic and non-enzymatic components, to endure extreme conditions[6].*S. fruticosa*, rich in bioactive compounds like phenol, flavonoids, tannin, alkaloids and saponin; now in-vitro and ex vivo assays revealed that the antioxidant, anti-hyperlipidaemic, anti- inflammatory and hypoglycaemic properties[7].

High-performance thin-layer chromatography (HPTLC), sometimes referred to as planar chromatography, is a modern technique that performs better in terms of accuracy and separation capacity than classic thin-layer chromatography (TLC). Unlike other analytical techniques, HPTLC produces a visual representation of the plate that includes comprehensive information about the entire extract. Because HPTLC is an offline method, the subsequent procedures are technically free and allow for the more than one type of sample at the same time during the study[8,9]. Antioxidant exhibit their protective function by directly interacting with free radicals, neutralizing them and so preventing damage to cellular components, which consequently mitigates illnesses[10,11]. Recently, there has been a significant rise in interest in identifying naturally occurring antioxidants to substitute manufactured ones, which are being limited due to their carcinogenic properties[12].Antioxidant phytochemicals, including polyphenol, flavonoids, and analogous substances present in medicinal plants, have generated more attention for their prospective role in the protection of human diseases[13]. Certain coastal plants have been studied and documented to possess antioxidant and radical scavenging capabilities[14,15]. FT-IR is not a sensitive technique but it has a number of benefits over other analytical techniques. This non-destructive method may identify functional groups, which gives information regarding chemical and structural changes in response to biotic or abiotic stress[16]. This is the first time we exemplify the chemical fingerprinting of halophytic species *S.fruticosa* using an influential technique like HPTLC. There is not any literature survey of this data available until now. Thus, the aim of the present work was to quantify phenolic and flavonoid compounds through HPTLC fingerprinting of methanolic extracts of *S. fruticosa* with their different parts and to evaluate the antioxidant capacity using DPPH (2,2-diphenyl-1-picrylhydrazyl) and reducing power assays as well as to analyse with FT-IR (Fourier transform infrared) technique.

MATERIALS AND METHODS

Plant collection and authentication of plant sample

A well grown halophytic plant species *S. fruticosa* was collected from Koddha in Patan district, inside the Little Rann of Kutch area (coordinates 23˚ 31′02.331′′N, 71˚ 28′ 31.0476′′ E)of Gujarat, India. *S. fruticosa* was collected during summer (April) and rainy (September) seasons. During the summer season, leaves and stem segments taken, while in

the rainy season, leaves, stem, and flower sections were collected. Plant identification was conducted using the Flora of Gujarat[17] and later the herbarium sheet was deposited in the Botany Department of Hemchandracharya North Gujarat University, its associated voucher number is LS/Bot-057. All parts were properly cleansed to remove the surrounding soil using clean water and thereafter allowed to shade dry at room temperature (26°C) within 3 to 6 days. A grinder with a mixture for dried parts was utilized to make powder, and each sample was used for extract preparation.

Extract preparation

Solvents Water, Methanol, Chloroform and Ethyl acetate were utilized at a ratio of 1:10 (1 gm dried plant powder: 10 mL solvent). The sets were thereafter placed on a shaker (250 rpm) for 24 hours. Subsequently, all extracts were separately filtered using Whatman filter no.1 and used for further analysis.

Qualitative analysis

Qualitative analysis was evaluated by the following tests[18,19].

Tests for flavonoids

Alkaline reagent test: Extracts were treated with few drops of 10% (w/v)sodium hydroxide solution. Formation of intense yellow colour, which becomes colourless on addition of dilute acid, indicates the presence of flavonoids.

Lead acetate test: Extracts were treated with few drops of 5% (w/v) lead acetate solution. Formation of yellow colour precipitation indicates the presence of flavonoids.

Test for phenols

Ferric chloride test: Extracts were treated with 3-4 drops of 10% (w/v) ferric chloride solution. Formation of bluish black colour indicates the presence of phenols.

Quantitative analysis

A standard protocol was used to evaluate the quantitative analysis.

Determination of flavonoid content (TFC)

The total flavonoid content was determined by[20]method with some modifications. 0.5 mL of the extracts, 0.3 mL of 5% sodium nitrate and after 5 minutes added 0.3 mL of aluminium chloride (10%). After that added 2 mL of 1 M sodium hydroxide. Immediately the content of the reaction mixture was diluted with 2.4 mL of distilled water, mix thoroughly and the absorbance of the mixture was estimated at 510 nm in UV- Spectrophotometer. Estimation of the flavonoid content were carried out in triplicate. The total flavonoid content was estimated in milligram using by quercetin (range in 1000-4000 µg/mL) as standard. The concentration of total flavonoid was indicated as mg of quercetin equivalent/g of plant extracts (mg QE/g DW).

Determination of total phenol content (TPC)

The total phenols in leaves, stem, flower extracts were estimated by the modified Folin- Ciocalteu's method[21]. 2.5 mL of 10% Folin Ciocalteu's reagent and 2 mL of 2% solution of Na_2CO_3 were added in 1 mL of leaves, stem and flower extracts. The mixture was incubated for 15 minutes at room temperature. The absorbance of the sample was measured at 750 nm in UV- Spectrophotometer. Estimation of total phenolic compounds was carried out in triplicate. Results were expressed as milligrams of gallic acid equivalent/g of plant extracts (mg GAE/g DW). The procedure was used for making gallic acid (range in 100-1000 µg/mL) standard curve.

HPTLC fingerprinting analysis

Sample preparation

The Soxhlet equipment was used for extract preparation (10 gm powder) using suitable HPLC grade polar solvent Methanol for all the plant parts. All the extracts were preserved in a refrigerator for further analysis.

Stationary phase

TLC plate Silica gel 60 F_{254} (Merck) 20 cm x 20 cm was cut in to 20 cm x10 cm size with the help of cutter and used as a stationary phase.

Sample application

The TLC plates are cleaned and dried for about 15 minutes and at 110 degrees in a hot air oven. Sample of plant parts (2 µl of leaves, stem, and flower) were loaded on the pre activated silica gel TLC plate. A CAMAG Linomat-5 sample applicator was used to apply the material. VisionCATS Planar Chromatography Manager was used to load the samples using Linomat-5 with an 8 mm band width, 15 mm from the plate bottom, and 2 mm between bands. All samples were loaded on track.

Chromatogram development

Sample loaded HPTLC plates were allowed to dry first afterwards they were placed in solvent saturated with 20 minutes in twin through glass chamber (size 20 x 10 cm) for the development of chromatogram. The chromatogram was allowed to develop up to 70 % saturation. HPTLC plate removed from the chamber and dried with a dryer.

Solvent system and derivatizing reagent

Ethyl acetate: Glacial acetic acid: Formic acid: Water (16.26:0.81:0.81:2.11 v/v/v/v) a standard solvent system for phenolic and flavonoid compounds.

- Alcoholic ferric chloride reagent - 1 gm $FeCl_3$ diluted with water added methanol make it 100 mL. (1% $FeCl_3$)
- Methanolic sulphuric acid reagent – 10 mL concentrated H_2SO_4 added in 100 mLmethanol carefully. (10% methanolic H_2SO_4)

Chromatogram scanning

After development, allow the TLC plate dry before taking chromatogram images in white (540 nm), UV (254 nm) and fluorescent (366 nm) light. Different wavelengths of the TLC Scanner-4 were used to scan the same plate. According to TLC scanner 4, slit dimension size 6.00×0.45 mm that controls the area of the sample bands and its scanning speed was 1 mm/s to 100 mm/s.The plate was subsequently derivatised with specific derivatising reagents. Remove the plate from the reagent after 5 seconds, heat it for 1-2 minutes at 100 °C on a hot plate, and then use a TLC Visualiser to view the chromatogram.

Antioxidant activity

Free radical scavenging activity by DPPH

Theprocedure was used to carry out DPPH radical scavenging activity. First, equal volumes of the sample in various concentrations were added to 1.0 mL of a solution containing 100 µM DPPH in methanol. The mixture was then incubated for 30 minutes in the dark condition (in amber bottle) at room temperature 30°C. The hue shift was seen in absorbance using a spectrophotometer assessed at 514 nm. Next, the control tube was filled with 1.0 mL methanol rather than the test liquid. Ascorbic acid at various concentrations served as the standard reference substance. Using the formula [(Absorbance of control - Absorbance of the test) / Absorbance of control] X 100, the percentage of inhibition was computed. Then, the IC_{50} value was determined[22].

Reducing power as say

Different concentrations of the methanolic extract of sample and its various fractions (10-50µg/mL) was added to 2.5 mL of 0.2 M phosphate buffer (pH 6.6) and 2.5 mL of 1% potassium ferricyanide [K3Fe (CN)6] solution. Using a vortex shaker, there action mixture was mixed well and then kept at 50°C for 20min. After the incubation,2.5mL of 10%trichloroaceticacidwasaddedtothemixture,which was then centrifuged at 3,000 rpm for 10 min. Thesupernatant(2.5mL)wasmixedwith2.5mLofdeionisedwaterand0.5mLof0.1%ferricchloride. The coloured solution was read at 700 nm against the blank with reference to standard using UV- Spectrophotometer. Here, ascorbic acid was used as a reference standard, the reducing power of the samples were comparable with the reference standard[23].

Fourier Transform Infrared (FT-IR) analysis

The FT-IR analysis was carried out to know the functional groups present in the methanolic extracts. The methanolic crude extracts of the selected plant parts were mixed with 200 mg KBr (FT-IR grade) pellet performed by Shimadzu 8400S FT-IR spectrophotometer. The measurements were taken in an automatic recording FT-IR spectrophotometer in the range of 4000 to 400 cm^{-1}. The FT-IR signal area was recorded and compared with the standard peak value and interpreted the functional groups.

RESULTS AND DISCUSSION

Qualitative phytochemical analysis

The phytochemical examination of different extracts of *S. fruticosa* is represented in (Table 1) extracts are displayed based on polarity. This expresses that water and methanol extracts had a wider solubility of bioactive compounds compared to chloroform and ethyl acetate. The extract prepared in ethyl acetate has the least solubility of phytochemicals phenol and flavonoid. Chloroform extract has a moderate presence of phenol and flavonoid compounds. Water and methanolic extracts of all the parts show more solubility in both seasons. This qualitative examination revealed the presence of phenolic and flavonoid phytochemicals in different extracts of *S. fruticosa*. From a prior investigation on the *S. fruticosa*[24],it was revealed that almost similar phytoconstituents results show rich in phenol and flavonoid. However, literature suggested that several phenolic and flavonoid compounds present in *S. fruticosa*, that significantly use to treat fever, flu, skin disease, rheumatism and helminthiasis livestock diseases[7].

Quantitative phytochemical analysis

Equation of calibration curve for TFC (total flavonoid content) determination was $y=0.0001x + 0.0705$, $R^2=0.9909$, where y is absorbance at 510 nm and x is concentration of Quercetin (mg QE/g DW) and for TPC (total phenol content) determination was $y=0.0009x - 0.0127$, $R^2=0.9952$, where y is absorbance at 750 nm and x is concentration of Gallic acid (mg GAE/g DW). Numerous recent investigations have demonstrated that phenolic components[25,26] are the most potent antioxidant agents. For that, total flavonoid and phenolic contents of different extracts of *S. fruticosa* parts were analysed. Results showed in (Table 2), the highest amount of flavonoid (3012.45±1.26 mg QE/g DW) and phenolic (960.31±3.42 mg GAE/g DW) content in *S. fruticosa* methanolic extracts of summer stem part.*S. fruticosa* from Tunisia exhibited 31.76 mg GAE/g DW polyphenol content, which is very low compare to our phenolic content[27]. Another species *S. nudiflora* revealed flavonoid and phenol content in methanolic extract 11.0 μg/mg and 43.66 μg/mg respectively[28]. These findings demonstrated the abundance of flavonoid and phenolic contents in methanolic extracts of *S.fruticosa*, prompting an evaluation of its biological activities.

HPTLC fingerprinting analysis

The HPTLC fingerprinting analysis conducted at various wavelengths for methanolic extracts of *S. fruticosa* with its different parts confirmed the presence of flavonoid and phenolic compounds in different quantities. The band R_f value of different range was obtained as shown in the (Fig.1&Fig. 2). The mobile phase comprising Ethyl acetate: Glacial acetic acid: Formic acid: Water (16.26: 0.81:0.81:2.11 v/v/v/v) for flavonoids and phenolic acids demonstrated satisfactory resolution and separation of the sample components. Peak generates distinct symmetrical peaks in this mobile phase. Furthermore, formic acid is included into the mobile phase to inhibit the ionization of acidic groups and enhance the visibility of chromatographic bands[29]. HPTLC is widely utilized in the analysis of pharmaceuticals, botanical specimens, culinary products, as well as environmental and clinicalsamples[30]. The primary activities essential for the method development are the selection of the stationary phase and mobile phase, sample preparation, chromatogram development, derivatization and detection of chromatogram[31]. HPTLC fingerprinting of flavonoid and phenol were obtained from three different parts like leaf, stem and flower of rainy season and two parts like leaf and stem of summer season of *S. fruticosa.*(Fig.1 &Fig. 2) demonstrated the pre derivatization and post derivatization chromatogram at three detection modes (254 nm, 366 nm and 540 nm). (Table 3 & Table 4) illustrated the R_f values of the separated band at different detection modes.

HPTLC obtained from methanolic extracts of different parts of *S. fruticosa* analyses derivatizing reagents and their corresponding chromatogram, the graphics depict two-dimensional data of R_f against intensity; yet, each profile holds greater significant due to the variation in color among the various bands. The images in (Fig. 1(A-D)) showed the chromatogram which used solvent system (Ethyl acetate: Glacial acetic acid: Formic acid: Water (16.26: 0.81:0.81:2.11 v/v/v/v)), detection in prior to derivatization in 254 and 366 nm; (Table 3) illustrates the comparative analysis in different parts with methanolic extracts, which displayed several bands with varying R_f values at distinct wavelengths. At a short wavelength 254 nm, (Fig.1A) track 1,3,4,5 of *S. fruticosa* displayed five distinct bands, while track 2 showed four bands in same detection mode. As a consequence, it shows that the presence of multiple compounds in this plant extracts can be separated under a short wavelength. After this chromatogram detected in long wavelength 366 nm, (Fig.1C) all tracks separated with different highlighted bands, while track 3 and 5 showed more separated bands from others. (Fig.1B & D) showed 3D images of their wavelengths related chromatograms. After scanning, for the better resolution of bands the chromatogram was dipped into the natural product derivatizing reagent (10% methanolic sulphuric acid). (Fig. 2A&C) visualised after being derivatized with natural product reagent under 366 and 540 nm. In (Fig. 2A) track 1,2,3,4 and 5 all the tracks showed fluorescent bands under 366 nm detection mode that confirmed the presence of flavonoid compounds. Track 1, the fluorescent band at R_f 0.10, track 2, R_f bands at 0.14 and 0.35, track 3, R_f bands at 0.10, 0.14, 0.35, 0.65 and 0.82, track 4, R_f bands at 0.10 and 0.14, track 5, R_f bands at 0.10 and 0.35, among the all-fluorescent bands confirm the presence of flavonoid compounds in *S. fruticosa* different parts. Under 540 nm (white /visible light), (Fig. 2C) confirmed flavonoid compounds with yellow color bands. (Fig. 2B&D) showed 3D images of after derivatizing chromatogram with 366 and 540 nm detection mode.

The images in (Fig. 1(A-D)) showed the chromatogram which used same solvent system (Ethyl acetate: Glacial acetic acid: Formic acid: Water (16.26: 0.81:0.81:2.11 v/v/v/v)) for identification of phenol compounds. For more visualisation of phenolic bands, the chromatogram was immersed in to the 1% alcoholic ferric chloride derivatizing reagent. (Fig. 2E & G) visualised after being derivatized under 366 and 540 nm mode. In Fig. 2G under 540 nm (visible light), track 3, 4 and 5 showed blue color bands that confirm the presence of phenolic compounds in *S. fruticosa* extracts. Track 3, the blue color band at R_f values 0.11 and 0.24, track 4, R_f bands at 0.11 and track 5, R_f bands at 0.11, 0.24, 0.40 and 0.55, all the blue color bands confirmed the presence of phenolic compounds in parts of *S. fruticosa*. (Fig. 2F & H) showed 3D images of after derivatizing chromatogram with 366 and 540 nm detection mode.
Derivatization is a chemical technique employed to see the separated fractions. 10% methanolic sulphuric acid (NP reagent) and 1% alcoholic ferric chloride reagent are prevalent reagents employed as derivatizing reagents in present fingerprinting analysis, which validated the presence of flavonoid and phenolic compounds on their specific color of the bands as per literature and this literature supported the current experimental work[8,32]. An asterisk (*) was used to show the presence of bands in the figures. A chromatographic fingerprinting generated by HPTLC on plant extracts signifies the chemically distinctive or pharmacologically active constituents found in the plants[33]. The hydroxyl groups in the structures of flavonoids and phenolic acids can enhance antioxidant activity[34]indicate that phenolic compounds possess several beneficial physiological properties, including antibacterial, antioxidants and preservative functions. HPLC (high-performance liquid chromatography) analysis of *S. fruticosa* exhibited some compounds like gallic acid, catechin, chlorogenic acid, caffeic acid, naringenin, andquercetin which are responsible for the high antioxidant activity of this plant[35]. In *S. fruticosa,* identification of the shoot part revealed gallic acid, chlorogenic acid, salicylic acid, rosmarinic acid, rutin hydrates, and quercetin like compounds, with many more identified through RP-HPLC (reverse phase high-performance liquid chromatography)[27].

Antioxidant activity

DPPH radical scavenging activity

The results of DPPH scavenging activity were shown in (Fig. 3) Although the radical scavenging activity of each extract of parts increased with an increase in concentration, they all demonstrated potent antioxidant activity. The lowest IC_{50} values suggests strong antioxidant power whereas the highest IC_{50} values suggests that the weak antioxidant activity of the extract. In *S. fruticosa* methanolic extracts, the maximum scavenging activity (%) was found in the summer stem part (89.06±0.98%) followed by rainy leaf (82.11±0.64%), rainy stem (78.34±0.73%), summer leaf (73.15±0.49%) and flower (67.38±1.65%).

Reducing power assay

The results of reducing power activity were shown in (Fig. 4) In *S. fruticosa* the maximum scavenging activity (%) was found in the summer stem (82.57±1.48%) followed by summer leaf (81.31±1.13%), rainy stem (74.06±0.63%), rainy leaf (71.51±0.85%) and flower (67.65±0.48%). DPPH is a free radical that can transform into a stable diamagnetic molecule by accepting an electron radical[36]. The DPPH radical reduction ability was examined by the reduction in absorbance caused by plants antioxidants[4].(Table 4) revealed the results of antioxidant activities according to IC_{50} values. In DPPH assay the lowest IC_{50} values (strong antioxidant) was recorded in summer leaf (38.98±0.94 µg/mL) and the higher IC_{50} (weak antioxidant) was recorded in flower (63.85±0.94 µg/mL). In FRAP activity the lowest IC_{50} (strong antioxidant) was recorded in summer leaf (40.46±0.57 µg/mL) and the higher IC_{50} (weak antioxidant) was recorded in flower (83.33±1.51 µg/mL). As per results leaf part of *S. fruticosa* exhibited highest antioxidant activity, that similar as this literature[27].According to this literature, the acetonic extract of *S. fruticosa* shoot part showed IC_{50} values at 37 µg/mL meaning it showed higher antioxidant activity. Another species, *S. maritima,* also exhibited IC_{50} at 49 µg/mL.*S. monoica* methanolic extracts of leaf part showed IC_{50} at 29.16 µg/mL through DPPH method. It exhibited 114.32% scavenging activity in leaf, as compared to *S. fruticosa,* which showed 82.11% scavenging activity[37]. Phenolics are secondary metabolites that help keep people healthy. Plants have phytoconstituents like phenols, flavonoids, and tannins that may have antioxidant properties. These properties may help prevent disease by getting rid of free radicals. Phenolic molecules are abundant in plants and have been shown to perform various biological functions, including antioxidant activities. A lot of research has focused on phenolic compounds' biological activities, which may include antioxidant and free radical scavenging properties[14]. Phenolic compounds are known for their antioxidant properties and their capacity to eliminate free radicals associated with oxidative damage.They have accumulated significant interest recently due to in vitro studies indicating their diverse positive biological effects, including anti-inflammatory, anticancer, and antibacterial activity. Research has indicated that antioxidant activities are attributable to the presence of phenols and flavonoids[38.39]. Flavonoids are significant secondary metabolites of plants that regulate lipid peroxidation implicated in atherogenesis, thrombosis, and cancer. The pharmacological effects of flavonoids have been proven to correlate with their antioxidant properties[40].

Fourier Transfer Infrared spectroscopy analysis

The FT-IR analysis of methanolic extracts of *S. fruticosa* showed various peaks that confirmed the presence of functional groups such as alcohol and phenol (O-H stretching for H bond, C-H cyclic ether, C=O, C-H, C=C terpenes, N-H amide, C=C-C, O-H aromatic ringrespectively (Fig.6& Table 5). By using FT-IR spectrum, work justify the functional groups are present in *S. fruticosa* extracts. These types of functional groups also present in another halophytic species *Sesuviumportulacastrum*[44].Peak values at 1113.02, 1113.74, 1408.68, and 1450.30 indicated phenol and aromatic ring like functional groups and displayed O-H band stretching and C-H stretching that confirmed the presence of phenolic content in *S. fruticosa* leaf, stem and flower extracts. All components exhibited several R_f bands that were distinguishable on the TLC plate, corroborated by FTIR spectroscopy investigation.

CONCLUSION

S. fruticosa leaf, stem and flower were found to be sources of phytochemicals such as extractable flavonoid and phenolic compounds, and have considerable antioxidant properties. We conducted HPTLC fingerprinting clearly revealed that the methanolic extracts of different parts contains a comparable concentration of phytoconstituents. Furthermore, the results of the qualitative analysis of the HPTLC fingerprinting may aid in the detection and standardization of the medication as well as assure protective benefits against fatal illnesses. The validated HPTLC fingerprint offers a reproducible chemical profile that ensure reliable authentication of the sample. It can be routinely applied as a quality control tool for batch consistency, adulteration detection, and standardization. The HPTLC evaluation of halophytic species *S. fruticosa* generate validated method of classic fingerprints, which can be used as a reference point of flavonoid and phenolic compounds identification. As a source of phenol and flavonoid contents, it also exhibited a good antioxidant activity. This discovery shows that halophytes could be a good source of phenolic compounds with useful properties. This could lead to health products in the food and drug industries. Future

research should concentrate on the isolation of the predominant bands identified in the HPTLC fingerprint. Subsequent structural elucidation will facilitate the identification and characterization of the principal bioactive constituents.

ACKNOWLEDGEMENTS

We extend our heartfelt gratitude to the CSIR (Council of Scientific and Industrial Research) for providing the research fellowship. Authors also acknowledge the Hemchandracharya North Gujarat University, Patan for the analysis of HPTLC fingerprinting, FTIR and other lab facilities.

Conflict of interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

ABSTRACT

In this disquisition we have scrutinize about the traits of semin open sets in generalized topological spaces using Neutrosophic sets. Depending on the nature of semi open Neutrosophic sets over the generalized topological spaces, some of the features has been contemplated

Keywords: Neutrosophic sets, topological spaces, fuzzy set

INTRODUCTION

The idea of fuzzy set which plays a vital role in almost all sectors of mathematics. Belatedly C.L Chang brought out fuzzy topological space and after that several notions in general topology were extended and enhanced in fuzzy topological spaces .K.T Attansov published his idea of intuitionistic set and some research works came into the literature. The concept of neutrosophy and neutrosophic sets were putforth by Samarandache with his idea later on Salama and Albowi introduced neutrosophic crisp sets. In this write up we have discussed about some important features of μ_N Semi Open Sets.

Necessities:

Definition 2.1[13]: Let X be a non-empty fixed set. A Neutrosophic set [NS for short] A is an object having the form$A = \{\langle x, \mu_A(x), \sigma_A(x), \gamma_A(x)\rangle : x \in X\}$ where $\mu_A(x), \sigma_A(x)$ and $\gamma_A(x)$ which represents the degree of membership

function , the degree of indeterminacy and the degree of non-membership function respectively of each element $x \in X$ to the set A.

Remark 2.4.[13] Every intuitionistic fuzzy set A is a non empty set in X is obviously on Neutrosophic sets having the form $A = \{\langle \mu_A(x), 1 - \mu_A(x) + \sigma_A(x), \gamma_A(x)\rangle : x \in X\}$.Since our main purpose is to construct the tools for developing Neutrosophic Set and Neutrosophic topology , we must introduce the neutrosophic sets 0_N and 1_N in X as follows:
0_N may be defined as follows
$(0_1) 0_N = \{\langle x, 0,1,1\rangle : x \epsilon X$
1_N may be defined as follows
$(1_1) 1_N = \{\langle x, 1,0,0\rangle : x \epsilon X$

Definition 2.5: [13] Let $A = \{\langle \mu_A, \sigma_A, \gamma_A\rangle\}$ be a NS on X , then the complement of the set A [C(A) for short] may be defined $(C_1)\ C(A) = \{\langle x, \gamma_A(x), 1 - \sigma_A(x), \mu_A(x)\rangle : x \in X\}$

Definition 2.6: [13] Let X be a non-empty set and neutrosophic sets A and B in the form $A = \{\langle x, \mu_A(x), \sigma_A(x), \gamma_A(x)\rangle : x \in X\}$ and B $= \{\langle x, \mu_B(x), \sigma_B(x), \gamma_B(x)\rangle : x \in X\}$.
$A \subseteq B$ may be defined as : $(A \subseteq B) \Leftrightarrow \mu_A(x) \leq \mu_B(x), \sigma_A(x) \geq \sigma_B(x), \gamma_A(x) \geq \gamma_B(x)\ \forall x \in X$

Proposition 2.7: [13] For any neutrosophic set A, the following conditions holds:
$0_N \subseteq$ A,
$A \subseteq 1_N$

Definition 2.8: [13] Let X be a non empty set and $A = \{\langle x, \mu_A(x), \sigma_A(x), \gamma_A(x)\rangle : x \in X\}$
$B = \{\langle x, \mu_B(x), \sigma_B(x), \gamma_B(x)\rangle : x \in X\}$ are NSs. Then $A \cap B$ may be defined as :
$(I_1)\ A \cap B = \langle x, \mu_A(x) \wedge \mu_B(x), \sigma_A(x) \vee \sigma_B(x), \gamma_A(x) \vee \gamma_B(x)\rangle$
$A \cup B$ may be defined as :
$(I_1)\ A \cup B = \langle x, \mu_A(x) \vee \mu_B(x), \sigma_A(x) \wedge \sigma_B(x), \gamma_A(x) \wedge \gamma_B(x)\rangle$

Definition 2.9: [12] A μ_N topology is a non - empty set X is a family of neutrosophic subsets in X satisfying the following axioms:
$(\mu_{N_1}) 0_N \in \mu_N$ and (μ_{N_2}) The union of any number of neutrosophic sets in μ_N belongs to μ_N.

Remark 2.10 [12] The elements of μ_N are μ_N open sets and their complement is called μ_N closed sets.

Definition 2.11: [12] The μ_NClosure of A is the intersection of all μ_N closed sets containing A.
Definition 2.12: [12] The μ_N Interior of A is the union of all μ_N open sets contained in A

Semi open sets in μ_N topological space
Definition 3.1: A neutrosophic set in a μ_N topological space is said to be μ_N Semi Open if $A \subseteq \mu_N Cl(\mu_N Int\ A)$.
Theorem 3.2: Every μ_N- open set is μ_NSemi Open **.**
Proof: Let U be a μ_N- open set in X which implies us that $\mu_N Int\ U = U$.Hence, we get $U \subseteq \mu_N\ Cl(U) \Rightarrow U = \mu_N Cl(\mu_N Int\ U)$ .Thus, $U \subseteq \mu_N\ Cl(\mu_N Int\ U)$.Hence , it is μ_NSemi Open.

Remark 3.3: Converse of the theorem need not be true. It is furnished by the following example. Let $X = \{a\}$; $\mu_N = \{0_N, A, B, C\}$ where $A = \langle 0.3,0.3,0.5\rangle, B = \langle 0.1,0.2,0.3\rangle, C = \langle 0.3,0.2,0.3\rangle, D = \langle 0.3,0.6,0.2\rangle, E = \langle 0.3,0.8,0.5\rangle$.Here, The μ_NSemi Open sets are $\{\varphi, A, B, C, E\}$ which tell us that E is μ_NSemi Open but it is not $\mu_N$open set .

Theorem 3.4: Let A be $\mu_N\ So$ set in $\mu_N TS$ and suppose $A \subseteq B \subseteq \mu_N Cl$.Then B is a $\mu_N\ So$ set.
Proof: There exists a $\mu_N$open set $\mu_N O$ such that $\mu_N O \subseteq A \subseteq \mu_N Cl(\mu_N O)$.Then $\mu_N O \subseteq B$ whereas $\mu_N Cl(A)) \subseteq \mu_N Cl(\mu_N O)$and thus$\subseteq \mu_N Cl(\mu_N O$).Therefore

$\mu_N O \subseteq B \subseteq \mu_N Cl(\mu_N O)$ and B is μ_N *Semi* open set.

Theorem 3.5: If $A, B \in \mu_N So$ then $A \cup B \in \mu_N So$.
Proof: Suppose $A, B \in \mu_N So$ then $A \subseteq \mu_N Cl(\mu_N IntA)$ and $B \subseteq \mu_N Cl(\mu_N IntB)$.
Now $\mu_N Cl(\mu_N Int(A \cup B)) \supseteq \mu_N Cl\big((\mu_N \text{Int A}) \cup (\mu_N IntB)\big) \supseteq \mu_N Cl(\mu_N \text{Int A}) \cup \mu_N Cl(\mu_N \text{Int B}) \supseteq A \cup B \Rightarrow A \cup B \in \mu_N So$.

Corollary 3.6: If $\{A\}_{i=1\ to\ \infty} \in \mu_N So$ then $\cup_{i=1}^{\infty} A_i \in \mu_N Semi$ open set.

Remark 3.7: If$A, B \in \mu_N So$then $A \cap B \notin \mu_N So$

Theorem 3.8: Every μ_N closed set is μ_NSemi closed.
Proof: Suppose $A \subseteq X$ is μ_N closed then $\mu_N Cl(A) = A$. Now, $\mu_N Int\big(\mu_N Cl(A)\big) \subseteq \mu_N Int(A) \subseteq A \Rightarrow A \subseteq X$ is μ_NSemi closed.

Remark 3.9: The reversal statement of theorem 3.8 is not valid.

Example: 3.10 Let $= \{a, b\}, Y = \{u, v\}$ *and* $(X, \tau), (Y, \sigma)$*be the* $\mu_N TS$ *where* $\tau = \{A, B, C, D, 0_N\}$,
$A = \langle 0.7,0.3,0.8\rangle\langle 0.5,0.8,0.9\rangle$, $B = \langle 0.4,0.9,0.9\rangle\langle 0.3,0.9,0.9\rangle$,
$C = \langle 0.5,0.8,0.7\rangle\langle 0.5,0.8,0.8\rangle$, $D = \langle 0.5,0.8,0.8\rangle\langle 0.5,0.8,0.7\rangle$, $E = \langle 0.3,0.9,0.9\rangle\langle 0.4,0.9,0.9\rangle$.
Here,$A^c, B^c, C^c, D^c, E^c, 0_N$ are $\mu_N$semi closed sets of (X, τ).Particularly E *is* μ_N *Semi* closed set of (X, τ) but it is not μ_N closed in (X, τ).

Theorem 3.11: If$A, B \in \mu_N$semi closed sets then $A \cap B \in \mu_N$semi closed sets.
Proof: Suppose $A, B$are $\mu_N$semi closed sets then $\mu_N Int(\mu_N Cl\ A) \subseteq A$&$\mu_N Int(\mu_N Cl\ B) \subseteq$B. Now $\mu_N Int(\mu_N Cl\ (A \cap B)) \subseteq \mu_N Int((\mu_N Cl\ (A) \cap \mu_N Cl\ (B)) \subseteq \mu_N Int\big(\mu_N Cl\ (A)\big) \cap \mu_N Int\big(\mu_N Cl\ (B)\big) \subseteq A \cap B \Rightarrow A \cap B$ *is* $\mu_N$semi closed.

Definition 3.12: Let (X, μ_N) be a $\mu_N TS$ and $A = \{\langle x, \mu_A(x), \sigma_A(x), \gamma_A(x)\rangle$ be a neutrosophic set in X. Then μ_N *Semi* Interior is the union of all μ_NSemi open sets contained in A.It is denoted by $\mu_N S\ Int$.

Definition 3.13: Let (X, μ_N) be a $\mu_N TS$ and $A = \{\langle x, \mu_A(x), \sigma_A(x), \gamma_A(x)\rangle$ be a neutrosophic set in X. Then μ_N *Semi* Closure is the intersection of all $\mu_N$semi closed sets containing A.It is denoted by $\mu_N S\ Cl$.

Note 3.14:
- $\mu_N S\ Int$ is the largest μ_N Semi open sets contained in A.
- $\mu_N S\ Cl$ is the smallest $\mu_N$semi closed sets containing$A$.

Remark 3.15 :
- $\mu_N S\ Cl\ (1_N) = 1_N$
- $\mu_N S\ Int(0_N) = 0_N$

Remark 3.16:
(i) $\mu_N S\ Cl(0_N) \neq 0_N$ since $\mu_N S\ Cl$is the intersection of all $\mu_N$semi closed sets.
$(ii)\mu_N S\ Int\ (1_N) \neq 1_N$ since $\mu_N S\ Int$ is the union of all μ_NSemi open sets.

Theorem3.17: Contraction Property of μ_NSemi Interior states that $\mu_N S\ Int \subseteq A$.
Proof: Since μ_NInt(A) is the union of $\mu_N$semi open sets contained in A .Hence $\mu_N S\ Int \subseteq A$.

Theorem 3.18: Monotonicity of μ_N *Semi Interior*. $(i.e) A \subseteq B \Rightarrow \mu_N SInt\ A \subseteq \mu_N SInt\ B$
Proof: Suppose $A \subseteq B$.By previous theorem 4.9,$\mu_N SInt\ A \subseteq A$. Hence $\mu_N SInt\ A \subseteq B$. But μ_N Int(B) is the largest $\mu_N$open sets contained in B. Hence, $\mu_N\ Int\ A \subseteq \mu_N\ Int\ B$.

Theorem 3.19: Idempotency of μ_NInterior states that $\mu_N\ Int(\mu_N\ Int\ A) = \mu_N\ Int\ A$
Proof: By theorem 4.9 we get: $\mu_N SInt\ A \subseteq A \Rightarrow \mu_N S\ Int(\mu_N\ S\ Int\ A) \subseteq \mu_N\ S\ Int\ A$. Let $B = \mu_N S\ Int\ A$. Let$x \notin \mu_N\ S\ Int\ B \Rightarrow x \notin \cup\ G\ ; G$ is $\mu_N$open sets contained in B.By theorem 4.9 $x \notin G\ ; for\ all\ \mu_N$ semi open sets contained in $A. \Rightarrow\ \mu_N\ SInt\ A \subseteq \mu_N\ SInt(\mu_N\ SInt\ A)$.

Theorem 3.20: $\mu_N\ SInt(A \cap B) \subseteq \mu_N S\ Int(A) \cap \mu_N S\ Int\ B$
Proof: We have $A \cap B \subseteq A \Rightarrow\ \mu_N S\ Int(A \cap B) \subseteq\ \mu_N SInt\ A$ and $A \cap B \subseteq B \Rightarrow\ \mu_N\ SInt(A \cap B) \subseteq\ \mu_N S\ Int\ B$. Thus we get $\mu_N S\ Int(A \cap B) \subseteq \mu_N\ SInt(A) \cap \mu_N\ S\ Int\ B$.

Example 3.21: Let $X = \{a, b\}, \mu_N = \{0_N, \rho, \varrho, \sigma\}$ where $\rho = \{\langle 0.2,0.4,0.6\rangle\langle 0.1,0.2,0.3\rangle\}, \varrho = \{\langle 0.6,0.8,0.5\rangle\langle 0.3,0.2,0.5\rangle\}, \sigma = \{\langle 0.6,0.4,0.5\rangle\langle 0.3,0.2,0.3\rangle\}$ .Here$A \cap B = \{\langle 0.2,0.8,0.6\rangle\langle 0.1,0.2,0.5\rangle\}$. $\mu_N SInt(\rho \cap \varrho)$=$\{\langle 0,1,1\rangle\langle 0,1,1\rangle\}\mu_N S\ Int(\rho) = \{\langle 0.2,0.4,0.6\rangle\langle 0.1,0.2,0.3\rangle\}\mu_N SInt\ \varrho = \langle 0.6,0.8,0.5\rangle\langle 0.3,0.2,0.5\rangle$ Then $\mu_N S\ Int(\rho) \cap \mu_N S\ Int\ \varrho = \langle 0.2,0.8,0.6\rangle\langle 0.1,0.2,0.5\rangle$ Hence $\mu_N\ Int(\rho) \cap \mu_N\ Int\ \varrho \supset\ \mu_N\ Int(\rho \cap \varrho)$

Example3.22: Let $X = \{a\}, \mu_N = \{0_N, \theta, \vartheta, \kappa\}$where $\theta = \{\langle 0.3,0.3,0.5\rangle\}, \vartheta = \{0.1,0.2,0.3\}, \kappa = \{\langle 0.3,0.2,0.3\rangle\}\psi = \{\langle 0.3,0.6,0.2\rangle\}, \omega = \{\langle 0.3,0.8,0.5\rangle\}$.Here $\mu_N S\ Int(\psi) = \{\langle 0,1,1\rangle\}$ and $\mu_N S\ Int(\omega) = \{\langle 0,1,1\rangle\}\mu_N SInt(\theta \cap \vartheta) = \{\langle 0,1,1\rangle\}$. Hence $\mu_N S\ Int(A) \cap \mu_N S\ Int\ B =\ \mu_N S\ Int\ (A \cap B)$.

Theorem 3.23 : Enhancing Property of $\mu_N S$ closure property states that$A \subseteq \mu_N SCl(A)$
Proof: Since $\mu_N SCl$ is the intersection of μ_N semi closed sets containing$A$. Hence $A \subseteq \mu_N S\ Cl(A)$.

Theorem 4.3: $\mu_N\ S$ closure is monotone$(i.e\ ) A \subseteq B \Rightarrow \mu_N SCl\ A \subseteq\ \mu_N SCl\ B$
Proof: Suppose $A \subseteq B$.Let $x \notin \mu_N SCl\ B\ \Rightarrow x \notin \cap\ F\ ; F$ is μ_N semi closed super sets of $B$and $B \subseteq F\ . \Rightarrow x \notin F\ ;$ for some μ_N semi closed super sets of B,$B \subseteq F$.Since , $A \subseteq B\ ,\ x \notin \cap\ F\ ; F$ is μ_N semi closed super set of A. Then, $x \notin \mu_N S\ Cl(A)$. Hence the proof.

Theorem 4.4: $\mu_N S\ Closure$ is idempotent$(i.e) \mu_N S\ Cl(\mu_N\ Cl\ A) = \mu_N SCl\ A$.
Proof: By theorem 3.23 we get : $A \subseteq \mu_N S\ Cl(A)$ which implies us that $\mu_N SCl\ (A) \subseteq \mu_N SCl(\mu_N SCl(A))$. Let $B = \mu_N S\ Cl(A)$. Let $x \notin B \Rightarrow x \notin \cap\ F\ ; F$ is μ_N semi closed sets and $B \subseteq F\ \Rightarrow\ x \notin F\ ;$ for some μ_N semi closed sets of $F\ ,B \subseteq F$. Hence $\notin \mu_N\ SCl\ (F)\ ;$ for some μ_N semi closed sets of μ_NScl$(F), \mu_N$Scl$(B) \subseteq \mu_N$Scl(F)(by theorem 3.23). Hence $x \notin \mu_N\ SCl\ (B)$.Hence $\mu_N S\ Cl(\mu_N SCl\ A) = \mu_N SCl\ A$.

Properties of $\mu_N\ S$ closure and $\mu_N\ S$ Interior using Complements
Theorem 5.1: Let$(X,\ \mu_N\ )$ be a μ_N topological space then the following statements hold:
a) $\mu_N S\ Cl\big(C(A)\big) = C\big(\mu_N S\ Int\ (A)\big)$.
b) $\mu_N S\ Int\ \big(C(A)\big) = C\big(\mu_N SCl(A)\big)$.
c) $C(\mu_N S\ Cl(C(A)) =\ \mu_N S\ Int(A)$.
d) $C\big(\mu_N\ S\ Int\ (C(A))\big) =\ \mu_N\ S\ Cl(A)$.
Proof:

- Let $x \in\ \mu_N\ S\ Cl\ \big(C(A)\big)$ then $x \in \cap\ F, F$ is μ_N semi closed sets and $C(A) \subseteq F$ which yields that $x \in F$, for each μ_N semi closed sets F such that $C(A) \subseteq F$.Hence, we get $x \notin X - F$ for allμ_N semi open sets $X - F$ such that $X - F \subseteq A$. Then $x \notin\ \mu_N SInt(A)$. Hence $X \in C\big(\mu_N S\ Int\ (A)\big) \Rightarrow \mu_N SCl\big(C(A)\big) \subseteq C\big(\mu_N SInt\ (A)\big)$.
- Suppose $x \notin\ \mu_N S\ Cl\big(C(A)\big) \Rightarrow x \notin \cap\ F,\ F$ is μ_N semi closed sets and $C(A) \subseteq F$ which implies that $x \notin F$, for some $\mu_N$semi closed sets contains $C(A)$. Therefore,$x \in X - F$ for some μ_N semi open set $X - F$ such that $X - F \subseteq A$ and hence $x \in\ \mu_N SInt(A)$ which implies that $x \notin C(\ \mu_N SInt(A))$.Henceforth, $C(\ \mu_N S\ Int(A)) \subseteq \mu_N S\ Cl\big(C(A)\big)$.Hencewe get $\mu_N\ Cl\big(C(A)\big) = C\big(\mu_N\ Int\ (A)\big)$.
- The proof is similar to a.
- The proof follows by taking complement in a)
- The proof can be implemented by replacing A by $\overline{A}$ in a) .

ABSTRACT

Soil pollution is a critical environmental issue driven by the accumulation of hazardous substances, including heavy metals, pesticides, industrial waste, and plastics. This contamination compromises soil health, reducing fertility, biodiversity, and the ability to support plant and microbial life. Plastic pollution in soils originates from agricultural practices, industrial activities, and improper waste disposal, leading to macroplastics and microplastics. The increasing prevalence of plastic pollution has necessitated the exploration of innovative and sustainable biodegradation methods. Earthworms, known for their critical role in organic matter decomposition, have recently garnered attention for their potential in plastic biodegradation. This review synthesizes current knowledge on the mechanisms and efficacy of plastic degradation within the earthworm gut. It explores the structural modifications of plastics, including polyethene and polystyrene, facilitated by earthworm digestive processes and gut microbiota. Studies highlight the enzymatic and microbial contributions to depolymerization and mineralization, leading to reduced plastic particle size and alterations in chemical composition. The review also addresses the physiological impacts of plastic ingestion on earthworms, emphasizing the balance between degradation efficiency and ecological health. Furthermore, it evaluates the potential of leveraging earthworm-assisted biodegradation in waste management systems, emphasizing the need for optimizing conditions and minimizing associated risks. Earthworms as eco-friendly agents in mitigating plastic pollution. Researching the plastic biodegradation prospects paves the way to reduce plastic contamination in the environment.

Keywords: Earthworm, Microplastics, gut microbiota, biodegradation, environmental issues, pollution, Microbiome

INTRODUCTION

Environmental pollution continues to escalate as one of the most pressing global threats, driven predominantly by the uncontrolled accumulation of synthetic materials, industrial chemicals, heavy metals, pesticides, petroleum-based compounds, and most notably plastics. Over the last few decades, plastic pollution has shifted from being a marine-focused concern to a major terrestrial environmental challenge, largely due to the increasing use of plastic-based agricultural films, packaging materials, disposable plastics, and synthetic fibres in daily human activity (Ritchie & Roser, 2023). The persistence of plastics in the environment stems from their origins which make them resistant to natural degradation. It is the unwanted waste released into the air, water, land and oceans. Several factors like fine particulate matter (PM2.5), ozone, nitrogen or sulfur oxides, mercury, plastics and petroleum, pesticides, industrial chemicals, E-waste and radioactive materials are the main causative agents of pollution (Richard York, 2022). It has a huge impact on soil health by altering its physical and chemical composition. About 29% of Earth's crust is covered by land, of which 7.5 to 11% of land is covered by agricultural soil. Soils represent the foundation of terrestrial life, supporting plant growth, nutrient cycling, water storage, and regulating the biogeochemical turnover of carbon and nitrogen.

However, increasing evidence demonstrates that terrestrial ecosystems may hold higher concentrations of microplastics than aquatic environments due to agricultural inputs, sewage sludge application, landfills, tire wear particles, textile shedding, and atmospheric deposition (Guo *et al*., 2023). These microplastic particles accumulate within the upper soil layers, where essential biological processes are carried out by microorganisms and soil macrofauna, including earthworms. Their presence disrupts soil pH, porosity, aeration, water-holding capacity, and microbial metabolic activity, thereby affecting plant productivity and ecosystem functioning (Meng *et al*., 2023). Soil not only plays a vital role in food production but is also necessary for waste disposal and for storing water and nutrients. Plastic, as a versatile, inexpensive and resistant material for a huge variety of products has without a doubt revolutionized our daily lives (Cole, 2011). Plastic has also developed into a serious environmental problem However, even though benefits to society are enormous (Andrady, 2009). In particular, there has been increasing awareness of the environmental problems caused by the accumulation of microplastic in the marine environment (Li, 2016). Microplastic forms by degradation of larger plastic pieces, or is already industrially produced as material of this small size.

It is often considered to be material <5 mm, but particles frequently are in the range of several micrometers only (Cole, 2011). Microplastics are thus likely widespread and, irrespective of their origin, are expected to arrive at the soil surface. Since microplastic could have potential adverse effects on soil biota, only when this material is transported into the soil can it be expected to lead to broad exposure of soil biota to these particles.As these materials fragment physically and chemically, they generate microplastics (<5 mm) and even nanoplastics, which further disperse in soil ecosystems, affecting soil chemistry, faunal diversity, and microbial community structure (Papazlatani *et al*., 2024). The different size gives rise to properties quite different from that of environmental contamination by larger plastic pieces. First, due to their small size they can be ingested and they may thus accumulate along the food chain. Secondly, the particles possess a large surface area, and pollutants may be sorbed to these surfaces (Ivar, 2014).Even though using plastic has many general advantages, the buildup of plastic in ecosystems particularly microplastic is a growing environmental problem. Earthworms, often referred to as "ecosystem engineers," play an integral role in determining soil structure and quality. Through burrowing, feeding, and casting activities, they enhance aeration, nutrient mineralisation, and organic matter decomposition.

Importantly, they contribute to the formation of the drilospherea zone enriched with organic carbon and diverse microorganisms that support accelerated decomposition processes (Sanchez-Hernandez *et al*., 2020). Over the last decade, the earthworm gut has emerged as a unique anaerobic–microaerophilicmicroenvironment capable of supporting specialized microbial communities that influence the degradation of environmental pollutants, including microplastics. Recent studies have highlighted that earthworm ingest microplastic particles present in soil during

feeding. Once inside the digestive tract, these particles undergo physical and biochemical transformation through a combination of grinding action in the gizzard, enzymatic modification by earthworm secretions, and microbial degradation mediated by gut-resident bacteria (Munhoz *et al*., 2024). This renewed interest has positioned earthworms as potential bio-reactors capable of facilitating early-stage plastic fragmentation and promoting microbial colonization on plastic surfaces.

As concerns about microplastic accumulation increase globally, understanding the ecological role of earthworms in plastic degradation has become essential. Their gut microbiotacomprising bacteria, fungi, actinomycetes, and yeasthas shown significant potential in altering the structural and chemical properties of synthetic polymers. Recent studies conducted have identified several plastic-degrading genera within earthworm guts, such as *Pseudomonas*, *Bacillus*, *Streptomyces*, *Rhodococcus*, *Anoxybacillus*, *Enterobacter*, and *Mycobacterium*. These microorganisms produce oxidative, hydrolytic, and depolymerizing enzymes that initiate the breakdown of plastics like polyethylene (PE), polypropylene (PP), polystyrene (PS), and polyurethane (PU) (Carpena *et al*., 2024).Although the degradation may not be complete, these processes promote fragmentation, reduce polymer molecular weight, and improve microbial accessibility, contributing significantly to the early stages of biodegradation. This expanding field highlights the transformative potential of earthworm-associated microbiomes as natural agents in mitigating soil microplastic pollution.

LITERATURE REVIEWS

Plastic Pollution

One of the predominantly generated human wastes is plastic. Globally, approximately 368 million tonnes of plastic are produced by the entire population, with India contributing 20 million metric tonnes of this total (Babita, 2024). Plastics are synthetic organic polymers with high molecular mass, primarily made from hydrocarbons sourced from crude oil and natural gas. There are two main types of plastic: thermoplastics, which can be repeatedly reshaped when heated and thermosets, which cannot be remoulded once formed. While plastics are typically made from fossil fuels, there is a growing use of biomass, like maize and plant oils, in their production. (Rhodes, 2018).The primary composition of plastic is carbon, hydrogen, silicon, oxygen, chloride and nitrogen. The high molecular weight, complex three-dimensional structure and hydrophobic nature of plastics make them resistant to degradation. The distribution of microplastics in rivers across an urban-rural gradient, revealing higher concentrations in urban areas due to industrial activities and inadequate waste management. The first synthetic plastic, Bakelite, was produced in 1907, marking the beginning of the global plastics industry. However, rapid growth in global plastic production didn't happen until the 1950s.

Annual production of plastics has increased nearly 230-fold to 460 million tonnes in 2019. Even just in the last two decades, global plastic production has doubled. (Hannah Ritchie, 2023). They are in various applications, with over a third of global plastic production which is often not recycled and becomes waste. Microplastic (MP) contamination has become a significant environmental concern, impacting soil ecosystems across various land uses. Studies have demonstrated that MPs, originating from sources such as plastic mulching, wastewater irrigation, and atmospheric deposition, are prevalent in both arable and residential soils. These contaminants adversely affect soil physical properties by altering texture and porosity, chemical properties by influencing pH and nutrient availability, and biological properties by disrupting microbial communities and soil fauna development. Microplastics (<5 mm) originate from the breakdown of larger plastics or as by products of consumer products. These tiny particles enter the soil through sewage sludge, compost, plastic mulch, and atmospheric fallout. The pervasive nature of MP pollution necessitates urgent attention to mitigate its effects on soil health and ecosystem services (Monisha Mondol, 2024).

Earthworm: Soil Engineers

Earthworm farmers' friends greatly influence the soil health. It stabilizes the soil's organic carbon, making the soil suitable for the growth of microorganisms, enhances the activity of microorganisms by producing an energy-rich

mucus, also produce signal molecules that have a hormone-like effect on plant genes, can be classified based on their influence on the soil biome and microbial activity: epigeic earthworms are the ones which feed on litter from the soil surface, endogeic earthworms feed on soil minerals and partially decomposed matter, and anecic earthworms live in the subsoil and feed on litter. The intestinal or cutaneous mucus of the earthworm activates the functioning of the soil microbiome, hence maintaining a mutualistic relationship with the soil microbiota (Medina-Sauza *et al*., 2019).

The presence of earthworms in the soil results in the formation of the drilosphere, which acts as a hotspot of fauna diversity, microbial proliferation and extracellular enzyme production (Sanchez-Hernandez *et al*., 2020).In order to improve microbial diversity, aeration, and nutrient cycling, earthworms are essential soil ecosystem engineers. However, recent research indicates that microplastic contamination has been shown to have a significant effect on earthworm physiology and behaviour, including reduction in growth and reproduction: Earthworms exposed to microplastics exhibit decreased cocoon development, postponed reproduction, and subpar biomass growth; Gut inflammation and tissue damage: ingested microplastics lead to intestinal abrasions and oxidative stress; (Victor Carpena-Istan *et al*., 2024) (Ke Meng *et al*., 2023). Earthworms are excellent model organisms for ecotoxicology studies due to their physiological activity and metabolic state, which facilitate the detection of soil contamination. By international standards, Lumbricus terrestris is a great model organism for ecotoxicology research because of its high activity and reproduction rate, short life cycle, sensitivity to pollutants, and ability to excavate channels up to several meters deep.

Role of Earthworms in Plastic Degradation

Earthworm-soil ecosystem engineers, play a pivotal role in nutrient cycling, phosphorus plant absorption, nitrogen mineralisation, and litter decomposition, deeply affecting soil health. Earthworms make the soil suitable for the growth of microorganisms and stabilize the soil's organic carbon. Earthworms express their effectiveness by producing energy-rich mucous curial for microorganism activation and also produce certain signal molecules that have a hormone-like effect on plant gene expression (Sauza, *et al*., 2019). Based on the earthworms influence on the soil biome and microbial activity Earthworms are classified as Epigeic earthworms which feed on litter from the soil surface, Endogeic earthworms which feed on soil minerals and partially decomposed matter and Anecic earthworms that live in the subsoil and feed on litter. Earthworms lead a mutualistic relationship with the soil microbiota, the intestinal or cutaneous mucus of the earthworm activates the functioning of the soil microbiome (Sauza, *et al*., 2019). The presence of earthworms in the soil results in the formation of Driloshpere which acts as a hotspot of fauna diversity, microbial proliferation and extracellular enzyme production (Hernandez, Capowiez, & Ro, 2020). Microorganisms thrive in extreme temperatures and are capable of deleting convectional or non-convection plastics and utilising the by-products as their primary carbon source. The gut microbiome of earthworms is rich with aerobic, anaerobic and facultative anaerobic microorganisms that play an essential role in the degradation of microplastic polymers by changing their chemical properties, surface morphology and density.(Babita, 2024). Earthworms are the major contributors to the soil microbiome community as their gut microbiome is essential for nutrient cycling, immunity and physiology (Papazlatani *et al*., 2024).

Role of Earthworms in bioremediation

The anthropogenic soil pollution caused by industrial waste disposal and agricultural pesticides imposes a huge impact on the soil microbiome and earthworm gut microbiomes (Papazlatani *et al*., 2024).Earthworms play a significant role in bioremediation by physically fixing and aerating the soil, by their feeding and burrowing activities earthworms enhance nitrogen mineralization, litter decomposition and water infiltration in soil. Earthworms form a mutualistic relationship with the soil microbiota. Their cutaneous or intestinal mucus secretion in the drilosphere is essential for the improved functioning and activity of the microorganisms in the soil. Earthworms improve soil quality by ingesting soil microbiota such as fungi and stimulating soil microbes hence improving certain bacterial taxa essential for degradation (Sauza, *et al*., 2019). The epithelium wall of earthworm gut secrets several exoenzymes such as cellulase, proteases, lipases, esterases, chitinase and phosphatase, which are essential for the degradation of the varied variety of microplastics present in the soil(Babita, 2024).

Earthworm Gut Microbiome

The gut microbiome of earthworms represents a highly diverse and metabolically active consortium comprising aerobic, anaerobic, and facultative anaerobic microorganisms that play a pivotal role in the biodegradation of microplastic polymers. These microbial communities facilitate the transformation of plastic materials by modifying their chemical composition, surface morphology, and physical properties such as density (Babita, 2024; Habib *et al*., 2020). The earthworm gut environment provides optimal conditions for the proliferation of plastic-degrading microorganisms belonging to the genera *Pseudomonas*, *Rhodococcus*, *Anoxybacillus*, *Mycobacterium*, *Streptomyces*, *Bacillus*, and *Sporosarcina*. These taxa employ a combination of enzymatic hydrolysis, oxidative depolymerization, biofilm formation, and metabolic assimilation to degrade a wide range of plastic polymers. Specific bacterial species, including *Pseudomonas putida*, *Rhodococcus jostii*, and *Anoxybacillus flavithermus*, have been extensively documented for their ability to catalyse the depolymerisation of plastic substrates through oxidative and hydrolytic enzymatic pathways. The degradation process involves the cleavage of high-molecular-weight polymers into lower-molecular-weight oligomers and monomers, which are subsequently utilised as carbon and energy sources.

Moreover, the secretion of bioemulsifying compounds by the host and associated microbiota enhances polymer surface accessibility and promotes enzymatic activity, thereby accelerating the depolymerization process.Empirical evidence supports the involvement of a wide range of microbial enzymes in the degradation of various synthetic polymers. *Anoxybacillus flavithermus* secretes α-amylase capable of acting on polyethylene microplastics (Sadin Ozdemir *et al*., 2022), while *Cladosporium sp.* produces oxidative enzymes such as laccase, manganese peroxidase, and lignin peroxidase that facilitate the breakdown of low-density polyethylene (Sathiyabama *et al*., 2024). Similarly, *Pseudomonas aeruginosa* synthesizes hydrolase and esterase enzymes that enable the biodegradation of polyethylene and polypropylene (Victor Carpena-Istan et al., 2024). The yeast *Candida rugosa* utilizes lipase to hydrolyze polyurethane polymers (Rajeeb Gautam et al., 2007), whereas *Sphingomonas* species employ oxygenases to oxidatively cleave polystyrene and polyvinyl chloride chains. Furthermore, white rot fungi possess an extensive repertoire of extracellular ligninolytic enzymes, including laccases and peroxidases, as well as organic acids and redox mediators, which collectively contribute to the degradation of polyethylene, polyethylene terephthalate analogues, polyvinyl chloride, and styrenic compounds (Paula *et al*., 2023).

The gut microbiota of earthworms constitutes a highly diverse and metabolically dynamic consortium that plays an essential role in soil detoxification and polymer degradation. Earthworm guts provide an enclosed, moist, neutral-to-slightly alkaline environment with low oxygen levels, conditions that selectively enrich bacteria capable of hydrolyzing complex substrates (Mathipi *et al*., 2020). The gut microbiome includes aerobic and anaerobic bacteria, filamentous fungi, yeasts, and actinomycetes that contribute to both nutrient turnover and xenobiotic degradation. The earthworm gut is rich in antioxidants like catalase, phosphatase, protease, and polyphenol oxidase, which induce oxidative stress in earthworms upon exposure to plastics and microplastics. Ingestion of plastics by the earthworms spikes the Reactive oxygen species (ROS), hence altering the physiological pathway (Babita, 2024). Studies have revealed that earthworm guts consistently contain plastic-degrading microbes belonging to the phyla *Proteobacteria, Actinobacteria, Firmicutes,* and *Bacteroidota.* Among these, the most frequently reported genera include: *Pseudomonas, Bacillus, Streptomyces, Rhodococcus, Sphingomonas, Anoxybacillus, Mycobacterium, and Sporosarcina.* These microorganisms attach to plastic surfaces, form biofilms, secrete extracellular enzymes, and induce oxidative or hydrolytic cleavage of polymer chains (Babita, 2024). The gut microbiome also enhances plastic fragmentation by reducing polymer crystallinity, increasing pores on polymer surfaces, and decreasing polymer molecular weight.
In addition to bacteria, earthworm guts harbour fungi such as *Cladosporium, Aspergillus,* and *Penicillium*, which produce ligninolytic and peroxidase enzymes associated with polyethylene and polystyrene degradation (Sathiyabama *et al*., 2024).

Mechanism of Plastic Degradation

Plastics have turned out to be an inseparable part of our day-to-day life. Being made up of inorganic and organic raw materials, extracted from oil, coal and natural gas, their stability and durability continuously improves, ultimately making them resistant to many natural influences. Degradation of plastic in the environment can be either physical

(structural) or chemical (molecular) changes, these changes in plastics are caused due to temperature, pH, climate and microbial action on the plastic. This degradation can occur mainly in four stages: Biodeterioration by physical and chemical factors of the environment, bio fragmentation or depolymerization by microbial enzymes, assimilation of the monomers (eg. TCA) and mineralization by conversion into CO2, H2O, CH4 and biomass (Ali Chamas *et al*., 2020). The earthworm digestive tract significantly contributes to plastic degradation within contaminated soils. Mechanical grinding in the gizzard enhances surface area, while gut microbes attach to plastic surfaces and secrete extracellular enzymes that accelerate depolymerization (Carpena-Istan *et al*., 2024).

Recent findings highlight four major steps through which earthworms and their gut microbiota influence microplastic degradation:

- Mechanical Disintegration in the Gizzard - Microplastics are physically broken down through grinding and abrasion, increasing surface area for microbial action (Meng *et al*., 2023).
- Microbial Adhesion & Biofilm Formation - Gut microbes adhere to the plastic surface, form biofilms, and secrete biosurfactants that soften polymer surfaces (Carpena-Istan *et al*., 2024).
- Enzymatic Depolymerization - Microbial enzymes cleave C–C or C–O linkages in polymer chains. Key enzymes: Laccases, Peroxidases, Esterases, Lipases, Cutinases, Oxygenases.
- Mineralisation - Degraded monomers enter metabolic pathways and are transformed into CO_2, H_2O, and biomass (Papazlatani *et al*., 2024).

CONCLUSION

The biodegradation of plastics by earthworm gut microbiomes is a challenge to undo the harmful effects of plastics on both terrestrial and aquatic ecosystems. Earthworms, who are considered the farmer's friend, are a very important soil organism that helps in providing a unique environment for the colonization of a wide variety of microorganisms. This vast diversity of microorganisms present in their guts is found to be capable of depolymerizing plastics and this helps emphasize the potential of naturally improving the environmental impact of microplastics. Their digestive processes and gut microbiota help in the breakdown of synthetic polymers into smaller fragments that are less harmful by-products, facilitating further microbial degradation and reduced accumulation of microplastics in soil and water. While the ability of certain microbes that degrade plastics is promising, there are also concerns for these microorganisms to produce by-products that may still be harmful to the environment, such as toxic monomers or nanoplastic fragments. Furthermore, the degradation of plastics in the gut might not always be complete, raising questions about the long-term persistence of microplastic particles within the soil and their possible release into the ecosystem. As earthworms are natural agents involved in plastic degradation, it is essential to understand the detailed mechanisms of plastic degradation by earthworms, as well as the long-term impact of plastic contamination on the environment. Future research should focus on metagenomics, microbial engineering, and pilot-scale biodegradation using earthworm-microbe consortia.

ABSTRACT

In this Paper, the patients having the symptoms of fever like Swine flu and Dengue has been collected. The awareness for the Swine flu and Dengue fever symptoms with in the field of medical diagnosis will be created by using fuzzy soft matrix. Here the fuzzy soft matrix is applied in Decision making problems. The proposed algorithms are used to finding fever affected patients.

Keywords: Fuzzy soft set, fuzzy soft matrix (FSM), fuzzy soft composition method.

INTRODUCTION

Let $U = \{u_1, u_2, .. , u_m\}$, $E = \{e_1, e_2, \ldots, e_n\}$, then R_A can be presented by a table as in the following form
If $a_{ij} = \chi_{R_A}(u_i, e_j)$, we can define a matrix

$$[a_{ij}]_{m\times n} = \begin{bmatrix} a_{11} & a_{12} & \ldots & a_{1n} \\ a_{21} & a_{22} & \ldots & a_{2n} \\ \ldots & \ldots & \ldots & \ldots \\ a_{m1} & a_{m2} & \ldots & a_{mn} \end{bmatrix}$$

Which is called a Soft matrix of order m×n corresponding to the soft set (F_A, E) over U.

A soft set *(FA, E)* is uniquely characterized by the matrix $[a_{ij}]_{m\times n}$. Therefore we shall identify any soft set with its soft matrix and use these two concepts as interchangeable.

Definition 2 (Fuzzy Soft Matrix)

Let *(FA, E)* be a fuzzy soft set over U. Then a subset of $U \times E$ is uniquely defined by $R_A = \{(u,e): e \in A, u \in F_A(e)\}$ This is called a relation form of (FA, E). Now the **Characteristic function** of R_A is written by,

$$\chi_{R_A} : U \times E \rightarrow [0,1] \; such\; that\; \chi_{R_A}(u,e) = \mu(u,e)$$

[Where $\mu(u,e)$ is the membership value of the object *u* associated with the parameter *e*.] Now if the set of universe *U* = {$u_1, u_2, \ldots, u_m$} and the set of parameters *E* = {$e_1, e_2, \ldots..,e_n$}, then R_A can be presented by a table as in the following form

If $a_{ij} = \chi_{R_A}(u_i, e_j)$, we can define a matrix

$$[a_{ij}]_{m\times n} = \begin{bmatrix} a_{11} & a_{12} & \ldots & a_{1n} \\ a_{21} & a_{22} & \ldots & a_{2n} \\ \ldots & \ldots & \ldots & \ldots \\ a_{m1} & a_{m2} & \ldots & a_{mn} \end{bmatrix}$$

Which is called a Fuzzy Soft matrix (FSM) of order m × n corresponding to the soft set *(FA, E)* over *U*. A Fuzzy soft set *(FA, E)* is uniquely characterized by the matrix $[a_{ij}]_{m\times n}$. Therefore we shall identify any Fuzzy soft set with its Fuzzy soft matrix and use these two concepts as interchangeable.

Definition 4.1.3 (Complement of fuzzy soft matrices)

Let $\tilde{A} = [(\overset{A}{a_{ij}}, 0)] \in FSM_{m\times n}$ where $\overset{A}{a_{ij}} = (\overset{A}{\mu_{ij}}, \overset{A}{\gamma_{ij}})$ according to the definition in *[13]*, the representation of the complement of the fuzzy matrix $\tilde{A}$ which is denoted $\tilde{A}`$ and $\tilde{A}`$ is called fuzzy soft complement matrix if $\tilde{A}` = [(1, \overset{A}{a_{ij}})]_{m\times n}$ for all $\overset{A}{a_{ij}} \in [0, 1]$. Then the matrix obtained from so called membership value would be the following $\tilde{A}` = [\overset{A}{a_{ij}}] = [(1 - \overset{A}{a_{ij}})]$ for all *i* and *j*.

Definition 4 (Product of fuzzy soft matrices)

Let $\tilde{A}` = [\overset{A}{a_{ij}}]_{m\times n}$, $\overset{A}{a_{ij}} = (\overset{A}{\mu_{ij}}, \overset{A}{\gamma_{ij}})$; where $\overset{A}{\mu_{ij}}$ and $\overset{A}{\gamma_{ij}}$ represent the fuzzy membership function and fuzzy reference function u_i, so that $\delta_{ij}\tilde{A} = \overset{A}{\mu_{ij}} - \overset{A}{\gamma_{ij}}$ gives the fuzzy membership value u_i. Also let $\tilde{B} = [\overset{B}{b_{jk}}]_{n\times p}$, $\overset{B}{b_{jk}} = (\overset{B}{\mu_{jk}}, \overset{B}{\gamma_{jk}})$; where $\overset{B}{\mu_{jk}}$ and $\overset{B}{\gamma_{jk}}$ represent the fuzzy membership function and fuzzy reference function of u_i. We now define $\tilde{A}.\tilde{B}$, the product of $\tilde{A}$ and $\tilde{B}$ as $\tilde{A}.\tilde{B} = [\overset{\tilde{AB}}{d_{ik}}]_{m\times p} = [\max\min(\overset{A}{\mu_{ij}}, \overset{B}{\mu_{jk}}), \min\max(\overset{A}{\gamma_{ij}}, \overset{B}{\gamma_{jk}})]_{m\times p}, 1 \le i \le m,\ 1 \le k \le p$ for $j = 1,2,3,\ldots n$.

Definition 4 (Value Matrix)[4]

If A= $\lfloor a_{ij} \rfloor \in$ IFSM $_{m\times n}$, where $a_{ij} = (\mu_j(c_i), \vartheta_j(c_i))$, then the Value matrix of the intuitionistic Fuzzy Soft Matrix of A is V (A) = $[\mu_j - \vartheta_j]$ i = 1, 2,…, m and j = 1,2, ……,n.

Definition 5 (Score Matrix)[5]

If ψ= $\lfloor a_{ij} \rfloor \in$ IFSM , φ= $\lfloor b_{ij} \rfloor \in$ IFSM of $m\times n$, then the Score matrix ψ and φ as S(ψ, φ) = $\lfloor d_{ij} \rfloor \in$ IFSM $_{m\times n}$, where S(ψ, φ) = [V - W], V = $[\mu(A\psi B) - \upsilon(A\psi B)]$, W = $\left[\mu\left(A'\psi B'\right) - \upsilon\left(A'\psi B'\right)\right]$.

METHODOLOGY

In this section, we are put forwarding the problem which is based upon FSM in medical diagnosis.

Fuzzy Soft Matrices in Medical Diagnosis

Let us assume S is the set of Symptoms of fever like Swine – flu and Dengue, D is the side effects related to these symptoms and P is the set of patients showing the symptoms present in the set S. We construct a fuzzy soft set ($\tilde{F}_x$, D) over S. A relation matrix $\tilde{x}$ is obtained from the fuzzy soft set ($\tilde{F}_x$, D). We would name the matrix as symptoms disease matrix. Similarly is complement ($\tilde{F}_x$, D)` gives another relation matrix $\tilde{x}$` called non symptom diseases matrix. We call the matrices $\tilde{x}$ and $\tilde{x}$` as medical knowledge of fuzzy soft set. Further, we construct another fuzzy soft set ( $\tilde{F}_y$, S) over P. This fuzzy sift set gives the relation matrix $\tilde{y}$ called patient – symptom matrix and its complement ( $\tilde{F}_y$, S)` gives the relation matrix $\tilde{y}$` is called patient – non symptom matrix. Then using Definition of product of fuzzy soft matrix, we obtain two new relation matrices $\tilde{Q}_1 = \tilde{y}\,\tilde{x}$ and $\tilde{Q}_2 = \tilde{y}\,\tilde{x}$` called the patient non – symptom disease matrix and patient non – symptom non – disease matrix respectively. Now $\tilde{Q}_1 = \tilde{y}\,\tilde{x}$, $\tilde{Q}_2 = \tilde{y}\,\tilde{x}$`, $\tilde{Q}_3 = \tilde{y}$`$\tilde{x}$ and $\tilde{Q}_4 = \tilde{y}$`$\tilde{x}$` Using definition we may obtain corresponding membership value matrices MV($\tilde{Q}_1$), MV $\tilde{Q}_2$), MV($\tilde{Q}_3$), MV($\tilde{Q}_4$). We calculate the diagnosis score S $\tilde{Q}_1$ and S $\tilde{Q}_2$ for and against the disease respectively as

$S\tilde{Q}_1 = [\gamma(\tilde{Q}_1)_{ij}]_{m\times n}$, where $\gamma(\tilde{Q}_1)_{ij} = \delta(\tilde{Q}_1)_{ij} - \delta(\tilde{Q}_3)_{ij}$ and $S\tilde{Q}_2 = [\gamma(\tilde{Q}_2)_{ij}]_{m\times n}$, where $\gamma(\tilde{Q}_2)_{ij} = \delta(\tilde{Q}_2)_{ij} - \delta(\tilde{Q}_4)_{ij}$. Now if $\max_j (S\tilde{Q}_1(p_i, d_j) - S\tilde{Q}_2(p_i, d_j))$ occurs for exactly (p_i, d_k) only, then we would be in a position to accept that diagnosis hypothesis for patient p_i is the disease d_k . In case there is a tie, the method is repeated for the patient p_i by reassessing the symptoms

Algorithm

1. Choose the set of parameter.
2. Construct the fuzzy soft set ($\tilde{F}_x$, D) and compute
3. ($\tilde{F}_x$, D)`. Compute the corresponding fuzzy soft set matrices $\tilde{x}$ and $\tilde{x}$`.
4. Construct the fuzzy soft set ($\tilde{F}_y$, D) and compute
5. ($\tilde{F}_y$, D)`. Compute the corresponding fuzzy soft set matrices $\tilde{y}$ and $\tilde{y}$`.
6. Compute $\tilde{Q}_1 = \tilde{y}\ \tilde{x}$, $\tilde{Q}_2 = \tilde{y}\ \tilde{x}$`, $\tilde{Q}_3 = \tilde{y}$` $\tilde{x}$ and $\tilde{Q}_4 = \tilde{y}$` $\tilde{x}$`
7. Compute corresponding membership value of fuzzy soft matrix MV ($\tilde{Q}_1$), MV ($\tilde{Q}_2$), MV ($\tilde{Q}_3$) and MV($\tilde{Q}_4$).
8. Find $S_r = \max_j \{S_{\tilde{Q}_1}(p_i, d_j) - S_{\tilde{Q}_2}(p_i, d_j)\}$. We conclude the patient p_i is suffering the disease d_k.

Example

Suppose there are three patients p_1, p_2, p_3 are admitted in the hospital those who affected by the disease of Swine – Flu and Dengue. If the patients affecting from dengue and swine – flu fever with symptoms of nausea, body aches, fever, bleeding from the noses and gums, weakness respectively. Let, we consider the set S= {e_1, e_2, e_3} has universal set where e_1, e_2, e_3 represent the symptoms. Let the set D = {d_1, d_2} where d_1 and d_2 represents the parameter of the fever in the human body.

Step 1: Choose the parameter

Step 2: Let the fuzzy soft set ($\tilde{F}_x$, D) over S, where $\tilde{F}_x$ is a mapping $\tilde{F}_x$: D $\rightarrow$ $\tilde{F}$ (S), gives an approximate description of fuzzy soft medical knowledge of the symptoms appeared due to the fevers.

Let ($\tilde{F}_x$, D) = { $\tilde{F}_x(d_1)$ = {(e_1, 0.3, 0), (e_2, 0.6, 0), (e_3, 0.5, 0)}, $\tilde{F}_x(d_2)$ = {(e_1, 0.9, 0), (e_2, 0.7, 0), (e_3, 0.8, 0)} }

Complement of($\tilde{F}_x$, D) i.e). ($\tilde{F}_y$, D)` is given by

($\tilde{F}_y$, D)` = { $\tilde{F}_x$`(d_1) = {(e_1, 1, 0.3), (e_2, 1, 0.6), (e_3, 1, 0.5)}, $\tilde{F}_x$`(d_2) = {(e_1, 1, 0.9), (e_2, 1, 0.7), (e_3, 1, 0.8)} }

$$\tilde{x} = \begin{array}{c} \\ e1 \\ e2 \\ e3 \end{array} \begin{array}{c} \begin{array}{cc} d_1 & d_2 \end{array} \\ \begin{pmatrix} (0.3,0) & (0.9,0) \\ (0.6,0) & (0.7,0) \\ (0.5,0) & (0.8,0) \end{pmatrix} \end{array} \quad \text{and} \quad \tilde{x}` = \begin{array}{c} \\ e1 \\ e2 \\ e3 \end{array} \begin{array}{c} \begin{array}{cc} d_1 & d_2 \end{array} \\ \begin{pmatrix} (1,0.3) & (1,0.9) \\ (1,0.6) & (1,0.7) \\ (1,0.5) & (1,0.8) \end{pmatrix} \end{array}$$

Step 3

Take P = {p_1, p_2, p_3} as the universal where p_1, p_2 and p_3 are three patients respectively and S= {e_1, e_2, e_3} as the set of parameters, where e_1, e_2 and e_3 represent the symptoms of fevers. Let the fuzzy soft set ($\tilde{F}_y$, s) over S, where $\tilde{F}_y$ is a mapping $\tilde{F}_y$: s $\rightarrow$ $\tilde{F}$ (P), gives an approximate description of the patient symptoms in the hospital.

Let $(\tilde{F}_y, s) = \{\tilde{F}_y(e_1) = \{(p_1, 0.7, 0), (p_2, 0.8, 0), (p_3, 0.2, 0)$

$\tilde{F}_x(e_2) = \{(p_1, 0.8, 0), (p_2, 0.5, 0), (p_3, 0.6, 0)\}$,

$\tilde{F}_x(e_3) = \{(p_1, 0.3, 0), (p_2, 0.6, 0), (p_3, 0.7, 0)\}\}$

Complement of $(\tilde{F}_y, s)$ i.e). $(\tilde{F}_y, s)'$ is given by

$(\tilde{F}_y, s)' = \{\tilde{F}_y'(e_1) = \{(p_1, 1, 0.7), (p_2, 1, 0.8), (p_3, 1, 0.2)\}$,

$\tilde{F}_x'(e_2) = \{(p_1, 1, 0.8), (p_2, 1, 0.5), (p_3, 1, 0.6)\}$,

$\tilde{F}_x'(e_3) = \{(p_1, 1, 0.3), (p_2, 1, 0.6), (p_3, 1, 0.7)\}\}$

$$\tilde{y} = \begin{array}{c} \\ p1 \\ p2 \\ p3 \end{array} \begin{array}{c} e_1 \quad e_2 \quad e_3 \\ \begin{pmatrix} (0.7,0) & (0.8,0) & (0.3,0) \\ (0.8,0) & (0.5,0) & (0.6,0) \\ (0.2,0) & (0.6,0) & (0.7,0) \end{pmatrix} \end{array} \text{ and } \quad \tilde{y}' = \begin{array}{c} \\ p1 \\ p2 \\ p3 \end{array} \begin{array}{c} e_1 \quad e_2 \quad e_3 \\ \begin{pmatrix} (1,0.7) & (1,0.8) & (1,0.3) \\ (1,0.8) & (1,0.5) & (1,0.6) \\ (1,0.2) & (1,0.6) & (1,0.7) \end{pmatrix} \end{array}$$

Note this fuzzy soft set $(\tilde{F}_y, s)'$ by the matrix $\tilde{y}'$ is called the patient non – symptoms matrix

Step 4

$$\tilde{Q} = \tilde{y} \tilde{x} = \begin{array}{c} \\ e1 \\ e2 \\ e3 \end{array} \begin{array}{c} d_1 \quad d_2 \\ \begin{pmatrix} (0.6,0) & (0.7,0) \\ (0.5,0) & (0.8,0) \\ (0.6,0) & (0.7,0) \end{pmatrix} \end{array}$$

$$\tilde{Q}_2 = \tilde{y}\,' = \begin{array}{c} \\ e1 \\ e2 \\ e3 \end{array} \begin{array}{c} d_1 \quad d_2 \\ \begin{pmatrix} (0.8,0.3) & (0.8,0.7) \\ (0.8,0.3) & (0.8,0.7) \\ (0.7,0.3) & (0.7,0.7) \end{pmatrix} \end{array}$$

$$\tilde{Q}_3 = \tilde{x}' = \begin{array}{c} \\ p1 \\ p2 \\ p3 \end{array} \begin{array}{c} d_1 \quad d_2 \\ \begin{pmatrix} (0.6,0.3) & (0.9,0.3) \\ (0.6,0.5) & (0.9,0.5) \\ (0.6,0.2) & (0.9,0.2) \end{pmatrix} \end{array}$$

$$\tilde{Q}_4 = \,' = \begin{array}{c} \\ p1 \\ p2 \\ p3 \end{array} \begin{array}{c} d_1 \quad d_2 \\ \begin{pmatrix} (1,0.5) & (1,0.8) \\ (1,0.6) & (1,0.7) \\ (1,0.3) & (1,0.7) \end{pmatrix} \end{array}$$

Step 5

$$MV(\tilde{Q}_1) = \begin{array}{c} \\ p1 \\ p2 \\ p3 \\ \\ \end{array} \begin{array}{c} d_1 \quad d_2 \\ \begin{pmatrix} 0.6 & 0.7 \\ 0.5 & 0.8 \\ 0.6 & 0.7 \end{pmatrix} \\ d_1 \quad d_2 \end{array}$$

$$MV(\tilde{Q}_2) = \begin{matrix} p1 \\ p2 \\ p3 \end{matrix} \begin{pmatrix} 0.5 & 0.1 \\ 0.5 & 0.1 \\ 0.4 & 0.0 \end{pmatrix}$$

$$MV(\tilde{Q}_3) = \begin{matrix} & d_1 & d_2 \\ p1 \\ p2 \\ p3 \end{matrix} \begin{pmatrix} 0.3 & 0.1 \\ 0.4 & 0.4 \\ 0.2 & 0.0 \end{pmatrix}$$

$$MV(\tilde{Q}_4) = \begin{matrix} & d_1 & d_2 \\ p1 \\ p2 \\ p3 \end{matrix} \begin{pmatrix} 0.0 & -0.1 \\ 0.1 & -0.2 \\ -0.3 & -0.3 \end{pmatrix}$$

Step 6

The diagnosis score $S\tilde{Q}_1$ and $S\tilde{Q}_2$ for and against the diseases below

$$S\tilde{Q}_1 = \begin{matrix} & d_1 & d_2 \\ p1 \\ p2 \\ p3 \end{matrix} \begin{pmatrix} 0.3 & 0.1 \\ 0.4 & 0.4 \\ 0.2 & 0.0 \end{pmatrix} \text{ and } S\tilde{Q}_2 = \begin{matrix} & d_1 & d_2 \\ p1 \\ p2 \\ p3 \end{matrix} \begin{pmatrix} 0.0 & -0.1 \\ 0.1 & -0.2 \\ -0.3 & -0.3 \end{pmatrix}$$

Step 7

Table No: 4.4.1

S_{Q1}-S_{Q2}	d_1	d_2
p_1	0.3	0.2
p_2	0.3	0.6
p_3	0.5	0.3

CONCLUSION

Conclude that p_2 is suffering from more serious Swine – Flu from disease d_2 and p_1 and p_2 are suffering from disease d_1

ABSTRACT

Buildings account for nearly 40% of global energy demand, with residences contributing significantly. Courtyard houses, one of the most widespread and climate-responsive typologies, have proven environmental and socio-cultural benefits. In India, similarities exist in social uses of courtyards, though environmental performance varies across climates. North India's recent urbanization has led to the disappearance or alteration of courtyards in residences, raising questions about their contemporary relevance. This study explores the socio-cultural attitudes and perceptions driving these changes in the composite climate zone of India. Key questions include why courtyards are vanishing or transforming, whether they remain significant today, and their potential role in future design. Data were collected through interviews and questionnaires, refined using the Delphi technique, and analyzed with Spearman and Kruskal-Wallis H tests. Findings show residents value courtyards for multiple functions and acknowledge their environmental and cultural importance, yet ongoing urban pressures not lack of awareness drive their decline.

Keywords: Courtyard houses; Cultural Heritage; Composite Climate; Sustainable Habitat; Socio-environmental; Traditional architecture.

INTRODUCTION

In all human communities, housing is essential to socio-cultural and national development. It is regarded as a significant economic asset and is commonly accepted as the second most fundamental human requirement after food [1]. Hayakawa (1983)emphasized that "housing which does not provide space for contemplation will not allow for the growth and development of individuality," highlighting its role in both cultural and moral development. A house is therefore a representation of the social structure that built it, reflecting civilization, achievement, and human progress. Traditional building methods are often more energy-efficient than modern ones. According to Purushothaman and Thirumaran(2021), historic architectural techniques provide sustainable solutions for modern residential construction. However, contemporary practices have increasingly imposed Western styles, overlooking environmental and socio-cultural considerations. Among traditional design strategies, courtyards are one of the most important architectural elements, adaptable to residential, institutional, commercial, and industrial forms. Their typological study demonstrates their suitability for contemporary design, as they contribute to spatial order, microclimate modification, and social interaction [4], [5]. Courtyard forms, though typically square or rectangular, have evolved into U, L, T, or Y shapes in response to site constraints, orientation, and environmental factors [5], [6]. Despite their environmental potential, courtyards in modern housing are often reduced to aesthetic garden spaces, while their role in passive cooling, ventilation, and thermal comfort remains underutilized [7], [8], [9].

The demand for high-rise and high-density housing has led to the decline of courtyard houses, resulting in the loss of spaces that historically fulfilled social and environmental needs [10], [11]. Liberalization and globalization in India further accelerated this transition, as advanced technologies and materials displaced traditional courtyard-based designs [12]. Yet, many households still value courtyard dwellings for their natural light, thermal efficiency, privacy, and year-round usability [13]. Scholars recommend renewed attention to courtyard design in the Indian context. Patherya (2012) emphasized the need for guidelines to support climate-responsive courtyard buildings [14],while Verma and Bano (2023) suggested integrating sustainable features to enhance socio-environmental performance. They also recommended further research to understand socio-cultural roles of courtyards in various climatic zones of India. Although some studies have examined traditional courtyard houses in northeastern Uttar Pradesh, most remain limited to specific cities or small samples, failing to highlight interconnections across northern India. A broader regional study with a larger dataset is essential to capture this bigger picture [15].

MATERIALS AND METHODS

The traditional courtyard buildings are still in use in the present day, although the demands of their users are changing over time. This study aims to uncover the underlying attitudes, perceptions, and social and cultural factors that influence individuals' choices when it comes to building a courtyard house. The research questions targeted in the study are as follows:

- What are the key issues behind the disappearance and transformation of the courtyards in the Composite climate region of India?
- What will be the way forward for designing courtyard houses in the future?
- What are the challenges faced by courtyard house dwellers in retaining the courtyards in North India's residential buildings?

This study focuses on traditional courtyard houses in Lucknow, Barabanki, Ayodhya, Unnao, Sultanpur, and Varanasi, Uttar Pradesh, India. The objective was to assess the potential of courtyard houses in adapting to modern users' needs by analyzing their socio-cultural, environmental, and functional relevance.

Data Collection

A mixed-method approach was adopted, combining physical measurements with structured surveys and interviews. Courtyard dimensions were recorded using a measuring tape and laser meter, complementing data partly published

in [1]. To capture stakeholder perspectives, three different questionnaire sets were designed for distinct respondent categories.

Category 1: Professionals

Respondents included architects, civil engineers, urban planners, contractors, and builders.

Independent variables such as gender, age, profession, and years of experience were collected.

Category 2: Courtyard House Dwellers

Targeted current residents of courtyard houses selected for case studies. Variables included gender, age, family size, education level, income level, house age, house size, and number of floors.

Category 3: Former Courtyard Residents

Covered individuals who previously lived in courtyard houses and had since moved to non-courtyard dwellings, Demographic details included gender, age, education level, and income level.

Survey Design: The questionnaires were structured with closed-ended, ranked, multiple-choice, and open-ended questions. A five-point Likert scale was used to evaluate functional, socio-cultural, environmental, and behavioral performance, with responses ranging from "strongly disagree" to "strongly agree" or "very unlikely" to "very likely". To enhance accessibility, the surveys were available in both Hindi and English and were conducted online (Google Forms) and through face-to-face interviews.

Response Rate: Data collection took place between November 2023 and January 2024. For professionals, over 500 questionnaires were distributed across major cities in Uttar Pradesh, yielding 142 valid responses. From courtyard dwellers (Category 2), 162 responses were recorded, while 109 responses were received from former courtyard residents (Category 3).

Outcomes: The collected data provides insight into the demographic, socio-cultural, and environmental dimensions of courtyard houses. These results will serve as background material for future research aimed at preserving and adapting courtyard architecture to contemporary housing needs, while contributing to the conservation of cultural and environmental heritage in the region.

Refinement and Validation of Questionnaires

For refinement and validation of the questionnaire Delphi technique was employed. A separate questionnaire form was created for expert review, which contains all the questions asked in Category 1, 2, and 3 forms. The expert review form was divided into four sections, Section A - Covers the questions for the general demographic information of the participants, Section B - covers questions of Category 1 (Professionals), Section C- covers questions of Category 2 (House dwellers), and Section D – covers the question of category 3 (associated people who ones lived in the courtyard house, now moved to a non-courtyard house). The experts have to rate each question on a scale of (1-5), that how relevant the question is in achieving the objectives of the research. The questionnaire was shared with 33 experts from academics, practitioners, and researchers who were requested to assess the questionnaire's content using pertinent hypotheses to determine the validity of the data collected. The Cronbach's alpha method was employed to assess the questionnaire's reliability in this investigation. First, the overall variance and the variance of the scores for each subgroup of the questionnaire are computed. Next, the alpha coefficient's value was computed. The reliability of the questionnaire's factors is outstanding because Cronbach's alpha coefficient for each category of form was 0.923, 0.942, and 0.918, which is more significant than 0.7.

RESULTS AND DISCUSSION

The SPSS 29.0.2.0 software (IBM Corp., Armonk, NY, USA) was used to analyze the answers to the closed-ended questions. Descriptive statistics in the form of mean, standard deviation, and percentages were used to assess the demographic data. Since the data were measured on an ordinal scale, a Shapiro-Wilk test was used to determine if the attitude scale's items were normally distributed. The scale's items were not normally distributed, according to the

test results (Shapiro-Wilk normality test, P <.001). As a result, statistical tests including the Spearman, and Kruskal-Wallis H tests were employed along with nonparametric descriptors.

Demographic data of professionals

Out of 141 participants, there were 62.4% (n = 88) male and 37.6% (n = 53) female in the sample. Majorly 48.2% (n=68), and 29.8 % (n=42) belong to the age group of 26-30 years, and 31-35 years of the total participants. Based on the professional core, 69.5% (n=98)of participants were architects, 19.1% (n=27) were Urban Planners and 11.3% (n=16) were Civil engineers, of which 78% (n= 110) were in job or practice in the field and 22% (n=31) were academician. The median of 'Years of professional experience' was 2, which is the group '11-15 years', and a maximum of 45.4% (n=64) of the professionals had experienced 1-6 years.

Demographic courtyard house dwellers

A total of 161 responses were received from the house dwellers who were still living in the courtyard houses, out of which there were 58.4% (n = 94) males and 41.6% (n = 67) females in the sample. A maximum of 36.6% (n = 59) belongs to the age group 18-20 and a minimum of 8.7% (n = 14) of the participants belong to the age group 51-60. On education level, a maximum of 35.4% (n = 57) of the participants attended UG as the highest education level. There was an even distribution of the participants belonging to the different groups based on 'age of the houses', around 80 no. of the responses were received the dwellers living in courtyard houses of more than 50 years. The responses were received from the various cities of the state Uttar Pradesh (North India), of which a maximum of 37.0% (n=60) was received from Varanasi. There is 62.1% (n=100) of participants belong to Urban areas (Urban courtyard houses) and 37.9% (n=61) belong to Rural areas (Rural courtyard houses). Based on responses received on physical parameters of the house, the median of the 'area of the courtyard house' was 5, which was '2501-3000 sqft', and the median of 'no. of the floor of the houses' was 2, which was 'First floor', and the median of the occupancy of the house was 5, which was 'Above 5'.

Demographic data of associated people with courtyard houses

A total of 108 responses were received from the house dwellers who were still living in the courtyard houses, out of which there were 45.4% (n = 49) males and 54.6% (n = 59) females in the sample. A maximum of 41.7% (n = 45) belongs to the age group 18-20 and a minimum of 1.9% (n = 2) of the participants belong to the age group of above 60 years. On education level, a maximum of 46.3% (n = 50) of the participants attended UG as the highest education level. There is 63% (n=68) of participants belong to Urban areas and 37% (n=40) belong to Rural areas. The median of the 'occupancy of the house' was 5, which was 'Above 5'. The 38% (n=41) participants live in Detached type houses, 35.2% (n=38) of the participants live in Row-type houses, 16.7% (n=18) participants live in Semi-detached type houses, and 10.2% (n=11) participants live in Flat (apartment) type houses. On the question of familiarity about the courtyard house 70.4% (n=76) of participants said "often" and "Always", which shows a higher degree of familiarity with the typology. On the question of awareness about the courtyard house, 87.6% (n=92) of participants said "Agree" and "Strongly agree", which shows a higher degree of awareness of the typology.

Further several questions 'grouped and coded' were asked within the questionnaires of all three categories (professionals, house dwellers, and associated public) which were targeted at, environmental awareness, socio-cultural awareness, degree of disappearance, reasons for disappearance, degree of geometrical and physical transformations, opinion on transformations, flexibility, and future aspects of the courtyard houses. For the analysis of the data, the median of all questions 'grouped and coded' was calculated. The questions over issues of disappearance and transformation and environmental awareness were targeted commonly with all groups. The behavioral and socio cultural questions (experience) were targeted at the courtyard house dwellers as they were still using the courtyard house. The questions over the need for the courtyard houses were targeted to the house dwellers and the associated public as both groups were the users.

Hypothesis tests

What are the key issues behind the disappearance and transformation of the courtyards in the Composite climate region of India?

The hypothesis framed for the above research question is "The disappearance and transformation of courtyards in the Composite climate region of India is due to the lack of awareness and knowledge about the benefits of passive design strategies."

To test the hypothesis Environmental Awareness, Experience/Socio-cultural Awareness, and Degree of disappearance of the courtyard house dwellers and professionals were considered from the survey, the mean and Std. deviation values are given in Tables 1 and 3 given below. To evaluate the differences in opinion of the Degree of the disappearance of courtyards in the Composite climate region of India due to the lack of awareness and knowledge about the benefits of passive design strategies were tested by using the Kruskal Wallis Test.The test revealed a significant difference (Asymp Sig. = 0.001) in the Environmental Awareness and opinion of Degree of disappearance (Strongly Disagree, n=4, Mean rank =18.25; Disagree, n=7, Mean rank =45.57; Neutral, n=23, Mean Rank=82.76; Agree, n=84, Mean rank=83.82; Strongly Agree, n=43, Mean Rank=86.15).The test revealed a significant difference (Asymp Sig. = <0.001) in the Experience/ Socio-Cultural Awareness and Degree of Disappearance (Strongly Disagree, n=4, Mean rank =18.25; Disagree, n=7, Mean rank =45.57; Neutral, n=23, Mean Rank=82.76; Agree, n=84, Mean rank=83.82; Strongly Agree, n=43, Mean Rank=86.15) of the courtyard house dwellers.

It can be stated that there is substantial evidence that suggests that opinions on the extent of courtyard disappearance vary significantly in terms of environmental, and socio-cultural understanding. There is no link between awareness and the disappearance opinion of courtyard house dwellers. It can be said that the "The disappearance and transformation of courtyards in the Composite climate region of India is not due to the lack of awareness and knowledge about the benefits of passive design strategies." for the courtyard house dwellers. The mean and Std. deviation value for the professional's Environmental Awareness, Socio-Cultural Awareness, and Degree of disappearance are given in Table 3. To evaluate the differences in opinion of the Degree of the disappearance of courtyards in the Composite climate region of India due to the lack of awareness and knowledge about the benefits of passive design strategies were tested using the Kruskal Wallis Test. The test revealed insignificant differences (Asymp Sig. = 0.137) in the Environmental Awareness and opinions of Degree of Disappearance (Strongly Disagree, n=3, Mean rank =80.67; Disagree, n=12, Mean rank =77.83; Neutral, n=34, Mean Rank=61.76; Agree, n=60, Mean rank=67.87; Strongly Agree, n=32, Mean Rank=83.22). It can be said thatthere is not enough evidence to conclude that opinions on the extent of the courtyard's disappearance differ considerably in terms of environmental awareness. All these categories show the same distribution of environmental awareness. There is asignificant difference (Asymp Sig. = 0.048) in the Experience/ Socio-Cultural Awareness and opinions of Degree of Disappearance (Strongly Disagree, n=3, Mean rank =41.33; Disagree, n=12, Mean rank =67.21; Neutral, n=34, Mean rank=57.56; Agree, n=60, Mean rank=73.87; Strongly Agree, n=32, Mean rank=84.11) of the professionals. There is substantial evidence that suggests that opinions on the extent of courtyard disappearance vary significantly in terms of socio-cultural understanding. The distribution of socio-cultural awareness varies across these categories. The results of both courtyard house dwellers' and professionals' opinions on socio-cultural awareness vary significantly. While for environmental awareness the opinions of the courtyard house dwellers vary, on the other hand, opinions of the professionals show similar distribution.

What will be the way forward for designing courtyard houses in the future?

The framed hypothesis for the above research question is: "The future of courtyard houses lies in their ability to adapt to changing environmental conditions, technological advancements, and flexibility." To evaluate the Future aspects of courtyards in the Composite climate region of India in professional opiniondue to the environmental awareness and flexibility in physical parameters of courtyards was tested using the Kruskal Wallis Test, summary of the data and hypothesis test is shown in the Table 5 and 6. The test revealed insignificant differences (Asymp Sig. = 0.354) in the Environmental Awareness and Future aspect of the courtyard (Strongly Disagree, n=5, Mean rank =82.40; Disagree, n=12, Mean rank =64.67; Neutral, n=35, Mean Rank=61.91; Agree, n=56, Mean rank=73.05; Strongly

Agree, n=33, Mean Rank=77.73), and insignificant differences (Asymp Sig. = 0.723) in the Flexibility in physical parameters in and Future aspect of the (Strongly Disagree, n=5, Mean rank =67.10; Disagree, n=12, Mean rank =66.17; Neutral, n=35, Mean Rank=65.86; Agree, n=56, Mean rank=71.63; Strongly Agree, n=33, Mean Rank=77.73) of the professionals opinion. There is sufficient information to conclude that opinions concerning the future aspects of courtyard dwellings do not differ considerably in terms of environmental consciousness and flexibility in the geometrical parameters of the courtyard. I can be said that "The future of courtyard houses lies in their ability to adapt to changing environmental conditions, technological advancements, and flexibility in the geometrical parameters of the courtyard as well as building parameters" in the opinion of professionals.

What are the challenges faced by courtyard house dwellers in retaining the courtyards in North India's residential buildings?

The hypothesis framed for the above research question is "The challenges faced by courtyard house dwellers in retaining the courtyards in North India's residential buildings are due to the lack of awareness about the cultural and environmental significance of courtyards, the high cost of maintenance, and the changing lifestyle patterns of Indian households." The descriptive data and the hypothesis test summary of the survey is shown in the Table 7 and 8 To evaluate the challenges faced by courtyard house dwellers in retaining the courtyards in North India's residential buildings across different age categories were tested using the Kruskal Wallis Test. Overall based on the Kruskal Wallis test it can be stated that in the majority of the cases, there is no significant difference in the distribution of responses across different age groups. From the test result it can be said that the key issues in retaining the courtyards in North India's residential buildings are due to the 'Lack of space in today's context'; 'Rise in the land cost'; and 'Higher construction cost'.

CONCLUSION

The study highlights that courtyard house dwellers possess a strong awareness of the socio-cultural and environmental significance of courtyards and remain deeply rooted in their diverse functions. Thus, lack of awareness is not a primary factor in their decline. Rather, the disappearance and transformation of courtyards in the composite climate of North India stem largely from limited urban space, escalating land prices, and high construction costs. Age-wise differences were evident, as respondents from older groups (31–60 years) demonstrated greater sensitivity to these issues compared to younger generations (18–30 years). From the perspective of professionals, the survival of courtyard houses depends on their adaptability to local climate, construction techniques, and materials, along with greater flexibility in building regulations. Recommended parameters for their successful integration include low-rise low-density, low-rise high-density, and mid-rise low-density developments, with plot sizes between 1501–2000 sq. ft. and heights limited to G+2 floors. The findings affirm that professionals, current dwellers, and associated public groups all value courtyards as an essential architectural element. However, their retention in contemporary housing faces challenges that can only be addressed through targeted policy interventions and amendments in building byelaws. By providing incentives, flexible FAR norms, and suitable coverage and setback allowances, courtyard houses can continue to thrive as sustainable, climate-responsive, and culturally significant living spaces in modern Indian cities.

Recommendation

This study provides valuable information for professional planners and designers to preserve cultural heritage in residential developments and enhance quality of life. The study promotes awareness of the relevance of these ancient traits to modern living. It draws attention to certain significant gaps in our understanding of the region's vernacular dwellings and emphasizes the urgent need for more field and lab research on the topic.

ACKNOWLEDGMENTS

The author gratefully acknowledges the invaluable guidance and encouragement of Dr. Farheen Bano throughout this research. Sincere thanks are extended to Ar. Pragati Verma for constructive feedback and helpful suggestions. The support of colleagues, students, house owners, architects, and experts who participated in surveys and interviews is also deeply appreciated. Finally, thanks to my family and friends for their constant encouragement and trust, which provided strength during this work.

Use of an artificial intelligence (AI) tool

The authors declare that the generative artificial intelligence (AI) tool ChatGPT was used for language editing and/or grammatical improvement. The use of AI did not influence or change the study, scientific content, analysis of data, interpretation, results, or conclusions of the manuscript. Full responsibility for the content remains with the authors.

ABSTRACT

The study of Diophantine Equations involves determining whether integer solutions exist and if so, finding all such solutions. These equations play a fundamental role in number theory and have applications in cryptography, computer science, coding theory etc. In this paper, we have solved a special quadratic Diophantine equation and derived its possible solutions.

Keywords: Quadratic Diophantine Equation, Positive integer solutions, Polar Form, Euler's Formula.

INTRODUCTION

Equations having integer solutions are known as Diophantine equations. The solutions of such equations are most often positive integers. In this paper, we have solved a special quadratic Diophantine equation $x^2 + y^2 = (a^2 + b^2)^n$ and provided its possible solutions. As special case, we obtain integer solutions of few Diophantine equations.

Theorem 1

If n is a positive integer, the positive integer solutions of the quadratic Diophantine equation of the form

$x^2 + y^2 = (a^2 + b^2)^n$ **(1)**

are $x = (a^2 + b^2)^{n/2} \left|\cos\left[n \tan^{-1}\left(\frac{b}{a}\right)\right]\right|$ **(2)**

$y = (a^2 + b^2)^{n/2} \left|\sin\left[n \tan^{-1}\left(\frac{b}{a}\right)\right]\right|$ **(3)**

Proof:

The polar form of $a + ib$ is

$a + ib = r\,e^{i\theta} = r\,(\cos\theta + i\sin\theta)$

$\Longrightarrow r\cos\theta = a\,, r\sin\theta = b$ **(4)**

Thus, $r^2 = a^2 + b^2$

$\Longrightarrow r = (a^2 + b^2)^{1/2}, \theta = tan^{-1}\left(\frac{b}{a}\right)$ **(5)**

Hence the polar form of $(a + ib)^n$ is given by

$(a + ib)^n = (a^2 + b^2)^{n/2} e^{in\ tan^{-1}\left(\frac{b}{a}\right)}$

Now using Euler's formula, we obtain

$(a + ib)^n = (a^2 + b^2)^{n/2}\left\{\cos\left[n\ tan^{-1}\left(\frac{b}{a}\right)\right] + i\sin\left[n\ tan^{-1}\left(\frac{b}{a}\right)\right]\right\}$ **(6)**

Let us assume that,

$x + i\,y = (a + ib)^n$ **(7)**

Then, $x - i\,y = (a - ib)^n$ **(8)**

Now multiplying (7) & (8), we get,

$x^2 + y^2 = (a^2 + b^2)^n$, which is (1).

Equating real & imaginary parts in (6) & (7), we get

$x = (a^2 + b^2)^{n/2}\cos\left[n\ tan^{-1}\left(\frac{b}{a}\right)\right]$ **(9)**

$y = (a^2 + b^2)^{n/2}\sin\left[n\ tan^{-1}\left(\frac{b}{a}\right)\right]$ **(10)**

Now from (9) and (10), if we consider $(|x|, |y|)$ then these pairs would provide positive integer solutions to the given Quadratic Diophantine Equation $x^2 + y^2 = (a^2 + b^2)^n$.

Hence the positive integer solutions to $x^2 + y^2 = (a^2 + b^2)^n$ are given by

$x = (a^2 + b^2)^{n/2}\left|\cos\left[n\ tan^{-1}\left(\frac{b}{a}\right)\right]\right|$ **(11)**

$y = (a^2 + b^2)^{n/2}\left|\sin\left[n\ tan^{-1}\left(\frac{b}{a}\right)\right]\right|$ **(12)**

This completes the proof.

We will now analyze some particular cases of Theorem 1.

Case 1: Let $a = 1, b = 3$. Then the quadratic Diophantine equation(1) is $x^2 + y^2 = 10^n$ and its solutions from (11) & (12) are of the form

$x = 10^{n/2}|\cos[n\ tan^{-1}(3)]|$ **(13)**

$y = 10^{n/2}|\sin[n\ tan^{-1}(3)]|$ **(14)**

For $= 1,2,3,4,5,6,7, \ldots$, the positive integer solutions (x, y) to $x^2 + y^2 = 10^n$ are given respectively by (1,3), (8,6), (26,18), (28,96), (316,12), (352,936), (2456,1992), ...

Case 2: Let $a = 3, b = 1$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 10^n$ and its solutions from (11) & (12) are of the form

$x = 10^{n/2}\left|\cos\left[n\ tan^{-1}\left(\frac{1}{3}\right)\right]\right|$ **(15)**

$y = 10^{n/2}\left|\sin\left[n\ tan^{-1}\left(\frac{1}{3}\right)\right]\right|$ **(16)**

For $n = 1,2,3,4,5,6,7, \ldots$, the positive integer solutions (x, y) to $x^2 + y^2 = 10^n$ are given respectively by (3,1), (8,6), (18,26), (28,96), (12,316), (352,936), (1992,2456), ...

Case 3: Let $a = 2, b = 3$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 13^n$ and its solutions from (11) & (12) are of the form

$x = 13^{n/2}\left|\cos\left[n\ tan^{-1}\left(\frac{3}{2}\right)\right]\right|$ **(17)**

$y = 13^{n/2}\left|\sin\left[n\ tan^{-1}\left(\frac{3}{2}\right)\right]\right|$ **(18)**

For $n = 1,2,3,4,5,6,7,8,9, \ldots$, the positive integer solutions $(x, y)$to $x^2 + y^2 = 13^n$ are given respectively by (2,3), (5,12), (46,9), (119,120), (122,597), (2035,828), (6554,4449), (239,28560), (86158,56403) ....

Case 4: Let $a = 3, b = 2$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 13^n$ and its solutions from (11) & (12) are of the form

$x = 13^{n/2} \left|\cos\left[n\ tan^{-1}\left(\frac{2}{3}\right)\right]\right|$ **(19)**

$y = 13^{n/2} \left|\sin\left[n\ tan^{-1}\left(\frac{2}{3}\right)\right]\right|$ **(20)**

For $n = 1,2,3,4,5,6,7,8,9, \ldots$, the positive integer solutions $(x, y)$to $x^2 + y^2 = 13^n$ are given respectively by(3,2), (5,12), (9,46), (119,120), (597,122), (2035,828), (4449,6554), (239,28560), (56403,86158) ....

Case 5: Let $a = 1, b = 4$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 17^n$ and its solutions from (11) & (12) are of the form

$x = 17^{n/2}|\cos[n\ tan^{-1}(4)]|$ **(21)**

$y = 17^{n/2}|\sin[n\ tan^{-1}(4)]|$ **(22)**

For $n = 1,2,3,4,5,6, \ldots$, the positive integer solutions $(x, y)$to $x^2 + y^2 = 17^n$ are given respectively by (1,4), (15,8), (47,52), (161,240), (1121,404), (495,4888), ...

Case 6: Let $a = 4, b = 1$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 17^n$ and its solutions from (11) & (12) are of the form

$x = 17^{n/2} \left|\cos\left[n\ tan^{-1}\left(\frac{1}{4}\right)\right]\right|$ **(23)**

$y = 17^{n/2} \left|\sin\left[n\ tan^{-1}\left(\frac{1}{4}\right)\right]\right|$ **(24)**

For $n = 1,2,3,4,5,6, \ldots$, the positive integer solutions $(x, y)$to $x^2 + y^2 = 17^n$ are given respectively by (4,1), (15,8), (52,47), (161,240), (404,1121), (495,4888), ...

Case 7: Let $a = 1, b = 7$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 50^n$ and its solutions from (11) & (12) are of the form

$x = 50^{n/2}|\cos[n\ tan^{-1}(7)]|$ **(25)**

$y = 50^{n/2}|\sin[n\ tan^{-1}(7)]|$ **(26)**

For $n = 1,2,3,4,5, \ldots$, the positive integer solutions $(x, y)$to $x^2 + y^2 = 50^n$ are given respectively by (1,7), (48,14), (146,322), (2108,1344), (11516,13412), ...

Case 8: Let $a = 7, b = 1$. Then the quadratic Diophantine equation (1)is $x^2 + y^2 = 50^n$ and its solutions from (11) & (12) are of the form

$x = 50^{n/2} \left|\cos\left[n\ tan^{-1}\left(\frac{1}{7}\right)\right]\right|$ **(27)**

$y = 50^{n/2} \left|\sin\left[n\ tan^{-1}\left(\frac{1}{7}\right)\right]\right|$ **(28)**

For $n = 1,2,3,4,5, \ldots$, the positive integer solutions $(x, y)$to $x^2 + y^2 = 50^n$ are given respectively by (7,1), (48,14), (322,146), (2108,1344), (13412,11516) ....

CASE 9: Let $a = 5, b = 5$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 50^n$ and its solutions from (11) & (12) are of the form

$x = 50^{n/2}|\cos[n\ tan^{-1}(1)]| = 50^{n/2} \left|\cos\left[\frac{n\pi}{4}\right]\right|$ **(29)**

$y = 50^{n/2}|\sin[n\ tan^{-1}(1)]| = 50^{n/2} \left|\sin\left[\frac{n\pi}{4}\right]\right|$ **(30)**

For $= 1,2,3,4,5, \ldots$, the positive integer solutions$(x, y)$to $x^2 + y^2 = 50^n$ are given respectively by (5,5), (0,50), (250,250), (2500,0), (12500,12500) .... We obtain positive integer solutions only if n is odd. If n is even of the form $4k + 2$, for some integer k, then $x = 0$ and if n is even of the form $4k$ for some integer k, then $y = 0$ in view of (29) and (30) respectively.

Case 10: Let $a = 1, b = 8$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 65^n$ and its solutions from (11) & (12) are of the form

$x = 65^{n/2}|\cos[n\ tan^{-1}(8)]|$ **(31)**

$y = 65^{n/2}|\sin[n\ tan^{-1}(8)]|$ **(32)**

For $n = 1,2,3,4,5,\ldots$, the positive integer solutions $(x, y)$to $x^2 + y^2 = 65^n$ are given respectively by $(1,8), (63,16), (191,488), (3713,2016), (19841,27688), \ldots.$

Case 11: Let $a = 8, b = 1$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 65^n$ and its solutions from (11) & (12) are of the form

$x = 65^{n/2}\left|\cos\left[n\ tan^{-1}\left(\frac{1}{8}\right)\right]\right|$ **(33)**

$y = 65^{n/2}\left|\sin\left[n\ tan^{-1}\left(\frac{1}{8}\right)\right]\right|$ **(34)**

For $n = 1,2,3,4,5,\ldots$, the positive integer solutions$(x, y)$to $x^2 + y^2 = 65^n$ are given respectively by $(8,1), (63,16), (488,191), (3713,2016), (27688,19841), \ldots.$

Case 12: Let $a = 4, b = 7$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 65^n$ and its solutions from (11) & (12) are of the form

$x = 65^{n/2}\left|\cos\left[n\ tan^{-1}\left(\frac{7}{4}\right)\right]\right|$ **(35)**

$y = 65^{n/2}\left|\sin\left[n\ tan^{-1}\left(\frac{7}{4}\right)\right]\right|$ **(36)**

For $n = 1,2,3,4,5,\ldots$, the positive integer solutions$(x, y)$to $x^2 + y^2 = 65^n$ are given respectively by $(4,7), (33,56), (524,7), (2047,3696), (17684,29113), \ldots.$

Case 13: Let $a = 7, b = 4$. Then the quadratic Diophantine equation (1) is $x^2 + y^2 = 65^n$ and its solutions from (11) & (12) are of the form

$x = 65^{n/2}\left|\cos\left[n\ tan^{-1}\left(\frac{4}{7}\right)\right]\right|$ **(37)**

$y = 65^{n/2}\left|\sin\left[n\ tan^{-1}\left(\frac{4}{7}\right)\right]\right|$ **(38)**

For $n = 1,2,3,4,5,\ldots$, the positive integer solutions $(x, y)$to $x^2 + y^2 = 65^n$ are given respectively by $(7,4), (33,56), (7,524), (2047,3696), (29113,17684), \ldots.$

Note: We notice that if we interchange the values of *a* and *b* then from above set of solutions, the values of *x* and *y* gets interchanged when *n* is odd and remains same, if *n* is even for *a<b* in comparison with *a>b*. This is because of the well-known arctangent identity given by $\tan^{-1}(X) + \tan^{-1}\left(\frac{1}{X}\right) = \frac{\pi}{2}$. Further for number like 50, 65 as in cases (7) to (13), we obtained two distinct pairs of solutions, since 50 and 65 are numbers which are expressible as sum of two squares in two different ways. We can similarly obtain multiple set of integer solutions by choosing numbers which are expressible as sum of two squares in multiple ways.

CONCLUSION

Considering the special quadratic Diophantine equation as in (1), we obtained the positive integer solutions in novel way. In particular, in Theorem 1, we obtained the positive integer solutions of$x^2 + y^2 = (a^2 + b^2)^n$, n is a positive integer for some particular cases ofa, b using the equations

$x = (a^2 + b^2)^{n/2}\left|\cos\left[n\ tan^{-1}\left(\frac{b}{a}\right)\right]\right|$

$y = (a^2 + b^2)^{n/2}\left|\sin\left[n\ tan^{-1}\left(\frac{b}{a}\right)\right]\right|$

Respectively, Thus, in this paper, we have proved one theorem and verified some particular cases for a and b.Using these ideas, we can solve the quadratic Diophantine equations in an interesting manner. Further, this method provides solutions for all numbers which can be expressed as sum of two squares$(ie) x^2 + y^2 = D^n$,where $D = a^2 + b^2$ but not for numbers which cannot be expressed as sum of two squares$(ie) x^2 + y^2 = D^n$, where $\neq a^2 + b^2$.

ABSTRACT

The rapid detection of viable microorganisms within the *Enterobacteriaceae* family is paramount for public health, as these bacteria are primary indicators of faecal contamination and include numerous human pathogens. Conventional microbiological methods, such as the Most Probable Number (MPN) and selective culturing, often require incubation periods of 24 to 48 hours, which is inadequate for real-time monitoring. This study investigated the development of a chemical biosensor utilizing resazurin (7-Hydroxy-3H-phenoxazin-3-one 10 oxide), a non-toxic redox indicator, to assess the viability of *Escherichia coli*, *Enterobacter*sp., and *Salmonella typhii*. The sensor operates by leveraging the metabolic activity of viable cells, where intracellular dehydrogenase enzymes reduce blue resazurin to pink, highly fluorescent resorufin. Experimental optimization determined that a 2 ppm resazurin concentration provided the ideal balance of sensitivity and speed, enabling the detection of low bacterial loads (30–50 cells/100 ml) within 4 to 6 hours. Furthermore, the biosensor was successfully applied to evaluate heavy metal toxicity (Chromium, Lead, and Mercury) and soil dehydrogenase activity (DHA). The resazurin-based method provides a rapid, cost-effective, and reproducible alternative to traditional diagnostic techniques, suitable for both clinical and environmental applications.

Key words: Resazurin, Biosensor, Entero bacteriaceae, Dehydrogenase, Resorufin, Viability, Fluorescence, Bioremediation

INTRODUCTION

Bacteria are prokaryotic microorganisms ranging in size from 0.5 μm to 5.0 μm in length. Morphologically, they appear in various forms, including bacilli, cocci, spirilla, and filamentous structures [1]. These organisms inhabit a vast array of environments, including water, soil, radioactive waste [2], and deep within the Earth's crust. Their growth and enzymatic activity are strictly governed by environmental parameters such as temperature and oxygen concentration. Based on oxygen requirements, bacteria are classified as obligate aerobes, obligate anaerobes, facultative anaerobes, or microaerophilic. Facultative anaerobes, which can grow in both the presence and absence of oxygen, include the family *Enterobacteriaceae*. The members of *Enterobacteriaceae*, often referred to as "enterics," are Gram-negative, non-spore-forming rods ubiquitous in nature. While the family includes harmless symbionts, it also contains significant pathogens such as *Escherichia coli, Salmonella typhii, Shigella* sp., and *Yersina* pestis [3]. Many species reside as commensal flora in the intestinal canals of humans and animals [4]. Because they are associated with improperly prepared food and contaminated water, they are primary causes of gastroenteritis, urinary tract infections, and pneumonia. Since testing for every waterborne pathogen is impractical, the World Health Organization (WHO) utilizes index organisms like *E. coli* to assess faecal contamination [5].

This research focuses on three key members of this family *Escherichia coli*(A facultative anaerobe (1–3 μm long) typically found in the lower intestine. While most strains are harmless normal flora that produce vitamin K2 [6], virulent serotypes like O157:H7 cause lethal food poisoning [7], *Salmonella typhii*: A rod-shaped, motile pathogen responsible for typhoid fever, which causes approximately 200,000 deaths annually worldwide [8]. It is characterized by specific H, O, and Vi antigens, the latter of which increases virulence [9] and *Enterobacter* sp.: This genus includes species like *E. cloacae*, which are utilized industrially for biogas production [10]and iron chelation via siderophores [11]. The early detection of these organisms is critical for public health. Conventional microbiological methods usually require 24 to 48 hours for results. Standard laboratory techniques like PCR are expensive and risk false positives if genetic probes are mismatched, while ELISA involves lengthy antibody production and multiple incubation steps [1, 12]. Consequently, there is a need for biosensors—devices that detect and record physiological or biological changes rapidly [13]. Chemical sensors are using redox dyes offer economic and social benefits for monitoring food safety and environmental emissions [14].

To simplify the detection of viable cells, this study utilizes resazurin (7-Hydroxy-3H-phenoxazin-3-one 10 oxide). Resazurin is a blue, water-soluble, and non-toxic phenoxazine dye [15]. It acts as an intermediate electron acceptor in the respiratory chain of viable cells. Intracellular dehydrogenase enzymes add hydrogen to the blue resazurin, reducing it irreversibly to resorufin, a pink, highly fluorescent compound [16]. This reduction is proportional to aerobic respiration and cell viability [17]. Resazurin is advantageous because it is rapid, accurate, inexpensive, and eco-friendly [18,19]. Furthermore, biosensors facilitate the detection of microorganisms in the presence of heavy metals, such as lead, arsenic, and mercury. While trace amounts of metals are necessary for enzyme catalysis, excessive concentrations disrupt metabolic processes and cause environmental pollution [20,21]. Microorganisms have developed tolerance mechanisms, such as anion efflux and metal reduction, to survive in contaminated environments [22]. Finally, biosensors can assess soil health by measuring dehydrogenase activity (DHA). Dehydrogenases are present in all living microbes, making DHA assays a critical indicator of overall microbial activity and ecosystem functioning [23]. Measuring DHA via resazurin allows for the investigation of soil disruptions caused by trace elements or pesticides [24]. The primary objectives of this study are to enumeration of *E. coli, Enterobacter* sp., and *S. typhii* using MPN and SPC methods; optimization of resazurin dye and quantitative analysis of its conversion to resorufin and assessment of bacterial cell viability under heavy metal toxicity and soil dehydrogenase activity using resazurin.

MATERIALS AND METHODS

The experimental procedures for developing and validating the resazurin-based chemical biosensor were conducted systematically, beginning with the formulation of specialized media and progressing through microbial enumeration, sensor optimization, and environmental application testing. All methodological steps were designed to ensure reproducibility and accuracy in assessing the viability of *Escherichia coli*, *Enterobacter* sp., and *Salmonella typhii*.

Preparation of Chemical Agents and Culture Media

The research utilized three primary types of media, each tailored for specific stages of bacterial growth and indicator testing. Nutrient Broth Composition: The standard growth medium was prepared using a specific formulation to support general microbial proliferation. The components included 5 g/l of peptic digest of animal tissue, 5 g/l of sodium chloride, 1.5 g/l of beef extract, and 1.5 g/l of yeast extract. These chemicals were initially dissolved in 800 ml of distilled water, after which the total volume was adjusted to 1 liter. The final pH was calibrated to 7.4 ± 0.2 at 25°C. Sterilization was achieved via autoclaving at 15 lbs of pressure for 15 minutes. For experiments requiring a solid substrate, nutrient agar was produced by adding 30 g of agar to the broth prior to the sterilization process, with 20 ml of the resulting medium poured into individual petri plates.

Modified *Escherichia coli* Broth Composition to selectively support and enhance the growth of coliforms, a modified *E. coli* broth was utilized. This medium comprised 5 g/l Hiveg Peptone, 5 g/l sodium chloride, 1 g/l potassium dihydrogen phosphate, 4 g/l dipotassium hydrogen phosphate, 1 g/l potassium nitrate, 5 g/l lactose, and 1.5 g/l bile salts. Similar to the nutrient broth, these constituents were dissolved in 800 ml of distilled water before being made up to 1 liter. The pH was adjusted to 7.4, and the medium was sterilized at 15 lbs for 15 minutes. MacConkey Lactose Bile Broth (MLBB) Composition: MLBB served as the primary medium for the Most Probable Number (MPN) assays. Its composition included 3 g/l peptone (meat and casein), 17 g/l pancreatic digest of gelatin, 10 g/l lactose monohydrate, 1.5 g/l bile salts, and 5 g/l sodium chloride. The medium also incorporated indicator dyes: 0.001 g/l crystal violet and 0.03 g/l neutral red. The final pH was set to 7.1 ± 0.2. After dissolving the components in 800 ml of distilled water and making up the volume to 1 liter, the broth was sterilized by autoclaving.

Microbial Enumeration Techniques

Accurate quantification of the test organisms *E. coli*, *Enterobacter* sp., and *S. typhii* was essential for establishing the sensor's sensitivity. Most Probable Number (MPN) Test: Bacterial cultures were initially grown for 24 hours in sterile nutrient broth, with their growth monitored by measuring absorbance at 600 nm. These cultures were then serially diluted from 10^{-1} to 10^{-10} in sterile normal saline. The MPN test utilized MacConkey's Lactose Bile Broth prepared in two concentrations: single strength (1X) at 40 g/l and double strength (2X) at 80 g/l. The distribution of the broth into sugar tubes followed a specific three-set protocol. Set 1: Five sugar tubes containing 10 ml of double-strength broth each.Set 2: Five sugar tubes containing 10 ml of single-strength broth each.Set 3: Five sugar tubes containing 10 ml of single-strength broth each. Durham's vials were added to all tubes to capture gas production before sterilization. Following preparation, 10 ml of the diluted culture (at 10^{-6}, 10^{-8}, and 10^{-10}) was added to the first set, 1 ml to the second set, and 0.1 ml to the third set. The tubes were incubated at 35–37°C for 24 to 48 hours. Tubes were marked positive if they exhibited turbidity, a color change, or gas production. The final MPN per 100 ml was calculated based on the number of positive tubes recorded. Spread Plate Count (SPC) Method: As a comparative enumeration method, the SPC was performed. Cultures grown for 24 hours were serially diluted in sterile normal saline. A 0.1 ml aliquot from the selected dilutions was pipetted onto the center of sterile nutrient agar plates and distributed evenly using a sterile spreader. Following incubation at 35–37°C for 24 hours, the resulting colonies were counted to determine the Colony Forming Units per milliliter (CFU/ml).

Optimization and Quantification of the Resazurin Biosensor

Resazurin was identified as a viable indicator due to its characteristic color transition from blue to fluorescent pink within a pH range of 6.5 to 8.5. Dye Optimization Cultures grown for 24 hours were inoculated (0.5 ml) into two

experimental sets to determine the ideal dye concentration. Set 1 utilized 5 ml of sterile nutrient broth with resazurin concentrations of 0.5, 1, 1.5, and 2 ppm. Set 2 utilized 5 ml of sterile modified *E. coli* broth with the same concentration range (0.5–2 ppm). Tubes were incubated at 37°C and monitored every two hours for the production of pink resorufin. Following observation, the tubes were centrifuged at 5000 rpm for 15 minutes to facilitate the capturing of resorufin's color intensity for digital analysis.

Quantitative Analysis via ImageJ: The conversion of resazurin to resorufin was quantified using ImageJ software (version 1.51p). Digital photographs of the tubes were loaded into the software, and a standardized box was drawn within the tube area to measure the area (mm^2), mean grey value, and integrated density. The mean grey value represented the average grey value of pixels within the selection, while the integrated density provided the sum of all pixel values. To ensure accuracy, background noise was accounted for by drawing a representative background box near the tube; this background value was subsequently subtracted from the tube's measurement using an Excel-based statistical approach as described by Rodriguez *et al.*[25]. Three random areas within each tube were sampled to maintain consistency, and the final fluorescence was calculated using the formula established by McCloy *et al.*[26].

Assessment of Heavy Metal Toxicity

The biosensor's ability to detect cell viability under environmental stress was tested using chromium, lead, and mercury. Initially, 0.1 ml of bacterial culture was inoculated into tubes containing 5 ml of nutrient broth supplemented with varying heavy metal concentrations (10, 20, 30, 40, and 50 ppm). A positive control with no heavy metals was included. Growth was measured via absorbance at 600 nm after 24 hours. To specifically check viability using the biosensor, cultures were inoculated into tubes containing 5 ml of nutrient broth with 2 ppm resazurin dye and the same range of heavy metal concentrations. These tubes were incubated at 37°C and monitored hourly for resorufin production.

Soil Dehydrogenase Activity (DHA) Methodology

The biosensor was further applied to soil health monitoring using rhizospheric soil from the ADIT campus in Gujarat, India. The DHA determination was based on a modified version of the method by Casida [27].

Soil (20 g) was weighed and mixed with calcium carbonate ($CaCO_3$) at a ratio of 0.1 g $CaCO_3$ per 10 g of soil. From this mixture, 2 g of soil was distributed into sterile tubes, which were treated with various resazurin concentrations ranging from 0.1 to 2 ppm. After adding 3.5 ml of sterile distilled water, the dye was mixed into the soil using a sterile glass rod. The tubes were capped and incubated at 37°C, with resorufin production observed every two hours. Additionally, a separate set was prepared where 2 g of the soil/$CaCO_3$ mixture was inoculated with 0.1 ml of bacterial culture to observe the enhanced conversion of 1, 1.5, and 2 ppm resazurin concentrations compared to a non-inoculated control set. Both sets were incubated at 37°C and monitored hourly for the blue-to-pink color transition.

RESULTS

Enumeration of Bacterial cultures using Most Probable Number (MPN) method and Spread Plate Count (SPC) method:

After incubation of MLBB tubes, positive tubes were selected on basis of gas production or change in colour from red to yellow or brown (Table 1). Number of cells per 100 ml was calculated as per formula mentioned in materials and method section 2.2 and cells present per ml were calculated. Enumeration by SPC method was carried out by calculating number of colonies on nutrient agar plates. CFU/ml was calculated as per formula mentioned in materials and methods section 2.3. MPN test shows that approximately 3.6 x 10^{13} cells/ml of *Escherichia coli* are present in culture. This is confirmed with SPC where 130 colonies are observed (Figure 1) thus, representing approximately 1.3 x 10^{13} cells/ml.

Optimization of resazurin dye:

Optimization of resazurin dye was carried out with *Escherichia coli*, *Enterobacter* sp. and *Salmonella typhii*. Bacterial cells were inoculated into sterile nutrient broth and *Escherichia coli* broth modified by Patel [20]. Number of bacterial

cells to be inoculated was kept constant and resazurin dye concentration was the variable parameter. Resazurin dye with different concentrations of 0.5 ppm, 1 ppm, 1.5 ppm and 2 ppm were added to the tubes. After 10 minutes, colour change was observed in modified *Escherichia coli* broth containing resazurin dye concentration 0.5 and 1 ppm. In tubes containing 1.5 ppm and 2ppm resazurin dye along with modified *Escherichia coli* broth, colour change was observed within 25 min. Further, various dye concentrations were added to sterile modified *Escherichia coli* broth (tubes were not inoculated with microorganisms). After 15 to 20 min., colour change was observed in all different dye concentrations. Further, test was carried out by using higher resazurin dye concentrations of 4 ppm, 6 ppm and 8 ppm and, colour change was observed within 30 to 40 min. with each dye concentration. Further optimization was carried out using sterile nutrient broth having approximately same microbial load in each tube but at different resazurin dye concentrations 0.5 ppm, 1ppm, 1.5 ppm and 2 ppm. After 2 hours, pink colour was observed in all tubes having nutrient broth. Thus, indicating production of resorufin and viability of cells. Tubes were further observed till 6 hours for resorufin production. It was observed that tubes with lower dye concentration shows lesser production of resorufin as compared to the one having higher resazurin dye concentration (Figure 2). Sharp colour change was observed in tubes containing 1.5 and 2 ppm resazurin dye concentration, thus further optimization in triplicates was carried out with 1.5 ppm and 2 ppm dye.

Quantification of resorufin production:

Pure bacterial culture was inoculated in nutrient broth containing 1.5 and 2 ppm resazurin dye concentration. The tubes were incubated and resazurin reduction was noted after interval of every 2 hours. The experiment was carried out in triplicates and the amount of resorufin produced was quantified based on fluorescence as mentioned in section 2.4.2.

***Escherichia coli*:** In dye concentrations of 1.5 and 2 ppm, fluorescence increases with time indicating more reduction of resazurin to resorufin (Figure 3). In dye concentration of 1.5ppm, fluorescence after 6 hours was 1211.48 RFU which is given in Table 2. The difference in fluorescence between 2 to 4 hours was 159.44 RFU and between 4 to 6 hours was 136.26 RFU. Thus, there is decrease in production of resorufin and fluorescence. In dye concentration of 2 ppm, fluorescence after 6 hours was 1299.50 RFU, which is given in Table 3. The difference in fluorescence between 2 to 4 hours was 204.83 RFU and between 4 to 6 hours was 11.43 RFU. This indicates very less reduction of resazurinhad taken place after 4 hours.

***Enterobacter* sp**

Fluorescence increases with time indicating more reduction of resazurin to resorufin (Figure 6). In dye concentration of 1.5 ppm, fluorescence after 6 hours was 1271.88 RFU which is given in Table 4. The difference in fluorescence between 2 to 4 hours was 241.49 RFU and between 4 to 6 hours was 117.98 RFU. In dye concentration of 2 ppm, fluorescence after 6 hours was 1350.19 RFU which is given in Table 5. The difference in fluorescence between 2 to 4 hours was 210.43 RFU and between 4 to 6 hours was 61.96 RFU. In both dye concentrations, the rate of resazurin reduction had slowed down after 6 hours.

***Salmonella typhii*:** In dye concentrations of 1.5 and 2 ppm, fluorescence increases with time indicating more reduction of resazurin to resorufin (Figure 8). At a dye concentration of 1.5 ppm, fluorescence after 6 hours was 1249.70 RFU which is given in Table 6. The difference in fluorescence between 2 to 4 hours was165.13 RFU and between 4 to 6 hours it was 85.96 RFU. At a dye concentration of 2 ppm, fluorescence after 6 hours was 1348.51 RFU which is given in Table 7. The difference in fluorescence between 2 to 4 hours was 27.66 RFU and between 4 to 6 hours, it was 77.17 RFU. Thus, there is gradual increase in fluorescence with time. This indicates, with increase in the dye concentration, amount of resorufin increases and thus there was increase in fluorescence (Figure 7).
